

—Seventh Edition—

JAVA™ HOW TO PROGRAM

Introducing
JAVA® SE 6 (Mustang) • Web Services
Ajax-Enabled Web Applications
JavaServer™ Faces

EARLY CLASSES/OBJECTS/OOP

- INHERITANCE, POLYMORPHISM
- INTERFACES, NESTED CLASSES
- OPTIONAL GUI/GRAPICS TRACK
- OOP CASE STUDIES, UML™ 2

FUNDAMENTALS

- I/O, TYPES, ARRAYS, OPERATORS
- METHODS, CONTROL STATEMENTS
- USING API DOCS, DEBUGGER
- SCANNER, PRINTF, ENHANCED FOR
- ENUM, BOXING, VARARGS

JAVA APIs

- SWING GUI, SWINGWORKER
- GROUP_LAYOUT, MULTIMEDIA
- EXCEPTIONS, STRINGS, REGEX
- JDBC™, GRAPHICS, JAVA 2D™
- THREADS, CONCURRENCY APIs

DATA STRUCTURES/DATABASE

- RECURSION, SEARCHING, SORTING
- FILES/STREAMS, DATA STRUCTURES
- GENERICS, COLLECTIONS
- JDBC™ 4, ROWSETS, JTABLE
- JAVA DB/APACHE DERBY, MySQL™

INTERNET/WEB APPLICATIONS

- NETWORKING, GOOGLE™ MAPS
- JAVA SERVER FACES (JSF), TOOLS
- AJAX-ENABLED WEB APPLICATIONS
- WEB SERVICES, ANNOTATIONS
- MASHUPS, WEB 2.0, REFACTORING

OOD/UML™ 2 ATM CASE STUDY

- [OPTIONAL] DIAGRAMS: CLASS, ACTIVITY, USE CASE, SEQUENCE, COMMUNICATION, STATE

Deitel® Series Page.....	5
Preface.....	8
Before You Begin.....	21
Chapter 1. Introduction to Computers, the Internet and the Web.....	28
Section 1.1. Introduction.....	29
Section 1.2. What Is a Computer?.....	31
Section 1.3. Computer Organization.....	31
Section 1.4. Early Operating Systems.....	32
Section 1.5. Personal, Distributed and Client/Server Computing.....	33
Section 1.6. The Internet and the World Wide Web.....	33
Section 1.7. Machine Languages, Assembly Languages and High-Level Languages.....	34
Section 1.8. History of C and C++.....	35
Section 1.9. History of Java.....	36
Section 1.10. Java Class Libraries.....	36
Section 1.11. Fortran, COBOL, Pascal and Ada.....	37
Section 1.12. BASIC, Visual Basic, Visual C++, C# and .NET.....	38
Section 1.13. Typical Java Development Environment.....	38
Section 1.14. Notes about Java and Java How to Program, 7/e.....	42
Section 1.15. Test-Driving a Java Application.....	43
Section 1.16. Software Engineering Case Study: Introduction to Object Technology and the UML.....	47
Section 1.17. Web 2.0.....	52
Section 1.18. Software Technologies.....	53
Section 1.19. Wrap-Up.....	54
Section 1.20. Web Resources.....	55
Summary.....	57
Terminology.....	60
Self-Review Exercises.....	61
Answers to Self-Review Exercises.....	62
Exercises.....	62
Chapter 2. Introduction to Java Applications.....	64
Section 2.1. Introduction.....	65
Section 2.2. A First Program in Java: Printing a Line of Text.....	65
Section 2.3. Modifying Our First Java Program.....	72
Section 2.4. Displaying Text with printf.....	75
Section 2.5. Another Java Application: Adding Integers.....	76
Section 2.6. Memory Concepts.....	81
Section 2.7. Arithmetic.....	82
Section 2.8. Decision Making: Equality and Relational Operators.....	85
Section 2.9. (Optional) Software Engineering Case Study: Examining the Requirements Document.....	90
Section 2.10. Wrap-Up.....	100
Summary.....	100
Terminology.....	103
Self-Review Exercises.....	104
Answers to Self-Review Exercises.....	105
Exercises.....	107
Chapter 3. Introduction to Classes and Objects.....	111
Section 3.1. Introduction.....	112
Section 3.2. Classes, Objects, Methods and Instance Variables.....	112
Section 3.3. Declaring a Class with a Method and Instantiating an Object of a Class.....	114
Section 3.4. Declaring a Method with a Parameter.....	118
Section 3.5. Instance Variables, set Methods and get Methods.....	121
Section 3.6. Primitive Types vs. Reference Types.....	126
Section 3.7. Initializing Objects with Constructors.....	127
Section 3.8. Floating-Point Numbers and Type double.....	130

Section 3.9. (Optional) GUI and Graphics Case Study: Using Dialog Boxes.....	135
Section 3.10. (Optional) Software Engineering Case Study: Identifying the Classes in a Requirements Document.....	138
Section 3.11. Wrap-Up.....	146
Summary.....	146
Terminology.....	149
Self-Review Exercises.....	150
Answers to Self-Review Exercises.....	151
Exercises.....	152
Chapter 4. Control Statements: Part 1.....	154
Section 4.1. Introduction.....	155
Section 4.2. Algorithms.....	155
Section 4.3. Pseudocode.....	156
Section 4.4. Control Structures.....	156
Section 4.5. if Single-Selection Statement.....	159
Section 4.6. if...else Double-Selection Statement.....	160
Section 4.7. while Repetition Statement.....	165
Section 4.8. Formulating Algorithms: Counter-Controlled Repetition.....	166
Section 4.9. Formulating Algorithms: Sentinel-Controlled Repetition.....	171
Section 4.10. Formulating Algorithms: Nested Control Statements.....	179
Section 4.11. Compound Assignment Operators.....	184
Section 4.12. Increment and Decrement Operators.....	185
Section 4.13. Primitive Types.....	188
Section 4.14. (Optional) GUI and Graphics Case Study: Creating Simple Drawings.....	188
Section 4.15. (Optional) Software Engineering Case Study: Identifying Class Attributes.....	193
Section 4.16. Wrap-Up.....	197
Summary.....	198
Terminology.....	203
Self-Review Exercises.....	204
Answers to Self-Review Exercises.....	206
Exercises.....	207
Chapter 5. Control Statements: Part 2.....	213
Section 5.1. Introduction.....	214
Section 5.2. Essentials of Counter-Controlled Repetition.....	214
Section 5.3. for Repetition Statement.....	216
Section 5.4. Examples Using the for Statement.....	220
Section 5.5. do...while Repetition Statement.....	225
Section 5.6. switch Multiple-Selection Statement.....	226
Section 5.7. break and continue Statements.....	234
Section 5.8. Logical Operators.....	236
Section 5.9. Structured Programming Summary.....	242
Section 5.10. (Optional) GUI and Graphics Case Study: Drawing Rectangles and Ovals.....	247
Section 5.11. (Optional) Software Engineering Case Study: Identifying Objects' States and Activities.....	250
Section 5.12. Wrap-Up.....	254
Summary.....	255
Terminology.....	259
Self-Review Exercises.....	260
Answers to Self-Review Exercises.....	261
Exercises.....	262
Chapter 6. Methods: A Deeper Look.....	266
Section 6.1. Introduction.....	267
Section 6.2. Program Modules in Java.....	268
Section 6.3. static Methods, static Fields and Class Math.....	269
Section 6.4. Declaring Methods with Multiple Parameters.....	272
Section 6.5. Notes on Declaring and Using Methods.....	276
Section 6.6. Method-Call Stack and Activation Records.....	277
Section 6.7. Argument Promotion and Casting.....	278
Section 6.8. Java API Packages.....	279
Section 6.9. Case Study: Random-Number Generation.....	281
Section 6.10. Case Study: A Game of Chance (Introducing Enumerations).....	287

Section 6.11. Scope of Declarations.....	291
Section 6.12. Method Overloading.....	294
Section 6.13. (Optional) GUI and Graphics Case Study: Colors and Filled Shapes.....	297
Section 6.14. (Optional) Software Engineering Case Study: Identifying Class Operations.....	300
Section 6.15. Wrap-Up.....	307
Summary.....	308
Terminology.....	311
Self-Review Exercises.....	312
Answers to Self-Review Exercises.....	314
Exercises.....	316
Chapter 7. Arrays.....	322
Section 7.1. Introduction.....	323
Section 7.2. Arrays.....	323
Section 7.3. Declaring and Creating Arrays.....	325
Section 7.4. Examples Using Arrays.....	326
Section 7.5. Case Study: Card Shuffling and Dealing Simulation.....	335
Section 7.6. Enhanced for Statement.....	339
Section 7.7. Passing Arrays to Methods.....	340
Section 7.8. Case Study: Class GradeBook Using an Array to Store Grades.....	344
Section 7.9. Multidimensional Arrays.....	349
Section 7.10. Case Study: Class GradeBook Using a Two-Dimensional Array.....	353
Section 7.11. Variable-Length Argument Lists.....	359
Section 7.12. Using Command-Line Arguments.....	360
Section 7.13. (Optional) GUI and Graphics Case Study: Drawing Arcs.....	362
Section 7.14. (Optional) Software Engineering Case Study: Collaboration Among Objects.....	365
Section 7.15. Wrap-Up.....	373
Summary.....	374
Terminology.....	376
Self-Review Exercises.....	377
Answers to Self-Review Exercises.....	378
Exercises.....	378
Special Section: Building Your Own Computer.....	388
Chapter 8. Classes and Objects: A Deeper Look.....	395
Section 8.1. Introduction.....	396
Section 8.2. Time Class Case Study.....	397
Section 8.3. Controlling Access to Members.....	401
Section 8.4. Referring to the Current Object's Members with the this Reference.....	402
Section 8.5. Time Class Case Study: Overloaded Constructors.....	404
Section 8.6. Default and No-Argument Constructors.....	409
Section 8.7. Notes on Set and Get Methods.....	410
Section 8.8. Composition.....	411
Section 8.9. Enumerations.....	414
Section 8.10. Garbage Collection and Method finalize.....	417
Section 8.11. static Class Members.....	418
Section 8.12. static Import.....	423
Section 8.13. final Instance Variables.....	424
Section 8.14. Software Reusability.....	426
Section 8.15. Data Abstraction and Encapsulation.....	427
Section 8.16. Time Class Case Study: Creating Packages.....	429
Section 8.17. Package Access.....	434
Section 8.18. (Optional) GUI and Graphics Case Study: Using Objects with Graphics.....	436
Section 8.19. (Optional) Software Engineering Case Study: Starting to Program the Classes of the ATM System.....	439
Section 8.20. Wrap-Up.....	445
Summary.....	445
Terminology.....	448
Self-Review Exercise.....	449
Answers to Self-Review Exercise.....	450
Exercises.....	450
Chapter 9. Object-Oriented Programming: Inheritance.....	454

Section 9.1. Introduction.....	455
Section 9.2. Superclasses and Subclasses.....	456
Section 9.3. protected Members.....	458
Section 9.4. Relationship between Superclasses and Subclasses.....	459
Section 9.5. Constructors in Subclasses.....	483
Section 9.6. Software Engineering with Inheritance.....	489
Section 9.7. Object Class.....	490
Section 9.8. (Optional) GUI and Graphics Case Study: Displaying Text and Images Using Labels.....	492
Section 9.9. Wrap-Up.....	494
Summary.....	495
Terminology.....	496
Self-Review Exercises.....	496
Answers to Self-Review Exercises.....	497
Exercises.....	497

Chapter 10. Object-Oriented Programming: Polymorphism..... 498

Section 10.1. Introduction.....	499
Section 10.2. Polymorphism Examples.....	501
Section 10.3. Demonstrating Polymorphic Behavior.....	502
Section 10.4. Abstract Classes and Methods.....	505
Section 10.5. Case Study: Payroll System Using Polymorphism.....	507
Section 10.6. final Methods and Classes.....	522
Section 10.7. Case Study: Creating and Using Interfaces.....	523
Section 10.8. (Optional) GUI and Graphics Case Study: Drawing with Polymorphism.....	535
Section 10.9. (Optional) Software Engineering Case Study: Incorporating Inheritance into the ATM System.....	537
Section 10.10. Wrap-Up.....	545
Summary.....	545
Terminology.....	547
Self-Review Exercises.....	548
Answers to Self-Review Exercises.....	548
Exercises.....	548

Chapter 11. GUI Components: Part 1..... 550

Section 11.1. Introduction.....	551
Section 11.2. Simple GUI-Based Input/Output with JOptionPane.....	552
Section 11.3. Overview of Swing Components.....	555
Section 11.4. Displaying Text and Images in a Window.....	558
Section 11.5. Text Fields and an Introduction to Event Handling with Nested Classes.....	563
Section 11.6. Common GUI Event Types and Listener Interfaces.....	569
Section 11.7. How Event Handling Works.....	572
Section 11.8. JButton.....	573
Section 11.9. Buttons That Maintain State.....	577
Section 11.10. JComboBox and Using an Anonymous Inner Class for Event Handling.....	583
Section 11.11. JList.....	587
Section 11.12. Multiple-Selection Lists.....	589
Section 11.13. Mouse Event Handling.....	592
Section 11.14. Adapter Classes.....	597
Section 11.15. JPanel Subclass for Drawing with the Mouse.....	600
Section 11.16. Key-Event Handling.....	604
Section 11.17. Layout Managers.....	607
Section 11.18. Using Panels to Manage More Complex Layouts.....	617
Section 11.19. JTextArea.....	618
Section 11.20. Wrap-Up.....	621
Summary.....	622
Terminology.....	628
Self-Review Exercises.....	630
Answers to Self-Review Exercises.....	631
Exercises.....	631

Chapter 12. Graphics and Java 2D™..... 636

Section 12.1. Introduction.....	637
Section 12.2. Graphics Contexts and Graphics Objects.....	639

Section 12.3. Color Control.....	640
Section 12.4. Font Control.....	647
Section 12.5. Drawing Lines, Rectangles and Ovals.....	653
Section 12.6. Drawing Arcs.....	657
Section 12.7. Drawing Polygons and Polylines.....	660
Section 12.8. Java 2D API.....	663
Section 12.9. Wrap-Up.....	670
Summary.....	670
Terminology.....	672
Self-Review Exercises.....	673
Answers to Self-Review Exercises.....	674
Exercises.....	674
Chapter 13. Exception Handling.....	679
Section 13.1. Introduction.....	680
Section 13.2. Exception-Handling Overview.....	681
Section 13.3. Example: Divide by Zero without Exception Handling.....	682
Section 13.4. Example: Handling ArithmeticExceptions and InputMismatchExceptions.....	684
Section 13.5. When to Use Exception Handling.....	689
Section 13.6. Java Exception Hierarchy.....	690
Section 13.7. finally Block.....	693
Section 13.8. Stack Unwinding.....	697
Section 13.9. printStackTrace, getStackTrace and getMessage.....	699
Section 13.10. Chained Exceptions.....	701
Section 13.11. Declaring New Exception Types.....	703
Section 13.12. Preconditions and Postconditions.....	704
Section 13.13. Assertions.....	705
Section 13.14. Wrap-Up.....	706
Summary.....	707
Terminology.....	710
Self-Review Exercises.....	710
Answers to Self-Review Exercises.....	711
Exercises.....	712
Chapter 14. Files and Streams.....	713
Section 14.1. Introduction.....	714
Section 14.2. Data Hierarchy.....	715
Section 14.3. Files and Streams.....	717
Section 14.4. Class File.....	719
Section 14.5. Sequential-Access Text Files.....	723
Section 14.6. Object Serialization.....	739
Section 14.7. Additional java.io Classes.....	748
Section 14.8. Opening Files with JFileChooser.....	750
Section 14.9. Wrap-Up.....	754
Summary.....	754
Terminology.....	756
Self-Review Exercises.....	757
Answers to Self-Review Exercises.....	759
Exercises.....	760
Chapter 15. Recursion.....	764
Section 15.1. Introduction.....	765
Section 15.2. Recursion Concepts.....	766
Section 15.3. Example Using Recursion: Factorials.....	767
Section 15.4. Example Using Recursion: Fibonacci Series.....	770
Section 15.5. Recursion and the Method-Call Stack.....	773
Section 15.6. Recursion vs. Iteration.....	774
Section 15.7. Towers of Hanoi.....	776
Section 15.8. Fractals.....	779
Section 15.9. Recursive Backtracking.....	790
Section 15.10. Wrap-Up.....	790
Section 15.11. Internet and Web Resources.....	791

Summary.....	792
Terminology.....	794
Self-Review Exercises.....	794
Answers to Self-Review Exercises.....	795
Exercises.....	795
Chapter 16. Searching and Sorting.....	800
Section 16.1. Introduction.....	801
Section 16.2. Searching Algorithms.....	802
Section 16.3. Sorting Algorithms.....	811
Section 16.4. Invariants.....	826
Section 16.5. Wrap-Up.....	827
Summary.....	828
Terminology.....	829
Self-Review Exercises.....	830
Answers to Self-Review Exercises.....	830
Exercises.....	830
Chapter 17. Data Structures.....	833
Section 17.1. Introduction.....	834
Section 17.2. Type-Wrapper Classes for Primitive Types.....	835
Section 17.3. Autoboxing and Auto-Unboxing.....	835
Section 17.4. Self-Referential Classes.....	836
Section 17.5. Dynamic Memory Allocation.....	837
Section 17.6. Linked Lists.....	837
Section 17.7. Stacks.....	848
Section 17.8. Queues.....	852
Section 17.9. Trees.....	854
Section 17.10. Wrap-Up.....	861
Summary.....	861
Terminology.....	863
Self-Review Exercises.....	864
Answers to Self-Review Exercises.....	865
Exercises.....	866
Chapter 18. Generics.....	886
Section 18.1. Introduction.....	887
Section 18.2. Motivation for Generic Methods.....	888
Section 18.3. Generic Methods: Implementation and Compile-Time Translation.....	890
Section 18.4. Additional Compile-Time Translation Issues: Methods That Use a Type Parameter as the Return Type.....	893
Section 18.5. Overloading Generic Methods.....	896
Section 18.6. Generic Classes.....	897
Section 18.7. Raw Types.....	907
Section 18.8. Wildcards in Methods That Accept Type Parameters.....	911
Section 18.9. Generics and Inheritance: Notes.....	915
Section 18.10. Wrap-Up.....	916
Section 18.11. Internet and Web Resources.....	916
Summary.....	916
Terminology.....	919
Self-Review Exercises.....	919
Answers to Self-Review Exercises.....	919
Exercises.....	920
Chapter 19. Collections.....	921
Section 19.1. Introduction.....	922
Section 19.2. Collections Overview.....	923
Section 19.3. Class Arrays.....	924
Section 19.4. Interface Collection and Class Collections.....	927
Section 19.5. Lists.....	928
Section 19.6. Collections Algorithms.....	939
Section 19.7. Stack Class of Package <code>java.util</code>	952
Section 19.8. Class <code>PriorityQueue</code> and Interface <code>Queue</code>	955
Section 19.9. Sets.....	956

Section 19.10. Maps.....	959
Section 19.11. Properties Class.....	964
Section 19.12. Synchronized Collections.....	967
Section 19.13. Unmodifiable Collections.....	967
Section 19.14. Abstract Implementations.....	968
Section 19.15. Wrap-Up.....	968
Summary.....	969
Terminology.....	972
Self-Review Exercises.....	973
Answers to Self-Review Exercises.....	973
Exercises.....	974
Chapter 20. Introduction to Java Applets.....	976
Section 20.1. Introduction.....	977
Section 20.2. Sample Applets Provided with the JDK.....	977
Section 20.3. Simple Java Applet: Drawing a String.....	982
Section 20.4. Applet Life-Cycle Methods.....	987
Section 20.5. Initializing an Instance Variable with Method init.....	988
Section 20.6. Sandbox Security Model.....	990
Section 20.7. Internet and Web Resources.....	990
Section 20.8. Wrap-Up.....	991
Summary.....	991
Terminology.....	993
Self-Review Exercise.....	993
Answers to Self-Review Exercise.....	993
Exercises.....	994
Chapter 21. Multimedia: Applets and Applications.....	995
Section 21.1. Introduction.....	996
Section 21.2. Loading, Displaying and Scaling Images.....	997
Section 21.3. Animating a Series of Images.....	1000
Section 21.4. Image Maps.....	1005
Section 21.5. Loading and Playing Audio Clips.....	1008
Section 21.6. Playing Video and Other Media with Java Media Framework.....	1011
Section 21.7. Wrap-Up.....	1016
Section 21.8. Web Resources.....	1016
Summary.....	1017
Terminology.....	1018
Self-Review Exercises.....	1019
Answers to Self-Review Exercises.....	1019
Exercises.....	1020
Special Section: Challenging Multimedia Projects.....	1020
Chapter 22. GUI Components: Part 2.....	1023
Section 22.1. Introduction.....	1024
Section 22.2. JSlider.....	1024
Section 22.3. Windows: Additional Notes.....	1028
Section 22.4. Using Menus with Frames.....	1029
Section 22.5. JPopupMenu.....	1037
Section 22.6. Pluggable Look-and-Feel.....	1040
Section 22.7. JDesktopPane and JInternalFrame.....	1044
Section 22.8. JTabbedPane.....	1048
Section 22.9. Layout Managers: BoxLayout and GridBagLayout.....	1050
Section 22.10. Wrap-Up.....	1063
Summary.....	1064
Terminology.....	1065
Self-Review Exercises.....	1067
Answers to Self-Review Exercises.....	1067
Exercises.....	1068
Chapter 23. Multithreading.....	1070
Section 23.1. Introduction.....	1071
Section 23.2. Thread States: Life Cycle of a Thread.....	1073

Section 23.3. Thread Priorities and Thread Scheduling.....	1075
Section 23.4. Creating and Executing Threads.....	1077
Section 23.5. Thread Synchronization.....	1081
Section 23.6. Producer/Consumer Relationship without Synchronization.....	1090
Section 23.7. Producer/Consumer Relationship: ArrayBlockingQueue.....	1097
Section 23.8. Producer/Consumer Relationship with Synchronization.....	1100
Section 23.9. Producer/Consumer Relationship: Bounded Buffers.....	1106
Section 23.10. Producer/Consumer Relationship: The Lock and Condition Interfaces.....	1114
Section 23.11. Multithreading with GUI.....	1120
Section 23.12. Other Classes and Interfaces in <code>java.util.concurrent</code>	1135
Section 23.13. Wrap-Up.....	1135
Summary.....	1136
Terminology.....	1142
Self-Review Exercises.....	1143
Answers to Self-Review Exercises.....	1144
Exercises.....	1144
Chapter 24. Networking.....	1146
Section 24.1. Introduction.....	1147
Section 24.2. Manipulating URLs.....	1148
Section 24.3. Reading a File on a Web Server.....	1153
Section 24.4. Establishing a Simple Server Using Stream Sockets.....	1157
Section 24.5. Establishing a Simple Client Using Stream Sockets.....	1158
Section 24.6. Client/Server Interaction with Stream Socket Connections.....	1159
Section 24.7. Connectionless Client/Server Interaction with Datagrams.....	1171
Section 24.8. Client/Server Tic-Tac-Toe Using a Multithreaded Server.....	1178
Section 24.9. Security and the Network.....	1193
Section 24.10. [Web Bonus] Case Study: DeitelMessenger Server and Client.....	1194
Section 24.11. Wrap-Up.....	1194
Summary.....	1194
Terminology.....	1196
Self-Review Exercises.....	1197
Answers to Self-Review Exercises.....	1197
Exercises.....	1198
Chapter 25. Accessing Databases with JDBC.....	1201
Section 25.1. Introduction.....	1202
Section 25.2. Relational Databases.....	1203
Section 25.3. Relational Database Overview: The books Database.....	1204
Section 25.4. SQL.....	1207
Section 25.5. Instructions for installing MySQL and MySQL Connector/J.....	1216
Section 25.6. Instructions for Setting Up a MySQL User Account.....	1217
Section 25.7. Creating Database books in MySQL.....	1218
Section 25.8. Manipulating Databases with JDBC.....	1219
Section 25.9. RowSet Interface.....	1236
Section 25.10. Java DB/Apache Derby.....	1239
Section 25.11. PreparedStatements.....	1254
Section 25.12. Stored Procedures.....	1256
Section 25.13. Transaction Processing.....	1256
Section 25.14. Wrap-Up.....	1257
Section 25.15. Web Resources and Recommended Readings.....	1257
Summary.....	1259
Terminology.....	1264
Self-Review Exercise.....	1265
Answers to Self-Review Exercise.....	1265
Exercises.....	1265
Chapter 26. Web Applications: Part 1.....	1268
Section 26.1. Introduction.....	1269
Section 26.2. Simple HTTP Transactions.....	1270
Section 26.3. Multitier Application Architecture.....	1272
Section 26.4. Java Web Technologies.....	1273

Section 26.5. Creating and Running a Simple Application in Java Studio Creator 2.....	1276
Section 26.6. JSF Components.....	1293
Section 26.7. Session Tracking.....	1308
Section 26.8. Wrap-Up.....	1336
Section 26.9. Web Resources.....	1337
Summary.....	1338
Terminology.....	1346
Self-Review Exercises.....	1347
Answers to Self-Review Exercises.....	1347
Exercises.....	1348
Chapter 27. Web Applications: Part 2.....	1349
Section 27.1. Introduction.....	1350
Section 27.2. Accessing Databases in Web Applications.....	1351
Section 27.3. Ajax-Enabled JSF Components.....	1363
Section 27.4. AutoComplete Text Field and Virtual Forms.....	1365
Section 27.5. Google Maps Map Viewer Component.....	1374
Section 27.6. Wrap-Up.....	1386
Section 27.7. Web Resources.....	1386
Summary.....	1387
Terminology.....	1389
Self-Review Exercises.....	1390
Answers to Self-Review Exercises.....	1390
Exercises.....	1391
Chapter 28. JAX-WS Web Services, Web 2.0 and Mash-Ups.....	1392
Section 28.1. Introduction.....	1393
Section 28.2. Java Web Services Basics.....	1396
Section 28.3. Creating, Publishing, Testing and Describing a Web Service.....	1396
Section 28.4. Consuming a Web Service.....	1406
Section 28.5. SOAP.....	1416
Section 28.6. Session Tracking in Web Services.....	1418
Section 28.7. Consuming a Database-Driven Web Service from a Web Application.....	1434
Section 28.8. Passing an Object of a User-Defined Type to a Web Service.....	1443
Section 28.9. Wrap-Up.....	1454
Section 28.10. Web Resources.....	1454
Summary.....	1455
Terminology.....	1460
Self-Review Exercises.....	1460
Answers to Self-Review Exercises.....	1461
Exercises.....	1461
Chapter 29. Formatted Output.....	1463
Section 29.1. Introduction.....	1464
Section 29.2. Streams.....	1464
Section 29.3. Formatting Output with printf.....	1465
Section 29.4. Printing Integers.....	1465
Section 29.5. Printing Floating-Point Numbers.....	1466
Section 29.6. Printing Strings and Characters.....	1468
Section 29.7. Printing Dates and Times.....	1469
Section 29.8. Other Conversion Characters.....	1472
Section 29.9. Printing with Field Widths and Precisions.....	1474
Section 29.10. Using Flags in the printf Format String.....	1476
Section 29.11. Printing with Argument Indices.....	1479
Section 29.12. Printing Literals and Escape Sequences.....	1480
Section 29.13. Formatting Output with Class Formatter.....	1481
Section 29.14. Wrap-Up.....	1482
Summary.....	1482

Preface

“Live in fragments no longer, only connect.”

—Edgar Morgan Foster

Welcome to Java and *Java How to Program, Seventh Edition!* At Deitel & Associates, we write programming language textbooks and professional books for Prentice Hall, deliver corporate training worldwide and develop Internet businesses. This book was a joy to create. It reflects significant changes to the Java language and to the preferred ways of teaching and learning programming. All of the chapters have been significantly tuned.

New and Updated Features

Here's a list of updates we've made to the sixth and seventh editions of *Java How to Program*:

- We updated the entire book to the new Java Standard Edition 6 (“Mustang”) and carefully audited the manuscript against the *Java Language Specification*.
- We audited the presentation against the ACM/IEEE curriculum recommendations and the Computer Science Advanced Placement Examination.
- We reinforced our early classes and objects pedagogy, paying careful attention to the guidance of the college instructors on our review teams to ensure that we got the conceptual level right. The book is object-oriented throughout and the treatment of OOP is clear and accessible. We introduce the basic concepts and terminology of object technology in Chapter 1. Students develop their first customized classes and objects in Chapter 3. Presenting objects and classes in the early chapters gets students “thinking about objects” immediately and mastering these concepts more thoroughly.
- The early classes and objects presentation features `Time`, `Employee` and `GradeBook` class case studies that weave their way through multiple sections and chapters, gradually introducing deeper OO concepts.
- Instructors teaching introductory courses have a broad choice of the amount of GUI and graphics to cover—from none, to a ten-brief-sections introductory sequence, to a deep treatment in Chapters 11, 12 and 22, and Appendix F.
- We tuned our object-oriented presentation to use the latest version of the *UML™ (Unified Modeling Language™)*—the *UML™ 2*—the industry-standard graphical language for modeling object-oriented systems.
- We introduced and tuned the optional OOD/UML 2 automated teller machine (ATM) case study in Chapters 1–8 and 10. We include a web bonus appendix with the complete code implementation. Check out the back cover testimonials.
- We added several substantial object-oriented web programming case studies.

xxvi Preface

- We updated Chapter 25, Accessing Databases with JDBC, to include JDBC 4 and to use the new Java DB/Apache Derby database management system, in addition to MySQL. The chapter features an OO case study on developing a database-driven address book that demonstrates prepared statements and JDBC 4's automatic driver discovery.
- We added Chapters 26 and 27, Web Applications: Parts 1 and 2, which introduce JavaServer Faces (JSF) technology and use it with Sun Java Studio Creator 2 to build web applications quickly and easily. Chapter 26 includes examples on building web application GUIs, handling events, validating forms and session tracking. The JSF material replaces our previous chapters on servlets and JavaServer Pages (JSP).
- We added Chapter 27, Web Applications: Part 2, that discusses developing Ajax-enabled web applications, using JavaServer Faces and Java BluePrints technology. The chapter features a database-driven multitier web address book application that allows users to add contacts, search for contacts and display contacts' addresses on Google™ Maps. This Ajax-enabled application gives the reader a real sense of Web 2.0 development. The application uses Ajax-enabled JSF components to suggest contact names while the user types a name to locate, and to display a located address on a Google Map.
- We added Chapter 28, JAX-WS Web Services, which uses a tools-based approach to creating and consuming web services—a signature Web 2.0 capability. Case studies include developing blackjack and airline reservation web services.
- We use the new tools-based approach for rapid web applications development; all the tools are available free for download.
- We launched the Deitel Internet Business Initiative with 60 new Resource Centers to support our academic and professional readers. Check out our new Resource Centers (www.deitel.com/resourcecenters.html) including Java SE 6 (Mustang), Java, Java Assessment and Certification, Java Design Patterns, Java EE 5, Code Search Engines and Code Sites, Game programming, Programming Projects and many more. Sign up for the free *Deitel® Buzz Online* e-mail newsletter (www.deitel.com/newsletter/subscribe.html)—each week we announce our latest Resource Center(s) and include other items of interest to our readers.
- We discuss key software engineering community concepts, such as Web 2.0, Ajax, SOA, web services, open source software, design patterns, mashups, refactoring, extreme programming, agile software development, rapid prototyping and more.
- We completely reworked Chapter 23, Multithreading [special thanks to Brian Goetz and Joseph Bowbeer—co-authors of *Java Concurrency in Practice*, Addison-Wesley, 2006].
- We discuss the new `SwingWorker` class for developing multithreaded user interfaces.
- We discuss the new Java Desktop Integration Components (JDIC), such as splash screens and interactions with the system tray.

New and Updated Features xxvii

- We discuss the new `GroupLayout` layout manager in the context of the NetBeans 5.5 Matisse GUI design tool to create portable GUIs that adhere to the underlying platform's GUI design guidelines.
- We present the new `JTable` sorting and filtering capabilities which allow the user to re-sort the data in a `JTable` and filter it by regular expressions.
- We present an in-depth treatment of generics and generic collections.
- We introduce mashups—applications typically built by calling the web services (and/or using the RSS feeds) of two or more other sites—another Web 2.0 signature capability.
- We discuss the new `StringBuilder` class, which performs better than `StringBuffer` in non-threaded applications.
- We present annotations, which greatly reduce the amount of code you have to write to build applications.

Capabilities introduced in Java How to Program, Sixth Edition include:

- obtaining formatted input with class `Scanner`
- displaying formatted output with the `System.out` object's `printf` method
- enhanced `for` statements to process array elements and collections
- declaring methods with variable-length argument lists (“varargs”)
- using `enum` classes that declare sets of constants
- importing the `static` members of one class for use in another
- converting primitive-type values to type-wrapper objects and vice versa, using autoboxing and auto-unboxing, respectively
- using generics to create general models of methods and classes that can be declared once, but used with many different data types
- using the generics-enhanced data structures of the Collections API
- using the Concurrency API to implement multithreaded applications
- using JDBC RowSets to access data in a database

All of this has been carefully reviewed by distinguished academics and industry developers who worked with us on *Java How to Program, 6/e* and *Java How to Program, 7/e*.

We believe that this book and its support materials will provide students and professionals with an informative, interesting, challenging and entertaining Java educational experience. The book includes a comprehensive suite of ancillary materials that help instructors maximize their students' learning experience.

Java How to Program, 7/e presents hundreds of complete, working Java programs and depicts their inputs and outputs. This is our signature “live-code” approach—we present most Java programming concepts in the context of complete working programs.

As you read this book, if you have questions, send an e-mail to deitel@deitel.com; we'll respond promptly. For updates on this book and the status of all supporting Java software, and for the latest news on all Deitel publications and services, visit www.deitel.com.

xxviii [Preface](#)

Sign up at www.deitel.com/newsletter/subscribe.html for the free *Deitel® Buzz Online* e-mail newsletter and check out www.deitel.com/resourcecenters.html for our growing list of Resource Centers.

Using the UML 2 to Develop an Object-Oriented Design of an ATM. UML 2 has become the preferred graphical modeling language for designing object-oriented systems. All the UML diagrams in the book comply with the UML 2 specification. We use UML activity diagrams to demonstrate the flow of control in each of Java's control statements, and we use UML class diagrams to visually represent classes and their inheritance relationships.

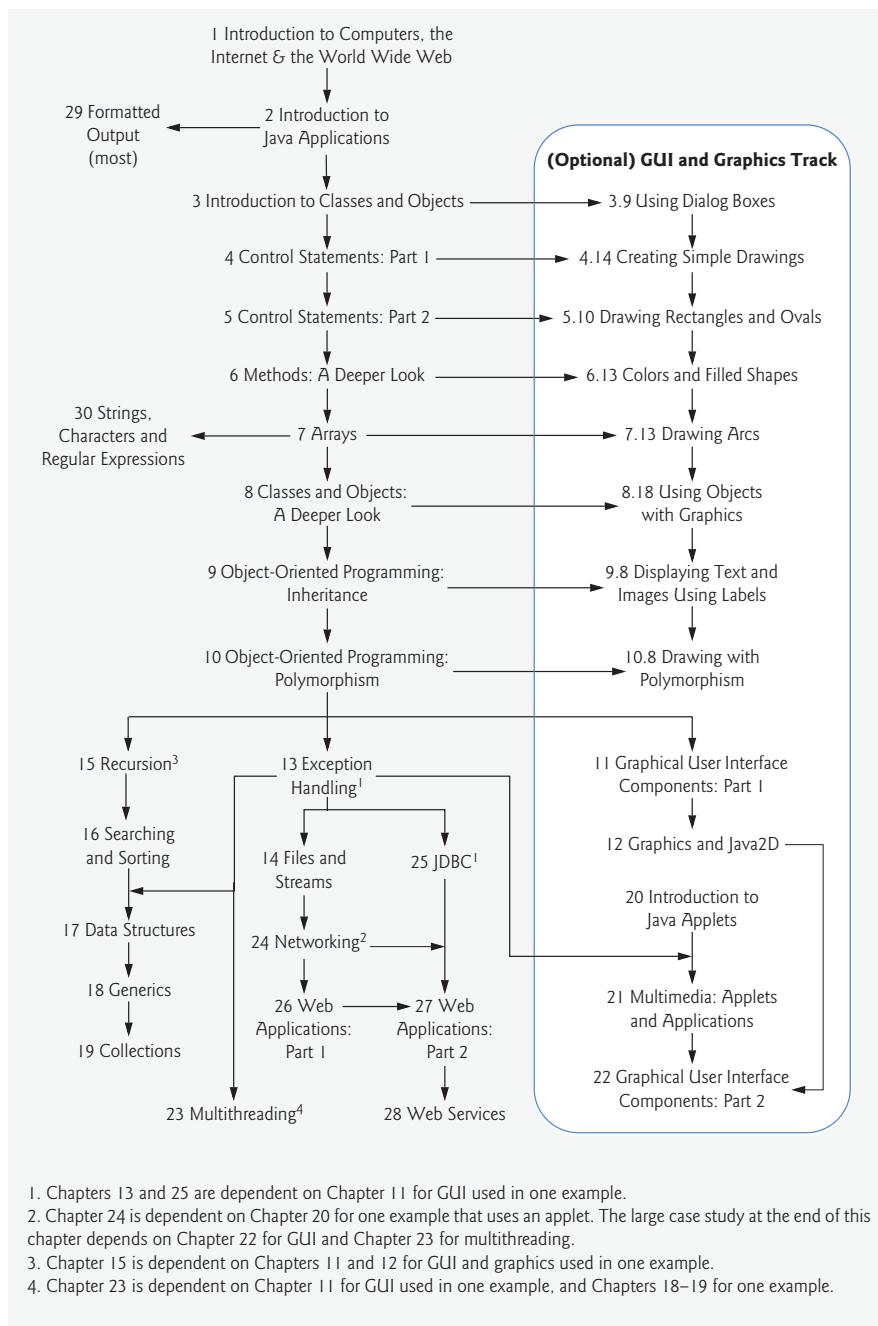

We include an optional (but highly recommended) case study on object-oriented design using the UML. The case study was reviewed by a distinguished team of OOD/UML academic and industry professionals, including leaders in the field from Rational (the creators of the UML) and the Object Management Group (responsible for evolving the UML). In the case study, we design and fully implement the software for a simple automated teller machine (ATM). The Software Engineering Case Study sections at the ends of Chapters 1–8 and 10 present a carefully paced introduction to object-oriented design using the UML. We introduce a concise, simplified subset of the UML 2, then guide the reader through a first design experience intended for the novice. The case study is not an exercise; rather, it is an end-to-end learning experience that concludes with a detailed walkthrough of the complete Java code. The Software Engineering Case Study sections help students develop an object-oriented design to complement the object-oriented programming concepts they begin learning in Chapter 1 and implementing in Chapter 3. In the first of these sections at the end of Chapter 1, we introduce basic concepts and terminology of OOD. In the optional Software Engineering Case Study sections at the ends of Chapters 2–5, we consider more substantial issues, as we undertake a challenging problem with the techniques of OOD. We analyze a typical requirements document that specifies a system to be built, determine the objects needed to implement that system, determine the attributes these objects need to have, determine the behaviors these objects need to exhibit, and specify how the objects must interact with one another to meet the system requirements. In a web bonus appendix, we include a complete Java code implementation of the object-oriented system that we designed in the earlier chapters. This case study helps prepare students for the kinds of substantial projects they will encounter in industry. We employ a carefully developed, incremental object-oriented design process to produce a UML 2 model for our ATM system. From this design, we produce a substantial working Java implementation using key object-oriented programming notions, including classes, objects, encapsulation, visibility, composition, inheritance and polymorphism.

Dependency Chart

The chart on the next page shows the dependencies among the chapters to help instructors plan their syllabi. *Java How to Program, 7/e* is a large book which is appropriate for a variety of programming courses at various levels. Chapters 1–14 form an accessible elementary programming sequence with a solid introduction to object-oriented programming. Chapters 11, 12, 20, 21 and 22 form a substantial GUI, graphics and multimedia sequence. Chapters 15–19 form a nice data structures sequence. Chapters 24–28 form a clear database-intensive web development sequence.

New and Updated Features

xxix

Teaching Approach

Java How to Program, 7/e contains a rich collection of examples. The book concentrates on the principles of good software engineering and stresses program clarity. We teach by example. We are educators who teach leading-edge topics in industry classrooms worldwide. Dr. Harvey M. Deitel has 20 years of college teaching experience and 17 years of industry teaching experience. Paul Deitel has 15 years of industry teaching experience. The Deitels have taught courses at all levels to government, industry, military and academic clients of Deitel & Associates.

Live-Code Approach. *Java How to Program, 7/e* is loaded with “live-code” examples—by this we mean that each new concept is presented in the context of a complete working Java application that is immediately followed by one or more actual executions showing the program’s inputs and outputs. This style exemplifies the way we teach and write about programming; we call this the “live-code” approach.

Syntax Coloring. We syntax color all the Java code, similar to the way most Java integrated-development environments and code editors syntax color code. This improves code readability—an important goal, given that this book contains about 20,000 lines of code in complete, working Java programs. Our syntax-coloring conventions are as follows:

```
comments appear in green
keywords appear in dark blue
errors appear in red
constants and literal values appear in light blue
all other code appears in black
```

Code Highlighting. We place gray rectangles around the key code segments in each program.

Using Fonts and Colors for Emphasis. We place the key terms and the index’s page reference for each defining occurrence in **bold blue** text for easier reference. We emphasize on-screen components in the **bold Helvetica** font (e.g., the **File** menu) and emphasize Java program text in the **Lucida** font (for example, `int x = 5`).

Web Access. All of the source-code examples for *Java How to Program, 7/e* (and for our other publications) are available for download from:

```
www.deitel.com/books/jhtp7
www.prenhall.com/deitel
```

Site registration is quick and easy. Download all the examples, then run each program as you read the corresponding text discussions. Making changes to the examples and seeing the effects of those changes is a great way to enhance your Java learning experience.

Objectives. Each chapter begins with a statement of objectives. This lets you know what to expect and gives you an opportunity, after reading the chapter, to determine if you have met the objectives.

Quotations. The learning objectives are followed by quotations. Some are humorous, philosophical or offer interesting insights. We hope that you enjoy relating the quotations to the chapter material.

Outline. The chapter outline helps you approach the material in a top-down fashion, so you can anticipate what is to come and set a comfortable and effective learning pace.

Illustrations/Figures. Abundant charts, tables, line drawings, programs and program output are included. We model the flow of control in control statements with UML activity diagrams. UML class diagrams model the fields, constructors and methods of classes. We make extensive use of six major UML diagram types in the optional OOD/UML 2 ATM case study.

Programming Tips. We include programming tips to help you focus on important aspects of program development. These tips and practices represent the best we have gleaned from a combined six decades of programming and teaching experience. One of our students—a mathematics major—told us that she feels this approach is like the highlighting of axioms, theorems and corollaries in mathematics books; it provides a basis on which to build good software.

Good Programming Practice

Good Programming Practices *call attention to techniques that will help you produce programs that are clearer, more understandable and more maintainable.*

Common Programming Error

Students tend to make certain kinds of errors frequently. Pointing out these Common Programming Errors reduces the likelihood that you'll make the same mistakes.

Error-Prevention Tip

These tips contain suggestions for exposing bugs and removing them from your programs; many describe aspects of Java that prevent bugs from getting into programs in the first place.

Performance Tip

Students like to “turbo charge” their programs. These tips highlight opportunities for making your programs run faster or minimizing the amount of memory that they occupy.

Portability Tip

We include Portability Tips to help you write code that will run on a variety of platforms and to explain how Java achieves its high degree of portability.

Software Engineering Observation

The Software Engineering Observations highlight architectural and design issues that affect the construction of software systems, especially large-scale systems.

Look-and-Feel Observations

We provide Look-and-Feel Observations to highlight graphical-user-interface conventions. These observations help you design attractive, user-friendly graphical user interfaces that conform to industry norms.

Wrap-Up Section. Each of the chapters ends with a brief “wrap-up” section that recaps the chapter content and transitions to the next chapter.

Summary Bullets. Each chapter ends with additional pedagogical devices. We present a thorough, bullet-list-style summary of the chapter, section by section.

xxxii [Preface](#)

Terminology. We include an alphabetized list of the important terms defined in each chapter. Each term also appears in the index, with its defining occurrence highlighted with a **bold, blue** page number.

Self-Review Exercises and Answers. Extensive self-review exercises and answers are included for self-study.

Exercises. Each chapter concludes with a substantial set of exercises including simple recall of important terminology and concepts; identifying the errors in code samples, writing individual program statements; writing small portions of methods and Java classes; writing complete methods, Java classes and programs; and building major term projects. The large number of exercises enables instructors to tailor their courses to the unique needs of their students and to vary course assignments each semester. Instructors can use these exercises to form homework assignments, short quizzes, major examinations and term projects. [NOTE: Please do not write to us requesting access to the Prentice Hall Instructor's Resource Center. Access is limited strictly to college instructors teaching from the book. Instructors may obtain access only through their Prentice Hall representatives.] Be sure to check out our Programming Projects Resource Center (<http://www.deitel.com/ProgrammingProjects/>) for lots of additional exercise and project possibilities.

Thousands of Index Entries. We have included an extensive index which is especially useful when you use the book as a reference.

"Double Indexing" of Java Live-Code Examples. For every source-code program in the book, we index the figure caption both alphabetically and as a subindex item under "Examples." This makes it easier to find examples using particular features.

Student Resources Included with Java How to Program, 7/e

A number of for-sale Java development tools are available, but you do not need any of these to get started with Java. We wrote *Java How to Program, 7/e* using only the new free Java Standard Edition Development Kit (JDK), version 6.0. The current JDK version can be downloaded from Sun's Java website java.sun.com/javase/downloads/index.jsp. This site also contains the JDK documentation downloads.

The CDs that accompany *Java How to Program, 7/e* contain the NetBeans™ 5.5 Integrated Development Environment (IDE) for developing all types of Java applications and Sun Java™ Studio Creator 2 Update 1 for web-application development. Windows and Linux versions of MySQL® 5.0 Community Edition 5.0.27 and MySQL Connector/J 5.0.4 are provided for the database processing performed in Chapters 25–28.

The CD also contains the book's examples and a web page with links to the Deitel & Associates, Inc. website and the Prentice Hall website. This web page can be loaded into a web browser to afford quick access to all the resources.

You can find additional resources and software downloads in our Java SE 6 (Mustang) Resource Center at:

www.deitel.com/JavaSE6Mustang/

Java Multimedia Cyber Classroom, 7/e

Java How to Program, 7/e includes a free, web-based, audio-intensive interactive multimedia ancillary to the book—*The Java Multimedia Cyber Classroom, 7/e*—available with new

Instructor Resources for Java How to Program, 7/e**xxxiii**

books purchased from Prentice Hall. Our Web-based *Cyber Classroom* includes audio walkthroughs of code examples in Chapters 1–14, solutions to about half of the exercises in the book, a lab manual and more. For more information about the web-based *Cyber Classroom*, please visit

www.prenhall.com/deitel/cyberclassroom/

Students who use our *Cyber Classrooms* like its interactivity and reference capabilities. Professors tell us that their students enjoy using the *Cyber Classroom* and consequently spend more time on the courses, mastering more of the material than in textbook-only courses.

Instructor Resources for Java How to Program, 7/e

Java How to Program, 7/e has extensive instructor resources. The Prentice Hall *Instructor's Resource Center* contains the *Solutions Manual* with solutions to the vast majority of the end-of-chapter exercises, a *Test Item File* of multiple-choice questions (approximately two per book section) and PowerPoint® slides containing all the code and figures in the text, plus bulleted items that summarize the key points in the text. Instructors can customize the slides. If you are not already a registered faculty member, contact your Prentice Hall representative or visit vig.prenhall.com/replocator/.

Computer Science AP Courses

Java How to Program, 7/e is a suitable textbook for teaching AP Computer Science classes and for preparing students to take the corresponding exams. *Java How to Program, 7/e* covers the vast majority of the information required for the exams. For detailed information on the Computer Science AP curriculum, please visit

apcentral.collegeboard.com

Deitel® Buzz Online Free E-mail Newsletter

Each week, the *Deitel® Buzz Online* announces our latest Resource Center(s) and includes commentary on industry trends and developments, links to free articles and resources from our published books and upcoming publications, product-release schedules, errata, challenges, anecdotes, information on our corporate instructor-led training courses and more. It's also a good way for you to keep posted about issues related to *Java How to Program, 7/e*. To subscribe, visit

www.deitel.com/newsletter/subscribe.html

What's New at Deitel

Resource Centers and the Deitel Internet Business Initiative. We have created many online Resource Centers (at www.deitel.com/resourcecenters.html) to enhance your Java learning experience. We announce new Resource Centers in each issue of the *Deitel® Buzz Online*. Those of particular interest to readers of this book include Java, Java Certification, Java Design Patterns, Java EE 5, Java SE 6, AJAX, Apache, Code Search Engines and Code Sites, Eclipse, Game Programming, Mashups, MySQL, Open Source, Programming

xxxiv [Preface](#)

Projects, Web 2.0, Web 3.0, Web Services and XML. Additional Deitel Resource Centers include Affiliate Programs, Alert Services, ASP.NET, Attention Economy, Building Web Communities, C, C++, C#, Computer Games, DotNetNuke, Firefox, Gadgets, Google AdSense, Google Analytics, Google Base, Google Services, Google Video, Google Web Toolkit, IE7, Internet Business Initiative, Internet Advertising, Internet Video, Linux, Microformats, .NET, Ning, OpenGL, Perl, PHP, Podcasting, Python, Recommender Systems, RSS, Ruby, Search Engines, Search Engine Optimization, Skype, Sudoku, Virtual Worlds, Visual Basic, Wikis, Windows Vista, WinFX and many more coming.

Free Content Initiative. We are pleased to bring you guest articles and free tutorials selected from our current and forthcoming publications as part of our Free Content Initiative. In each issue of the *Deitel® Buzz Online* newsletter, we announce the latest additions to our free content library.

Acknowledgments

It is a great pleasure to acknowledge the efforts of many people whose names may not appear on the cover, but whose hard work, cooperation, friendship and understanding were crucial to the production of the book. Many people at Deitel & Associates, Inc. devoted long hours to this project—thanks especially to Abbey Deitel and Barbara Deitel.

We'd also like to thank two participants of our Honors Internship program who contributed to this publication—Megan Schuster, a computer science major at Swarthmore College, and Henry Klementowicz, a computer science major at Columbia University.

We'd like to mention again our colleagues who made substantial contributions to *Java How to Program 6/e*: Andrew B. Goldberg, Jeff Listfield, Su Zhang, Cheryl Yaeger, Jing Hu, Sin Han Lo, John Paul Casiello, and Christi Kelsey.

We are fortunate to have worked on this project with the talented and dedicated team of publishing professionals at Prentice Hall. We appreciate the extraordinary efforts of Marcia Horton, Editorial Director of Prentice Hall's Engineering and Computer Science Division. Jennifer Cappello and Dolores Mars did an extraordinary job recruiting the book's review team and managing the review process. Francesco Santalucia (an independent artist) and Kristine Carney of Prentice Hall did a wonderful job designing the book's cover; we provided the concept, and they made it happen. Vince O'Brien, Bob Engelhardt, Donna Crilly and Marta Samsel did a marvelous job managing the book's production.

We wish to acknowledge the efforts of our reviewers. Adhering to a tight time schedule, they scrutinized the text and the programs, providing countless suggestions for improving the accuracy and completeness of the presentation.

We sincerely appreciate the efforts of our sixth edition post-publication reviewers and our seventh edition reviewers:

Java How to Program, 7/e Reviewers (including 6/e Post-Publication Reviewers)

Sun Microsystems Reviewers: Lance Andersen (JDBC/Rowset Specification Lead, Java SE Engineering), Ed Burns, Ludovic Champenois (Sun's Application Server for Java EE programmers with Sun Application Server and tools—NetBeans, Studio Enterprise and Studio Creator), James Davidson, Vadiraj Deshpande (Java Enterprise System Integration Group, Sun Microsystems India), Sanjay Dhamankar (Core Developer Platform Group), Jesse Glick (NetBeans Group), Brian Goetz (author of *Java Concurrency in Practice*, Addison-Wesley, 2006), Doug Kohlert (Web Technologies and Standards Group), Sandeep

Hussey (IBM), Joe Kasprzyk (Salem State College), Dan McCracken (City College of New York), Paul Monday (Sun Microsystems, Inc.), Davyd Norris (Rational Software), Cameron Skinner (Embarcadero Technologies, Inc.), Craig Slinkman (University of Texas at Arlington), and Steve Tockey (Construx Software).

These reviewers scrutinized every aspect of the text and made countless suggestions for improving the accuracy and completeness of the presentation.

Well, there you have it! Java is a powerful programming language that will help you write programs quickly and effectively. It scales nicely into the realm of enterprise systems development to help organizations build their critical information systems. As you read the book, we would sincerely appreciate your comments, criticisms, corrections and suggestions for improving the text. Please address all correspondence to:

deitel@deitel.com

We'll respond promptly, and post corrections and clarifications on:

www.deitel.com/books/jHTP7/

We hope you enjoy reading *Java How to Program, Seventh Edition* as much as we enjoyed writing it!

*Paul J. Deitel
Dr. Harvey M. Deitel*

*Maynard, Massachusetts
December 2006*

About the Authors

Paul J. Deitel, CEO and Chief Technical Officer of Deitel & Associates, Inc., is a graduate of MIT's Sloan School of Management, where he studied Information Technology. He holds the Java Certified Programmer and Java Certified Developer certifications, and has been designated by Sun Microsystems as a Java Champion. Through Deitel & Associates, Inc., he has delivered Java, C, C++, C# and Visual Basic courses to industry clients, including IBM, Sun Microsystems, Dell, Lucent Technologies, Fidelity, NASA at the Kennedy Space Center, the National Severe Storm Laboratory, White Sands Missile Range, Rogue Wave Software, Boeing, Stratus, Cambridge Technology Partners, Open Environment Corporation, One Wave, Hyperion Software, Adra Systems, Entergy, CableData Systems, Nortel Networks, Puma, iRobot, Invensys and many more. He has also lectured on Java and C++ for the Boston Chapter of the Association for Computing Machinery. He and his father, Dr. Harvey M. Deitel, are the world's best-selling programming language textbook authors.

Dr. Harvey M. Deitel, Chairman and Chief Strategy Officer of Deitel & Associates, Inc., has 45 years of academic and industry experience in the computer field. Dr. Deitel earned B.S. and M.S. degrees from the MIT and a Ph.D. from Boston University. He has 20 years of college teaching experience, including earning tenure and serving as the Chairman of the Computer Science Department at Boston College before founding Deitel & Associates, Inc., with his son, Paul J. Deitel. He and Paul are the co-authors of several dozen books and multimedia packages and they are writing many more. With

[About Deitel & Associates, Inc.](#) **xxxvii**

translations published in Japanese, German, Russian, Spanish, Traditional Chinese, Simplified Chinese, Korean, French, Polish, Italian, Portuguese, Greek, Urdu and Turkish, the Deitels' texts have earned international recognition. Dr. Deitel has delivered hundreds of professional seminars to major corporations, academic institutions, government organizations and the military.

About Deitel & Associates, Inc.

Deitel & Associates, Inc., is an internationally recognized corporate training and content-creation organization specializing in computer programming languages, Internet and World Wide Web software technology, object technology education and Internet business development through its Internet Business Initiative. The company provides instructor-led courses on major programming languages and platforms, such as Java, Advanced Java, C, C++, C#, Visual C++, Visual Basic, XML, Perl, Python, object technology and Internet and World Wide Web programming. The founders of Deitel & Associates, Inc., are Dr. Harvey M. Deitel and Paul J. Deitel. The company's clients include many of the world's largest companies, government agencies, branches of the military, and academic institutions. Through its 30-year publishing partnership with Prentice Hall, Deitel & Associates, Inc. publishes leading-edge programming textbooks, professional books, interactive multimedia *Cyber Classrooms*, *Complete Training Courses*, Web-based training courses and e-content for the popular course management systems WebCT, Blackboard and Pearson's CourseCompass. Deitel & Associates, Inc., and the authors can be reached via e-mail at:

deitel@deitel.com

To learn more about Deitel & Associates, Inc., its publications and its worldwide *DIVE INTO®* Series Corporate Training curriculum, visit:

www.deitel.com

and subscribe to the free *Deitel® Buzz Online* e-mail newsletter at:

Bulk orders by corporations, the government, the military and academic institutions should be placed directly with Prentice Hall. For more information, visit

www.prenhall.com/mischtm/support.html#order

Before You Begin

Please follow the instructions in this section to ensure that Java is installed properly on your computer before you begin using this book.

Font and Naming Conventions

We use fonts to distinguish between on-screen components (such as menu names and menu items) and Java code or commands. Our convention is to emphasize on-screen components in a sans-serif bold **Helvetica** font (for example, **File** menu) and to emphasize Java code and commands in a sans-serif **Lucida** font (for example, `System.out.println()`).

Java Standard Edition Development Kit (JDK) 6

The examples in this book were developed with the Java Standard Edition Development Kit (JDK) 6. You can download the latest version of JDK 6 and its documentation from

java.sun.com/javase/6/download.jsp

If you have any questions, please feel free to email us at deitel@deitel.com. We will respond promptly.

Software and Hardware System Requirements

- 500 MHz (minimum) Pentium III or faster processor; Sun® Java™ Studio Creator 2 Update 1 requires a 1 GHz Intel Pentium 4 processor (or equivalent)
- Microsoft Windows Server 2003, Windows XP (with Service Pack 2), Windows 2000 Professional (with Service Pack 4) or
- One of the following Linux distributions: Red Hat® Enterprise Linux 3, or Red Hat Fedora Core 3
- Minimum of 512 MB of RAM; Sun Java Studio Creator 2 Update 1 requires 1 GB of RAM
- Minimum of 1.5 GB of hard disk space
- CD-ROM drive
- Internet connection
- Web browser, Adobe® Acrobat® Reader® and a zip decompression utility

Using the CDs

The examples for *Java How To Program, Seventh Edition* are included on the CDs (Windows and Linux) that accompany this book. Follow the steps in the next section, *Copying the Book Examples from the CD*, to copy the examples directory from the appropriate CD to your hard drive. We suggest that you work from your hard drive rather than your CD

Copying the Book Examples from the CD xxxix

drive for two reasons: The CDs are read-only, so you cannot save your applications to the CDs, and files can be accessed faster from a hard drive than from a CD. The examples from the book are also available for download from:

www.deitel.com/books/jhttp7/
www.prenhall.com/deitel/

The interface to the contents of the Microsoft® Windows® CD is designed to start automatically through the AUTORUN.EXE file. If a startup screen does not appear when you insert the CD into your computer, double click the `welcome.htm` file to launch the Student CD's interface or refer to the file `readme.txt` on the CD. To launch the Linux CD's interface, double click the `welcome.htm` file.

Copying the Book Examples from the CD

Screen shots in this section might differ slightly from what you see on your computer, depending on your operating system and web browser. The instructions in the following steps assume you are running Microsoft Windows.

1. *Inserting the CD.* Insert the CD that accompanies *Java How To Program, Seventh Edition* into your computer's CD drive. The `welcome.htm` web page (Fig. 1) should automatically appear on Windows. You can also use Windows Explorer to view the CD's contents and double click `welcome.htm` to display this page.
2. *Opening the CD-ROM directory.* Click the **Browse CD Contents** link (Fig. 1) to view the CD's contents.
3. *Copying the examples directory.* Right click the `examples` directory (Fig. 2), then select **Copy**. Next, use Windows Explorer to view the contents of your **C:** drive. (You may need to click a link to display the drive's contents.) Once the contents are displayed, right click anywhere and select the **Edit** menu's **Paste** option to copy the `examples` directory from the CD to your **C:** drive. [Note: We save the

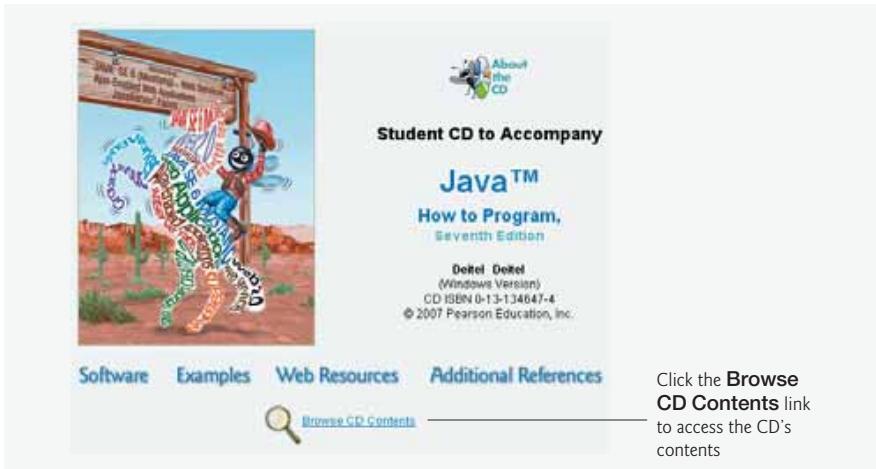

Fig. 1 | Welcome page for *Java How to Program* CD.

xI Before You Begin

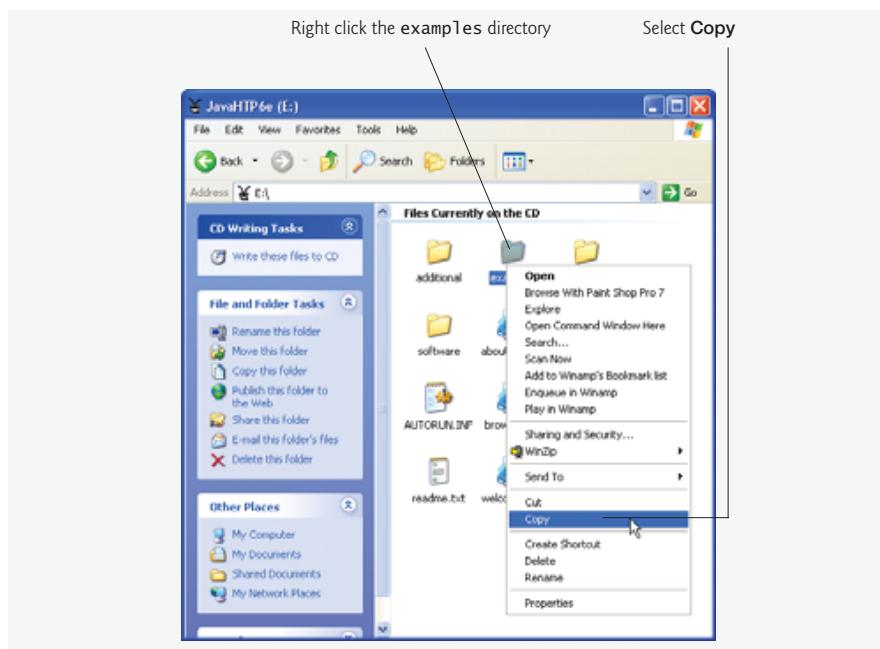

Fig. 2 | Copying the `examples` directory.

examples to the **C:** drive directly and refer to this drive throughout the text. You may choose to save your files to a different drive based on your computer's set up, the setup in your school's lab or personal preferences. If you are working in a computer lab, please see your instructor for more information to confirm where the examples should be saved.]

Changing the Read-Only Property of Files

The example files you copied to your computer from the CD are read-only. Next, you will remove the read-only property so you can modify and run the examples.

1. *Opening the Properties dialog.* Right click the `examples` directory and select **Properties** from the menu. The `examples` **Properties** dialog appears (Fig. 3).
2. *Changing the read-only property.* In the **Attributes** section of this dialog, click the box next to **Read-only** to remove the check mark (Fig. 4). Click **Apply** to apply the changes.
3. *Changing the property for all files.* Clicking **Apply** will display the **Confirm Attribute Changes** window (Fig. 5). In this window, click the radio button next to **Apply changes to this folder, subfolders and files** and click **OK** to remove the read-only property for all of the files and directories in the `examples` directory.

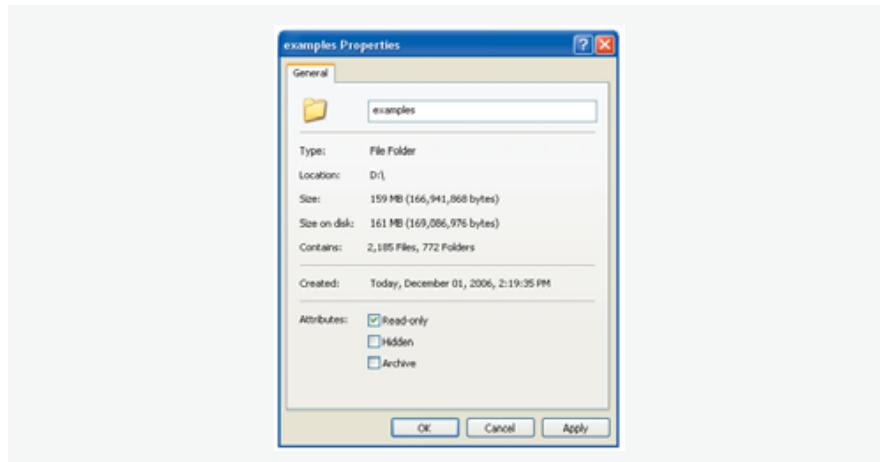

Changing the Read-Only Property of Files **xli**

Fig. 3 | examples Properties dialog.

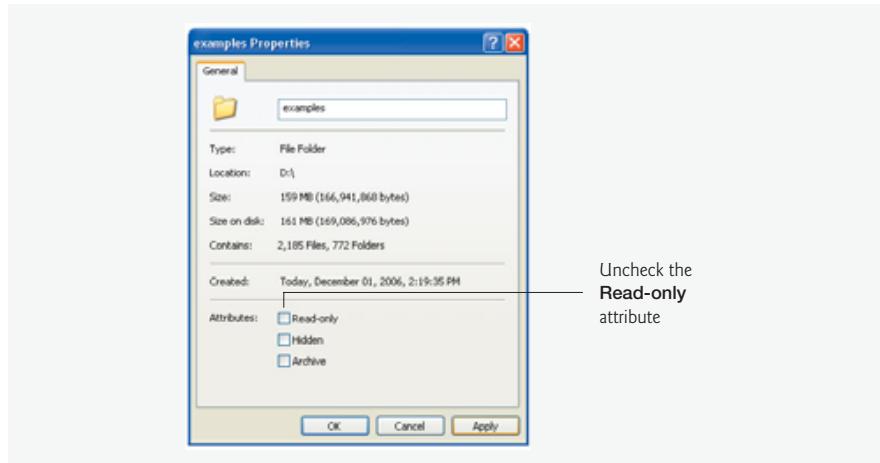

Fig. 4 | Unchecking the **Read-only** check box.

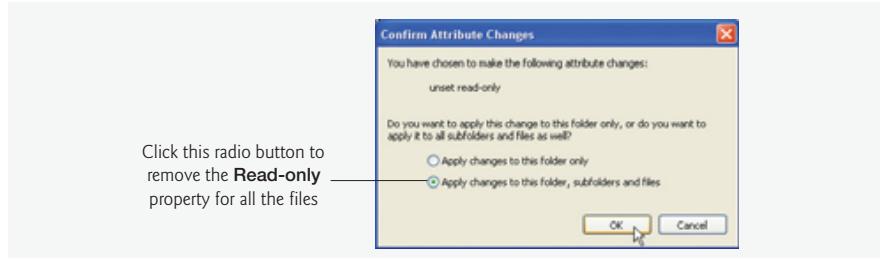

Fig. 5 | Removing read-only for all the files in the **examples** directory.

xlii Before You Begin

Installing the Java Standard Edition Development Kit (JDK)

Before you can run the applications in *Java How To Program, Seventh Edition* or build your own applications, you must install the Java Standard Edition Development Kit (JDK) 6 or a Java development tool that supports Java SE 6.

You can download the JDK 6 and its documentation from java.sun.com/javase/6/download.jsp. Click the » DOWNLOAD button for JDK 6. You must accept the license agreement before downloading. Once you accept the license agreement, click the link for your platform's installer. Save the installer on your hard disk and keep track of where you save it. Before installing, carefully read the JDK installation instructions for your platform, which are located at java.sun.com/javase/6/webnotes/install/index.html.

After downloading the JDK installer, double click the installer program to begin installing the JDK. We recommend that you accept all the default installation options. If you change the default installation directory, be sure to write down the exact name and location of the directory you choose, as you will need this information later in the installation process. On Windows, the JDK is placed in the following directory by default:

```
C:\Program Files\Java\jdk1.6.0
```

Setting the PATH Environment Variable

The PATH environment variable on your computer designates which directories the computer searches when looking for applications, such as the applications that enable you to compile and run your Java applications (called `javac.exe` and `java.exe`, respectively). You will now learn how to set the PATH environment variable on your computer to indicate where the JDK's tools are installed.

1. *Opening the System Properties dialog.* Start > Control Panel > System to display the System Properties dialog (Fig. 6). [Note: Your System Properties dialog may appear different than the one shown in Fig. 6, depending on your version of

Fig. 6 | System Properties dialog.

Setting the PATH Environment Variable

xliii

Microsoft Windows. This particular dialog is from a computer running Microsoft Windows XP. Your dialog might include different information.]

2. **Opening the Environment Variables dialog.** Select the **Advanced** tab at the top of the **System Properties** dialog (Fig. 7). Click the **Environment Variables** button to display the **Environment Variables** dialog (Fig. 8).
3. **Editing the PATH variable.** Scroll down inside the **System variables** box to select the **PATH** variable. Click the **Edit** button. This will cause the **Edit System Variable** dialog to appear (Fig. 9).

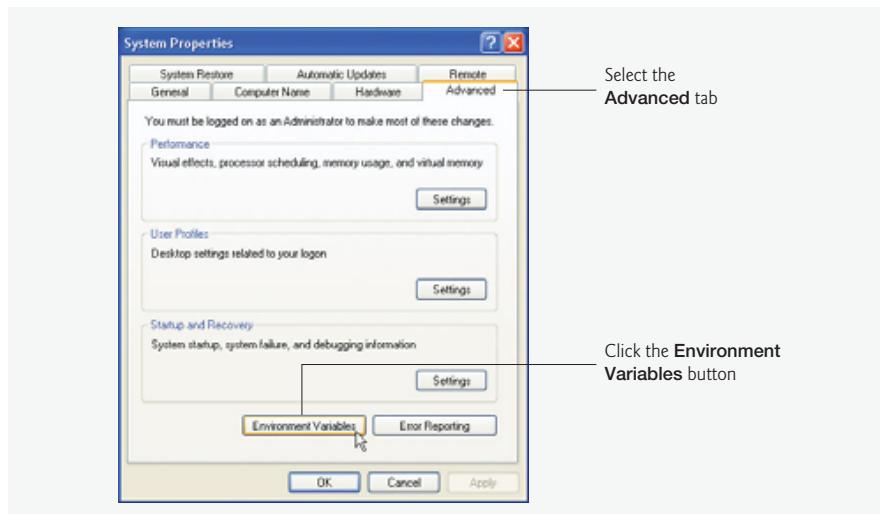

Fig. 7 | Advanced tab of System Properties dialog.

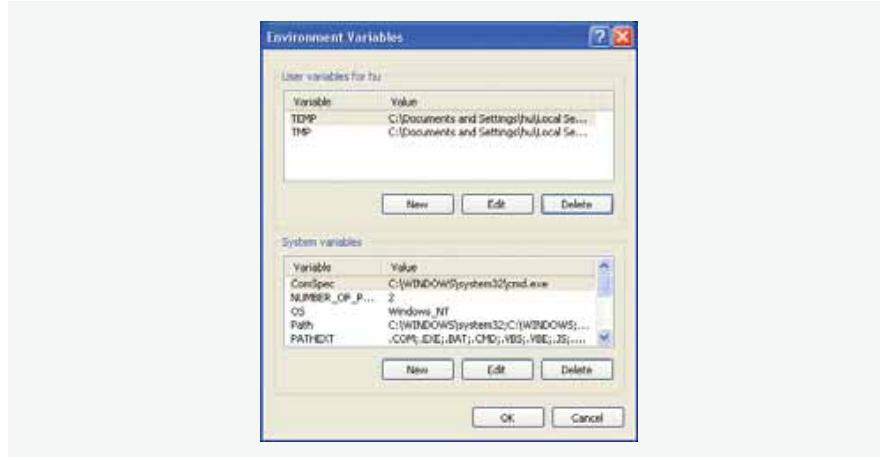

Fig. 8 | Environment Variables dialog.

xliv Before You Begin

- 4. Changing the PATH.** Place the cursor inside the **Variable Value** field. Use the left-arrow key to move the cursor to the beginning of the list. At the beginning of the list, type the name of the directory in which you placed the JDK followed by `\bin`; (Fig. 10). Add `C:\Program Files\Java\jdk1.6.0\bin;` to the PATH variable, if you chose the default installation directory. *Do not place any spaces before or after what you type.* Spaces are not allowed before or after each value in an environment variable. Click the **OK** button to apply your changes to the PATH variable.

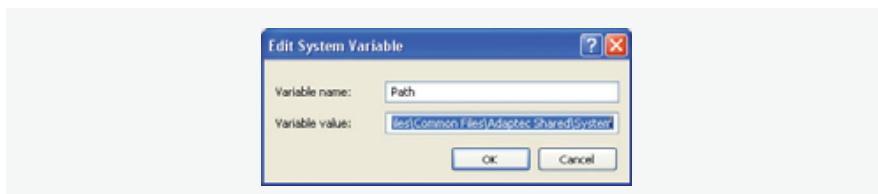

Fig. 9 | Edit System Variable dialog.

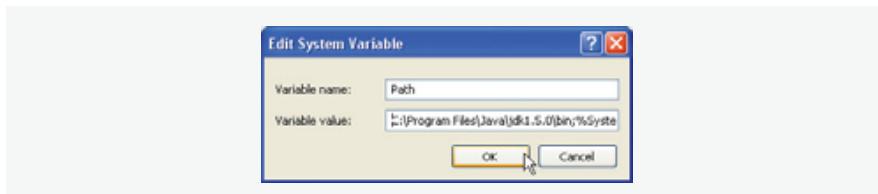

Fig. 10 | Editing the PATH variable.

If you do not set the PATH variable correctly, when you use the JDK's tools, you will receive a message like:

```
'java' is not recognized as an internal or external command,
operable program or batch file.
```

In this case, go back to the beginning of this section and recheck your steps. If you've downloaded a newer version of the JDK, you may need to change the name of the JDK's installation directory in the PATH variable.

Setting the CLASSPATH Environment Variable

If you attempt to run a Java program and receive a message like

```
Exception in thread "main" java.lang.NoClassDefFoundError: YourClass
```

then your system has a CLASSPATH environment variable that must be modified. To fix the preceding error, follow the steps in setting the PATH environment variable, to locate the CLASSPATH variable, then edit the variable's value to include

```
.;
```

at the beginning of its value (with no spaces before or after these characters).

You are now ready to begin your Java studies with *Java How to Program, Seventh Edition*. We hope you enjoy the book!

Our life is frittered away by detail. ... Simplify, simplify.

—Henry David Thoreau

The chief merit of language is clearness.

—Galen

I

Introduction to Computers, the Internet and the Web

OBJECTIVES

In this chapter you will learn:

- Basic computer hardware and software concepts.
- Basic object technology concepts, such as classes, objects, attributes, behaviors, encapsulation, inheritance and polymorphism.
- The different types of programming languages.
- Which programming languages are most widely used.
- A typical Java program development environment.
- Java's role in developing distributed client/server applications for the Internet and the web.
- The history of UML—the industry-standard object-oriented design language, the UML.
- The history of the Internet and the World Wide Web.
- To test-drive Java applications.

2 Chapter I Introduction to Computers, the Internet and the Web**Outline**

- 1.1** Introduction
- 1.2** What Is a Computer?
- 1.3** Computer Organization
- 1.4** Early Operating Systems
- 1.5** Personal, Distributed and Client/Server Computing
- 1.6** The Internet and the World Wide Web
- 1.7** Machine Languages, Assembly Languages and High-Level Languages
- 1.8** History of C and C++
- 1.9** History of Java
- 1.10** Java Class Libraries
- 1.11** Fortran, COBOL, Pascal and Ada
- 1.12** BASIC, Visual Basic, Visual C++, C# and .NET
- 1.13** Typical Java Development Environment
- 1.14** Notes about Java and *Java How to Program, 7/e*
- 1.15** Test-Driving a Java Application
- 1.16** Software Engineering Case Study: Introduction to Object Technology and the UML
- 1.17** Web 2.0
- 1.18** Software Technologies
- 1.19** Wrap-Up
- 1.20** Web Resources

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

1.1 Introduction

Welcome to Java! We have worked hard to create what we hope you'll find to be an informative, entertaining and challenging learning experience. Java is a powerful computer programming language that is fun for novices to learn, and appropriate for experienced programmers to use in building substantial information systems. *Java How to Program, Seventh Edition* is an effective learning tool for each of these audiences.

Pedagogy

The core of the book emphasizes achieving program *clarity* through the proven techniques of *object-oriented programming*. Nonprogrammers will learn programming the right way from the beginning. The presentation is clear, straightforward and abundantly illustrated. It includes hundreds of complete working Java programs and shows the outputs produced when those programs are run on a computer. We teach Java features in the context of complete working Java programs—we call this the [live-code approach](#). The example programs are included on the CD that accompanies this book. You may also download them from www.deitel.com/books/jhttp7/ or www.prenhall.com/deitel.

Fundamentals

The early chapters introduce the fundamentals of computers, computer programming and the Java programming language, providing a solid foundation for the deeper treatment of Java in the later chapters. Experienced programmers tend to read the early chapters quickly and find the treatment of Java in the later chapters rigorous and challenging.

1.1 Introduction **3**

Most people are familiar with the exciting tasks computers perform. Using this textbook, you'll learn how to command computers to perform those tasks. It is software (i.e., the instructions you write to command computers to perform **actions** and make **decisions**) that controls computers (often referred to as hardware). Java, developed by Sun Microsystems, is one of today's most popular software development languages.

Java Standard Edition 6 (Java SE 6) and the Java Development Kit 6 (JDK 6)

This book is based on Sun's **Java Standard Edition 6 (Java SE 6)**, also known as Mustang. Sun provides a Java SE 6 implementation, called the **Java Development Kit (JDK)**, that includes the tools you need to write software in Java. We used JDK version 6.0 for the programs in this book. Sun updates the JDK on a regular basis to fix bugs. To download the most recent version of JDK 6, visit java.sun.com/javase/6/download.jsp.

Evolution of Computing and Programming

Computer use is increasing in almost every field of endeavor. Computing costs have been decreasing dramatically due to rapid developments in both hardware and software technologies. Computers that might have filled large rooms and cost millions of dollars decades ago can now be inscribed on silicon chips smaller than a fingernail, costing perhaps a few dollars each. Fortunately, silicon is one of the most abundant materials on earth—it is an ingredient in common sand. Silicon chip technology has made computing so economical that about a billion general-purpose computers are in use worldwide, helping people in business, industry and government, and in their personal lives. The number could easily double in the next few years.

Over the years, many programmers learned the programming methodology called structured programming. You will learn structured programming and an exciting newer methodology, **object-oriented programming**. Why do we teach both? Object orientation is the key programming methodology used by programmers today. You will create and work with many software objects in this text. But you will discover that their internal structure is often built using structured-programming techniques. Also, the logic of manipulating objects is occasionally expressed with structured programming.

Language of Choice for Networked Applications

Java has become the language of choice for implementing Internet-based applications and software for devices that communicate over a network. Stereos and other devices in homes are now being networked together by Java technology. At the May 2006 JavaOne conference, Sun announced that there were one billion java-enabled mobile phones and handheld devices! Java has evolved rapidly into the large-scale applications arena. It's the preferred language for meeting many organizations' enterprise-wide programming needs.

Java has evolved so rapidly that this seventh edition of *Java How to Program* was published just 10 years after the first edition was published. Java has grown so large that it has two other editions. The **Java Enterprise Edition (Java EE)** is geared toward developing large-scale, distributed networking applications and web-based applications. The **Java Micro Edition (Java ME)** is geared toward developing applications for small, memory-constrained devices, such as cell phones, pagers and PDAs.

Staying in Touch with Us

You are embarking on a challenging and rewarding path. As you proceed, if you would like to communicate with us, please send e-mail to deitel@deitel.com or browse our

4 Chapter I Introduction to Computers, the Internet and the Web

website at www.deitel.com. We will respond promptly. To keep up to date with Java developments at Deitel & Associates, please register for our free e-mail newsletter, the *Deitel® Buzz Online*, at

For lots of additional Java material, please visit our growing list of Java Resource centers at www.deitel.com/ResourceCenters.html. We hope that you will enjoy learning with *Java How to Program, Seventh Edition*.

1.2 What Is a Computer?

A **computer** is a device capable of performing computations and making logical decisions at speeds millions (even billions) of times faster than human beings can. For example, many of today's personal computers can perform several billion calculations in one second. A person operating a desk calculator could not perform that many calculations in a lifetime. (Points to ponder: How would you know whether the person added the numbers correctly? How would you know whether the computer added the numbers correctly?) Today's fastest **supercomputers** are already performing *trillions* of instructions per second!

Computers process **data** under the control of sets of instructions called **computer programs**. These programs guide the computer through orderly sets of actions specified by people called **computer programmers**.

A computer consists of various devices referred to as **hardware** (e.g., the keyboard, screen, mouse, disks, memory, DVD, CD-ROM and processing units). The programs that run on a computer are referred to as **software**. Hardware costs have been declining dramatically in recent years, to the point that personal computers have become a commodity. In this book, you'll learn proven methodologies that *can* reduce software development costs—object-oriented programming and (in our optional Software Engineering Case Study in Chapters 2–8 and 10) object-oriented design.

1.3 Computer Organization

Regardless of differences in physical appearance, virtually every computer may be envisioned as divided into six **logical units** or sections:

1. **Input unit.** This “receiving” section obtains information (data and computer programs) from **input devices** and places this information at the disposal of the other units so that it can be processed. Most information is entered into computers through keyboards and mouse devices. Information also can be entered in many other ways, including by speaking to your computer, by scanning images and by having your computer receive information from a network, such as the Internet.
2. **Output unit.** This “shipping” section takes information that the computer has processed and places it on various **output devices** to make the information available for use outside the computer. Most information output from computers today is displayed on screens, printed on paper or used to control other devices. Computers also can output their information to networks, such as the Internet.
3. **Memory unit.** This rapid-access, relatively low-capacity “warehouse” section retains information that has been entered through the input unit, so that it will be immediately available for processing when needed. The memory unit also retains

1.4 Early Operating Systems **5**

processed information until it can be placed on output devices by the output unit. Information in the memory unit is typically lost when the computer's power is turned off. The memory unit is often called either **memory** or **primary memory**.

4. **Arithmetic and logic unit (ALU)**. This “manufacturing” section is responsible for performing calculations, such as addition, subtraction, multiplication and division. It contains the decision mechanisms that allow the computer, for example, to compare two items from the memory unit to determine whether they are equal.
5. **Central processing unit (CPU)**. This “administrative” section coordinates and supervises the operation of the other sections. The CPU tells the input unit when information should be read into the memory unit, tells the ALU when information from the memory unit should be used in calculations and tells the output unit when to send information from the memory unit to certain output devices. Many of today's computers have multiple CPUs and, hence, can perform many operations simultaneously—such computers are called **multiprocessors**.
6. **Secondary storage unit**. This is the long-term, high-capacity “warehousing” section. Programs or data not actively being used by the other units normally are placed on secondary storage devices (e.g., your hard drive) until they are again needed, possibly hours, days, months or even years later. Information in secondary storage takes much longer to access than information in primary memory, but the cost per unit of secondary storage is much less than that of primary memory. Examples of secondary storage devices include CDs and DVDs, which can hold up to hundreds of millions of characters and billions of characters, respectively.

1.4 Early Operating Systems

Early computers could perform only one **job** or **task** at a time. This is often called single-user **batch processing**. The computer runs a single program at a time while processing data in groups or **batches**. In these early systems, users generally submitted their jobs to a computer center on decks of punched cards and often had to wait hours or even days before printouts were returned to their desks.

Software systems called **operating systems** were developed to make using computers more convenient. Early operating systems smoothed and speeded up the transition between jobs, increasing the amount of work, or **throughput**, computers could process.

As computers became more powerful, it became evident that single-user batch processing was inefficient, because so much time was spent waiting for slow input/output devices to complete their tasks. It was thought that many jobs or tasks could *share* the resources of the computer to achieve better utilization. This is called **multiprogramming**. Multiprogramming involves the simultaneous operation of many jobs that are competing to share the computer's resources. With early multiprogramming operating systems, users still submitted jobs on decks of punched cards and waited hours or days for results.

In the 1960s, several groups in industry and the universities pioneered **timesharing** operating systems. Timesharing is a special case of multiprogramming in which users access the computer through terminals, typically devices with keyboards and screens. Dozens or even hundreds of users share the computer at once. The computer actually does not run them all simultaneously. Rather, it runs a small portion of one user's job, then moves on to service the next user, perhaps providing service to each user several times per

6 Chapter I Introduction to Computers, the Internet and the Web

second. Thus, the users' programs *appear* to be running simultaneously. An advantage of timesharing is that user requests receive almost immediate responses.

1.5 Personal, Distributed and Client/Server Computing

In 1977, Apple Computer popularized **personal computing**. Computers became so economical that people could buy them for their own personal or business use. In 1981, IBM, the world's largest computer vendor, introduced the IBM Personal Computer. This quickly legitimized personal computing in business, industry and government organizations.

These computers were "standalone" units—people transported disks back and forth between them to share information (often called "sneakernet"). Although early personal computers were not powerful enough to timeshare several users, these machines could be linked together in computer networks, sometimes over telephone lines and sometimes in **local area networks (LANs)** within an organization. This led to the phenomenon of **distributed computing**, in which an organization's computing, instead of being performed only at some central computer installation, is distributed over networks to the sites where the organization's work is performed. Personal computers were powerful enough to handle the computing requirements of individual users as well as the basic communications tasks of passing information between computers electronically.

Today's personal computers are as powerful as the million-dollar machines of just a few decades ago. The most powerful desktop machines—called **workstations**—provide individual users with enormous capabilities. Information is shared easily across computer networks where computers called **servers** store data that may be used by **client** computers distributed throughout the network, hence the term **client/server computing**. Java has become widely used for writing software for computer networking and for distributed client/server applications. Today's popular operating systems, such as Linux, Apple's Mac OS X (pronounced "O-S ten") and Microsoft Windows, provide the kinds of capabilities discussed in this section.

1.6 The Internet and the World Wide Web

The **Internet**—a global network of computers—has its roots in the 1960s with funding supplied by the U.S. Department of Defense. Originally designed to connect the main computer systems of about a dozen universities and research organizations, the Internet is accessible by more than a billion computers and computer-controlled devices worldwide.

With the introduction of the **World Wide Web**—which allows computer users to locate and view multimedia-based documents on almost any subject over the Internet—the Internet has exploded into one of the world's premier communication mechanisms.

The Internet and the World Wide Web are surely among humankind's most important and profound creations. In the past, most computer applications ran on computers that were not connected to one another. Today's applications can be written to communicate among the world's computers. The Internet mixes computing and communications technologies. It makes our work easier. It makes information instantly and conveniently accessible worldwide. It enables individuals and local small businesses to get worldwide exposure. It is changing the way business is done. People can search for the best prices on virtually any product or service. Special-interest communities can stay in touch with one another. Researchers can be made instantly aware of the latest breakthroughs.

1.7 Machine Languages, Assembly Languages and High-Level Languages 7

Java How to Program, 7/e presents programming techniques that allow Java applications to use the Internet and the web to interact with other applications. These capabilities and others allow Java programmers to develop the kind of enterprise-level distributed applications that are used in industry today. Java applications can be written to execute on every major type of computer, greatly reducing the time and cost of systems development. If you are interested in developing applications to run over the Internet and the web, learning Java may be the key to rewarding career opportunities for you.

1.7 Machine Languages, Assembly Languages and High-Level Languages

Programmers write instructions in various programming languages, some directly understandable by computers and others requiring intermediate [translation](#) steps. Hundreds of computer languages are in use today. These may be divided into three general types:

1. Machine languages
2. Assembly languages
3. High-level languages

Any computer can directly understand only its own [machine language](#). Machine language is the “natural language” of a computer and as such is defined by its hardware design. Machine languages generally consist of strings of numbers (ultimately reduced to 1s and 0s) that instruct computers to perform their most elementary operations one at a time. Machine languages are [machine dependent](#) (i.e., a particular machine language can be used on only one type of computer). Such languages are cumbersome for humans, as illustrated by the following section of an early machine-language program that adds overtime pay to base pay and stores the result in gross pay:

```
+1300042774
+1400593419
+1200274027
```

Machine-language programming was simply too slow and tedious for most programmers. Instead of using the strings of numbers that computers could directly understand, programmers began using English-like abbreviations to represent elementary operations. These abbreviations formed the basis of [assembly languages](#). [Translator programs](#) called [assemblers](#) were developed to convert early assembly-language programs to machine language at computer speeds. The following section of an assembly-language program also adds overtime pay to base pay and stores the result in gross pay:

```
load  basepay
add   overpay
store grosspay
```

Although such code is clearer to humans, it is incomprehensible to computers until translated to machine language.

Computer usage increased rapidly with the advent of assembly languages, but programmers still had to use many instructions to accomplish even the simplest tasks. To speed the programming process, [high-level languages](#) were developed in which single statements could be written to accomplish substantial tasks. Translator programs called

8 Chapter I Introduction to Computers, the Internet and the Web

compilers convert high-level language programs into machine language. High-level languages allow programmers to write instructions that look almost like everyday English and contain commonly used mathematical notations. A payroll program written in a high-level language might contain a statement such as

```
grossPay = basePay + overtimePay
```

Obviously, high-level languages are preferable to machine and assembly language from the programmer's standpoint. C, C++, Microsoft's .NET languages (e.g., Visual Basic .NET, Visual C++ .NET and C#) are among the most widely used high-level programming languages; Java is *the* most widely used.

The process of compiling a high-level language program into machine language can take a considerable amount of computer time. **Interpreter** programs were developed to execute high-level language programs directly, although more slowly. Interpreters are popular in program-development environments in which new features are being added and errors corrected. Once a program is fully developed, a compiled version can be produced to run most efficiently.

You now know that there are ultimately two ways to translate a high-level language program into a form that the computer understands—compilation and interpretation. As you will learn in Section 1.13, Java uses a clever mixture of these technologies.

1.8 History of C and C++

Java evolved from C++, which evolved from C, which evolved from BCPL and B. BCPL was developed in 1967 by Martin Richards as a language for writing operating systems software and compilers. Ken Thompson modeled many features in his language B after their counterparts in BCPL, using B to create early versions of the UNIX operating system at Bell Laboratories in 1970.

The C language was evolved from B by Dennis Ritchie at Bell Laboratories and was originally implemented in 1972. It initially became widely known as the development language of the UNIX operating system. Today, most of the code for general-purpose operating systems (e.g., those found in notebooks, desktops, workstations and small servers) is written in C or C++.

C++, an extension of C, was developed by Bjarne Stroustrup in the early 1980s at Bell Laboratories. C++ provides a number of features that “spruce up” the C language, but more important, it provides capabilities for *object-oriented programming* (discussed in more detail in Section 1.16 and throughout this book). C++ is a hybrid language—it is possible to program in either a C-like style, an object-oriented style or both.

A revolution is brewing in the software community. Building software quickly, correctly and economically remains an elusive goal at a time when demands for new and more powerful software are soaring. *Objects*, or more precisely—as we will see in Section 1.16—the classes objects come from, are essentially reusable software components. There are date objects, time objects, audio objects, automobile objects, people objects and so on. In fact, almost any noun can be represented as a software object in terms of **attributes** (e.g., name, color and size) and **behaviors** (e.g., calculating, moving and communicating). Software developers are discovering that using a modular, object-oriented design and implementation approach can make software-development groups much more productive than was possible with earlier popular programming techniques like structured programming.

1.9 History of Java 9

Object-oriented programs are often easier to understand, correct and modify. Java is the world's most widely used object-oriented programming language.

1.9 History of Java

The microprocessor revolution's most important contribution to date is that it made possible the development of personal computers, which now number about a billion worldwide. Personal computers have profoundly affected people's lives and the ways organizations conduct and manage their business.

Microprocessors are having a profound impact in intelligent consumer-electronic devices. Recognizing this, Sun Microsystems in 1991 funded an internal corporate research project code-named Green, which resulted in a C++-based language that its creator, James Gosling, called Oak after an oak tree outside his window at Sun. It was later discovered that there already was a computer language by that name. When a group of Sun people visited a local coffee shop, the name Java was suggested, and it stuck.

The Green project ran into some difficulties. The marketplace for intelligent consumer-electronic devices was not developing in the early 1990s as quickly as Sun had anticipated. The project was in danger of being canceled. By sheer good fortune, the World Wide Web exploded in popularity in 1993, and Sun people saw the immediate potential of using Java to add **dynamic content**, such as interactivity and animations, to web pages. This breathed new life into the project.

Sun formally announced Java at an industry conference in May 1995. Java garnered the attention of the business community because of the phenomenal interest in the World Wide Web. Java is now used to develop large-scale enterprise applications, to enhance the functionality of web servers (the computers that provide the content we see in our web browsers), to provide applications for consumer devices (e.g., cell phones, pagers and personal digital assistants) and for many other purposes.

1.10 Java Class Libraries

Java programs consist of pieces called **classes**. Classes include pieces called **methods** that perform tasks and return information when they complete them. Programmers can create each piece they need to form Java programs. However, most Java programmers take advantage of the rich collections of existing classes in the **Java class libraries**, which are also known as the **Java APIs (Application Programming Interfaces)**. Thus, there are really two aspects to learning the Java "world." The first is the Java language itself, so that you can program your own classes, and the second is the classes in the extensive Java class libraries. Throughout this book, we discuss many library classes. Class libraries are provided primarily by compiler vendors, but many are supplied by independent software vendors (ISVs).

Software Engineering Observation 1.1

Use a building-block approach to create programs. Avoid reinventing the wheel—use existing pieces wherever possible. This software reuse is a key benefit of object-oriented programming.

We include many tips such as these **Software Engineering Observations** throughout the book to explain concepts that affect and improve the overall architecture and quality of software systems. We also highlight other kinds of tips, including **Good Programming Practices** (to help you write programs that are clearer, more understandable, more main-

10 Chapter I Introduction to Computers, the Internet and the Web

tainable and easier to test and **debug**, i.e., remove programming errors), **Common Programming Errors** (problems to watch out for and avoid), **Performance Tips** (techniques for writing programs that run faster and use less memory), **Portability Tips** (techniques to help you write programs that can run, with little or no modification, on a variety of computers—these tips also include general observations about how Java achieves its high degree of portability), **Error-Prevention Tips** (techniques for removing bugs from your programs and, more important, techniques for writing bug-free programs in the first place) and **Look-and-Feel Observations** (techniques to help you design the “look” and “feel” of your applications’ user interfaces for appearance and ease of use). Many of these are only guidelines. You will, no doubt, develop your own preferred programming style.

Software Engineering Observation 1.2

When programming in Java, you will typically use the following building blocks: classes and methods from class libraries, classes and methods you create yourself and classes and methods that others create and make available to you.

The advantage of creating your own classes and methods is that you know exactly how they work and you can examine the Java code. The disadvantage is the time-consuming and potentially complex effort that is required.

Performance Tip 1.1

Using Java API classes and methods instead of writing your own versions can improve program performance, because they are carefully written to perform efficiently. This technique also shortens program development time.

Portability Tip 1.1

Using classes and methods from the Java API instead of writing your own improves program portability, because they are included in every Java implementation.

Software Engineering Observation 1.3

Extensive class libraries of reusable software components are available over the Internet and the web, many at no charge.

To download the Java API documentation, go to the Sun Java site java.sun.com/javase/6/download.jsp.

1.11 Fortran, COBOL, Pascal and Ada

Hundreds of high-level languages have been developed, but only a few have achieved broad acceptance. **Fortran** (FORmula TRANslator) was developed by IBM Corporation in the mid-1950s to be used for scientific and engineering applications that require complex mathematical computations. Fortran is still widely used in engineering applications.

COBOL (C)OMMON BUSINESS Oriented Language was developed in the late 1950s by computer manufacturers, the U.S. government and industrial computer users. COBOL is used for commercial applications that require precise and efficient manipulation of large amounts of data. Much business software is still programmed in COBOL.

During the 1960s, many large software-development efforts encountered severe difficulties. Software deliveries were typically late, costs greatly exceeded budgets and the finished products were unreliable. People began to realize that software development was a

1.12 BASIC, Visual Basic, Visual C++, C# and .NET 11

far more complex activity than they had imagined. Research in the 1960s resulted in the evolution of **structured programming**—a disciplined approach to writing programs that are clearer, easier to test and debug and easier to modify than large programs produced with previous techniques.

One of the more tangible results of this research was the development of the Pascal programming language by Professor Niklaus Wirth in 1971. Named after the seventeenth-century mathematician and philosopher Blaise Pascal, it was designed for teaching structured programming in academic environments and rapidly became the preferred programming language in most colleges. Pascal lacks many features needed to make it useful in commercial, industrial and government applications, so it has not been widely accepted in these environments.

The **Ada** programming language was developed under the sponsorship of the U.S. Department of Defense (DOD) during the 1970s and early 1980s. Hundreds of separate languages were being used to produce the DOD's massive command-and-control software systems. The DOD wanted a single language that would fill most of its needs. The Ada language was named after Lady Ada Lovelace, daughter of the poet Lord Byron. Lady Lovelace is credited with writing the world's first computer program in the early 1800s (for the Analytical Engine mechanical computing device designed by Charles Babbage). One important capability of Ada, called **multitasking**, allows programmers to specify that many activities are to occur in parallel. Java, through a technique called *multithreading*, also enables programmers to write programs with parallel activities.

1.12 BASIC, Visual Basic, Visual C++, C# and .NET

The **BASIC** (Beginner's All-Purpose Symbolic Instruction Code) programming language was developed in the mid-1960s at Dartmouth College as a means of writing simple programs. BASIC's primary purpose was to familiarize novices with programming techniques.

Microsoft's Visual Basic language was introduced in the early 1990s to simplify the development of Microsoft Windows applications and is one of the world's most popular programming languages.

Microsoft's latest development tools are part of its corporate-wide strategy for integrating the Internet and the web into computer applications. This strategy is implemented in Microsoft's **.NET platform**, which provides developers with the capabilities they need to create and run computer applications that can execute on computers distributed across the Internet. Microsoft's three primary programming languages are **Visual Basic .NET** (based on the original BASIC), **Visual C++ .NET** (based on C++) and **C#** (based on C++ and Java, and developed expressly for the .NET platform). Developers using .NET can write software components in the language they are most familiar with then form applications by combining those components with components written in any .NET language.

1.13 Typical Java Development Environment

We now explain the commonly used steps in creating and executing a Java application using a Java development environment (illustrated in Fig. 1.1).

Java programs normally go through five phases—**edit**, **compile**, **load**, **verify** and **execute**. We discuss these phases in the context of the JDK 6.0 from Sun Microsystems, Inc., You can download the most up-to-date JDK and its documentation from java.sun.com/

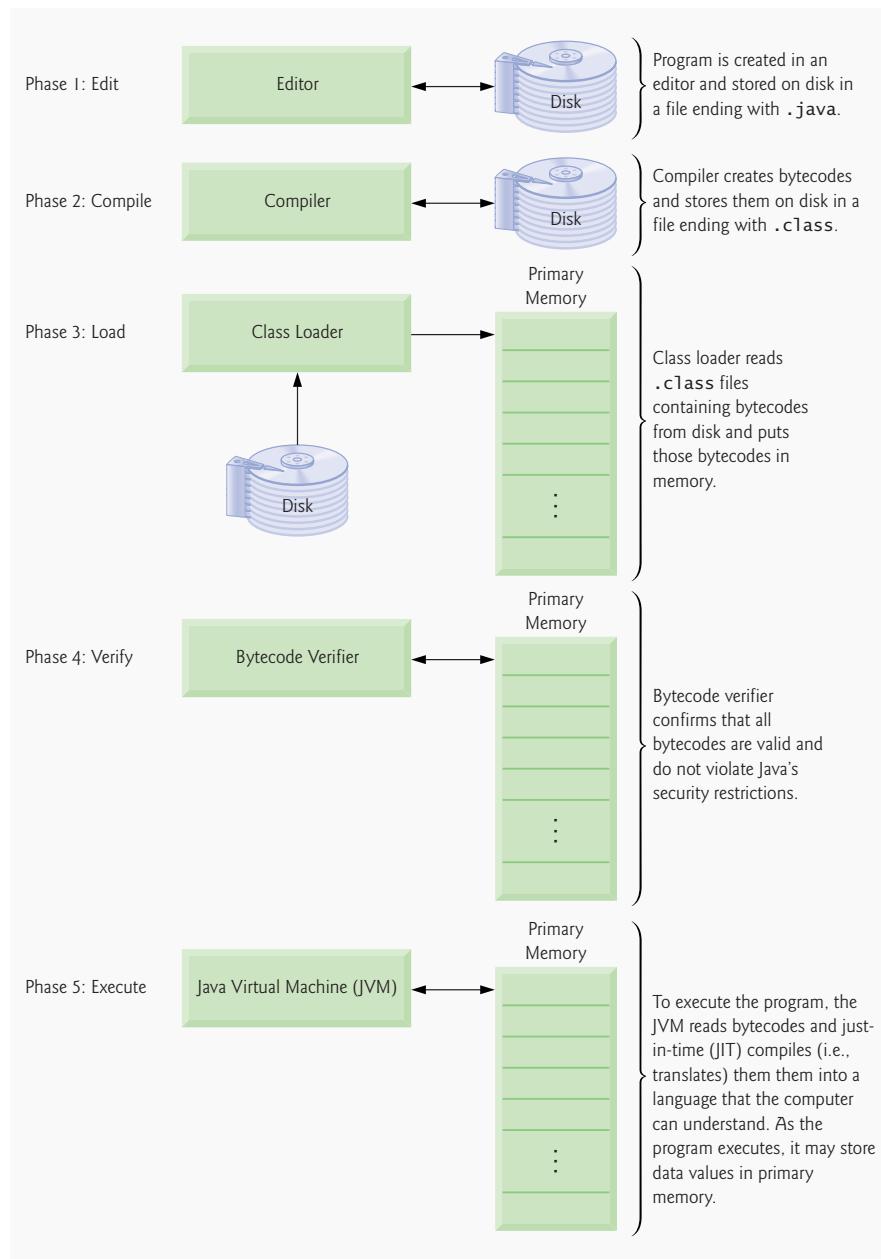

12 Chapter I Introduction to Computers, the Internet and the Web

Fig. 1.1 | Typical Java development environment.

1.13 Typical Java Development Environment 13

[javase/6/download.jsp](http://java.sun.com/javase/6/download.jsp). Carefully follow the installation instructions for the JDK provided in the Before You Begin section of this book (or at java.sun.com/javase/6/webnotes/install/index.html) to ensure that you set up your computer properly to compile and execute Java programs. You may also want to visit Sun's New to Java Center at:

java.sun.com/developer/onlineTraining/new2java/index.html

[*Note:* This website provides installation instructions for Windows, Linux and Mac OS X. If you are not using one of these operating systems, refer to the manuals for your system's Java environment or ask your instructor how to accomplish these tasks based on your computer's operating system. In addition, please keep in mind that web links occasionally break as companies evolve their websites. If you encounter a problem with this link or any other links referenced in this book, please check www.deitel.com for errata and please notify us by e-mail at deitel@deitel.com. We will respond promptly.]

Phase 1: Creating a Program

Phase 1 consists of editing a file with an **editor program** (normally known simply as an **editor**). You type a Java program (typically referred to as **source code**) using the editor, make any necessary corrections and save the program on a secondary storage device, such as your hard drive. A file name ending with the **.java extension** indicates that the file contains Java source code. We assume that the reader knows how to edit a file.

Two editors widely used on Linux systems are **vi** and **emacs**. On Windows, a simple editing program like Windows Notepad will suffice. Many freeware and shareware editors are also available for download from the Internet on sites like www.download.com.

For organizations that develop substantial information systems, **integrated development environments (IDEs)** are available from many major software suppliers, including Sun Microsystems. IDEs provide tools that support the software development process, including editors for writing and editing programs and debuggers for locating logic errors.

Popular IDEs include Eclipse (www.eclipse.org), NetBeans (www.netbeans.org), JBuilder (www.borland.com), JCreator (www.jcreator.com), BlueJ (www.bluej.org), jGRASP (www.jgrasp.org) and jEdit (www.jedit.org). Sun Microsystems's Java Studio Enterprise (developers.sun.com/prodtech/javatools/jseenterprise/index.jsp) is an enhanced version of NetBeans. [*Note:* Most of our example programs should operate properly with any Java integrated development environment that supports the JDK 6.]

Phase 2: Compiling a Java Program into Bytecodes

In Phase 2, the programmer uses the command **javac** (the **Java compiler**) to **compile** a program. For example, to compile a program called **Welcome.java**, you would type

javac Welcome.java

in the command window of your system (i.e., the **MS-DOS prompt** in Windows 95/98/ME, the **Command Prompt** in Windows NT/2000/XP, the **shell prompt** in Linux or the **Terminal application** in Mac OS X). If the program compiles, the compiler produces a **.class** file called **Welcome.class** that contains the compiled version of the program.

The Java compiler translates Java source code into **bytecodes** that represent the tasks to execute in the execution phase (Phase 5). Bytecodes are executed by the **Java Virtual Machine (JVM)**—a part of the JDK and the foundation of the Java platform. A **virtual machine (VM)** is a software application that simulates a computer, but hides the under-

14 Chapter I Introduction to Computers, the Internet and the Web

lying operating system and hardware from the programs that interact with the VM. If the same VM is implemented on many computer platforms, applications that it executes can be used on all those platforms. The JVM is one of the most widely used virtual machines.

Unlike machine language, which is dependent on specific computer hardware, bytecodes are platform-independent instructions—they are not dependent on a particular hardware platform. So Java's bytecodes are **portable**—that is, the same bytecodes can execute on any platform containing a JVM that understands the version of Java in which the bytecodes were compiled. The JVM is invoked by the **java** command. For example, to execute a Java application called `Welcome`, you would type the command

```
java Welcome
```

in a command window to invoke the JVM, which would then initiate the steps necessary to execute the application. This begins Phase 3.

Phase 3: Loading a Program into Memory

In Phase 3, the program must be placed in memory before it can execute—known as **loading**. The **class loader** takes the `.class` files containing the program's bytecodes and transfers them to primary memory. The class loader also loads any of the `.class` files provided by Java that your program uses. The `.class` files can be loaded from a disk on your system or over a network (e.g., your local college or company network, or the Internet).

Phase 4: Bytecode Verification

In Phase 4, as the classes are loaded, the **bytecode verifier** examines their bytecodes to ensure that they are valid and do not violate Java's security restrictions. Java enforces strong security, to make sure that Java programs arriving over the network do not damage your files or your system (as computer viruses and worms might).

Phase 5: Execution

In Phase 5, the JVM executes the program's bytecodes, thus performing the actions specified by the program. In early Java versions, the JVM was simply an interpreter for Java bytecodes. This caused most Java programs to execute slowly because the JVM would interpret and execute one bytecode at a time. Today's JVMs typically execute bytecodes using a combination of interpretation and so-called **just-in-time (JIT) compilation**. In this process, The JVM analyzes the bytecodes as they are interpreted, searching for **hot spots**—parts of the bytecodes that execute frequently. For these parts, a **just-in-time (JIT) compiler**—known as the **Java HotSpot compiler**—translates the bytecodes into the underlying computer's machine language. When the JVM encounters these compiled parts again, the faster machine-language code executes. Thus Java programs actually go through two compilation phases—one in which source code is translated into bytecodes (for portability across JVMs on different computer platforms) and a second in which, during execution, the bytecodes are translated into machine language for the actual computer on which the program executes.

Problems That May Occur at Execution Time

Programs might not work on the first try. Each of the preceding phases can fail because of various errors that we'll discuss throughout this book. For example, an executing program might try to divide by zero (an illegal operation for whole-number arithmetic in Java).

1.14 Notes about Java and Java How to Program, 7/e **15**

This would cause the Java program to display an error message. If this occurs, you would have to return to the edit phase, make the necessary corrections and proceed through the remaining phases again to determine that the corrections fix the problem(s). [Note: Most programs in Java input or output data. When we say that a program displays a message, we normally mean that it displays that message on your computer's screen. Messages and other data may be output to other devices, such as disks and hardcopy printers, or even to a network for transmission to other computers.]

**Common Programming Error 1.1**

*Errors like division by zero occur as a program runs, so they are called **runtime errors** or **execution-time errors**. Fatal runtime errors cause programs to terminate immediately without having successfully performed their jobs. Nonfatal runtime errors allow programs to run to completion, often producing incorrect results.*

1.14 Notes about Java and Java How to Program, 7/e

Java is a powerful programming language. Experienced programmers sometimes take pride in creating weird, contorted, convoluted usage of a language. This is a poor programming practice. It makes programs more difficult to read, more likely to behave strangely, more difficult to test and debug, and more difficult to adapt to changing requirements. This book stresses *clarity*. The following is our first Good Programming Practice tip.

**Good Programming Practice 1.1**

Write your Java programs in a simple and straightforward manner. This is sometimes referred to as KIS ("keep it simple"). Do not "stretch" the language by trying bizarre usages.

You have heard that Java is a portable language and that programs written in Java can run on many different computers. In general, *portability is an elusive goal*.

**Portability Tip 1.2**

Although it is easier to write portable programs in Java than in most other programming languages, differences between compilers, JVMs and computers can make portability difficult to achieve. Simply writing programs in Java does not guarantee portability.

**Error-Prevention Tip 1.1**

Always test your Java programs on all systems on which you intend to run them, to ensure that they will work correctly for their intended audiences.

We audited our presentation against Sun's Java documentation for completeness and accuracy. However, Java is a rich language, and no textbook can cover every topic. A web-based version of the Java API documentation can be found at java.sun.com/javase/6/docs/api/index.html or you can download this documentation to your own computer from java.sun.com/javase/6/download.jsp. For additional technical details on many aspects of Java development, visit java.sun.com/reference/docs/index.html.

**Good Programming Practice 1.2**

Read the documentation for the version of Java you are using. Refer to it frequently to be sure you are aware of the rich collection of Java features and are using them correctly.

16 Chapter I Introduction to Computers, the Internet and the Web

Good Programming Practice 1.3

*Your computer and compiler are good teachers. If, after carefully reading your Java documentation, you are not sure how a feature of Java works, experiment and see what happens. Study each error or warning message you get when you compile your programs (called **compile-time errors** or **compilation errors**), and correct the programs to eliminate these messages.*

Software Engineering Observation 1.4

Some programmers like to read the source code for the Java API classes to determine how the classes work and to learn additional programming techniques.

1.15 Test-Driving a Java Application

In this section, you'll run and interact with your first Java application. You'll begin by running an ATM application that simulates the transactions that take place when using an ATM machine (e.g., withdrawing money, making deposits and checking account balances). You'll learn how to build this application in the optional, object-oriented case study included in Chapters 1–8 and 10. Figure 1.10 at the end of this section suggests other interesting applications that you may also want to test-drive after completing the ATM test-drive. For the purpose of this section, we assume you are running Microsoft Windows.

In the following steps, you'll run the application and perform various transactions. The elements and functionality you see in this application are typical of what you'll learn to program in this book. [Note: We use fonts to distinguish between features you see on a screen (e.g., the **Command Prompt**) and elements that are not directly related to a screen. Our convention is to emphasize screen features like titles and menus (e.g., the **File** menu) in a semibold **sans-serif Helvetica** font and to emphasize non-screen elements, such as file names or input (e.g., **ProgramName.java**) in a **sans-serif Lucida** font. As you have already noticed, the defining occurrence of each term is set in bold blue. In the figures in this section, we highlight in yellow the user input required by each step and point out significant parts of the application with lines and text. To make these features more visible, we have modified the background color of the **Command Prompt** windows.]

1. **Checking your setup.** Read the *Before You Begin* section of the book to confirm that you have set up Java properly on your computer and that you have copied the book's examples to your hard drive.
2. **Locating the completed application.** Open a **Command Prompt** window. This can be done by selecting **Start > All Programs > Accessories > Command Prompt**. Change to the ATM application directory by typing **cd C:\examples\ch01\ATM**, then press **Enter** (Fig. 1.2). The command **cd** is used to change directories.

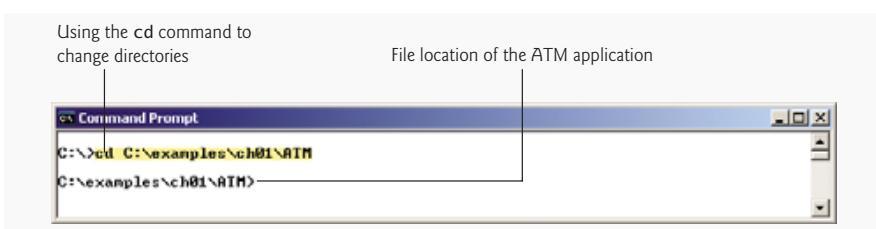

Fig. 1.2 | Opening a Windows XP **Command Prompt** and changing directories.

1.15 Test-Driving a Java Application **17**

3. **Running the ATM application.** Type the command `java ATMCaseStudy` (Fig. 1.3) and press *Enter*. Recall that the `java` command, followed by the name of the application's `.class` file (in this case, `ATMCaseStudy`), executes the application. Specifying the `.class` extension when using the `java` command results in an error. [Note: Java commands are case sensitive. It is important to type the name of this application with a capital A, T and M in "ATM," a capital C in "Case" and a capital S in "Study." Otherwise, the application will not execute.] If you receive the error message, "Exception in thread "main" java.lang.NoClassDefFoundError: ATMCaseStudy," your system has a CLASSPATH problem. Please refer to the *Before You Begin* section of the book for instructions to help you fix this problem.
4. **Entering an account number.** When the application first executes, it displays a "Welcome!" greeting and prompts you for an account number. Type `12345` at the "Please enter your account number:" prompt (Fig. 1.4) and press *Enter*.
5. **Entering a PIN.** Once a valid account number is entered, the application displays the prompt "Enter your PIN:". Type "54321" as your valid PIN (Personal Identification Number) and press *Enter*. The ATM main menu containing a list of options will be displayed (Fig. 1.5).

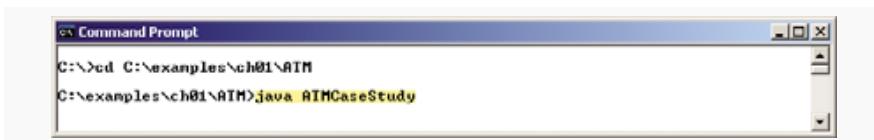

Fig. 1.3 | Using the `java` command to execute the ATM application.

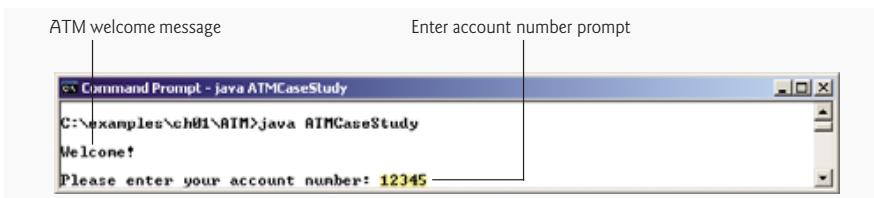

Fig. 1.4 | Prompting the user for an account number.

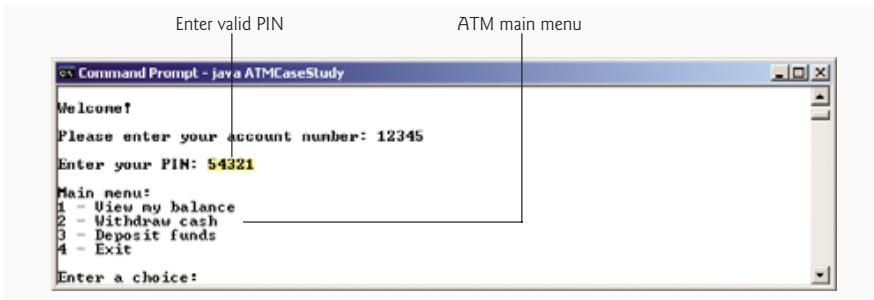

Fig. 1.5 | Entering a valid PIN number and displaying the ATM application's main menu.

18 Chapter I Introduction to Computers, the Internet and the Web

6. **Viewing the account balance.** Select option 1, "View my balance", from the ATM menu (Fig. 1.6). The application then displays two numbers—the Available balance (\$1000.00) and the Total balance (\$1,200.00). The available balance is the maximum amount of money in your account which is available for withdrawal at a given time. In some cases, certain funds, such as recent deposits, are not immediately available for the user to withdraw, so the available balance may be less than the total balance, as it is here. After the account balance information is shown, the application's main menu is displayed again.
7. **Withdrawing money from the account.** Select option 2, "Withdraw cash", from the application menu. You are then presented (Fig. 1.7) with a list of dollar amounts (e.g., 20, 40, 60, 100 and 200). You are also given the option to cancel the transaction and return to the main menu. Withdraw \$100 by selecting option 4. The application displays "Please take your cash now." and returns to the main menu. [Note: Unfortunately, this application only *simulates* the behavior of a real ATM and thus does not actually dispense money.]

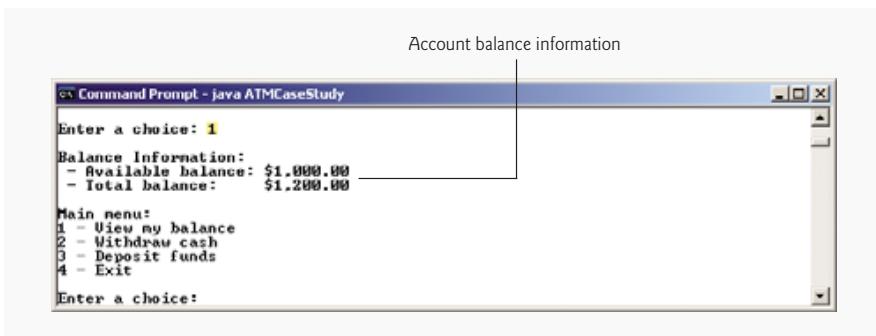

Fig. 1.6 | ATM application displaying user account balance information.

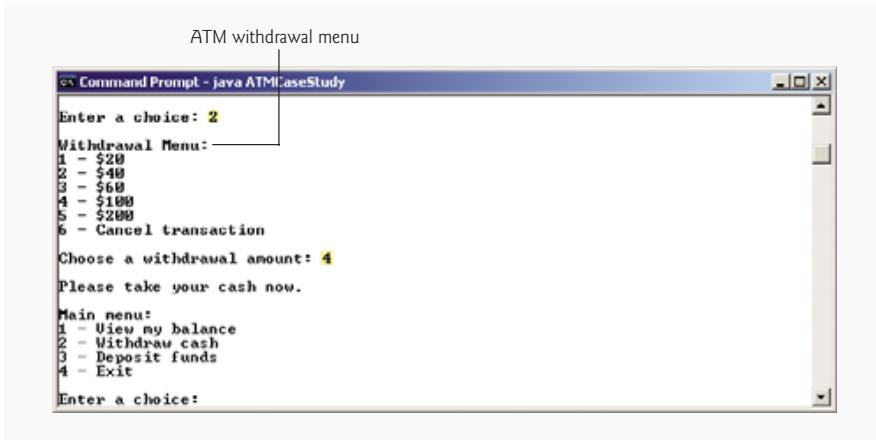

Fig. 1.7 | Withdrawing money from the account and returning to the main menu.

1.15 Test-Driving a Java Application **19**

8. *Confirming that the account information has been updated.* From the main menu, select option 1 again to view your current account balance (Fig. 1.8). Note that both the available balance and the total balance have been updated to reflect your withdrawal transaction.
9. *Ending the transaction.* To end your current ATM session, select option 4, "Exit" from the main menu (Fig. 1.9). The ATM will exit the system and display a good-bye message to the user. The application will then return to its original prompt asking for the next user's account number.
10. *Exiting the ATM application and closing the Command Prompt window.* Most applications provide an option to exit and return to the Command Prompt directory from which the application was run. A real ATM does not provide a user with the option to turn off the ATM machine. Rather, when a user has completed all desired transactions and chooses the menu option to exit, the ATM resets itself and displays a prompt for the next user's account number. As Fig. 1.9 illustrates, the ATM application here behaves similarly. Choosing the menu option to exit ends only the current user's ATM session, not the entire ATM application. To actually exit the ATM application, click the close (x) button in the upper-right corner of the Command Prompt window. Closing the window causes the running application to terminate.

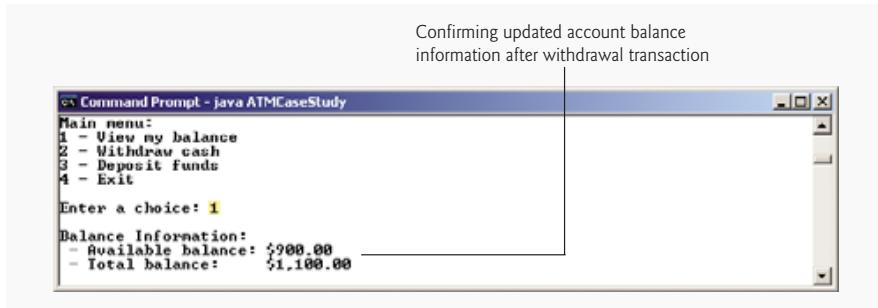

Fig. 1.8 | Checking the new balance.

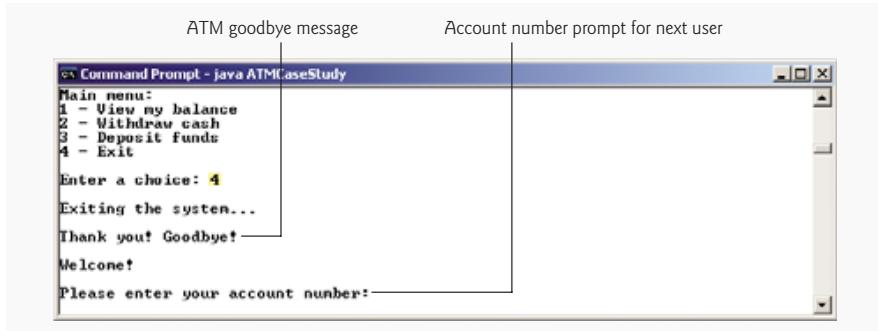

Fig. 1.9 | Ending an ATM transaction session.

20 Chapter I Introduction to Computers, the Internet and the Web

Additional Applications Found in Java How to Program, 7/e

Figure 1.10 lists a few of the hundreds of applications found in the book's examples and exercises. These programs introduce many of the powerful and fun features of Java. Run these programs to see more of the types of applications you'll learn how to build in this textbook. The examples folder for this chapter contains all the files required to run each application. Simply type the commands listed in Fig. 1.10 in a **Command Prompt** window.

Application Name	Chapter Location	Commands to Run
Tic-Tac-Toe	Chapters 8 and 24	cd C:\examples\ch01\Tic-Tac-Toe java TicTacToeTest
Guessing Game	Chapter 11	cd C:\examples\ch01\GuessGame java GuessGame
Logo Animator	Chapter 21	cd C:\examples\ch01\LogoAnimator java LogoAnimator
Bouncing Ball	Chapter 23	cd C:\examples\ch01\BouncingBall java BouncingBall

Fig. 1.10 | Examples of additional Java applications found in *Java How to Program, 7/e*.

1.16 Software Engineering Case Study: Introduction to Object Technology and the UML

Now we begin our early introduction to object orientation, a natural way of thinking about the world and writing computer programs. Chapters 1–8 and 10 all end with a brief Software Engineering Case Study section in which we present a carefully paced introduction to object orientation. Our goal here is to help you develop an object-oriented way of thinking and to introduce you to the **Unified Modeling Language™ (UML™)**—a graphical language that allows people who design software systems to use an industry standard notation to represent them.

In this only required section (1.16), we introduce object-oriented concepts and terminology. The optional sections in Chapters 2–8 and 10 present an object-oriented design and implementation of the software for a simple automated teller machine (ATM). The Software Engineering Case Study sections at the ends of Chapters 2–7

- analyze a typical requirements document that describes a software system (the ATM) to be built
- determine the objects required to implement that system
- determine the attributes the objects will have
- determine the behaviors these objects will exhibit
- specify how the objects interact with one another to meet the system requirements.

The Software Engineering Case Study sections at the ends of Chapters 8 and 10 modify and enhance the design presented in Chapters 2–7. Appendix M contains a complete, working Java implementation of the object-oriented ATM system.

1.16 Introduction to Object Technology and the UML 21

You will experience a concise, yet solid introduction to object-oriented design with the UML. Also, you'll sharpen your code-reading skills by touring the complete, carefully written and well-documented Java implementation of the ATM in Appendix M.

Basic Object Technology Concepts

We begin our introduction to object orientation with some key terminology. Everywhere you look in the real world you see **objects**—people, animals, plants, cars, planes, buildings, computers and so on. Humans think in terms of objects. Telephones, houses, traffic lights, microwave ovens and water coolers are just a few more objects. Computer programs, such as the Java programs you'll read in this book and the ones you'll write, are composed of lots of interacting software objects.

We sometimes divide objects into two categories: animate and inanimate. Animate objects are “alive” in some sense—they move around and do things. Inanimate objects, on the other hand, do not move on their own. Objects of both types, however, have some things in common. They all have **attributes** (e.g., size, shape, color and weight), and they all exhibit **behaviors** (e.g., a ball rolls, bounces, inflates and deflates; a baby cries, sleeps, crawls, walks and blinks; a car accelerates, brakes and turns; a towel absorbs water). We will study the kinds of attributes and behaviors that software objects have.

Humans learn about existing objects by studying their attributes and observing their behaviors. Different objects can have similar attributes and can exhibit similar behaviors. Comparisons can be made, for example, between babies and adults and between humans and chimpanzees.

Object-oriented design (OOD) models software in terms similar to those that people use to describe real-world objects. It takes advantage of **class** relationships, where objects of a certain class, such as a class of vehicles, have the same characteristics—cars, trucks, little red wagons and roller skates have much in common. OOD also takes advantage of **inheritance** relationships, where new classes of objects are derived by absorbing characteristics of existing classes and adding unique characteristics of their own. An object of class “convertible” certainly has the characteristics of the more general class “automobile,” but more specifically, the roof goes up and down.

Object-oriented design provides a natural and intuitive way to view the software design process—namely, modeling objects by their attributes and behaviors just as we describe real-world objects. OOD also models communication between objects. Just as people send messages to one another (e.g., a sergeant commands a soldier to stand at attention), objects also communicate via messages. A bank account object may receive a message to decrease its balance by a certain amount because the customer has withdrawn that amount of money.

OOD **encapsulates** (i.e., wraps) attributes and **operations** (behaviors) into objects—an object's attributes and operations are intimately tied together. Objects have the property of **information hiding**. This means that objects may know how to communicate with one another across well-defined **interfaces**, but normally they are not allowed to know how other objects are implemented—implementation details are hidden within the objects themselves. We can drive a car effectively, for instance, without knowing the details of how engines, transmissions, brakes and exhaust systems work internally—as long as we know how to use the accelerator pedal, the brake pedal, the wheel and so on. Information hiding, as we will see, is crucial to good software engineering.

22 Chapter I Introduction to Computers, the Internet and the Web

Languages like Java are **object oriented**. Programming in such a language is called **object-oriented programming (OOP)**, and it allows computer programmers to implement an object-oriented design as a working system. Languages like C, on the other hand, are **procedural**, so programming tends to be **action oriented**. In C, the unit of programming is the **function**. Groups of actions that perform some common task are formed into functions, and functions are grouped to form programs. In Java, the unit of programming is the class from which objects are eventually **instantiated** (created). Java classes contain **methods** (which implement operations and are similar to functions in C) as well as **fields** (which implement attributes).

Java programmers concentrate on creating classes. Each class contains fields, and the set of methods that manipulate the fields and provide services to **clients** (i.e., other classes that use the class). The programmer uses existing classes as the building blocks for constructing new classes.

Classes are to objects as blueprints are to houses. Just as we can build many houses from one blueprint, we can instantiate (create) many objects from one class. You cannot cook meals in the kitchen of a blueprint; you can cook meals in the kitchen of a house.

Classes can have relationships with other classes. For example, in an object-oriented design of a bank, the “bank teller” class needs to relate to the “customer” class, the “cash drawer” class, the “safe” class, and so on. These relationships are called **associations**.

Packaging software as classes makes it possible for future software systems to **reuse** the classes. Groups of related classes are often packaged as reusable **components**. Just as realtors often say that the three most important factors affecting the price of real estate are “location, location and location,” people in the software community often say that the three most important factors affecting the future of software development are “reuse, reuse and reuse.” Reuse of existing classes when building new classes and programs saves time and effort. Reuse also helps programmers build more reliable and effective systems, because existing classes and components often have gone through extensive testing, debugging and performance tuning.

Indeed, with object technology, you can build much of the software you will need by combining classes, just as automobile manufacturers combine interchangeable parts. Each new class you create will have the potential to become a valuable software asset that you and other programmers can use to speed and enhance the quality of future software development efforts.

Introduction to Object-Oriented Analysis and Design (OOAD)

Soon you will be writing programs in Java. How will you create the code for your programs? Perhaps, like many beginning programmers, you will simply turn on your computer and start typing. This approach may work for small programs (like the ones we present in the early chapters of the book), but what if you were asked to create a software system to control thousands of automated teller machines for a major bank? Or suppose you were asked to work on a team of 1,000 software developers building the next U.S. air traffic control system. For projects so large and complex, you could not simply sit down and start writing programs.

To create the best solutions, you should follow a detailed process for **analyzing** your project’s **requirements** (i.e., determining *what* the system is supposed to do) and developing a **design** that satisfies them (i.e., deciding *how* the system should do it). Ideally, you would go through this process and carefully review the design (or have your design

1.16 Introduction to Object Technology and the UML 23

reviewed by other software professionals) before writing any code. If this process involves analyzing and designing your system from an object-oriented point of view, it is called an **object-oriented analysis and design (OOAD) process**. Experienced programmers know that analysis and design can save many hours by helping them to avoid an ill-planned system-development approach that has to be abandoned part of the way through its implementation, possibly wasting considerable time, money and effort.

OOAD is the generic term for the process of analyzing a problem and developing an approach for solving it. Small problems like the ones discussed in these first few chapters do not require an exhaustive OOAD process. It may be sufficient to write **pseudocode** before we begin writing Java code—pseudocode is an informal means of expressing program logic. It is not actually a programming language, but we can use it as a kind of outline to guide us as we write our code. We introduce pseudocode in Chapter 4.

As problems and the groups of people solving them increase in size, the methods of OOAD become more appropriate than pseudocode. Ideally, a group should agree on a strictly defined process for solving its problem and a uniform way of communicating the results of that process to one another. Although many different OOAD processes exist, a single graphical language for communicating the results of *any* OOAD process has come into wide use. This language, known as the Unified Modeling Language (UML), was developed in the mid-1990s under the initial direction of three software methodologists—Grady Booch, James Rumbaugh and Ivar Jacobson.

History of the UML

In the 1980s, increasing numbers of organizations began using OOP to build their applications, and a need developed for a standard OOAD process. Many methodologists—including Booch, Rumbaugh and Jacobson—individually produced and promoted separate processes to satisfy this need. Each process had its own notation, or “language” (in the form of graphical diagrams), to convey the results of analysis and design.

By the early 1990s, different organizations, and even divisions within the same organization, were using their own unique processes and notations. At the same time, these organizations also wanted to use software tools that would support their particular processes. Software vendors found it difficult to provide tools for so many processes. A standard notation and standard processes were needed.

In 1994, James Rumbaugh joined Grady Booch at Rational Software Corporation (now a division of IBM), and the two began working to unify their popular processes. They soon were joined by Ivar Jacobson. In 1996, the group released early versions of the UML to the software engineering community and requested feedback. Around the same time, an organization known as the **Object Management Group™ (OMG™)** invited submissions for a common modeling language. The OMG (www.omg.org) is a nonprofit organization that promotes the standardization of object-oriented technologies by issuing guidelines and specifications, such as the UML. Several corporations—among them HP, IBM, Microsoft, Oracle and Rational Software—had already recognized the need for a common modeling language. In response to the OMG’s request for proposals, these companies formed **UML Partners**—the consortium that developed the UML version 1.1 and submitted it to the OMG. The OMG accepted the proposal and, in 1997, assumed responsibility for the continuing maintenance and revision of the UML. The UML version 2 now available marks the first major revision of the UML since the 1997 version 1.1 standard. We present UML 2 terminology and notation throughout this book.

24 Chapter I Introduction to Computers, the Internet and the Web

What Is the UML?

The UML is now the most widely used graphical representation scheme for modeling object-oriented systems. It has indeed unified the various popular notational schemes. Those who design systems use the language (in the form of diagrams) to model their systems.

An attractive feature of the UML is its flexibility. The UML is **extensible** (i.e., capable of being enhanced with new features) and is independent of any particular OOAD process. UML modelers are free to use various processes in designing systems, but all developers can now express their designs with one standard set of graphical notations.

The UML is a complex, feature-rich graphical language. In our Software Engineering Case Study sections, we present a simple, concise subset of these features. We then use this subset to guide you through a first design experience with the UML intended for novice object-oriented programmers in first- or second-semester programming courses.

Web UML Resources

For more information about the UML, refer to the following websites:

www.uml.org

This UML resource page from the Object Management Group (OMG) provides specification documents for the UML and other object-oriented technologies.

www.ibm.com/software/rational/uml

This is the UML resource page for IBM Rational—the successor to the Rational Software Corporation (the company that created the UML).

en.wikipedia.org/wiki/Unified_Modeling_Language

Rumbaugh, J., I. Jacobson and G. Booch. *The Unified Modeling Language User Guide, Second Edition*. Boston: Addison-Wesley Professional, 2006.

Section 1.16 Self-Review Exercises

1.1 List three examples of real-world objects that we did not mention. For each object, list several attributes and behaviors.

1.2 Pseudocode is _____.

- a) another term for OOAD
- b) a programming language used to display UML diagrams
- c) an informal means of expressing program logic
- d) a graphical representation scheme for modeling object-oriented systems

1.3 The UML is used primarily to _____.

- a) test object-oriented systems
- b) design object-oriented systems
- c) implement object-oriented systems
- d) Both a and b

Answers to Section 1.16 Self-Review Exercises

1.1 [Note: Answers may vary.] a) A television's attributes include the size of the screen, the number of colors it can display, its current channel and its current volume. A television turns on and off, changes channels, displays video and plays sounds. b) A coffee maker's attributes include the maximum volume of water it can hold, the time required to brew a pot of coffee and the temperature of the heating plate under the coffee pot. A coffee maker turns on and off, brews coffee and heats coffee. c) A turtle's attributes include its age, the size of its shell and its weight. A turtle walks, retreats into its shell, emerges from its shell and eats vegetation.

1.2 c.

1.3 b.

1.17 Web 2.0

The web literally exploded in the mid-to-late 1990s, but hard times hit in the early 2000s due to the dot com economic bust. The resurgence that began in 2004 or so, has been named Web 2.0. The first Web 2.0 Conference was held in 2004. A year into its life, the term “Web 2.0” garnered about 10 million hits on the [Google](#) search engine, growing to 60 million a year later. Google is widely regarded as the signature company of Web 2.0. Some others are Craigslist (free classified listings), Flickr (photo sharing), del.icio.us (social bookmarking), YouTube (video sharing), MySpace and FaceBook (social networking), Salesforce (business software offered as an online service), Second Life (a virtual world), Skype (Internet telephony) and Wikipedia (a free online encyclopedia).

At Deitel & Associates, we launched our Web 2.0-based [Internet Business Initiative](#) in 2005. We're researching the key technologies of Web 2.0 and using them to build Internet businesses. We're sharing our research in the form of Resource Centers at www.deitel.com/resourcecenters.html. Each week, we announce the latest Resource Centers in our newsletter, the *Deitel® Buzz Online* (www.deitel.com/newsletter/subscribe.html). Each lists many links to free content and software on the Internet.

We include a substantial treatment of [web services](#) (Chapter 28) and introduce the new applications development methodology of [mashups](#) (Appendix H) in which you can rapidly develop powerful and intriguing applications by combining complementary web services and other forms of information feeds of two or more organizations. A popular mashup is www.housingmaps.com which combines the real estate listings of www.craigslist.org with the mapping capabilities of [Google Maps](#) to offer maps that show the locations of apartments for rent in a given area.

[Ajax](#) is one of the premier technologies of Web 2.0. Though the term's use exploded in 2005, it's just a term that names a group of technologies and programming techniques that have been in use since the late 1990s. Ajax helps Internet-based applications perform like desktop applications—a difficult task, given that such applications suffer transmission delays as data is shuttled back and forth between your computer and other computers on the Internet. Using Ajax, applications like Google Maps have achieved excellent performance and the look and feel of desktop applications. Although we don't discuss “raw” Ajax programming (which is quite complex) in this text, we do show in Chapter 27 how to build Ajax-enabled applications using JavaServer Faces (JSF) Ajax-enabled components.

[Blogs](#) are web sites (currently about 60 million of them) that are like online diaries, with the most recent entries appearing first. Bloggers quickly post their opinions about

26 Chapter I Introduction to Computers, the Internet and the Web

news, product releases, political candidates, controversial issues, and just about everything else. The collection of all blogs and the blogging community is called the **blogosphere** and is becoming increasingly influential. **Technorati** is the leading blog search engine.

RSS feeds enable sites to push information to subscribers. A common use of RSS feeds is to deliver the latest blog postings to people who subscribe to blogs. The RSS information flows on the Internet are growing exponentially.

Web 3.0 is another name for the next generation of the web also called the **Semantic Web**. Web 1.0 was almost purely HTML-based. Web 2.0 is making increasing use of XML, especially in technologies like RSS feeds. Web 3.0 will make deep use of XML, creating a “web of meaning.” If you’re a student looking for a great research paper or thesis topic, or an entrepreneur looking for business opportunities, check out our Web 3.0 Resource Center.

To follow the latest developments in Web 2.0, read www.techcrunch.com and [www.Slashdot.org](http://wwwSlashdot.org) and check out the growing list of Web 2.0-related Resource Centers at www.deitel.com/resourcecenters.html.

1.18 Software Technologies

In this section, we discuss a number of software engineering buzzwords that you’ll hear in the software development community. We’ve created Resource Centers on most of these topics, with many more on the way.

Agile Software Development is a set of methodologies that try to get software implemented quickly with fewer resources than previous methodologies. Check out the Agile Alliance (www.agilealliance.org) and the Agile Manifesto (www.agilemanifesto.org).

Extreme programming (XP) is one of many agile development methodologies. It tries to develop software quickly. The software is released frequently in small increments to encourage rapid user feedback. XP recognizes that the users’ requirements change often and that software must meet those new requirements quickly. Programmers work in pairs at one machine so code review is done immediately as the code is created. Everyone on the team should be able to work on any part of the code.

Refactoring involves reworking code to make it clearer and easier to maintain while preserving its functionality. It’s widely employed with agile development methodologies. Many refactoring tools are available to do major portions of the reworking automatically.

Design patterns are proven architectures for constructing flexible and maintainable object-oriented software (see web bonus Appendix P). The field of design patterns tries to enumerate those recurring patterns, and encourage software designers to reuse them to develop better quality software with less time, money and effort.

Game programming. The computer game business is larger than the first-run movie business. College courses and even majors are now devoted to the sophisticated software techniques used in game programming. Check out our Game Programming and Programming Projects Resource Centers.

Open source software is a style of developing software in contrast to proprietary development that dominated software’s early years. With open source development, individuals and companies contribute their efforts in developing, maintaining and evolving software in exchange for the right to use that software for their own purposes, typically at no charge. Open source code generally gets scrutinized by a much larger audience than

1.19 Wrap-Up **27**

proprietary software, so bugs get removed faster. Open source also encourages more innovation. Sun recently announced that it is open sourcing Java. Some organizations you'll hear a lot about in the open source community are the Eclipse Foundation (the Eclipse IDE is popular for Java software development), the Mozilla Foundation (creators of the Firefox browser), the Apache Software Foundation (creators of the Apache web server) and SourceForge (which provides the tools for managing open source projects and currently has over 100,000 open source projects under development).

Linux is an open source operating system and one of the greatest successes of the open source movement. **MySQL** is an open source database management system. **PHP** is the most popular open source server-side Internet “scripting” language for developing Internet-based applications. **LAMP** is an acronym for the set of open source technologies that many developers used to build web applications—it stands for Linux, Apache, MySQL and PHP (or Perl or Python—two other languages used for similar purposes).

Ruby on Rails combines the scripting language Ruby with the Rails web application framework developed by the company 37Signals. Their book, *Getting Real*, is a must read for today's web application developers; read it free at gettingreal.37signals.com/toc.php. Many Ruby on Rails developers have reported significant productivity gains over using other languages when developing database-intensive web applications.

Software has generally been viewed as a product; most software still is offered this way. If you want to run an application, you buy a software package from a software vendor. You then install that software on your computer and run it as needed. As new versions of the software appear you upgrade your software, often at significant expense. This process can become cumbersome for organizations with tens of thousands of systems that must be maintained on a diverse array of computer equipment. With **Software as a Service (SaaS)** the software runs on servers elsewhere on the Internet. When that server is updated, all clients worldwide see the new capabilities; no local installation is needed. You access the service through a browser—these are quite portable so you can run the same applications on different kinds of computers from anywhere in the world. Salesforce.com, Google, and Microsoft's Office Live and Windows Live all offer SaaS.

1.19 Wrap-Up

This chapter introduced basic hardware and software concepts, and basic object technology concepts, including classes, objects, attributes, behaviors, encapsulation, inheritance and polymorphism. We discussed the different types of programming languages and which are most widely used. You learned the steps for creating and executing a Java application using Sun's JDK 6. The chapter explored the history of the Internet and the World Wide Web, and Java's role in developing distributed client/server applications for the Internet and the web. You also learned about the history and purpose of the UML—the industry-standard graphical language for modeling software systems. Finally, you “test drove” one or more sample Java applications similar to the types of applications you will learn to program in this book.

In Chapter 2, you'll create your first Java applications. You'll see examples that show how programs display messages and obtain information from the user for processing. We analyze and explain each example to help ease your way into Java programming.

28 Chapter I Introduction to Computers, the Internet and the Web

1.20 Web Resources

This section provides many resources that will be useful to you as you learn Java. The sites include Java resources, Java development tools for students and professionals, and our own websites where you can find downloads and resources associated with this book. Deitel Java Resource Centers

www.deitel.com/Java/

Our Java Resource Center focuses on the enormous amount of Java free content available online. Start your search here for resources, downloads, tutorials, documentation, books, e-books, journals, articles, blogs and more that will help you develop Java applications.

www.deitel.com/JavaSE6Mustang/

Our Java SE 6 (Mustang) Resource Center is your guide to the latest release of Java. The site includes the best resources we found online to help you get started with Java SE 6 development.

www.deitel.com/JavaEE5/

Our Java Enterprise Edition 5 (Java EE 5) Resource Center.

www.deitel.com/JavaCertification/

Our Java Certification and Assessment Testing Resource Center.

www.deitel.com/JavaDesignPatterns/

Our Java Design Patterns Resource Center. In their book, *Design Patterns: Elements of Reusable Object-Oriented Software* (Boston: Addison-Wesley Professional, 1995), the “Gang of Four” (E. Gamma, R. Helm, R. Johnson, and J. Vlissides) describe 23 design patterns that provide proven architectures for building object-oriented software systems. In this resource center, you'll find discussions of many of these and other design patterns.

www.deitel.com/CodeSearchEngines/

Our Code Search Engines and Code Sites Resource Center includes resources developers use to find source code online.

www.deitel.com/ProgrammingProjects/

Our Programming Projects Resource Center is your guide to student programming projects online.

Sun Microsystems Websites

java.sun.com/developer/onlineTraining/new2java/index.html

The “New to Java Center” on the Sun Microsystems website features online training resources to help you get started with Java programming.

I.20 Web Resources **29**

java.sun.com/javase/6/download.jsp

The download page for the Java Development Kit 6 (JDK 6) and its documentation. The JDK includes everything you need to compile and execute your Java SE 6 (Mustang) applications.

java.sun.com/javase/6/webnotes/install/index.html

Instructions for installing JDK 6 on Solaris, Windows and Linux platforms.

java.sun.com/javase/6/docs/api/index.html

The online site for the Java SE 6 API documentation.

java.sun.com/javase

The home page for the Java Standard Edition platform.

java.sun.com

Sun's Java technology home page provides downloads, references, forums, online tutorials and more.

java.sun.com/reference/docs/index.html

Sun's documentation site for all Java technologies.

developers.sun.com

Sun's home page for Java developers provides downloads, APIs, code samples, articles with technical advice and other resources on the best Java development practices.

Editors and Integrated Development Environments

www.eclipse.org

The Eclipse development environment can be used to develop code in any programming language. You can download the environment and several Java plug-ins to develop your Java programs.

www.netbeans.org

The NetBeans IDE. One of the most widely used, freely distributed Java development tools.

borland.com/products/downloads/download_jbuilder.html

Borland provides a free Foundation Edition version of its popular Java IDE JBuilder. The site also provides 30-day trial versions of the Enterprise and Developer editions.

www.bluej.org

BlueJ—a free tool designed to help teach object-oriented Java to new programmers.

www.jgrasp.org

jGRASP downloads, documentation and tutorials. This tool displays visual representations of Java programs to aid comprehension.

www.jedit.org

jEdit—a text editor written in Java.

developers.sun.com/prodtech/javatools/jseenterprise/index.jsp

Sun Java Studio Enterprise IDE—the Sun Microsystems enhanced version of NetBeans.

www.jcreator.com

JCreator—a popular Java IDE. JCreator Lite Edition is available as a free download. A 30-day trial version of JCreator Pro Edition is also available.

www.textpad.com

TextPad—compile, edit and run your Java programs from this editor that provides syntax coloring and an easy-to-use interface.

www.download.com

A site that contains freeware and shareware application downloads, including, editor programs.

Additional Java Resource Sites

www.javalobby.org

Provides up-to-date Java news, forums where developers can exchange tips and advice, and a comprehensive Java knowledge base organizing articles and downloads from across the web.

30 Chapter I Introduction to Computers, the Internet and the Web

www.jguru.com

Provides forums, downloads, articles, online courses and a large collection of Java FAQs (Frequently Asked Questions).

www.javaworld.com

Provides resources for Java developers, such as articles, indices of popular Java books, tips and FAQs.

www.ftponline.com/javapro

JavaPro magazine features monthly articles, programming tips, book reviews and more.

sys-con.com/java/

Java Developer's Journal from Sys-Con Media provides articles, e-books and other Java resources.

Summary

Section 1.1 Introduction

- Java has become the language of choice for implementing Internet-based applications and software for devices that communicate over a network.
- Java Enterprise Edition (Java EE) is geared toward developing large-scale, distributed networking applications and web-based applications.
- Java Micro Edition (Java ME) is geared toward developing applications for small, memory-constrained devices, such as cell phones, pagers and PDAs.

Section 1.2 What Is a Computer?

- A computer is a device capable of performing computations and making logical decisions at speeds millions (even billions) of times faster than human beings can.
- Computers process data under the control of sets of instructions called computer programs. Programs guide computers through actions specified by people called computer programmers.
- A computer consists of various devices referred to as hardware. The programs that run on a computer are referred to as software.

Section 1.3 Computer Organization

- Virtually every computer may be envisioned as divided into six logical units or sections.
- The input unit obtains information from input devices and places this information at the disposal of the other units so that it can be processed.
- The output unit takes information that the computer has processed and places it on various output devices to make the information available for use outside the computer.
- The memory unit is the rapid-access, relatively low-capacity "warehouse" section of the computer. It retains information that has been entered through the input unit, so that it will be immediately available for processing when needed. It also retains processed information until it can be placed on output devices by the output unit.
- The arithmetic and logic unit (ALU) is responsible for performing calculations (such as addition, subtraction, multiplication and division) and making decisions.
- The central processing unit (CPU) coordinates and supervises the operation of the other sections. The CPU tells the input unit when information should be read into the memory unit, tells the ALU when information from the memory unit should be used in calculations and tells the output unit when to send information from the memory unit to certain output devices.
- Multiprocessors have multiple CPUs and, hence, can perform many operations simultaneously.

Summary 31

- The secondary storage unit is the long-term, high-capacity “warehousing” section of the computer. Programs or data not actively being used by the other units normally are placed on secondary storage devices until they are again needed.

Section 1.4 Early Operating Systems

- Early computers could perform only one job or task at a time.
- Operating systems were developed to make using computers more convenient.
- Multiprogramming involves the simultaneous operation of many jobs.
- With timesharing, the computer runs a small portion of one user’s job, then moves on to service the next user, perhaps providing service to each user several times per second.

Section 1.5 Personal, Distributed and Client/Server Computing

- In 1977, Apple Computer popularized personal computing.
- In 1981, IBM, the world’s largest computer vendor, introduced the IBM Personal Computer, which quickly legitimized personal computing in business, industry and government.
- In distributed computing, instead of computing being performed only at a central computer, it is distributed over networks to the sites where the organization’s work is performed.
- Servers store data that may be used by client computers distributed throughout the network, hence the term client/server computing.
- Java has become widely used for writing software for computer networking and for distributed client/server applications.

Section 1.6 The Internet and the World Wide Web

- The Internet is accessible by more than a billion computers and computer-controlled devices.
- With the introduction of the World Wide Web the Internet has exploded into one of the world’s premier communication mechanisms.

Section 1.7 Machine Languages, Assembly Languages and High-Level Languages

- Any computer can directly understand only its own machine language.
- Machine language is the “natural language” of a computer.
- Machine languages generally consist of strings of numbers (ultimately reduced to 1s and 0s) that instruct computers to perform their most elementary operations one at a time.
- Machine languages are machine dependent.
- Programmers began using English-like abbreviations to represent elementary operations. These abbreviations formed the basis of assembly languages.
- Translator programs called assemblers were developed to convert early assembly-language programs to machine language at computer speeds.
- High-level languages allow programmers to write instructions that look almost like everyday English and contain commonly used mathematical notations.
- Java is the most widely used high-level programming language.
- Interpreter programs execute high-level language programs directly.

Section 1.8 History of C and C++

- Java evolved from C++, which evolved from C, which evolved from BCPL and B.
- The C language was developed by Dennis Ritchie at Bell Laboratories. It initially became widely known as the development language of the UNIX operating system.

32 Chapter I Introduction to Computers, the Internet and the Web

- C++, an extension of C, was developed by Bjarne Stroustrup in the early 1980s at Bell Laboratories. C++ provides a number of features that “spruce up” the C language, and capabilities for object-oriented programming.

Section 1.9 History of Java

- Java is used to develop large-scale enterprise applications, to enhance the functionality of web servers, to provide applications for consumer devices and for many other purposes.
- Java programs consist of pieces called classes. Classes include pieces called methods that perform tasks and return information when the tasks are completed.

Section 1.10 Java Class Libraries

- Most Java programmers take advantage of the rich collections of existing classes in the Java class libraries, which are also known as the Java APIs (Application Programming Interfaces).
- The advantage of creating your own classes and methods is that you know how they work and can examine the code. The disadvantage is the time-consuming and potentially complex effort.

Section 1.11 Fortran, COBOL, Pascal and Ada

- Fortran (FORmula TRANslator) was developed by IBM Corporation in the mid-1950s for use in scientific and engineering applications that require complex mathematical computations.
- COBOL (COmmon Business Oriented Language) is used for commercial applications that require precise and efficient manipulation of large amounts of data.
- Research in the 1960s resulted in structured programming—an approach to writing programs that are clearer, and easier to test, debug and modify than those produced with earlier techniques.
- Pascal was designed for teaching structured programming in academic environments and rapidly became the preferred programming language in most colleges.
- The Ada programming language was developed under the sponsorship of the U.S. Department of Defense (DOD) to fill most of its needs. An Ada capability called multitasking allows programmers to specify that activities are to occur in parallel. Java, through a technique called *multithreading*, also enables programmers to write programs with parallel activities.

Section 1.12 BASIC, Visual Basic, Visual C++, C# and .NET

- BASIC was developed in the mid-1960s for writing simple programs.
- Microsoft’s Visual Basic language simplifies the development of Windows applications.
- Microsoft’s .NET platform integrates the Internet and the web into computer applications.

Section 1.13 Typical Java Development Environment

- Java programs normally go through five phases—edit, compile, load, verify and execute.
- Phase 1 consists of editing a file with an editor. You type a program using the editor, make corrections and save the program on a secondary storage device, such as your hard drive.
- A file name ending with the .java extension indicates that the file contains Java source code.
- Integrated development environments (IDEs) provide tools that support software development, including editors for writing and editing programs and debuggers for locating logic errors.
- In Phase 2, the programmer uses the command javac to compile a program.
- If a program compiles, the compiler produces a .class file that contains the compiled program.
- The Java compiler translates Java source code into bytecodes that represent the tasks to be executed. Bytecodes are executed by the Java Virtual Machine (JVM).

Terminology **33**

- In Phase 3, loading, the class loader takes the .class files containing the program's bytecodes and transfers them to primary memory.
- In Phase 4, as the classes are loaded, the bytecode verifier examines their bytecodes to ensure that they are valid and do not violate Java's security restrictions.
- In Phase 5, the JVM executes the program's bytecodes.

Section 1.16 Software Engineering Case Study: Introduction to Object Technology and the UML (Required)

- The Unified Modeling Language (UML) is a graphical language that allows people who build systems to represent their object-oriented designs in a common notation.
- Object-oriented design (OOD) models software components in terms of real-world objects.
- Objects have the property of information hiding—objects of one class are normally not allowed to know how objects of other classes are implemented.
- Object-oriented programming (OOP) implements object-oriented designs.
- Java programmers concentrate on creating their own user-defined types called classes. Each class contains data and methods that manipulate that data and provide services to clients.
- The data components of a class are attributes or fields; the operation components are methods.
- Classes can have relationships with other classes; these relationships are called associations.
- Packaging software as classes makes it possible for future software systems to reuse the classes.
- An instance of a class is called an object.
- The process of analyzing and designing a system from an object-oriented point of view is called object-oriented analysis and design (OOAD).

Terminology

Ada	compile-time error
ALU (arithmetic and logic unit)	computer
ANSI C	computer program
arithmetic and logic unit (ALU)	computer programmer
assembler	CPU (central processing unit)
assembly language	disk
attribute	distributed computing
BASIC	dynamic content
behavior	edit phase
bytecode	editor
bytecode verifier	encapsulation
C	execute phase
C#	execution-time error
C++	fatal runtime error
central processing unit (CPU)	file server
class	Fortran
.class file	hardware
class libraries	high-level language
class loader	HotSpot™ compiler
client/server computing	HTML (Hypertext Markup Language)
COBOL	IDE (Integrated Development Environment)
compile phase	information hiding
compiler	inheritance

34 Chapter I Introduction to Computers, the Internet and the Web

input device	object
input unit	object-oriented design (OOD)
input/output (I/O)	object-oriented programming (OOP)
Internet	operating system
interpreter	output device
Java	output unit
Java API (Java Application Programming Interface)	Pascal
Java Development Kit (JDK)	personal computing
Java Enterprise Edition (Java EE)	platform
.java file-name extension	portability
java interpreter	primary memory
Java Micro Edition (Java ME)	problem statement
Java Standard Edition (Java SE)	procedural programming
Java Virtual Machine (JVM)	programmer-defined type
javac compiler	pseudocode
JIT (just-in-time) compiler	requirements document
KIS ("keep it simple")	reusable componentry
LAN (local area network)	runtime error
legacy system	secondary storage unit
live-code approach	software
load phase	software reuse
machine language	structured programming
memory unit	Sun Microsystems
method	throughput
Microsoft Internet Explorer web browser	timesharing
modeling	translation
multiprocessor	translator program
multiprogramming	Unified Modeling Language (UML)
multithreading	verify phase
.NET	Visual Basic .NET
nonfatal runtime error	Visual C++ .NET
	World Wide Web

Self-Review Exercises

- 1.1** Fill in the blanks in each of the following statements:
- The company that popularized personal computing was _____.
 - The computer that made personal computing legitimate in business and industry was the _____.
 - Computers process data under the control of sets of instructions called _____.
 - The six key logical units of the computer are the _____, _____, _____, _____, _____ and _____.
 - The three types of languages discussed in the chapter are _____, _____ and _____.
 - The programs that translate high-level language programs into machine language are called _____.
 - The _____ allows computer users to locate and view multimedia-based documents on almost any subject over the Internet.
 - _____ allows a Java program to perform multiple activities in parallel.
- 1.2** Fill in the blanks in each of the following sentences about the Java environment:
- The _____ command from the JDK executes a Java application.

Answers to Self-Review Exercises **35**

- b) The _____ command from the JDK compiles a Java program.
 c) A Java program file must end with the _____ file extension.
 d) When a Java program is compiled, the file produced by the compiler ends with the _____ file extension.
 e) The file produced by the Java compiler contains _____ that are executed by the Java Virtual Machine.
- 1.3** Fill in the blanks in each of the following statements (based on Section 1.16):
 a) Objects have the property of _____—although objects may know how to communicate with one another across well-defined interfaces, they normally are not allowed to know how other objects are implemented.
 b) Java programmers concentrate on creating _____, which contain fields and the set of methods that manipulate those fields and provide services to clients.
 c) Classes can have relationships with other classes called _____.
 d) The process of analyzing and designing a system from an object-oriented point of view is called _____.
 e) OOD takes advantage of _____ relationships, where new classes of objects are derived by absorbing characteristics of existing classes then adding unique characteristics of their own.
 f) _____ is a graphical language that allows people who design software systems to use an industry standard notation to represent them.
 g) The size, shape, color and weight of an object are considered _____ of the object.

Answers to Self-Review Exercises

- 1.1** a) Apple. b) IBM Personal Computer. c) programs. d) input unit, output unit, memory unit, arithmetic and logic unit, central processing unit, secondary storage unit. e) machine languages, assembly languages, high-level languages. f) compilers. g) World Wide Web. h) Multi-threading.
- 1.2** a) java. b) javac. c) .java. d) .class. e) bytecodes.
- 1.3** a) information hiding. b) classes. c) associations. d) object-oriented analysis and design (OOAD). e) inheritance. f) The Unified Modeling Language (UML). g) attributes.

Exercises

- 1.4** Categorize each of the following items as either hardware or software:
 a) CPU
 b) Java compiler
 c) JVM
 d) input unit
 e) editor
- 1.5** Fill in the blanks in each of the following statements:
 a) The logical unit of the computer that receives information from outside the computer for use by the computer is the _____.
 b) The process of instructing the computer to solve a problem is called _____.
 c) _____ is a type of computer language that uses English-like abbreviations for machine-language instructions.
 d) _____ is a logical unit of the computer that sends information which has already been processed by the computer to various devices so that it may be used outside the computer.
 e) _____ and _____ are logical units of the computer that retain information.

36 Chapter I Introduction to Computers, the Internet and the Web

- f) _____ is a logical unit of the computer that performs calculations.
- g) _____ is a logical unit of the computer that makes logical decisions.
- h) _____ languages are most convenient to the programmer for writing programs quickly and easily.
- i) The only language a computer can directly understand is that computer's _____.
- j) _____ is a logical unit of the computer that coordinates the activities of all the other logical units.

1.6 What is the difference between fatal errors and nonfatal errors? Why might you prefer to experience a fatal error rather than a nonfatal error?

1.7 Fill in the blanks in each of the following statements:

- a) _____ is now used to develop large-scale enterprise applications, to enhance the functionality of web servers, to provide applications for consumer devices and for many other purposes.
- b) _____ was designed specifically for the .NET platform to enable programmers to migrate easily to .NET.
- c) _____ initially became widely known as the development language of the UNIX operating system.
- d) _____ was developed at Dartmouth College in the mid-1960s as a means of writing simple programs.
- e) _____ was developed by IBM Corporation in the mid-1950s to be used for scientific and engineering applications that require complex mathematical computations.
- f) _____ is used for commercial applications that require precise and efficient manipulation of large amounts of data.
- g) The _____ programming language was developed by Bjarne Stroustrup in the early 1980s at Bell Laboratories.

1.8 Fill in the blanks in each of the following statements (based on Section 1.13):

- a) Java programs normally go through five phases—_____, _____, _____, _____ and _____.
- b) A(n) _____ provides many tools that support the software development process, such as editors for writing and editing programs, debuggers for locating logic errors in programs, and many other features.
- c) The command `java` invokes the _____, which executes Java programs.
- d) A(n) _____ is a software application that simulates a computer, but hides the underlying operating system and hardware from the programs that interact with the VM.
- e) A(n) _____ program can run on multiple platforms.
- f) The _____ takes the `.class` files containing the program's bytecodes and transfers them to primary memory.
- g) The _____ examines bytecodes to ensure that they are valid.

1.9 Explain the two compilation phases of Java programs.

*What's in a name?
That which we call a rose
By any other name
would smell as sweet.*

—William Shakespeare

*When faced with a decision,
I always ask, "What would
be the most fun?"*

—Peggy Walker

*"Take some more tea," the
March Hare said to Alice,
very earnestly. "I've had
nothing yet," Alice replied in
an offended tone: "so I can't
take more." "You mean you
can't take less," said the
Hatter: "it's very easy to take
more than nothing."*

—Lewis Carroll

2

Introduction to Java Applications

OBJECTIVES

In this chapter you will learn:

- To write simple Java applications.
- To use input and output statements.
- Java's primitive types.
- Basic memory concepts.
- To use arithmetic operators.
- The precedence of arithmetic operators.
- To write decision-making statements.
- To use relational and equality operators.

38 Chapter 2 Introduction to Java Applications**Outline**

- 2.1** Introduction
- 2.2** A First Program in Java: Printing a Line of Text
- 2.3** Modifying Our First Java Program
- 2.4** Displaying Text with `printf`
- 2.5** Another Java Application: Adding Integers
- 2.6** Memory Concepts
- 2.7** Arithmetic
- 2.8** Decision Making: Equality and Relational Operators
- 2.9** (Optional) Software Engineering Case Study: Examining the Requirements Document
- 2.10** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

2.1 Introduction

We now introduce Java application programming, which facilitates a disciplined approach to program design. Most of the Java programs you will study in this book process information and display results. We present six examples that demonstrate how your programs can display messages and how they can obtain information from the user for processing. We begin with several examples that simply display messages on the screen. We then demonstrate a program that obtains two numbers from a user, calculates their sum and displays the result. You will learn how to perform various arithmetic calculations and save their results for later use. The last example in this chapter demonstrates decision-making fundamentals by showing you how to compare numbers, then display messages based on the comparison results. For example, the program displays a message indicating that two numbers are equal only if they have the same value. We analyze each example one line at a time to help you ease your way into Java programming. To help you apply the skills you learn here, we provide many challenging and entertaining problems in the chapter's exercises.

2.2 A First Program in Java: Printing a Line of Text

Every time you use a computer, you execute various applications that perform tasks for you. For example, your e-mail application helps you send and receive e-mail, and your web browser lets you view web pages from websites around the world. Computer programmers create such applications by writing [computer programs](#).

A Java [application](#) is a computer program that executes when you use the `java` command to launch the Java Virtual Machine (JVM). Let us consider a simple application that displays a line of text. (Later in this section we will discuss how to compile and run an application.) The program and its output are shown in Fig. 2.1. The output appears in the light blue box at the end of the program. The program illustrates several important Java language features. Java uses notations that may look strange to nonprogrammers. In addition, for your convenience, each program we present in this book includes line numbers, which are not part of actual Java programs. We will soon see that line 9 does the real work of the program—namely, displaying the phrase `Welcome to Java Programming!` on the screen. We now consider each line of the program in order.

2.2 A First Program in Java: Printing a Line of Text 39

```

1 // Fig. 2.1: Welcome1.java
2 // Text-printing program.
3
4 public class Welcome1
5 {
6     // main method begins execution of Java application
7     public static void main( String args[] )
8     {
9         System.out.println( "Welcome to Java Programming!" );
10    }
11 }
12 } // end class Welcome1

```

Welcome to Java Programming!

Fig. 2.1 | Text-printing program.

Line 1

```
// Fig. 2.1: Welcome1.java
```

begins with `//`, indicating that the remainder of the line is a **comment**. Programmers insert comments to **document programs** and improve their readability. This helps other people read and understand your programs. The Java compiler ignores comments, so they do not cause the computer to perform any action when the program is run. By convention, we begin every program with a comment indicating the figure number and file name.

A comment that begins with `//` is called an **end-of-line** (or **single-line**) **comment**, because the comment terminates at the end of the line on which it appears. A `//` comment also can begin in the middle of a line and continue until the end of that line (as in lines 11 and 13).

Traditional comments (also called **multiple-line comments**), such as

```
/* This is a traditional
   comment. It can be
   split over many lines */
```

can be spread over several lines. This type of comment begins with the delimiter `/*` and ends with `*/`. All text between the delimiters is ignored by the compiler. Java incorporated traditional comments and end-of-line comments from the C and C++ programming languages, respectively. In this book, we use end-of-line comments.

Java also provides **Javadoc comments** that are delimited by `/**` and `*/`. As with traditional comments, all text between the Javadoc comment delimiters is ignored by the compiler. Javadoc comments enable programmers to embed program documentation directly in their programs. Such comments are the preferred Java commenting format in industry. The **javadoc** utility program (part of the Java SE Development Kit) reads Javadoc comments and uses them to prepare your program's documentation in HTML format. We demonstrate Javadoc comments and the **javadoc** utility in Appendix H, Creating Documentation with **javadoc**. For complete information, visit Sun's **javadoc** Tool Home Page at java.sun.com/javase/6/docs/technotes/guides/javadoc/index.html.

40 Chapter 2 Introduction to Java Applications

Common Programming Error 2.1

*Forgetting one of the delimiters of a traditional or Javadoc comment is a syntax error. The **syntax** of a programming language specifies the rules for creating a proper program in that language. A **syntax error** occurs when the compiler encounters code that violates Java's language rules (i.e., its **syntax**). In this case, the compiler issues an error message to help the programmer identify and fix the incorrect code. Syntax errors are also called **compiler errors**, **compile-time errors** or **compilation errors**, because the compiler detects them during the compilation phase. You will be unable to execute your program until you correct all the syntax errors in it.*

Line 2

```
// Text-printing program.
```

is an end-of-line comment that describes the purpose of the program.

Good Programming Practice 2.1

Every program should begin with a comment that explains the purpose of the program, the author and the date and time the program was last modified. (We are not showing the author, date and time in this book's programs because this information would be redundant.)

Line 3 is a blank line. Programmers use blank lines and space characters to make programs easier to read. Together, blank lines, space characters and tab characters are known as **white space**. (Space characters and tabs are known specifically as **white-space characters**.) White space is ignored by the compiler. In this chapter and the next several chapters, we discuss conventions for using white space to enhance program readability.

Good Programming Practice 2.2

Use blank lines and space characters to enhance program readability.

Line 4

```
public class Welcome1
```

begins a **class declaration** for class `Welcome1`. Every program in Java consists of at least one class declaration that is defined by you—the programmer. These are known as **programmer-defined classes** or **user-defined classes**. The **class keyword** introduces a class declaration in Java and is immediately followed by the **class name** (`Welcome1`). Keywords (sometimes called **reserved words**) are reserved for use by Java (we discuss the various keywords throughout the text) and are always spelled with all lowercase letters. The complete list of Java keywords is shown in Appendix C.

By convention, all class names in Java begin with a capital letter and capitalize the first letter of each word they include (e.g., `SampleClassName`). A Java class name is an **identifier**—a series of characters consisting of letters, digits, underscores (_) and dollar signs (\$) that does not begin with a digit and does not contain spaces. Some valid identifiers are `Welcome1`, `$value`, `_value`, `m_inputField1` and `button7`. The name `7button` is not a valid identifier because it begins with a digit, and the name `input field` is not a valid identifier because it contains a space. Normally, an identifier that does not begin with a capital letter is not the name of a Java class. Java is **case sensitive**—that is, uppercase and lowercase letters are distinct, so `a1` and `A1` are different (but both valid) identifiers.

2.2 A First Program in Java: Printing a Line of Text 41

Good Programming Practice 2.3

By convention, always begin a class name's identifier with a capital letter and start each subsequent word in the identifier with a capital letter. Java programmers know that such identifiers normally represent Java classes, so naming your classes in this manner makes your programs more readable.

Common Programming Error 2.2

Java is case sensitive. Not using the proper uppercase and lowercase letters for an identifier normally causes a compilation error.

In Chapters 2–7, every class we define begins with the `public` keyword. For now, we will simply require this keyword. When you save your `public` class declaration in a file, the file name must be the class name followed by the `.java` file-name extension. For our application, the file name is `Welcome1.java`. You will learn more about `public` and non-`public` classes in Chapter 8.

Common Programming Error 2.3

A `public` class must be placed in a file that has the same name as the class (in terms of both spelling and capitalization) plus the `.java` extension; otherwise, a compilation error occurs.

Common Programming Error 2.4

It is an error not to end a file name with the `.java` extension for a file containing a class declaration. The Java compiler compiles only files with the `.java` extension.

A **left brace** (at line 5 in this program), `{`, begins the **body** of every class declaration. A corresponding **right brace** (at line 13), `}`, must end each class declaration. Note that lines 6–11 are indented. This indentation is one of the spacing conventions mentioned earlier. We define each spacing convention as a Good Programming Practice.

Good Programming Practice 2.4

Whenever you type an opening left brace, `{`, in your program, immediately type the closing right brace, `}`, then reposition the cursor between the braces and indent to begin typing the body. This practice helps prevent errors due to missing braces.

Good Programming Practice 2.5

Indent the entire body of each class declaration one “level” of indentation between the left brace, `{`, and the right brace, `}`, that delimit the body of the class. This format emphasizes the class declaration’s structure and makes it easier to read.

Good Programming Practice 2.6

Set a convention for the indent size you prefer, and then uniformly apply that convention. The `Tab` key may be used to create indents, but tab stops vary among text editors. We recommend using three spaces to form a level of indent.

Common Programming Error 2.5

It is a syntax error if braces do not occur in matching pairs.

42 Chapter 2 Introduction to Java Applications

Line 6

```
// main method begins execution of Java application
```

is an end-of-line comment indicating the purpose of lines 7–11 of the program. Line 7

```
public static void main( String args[] )
```

is the starting point of every Java application. The **parentheses** after the identifier `main` indicate that it is a program building block called a **method**. Java class declarations normally contain one or more methods. For a Java application, exactly one of the methods must be called `main` and must be defined as shown in line 7; otherwise, the JVM will not execute the application. Methods are able to perform tasks and return information when they complete their tasks. Keyword `void` indicates that this method will perform a task but will not return any information when it completes its task. Later, we will see that many methods return information when they complete their task. You will learn more about methods in Chapters 3 and 6. For now, simply mimic `main`'s first line in your Java applications. In line 7, the `String args[]` in parentheses is a required part of the method `main`'s declaration. We discuss this in Chapter 7, Arrays.

The left brace, `{`, in line 8 begins the **body of the method declaration**. A corresponding right brace, `}`, must end the method declaration's body (line 11 of the program). Note that line 9 in the body of the method is indented between the braces.

Good Programming Practice 2.7

Indent the entire body of each method declaration one “level” of indentation between the left brace, {, and the right brace, }, that define the body of the method. This format makes the structure of the method stand out and makes the method declaration easier to read.

Line 9

```
System.out.println( "Welcome to Java Programming!" );
```

instructs the computer to **perform an action**—namely, to print the **string** of characters contained between the double quotation marks (but not the quotation marks themselves). A string is sometimes called a **character string**, a **message** or a **string literal**. We refer to characters between double quotation marks simply as **strings**. White-space characters in strings are not ignored by the compiler.

`System.out` is known as the **standard output object**. `System.out` allows Java applications to display sets of characters in the **command window** from which the Java application executes. In Microsoft Windows 95/98/ME, the command window is the **MS-DOS prompt**. In more recent versions of Microsoft Windows, the command window is the **Command Prompt**. In UNIX/Linux/Mac OS X, the command window is called a **terminal window** or a **shell**. Many programmers refer to the command window simply as the **command line**.

Method `System.out.println` (or `prints`) a line of text in the command window. The string in the parentheses in line 9 is the **argument** to the method. Method `System.out.println` performs its task by displaying (also called outputting) its argument in the command window. When `System.out.println` completes its task, it positions the **output cursor** (the location where the next character will be displayed) to the beginning

2.2 A First Program in Java: Printing a Line of Text 43

of the next line in the command window. (This move of the cursor is similar to when a user presses the *Enter* key while typing in a text editor—the cursor appears at the beginning of the next line in the file.)

The entire line 9, including `System.out.println`, the argument "Welcome to Java Programming!" in the parentheses and the `semicolon` (;), is called a **statement**. Each statement ends with a semicolon. When the statement in line 9 of our program executes, it displays the message Welcome to Java Programming! in the command window. As we will see in subsequent programs, a method is typically composed of one or more statements that perform the method's task.

Common Programming Error 2.6

Omitting the semicolon at the end of a statement is a syntax error.

Error-Prevention Tip 2.1

When learning how to program, sometimes it is helpful to "break" a working program so you can familiarize yourself with the compiler's syntax-error messages. These messages do not always state the exact problem in the code. When you encounter such syntax-error messages in the future, you will have an idea of what caused the error. Try removing a semicolon or brace from the program of Fig. 2.1, then recompile the program to see the error messages generated by the omission.

Error-Prevention Tip 2.2

When the compiler reports a syntax error, the error may not be on the line number indicated by the error message. First, check the line for which the error was reported. If that line does not contain syntax errors, check several preceding lines.

Some programmers find it difficult when reading or writing a program to match the left and right braces ({ and }) that delimit the body of a class declaration or a method declaration. For this reason, some programmers include an end-of-line comment after a closing right brace (}) that ends a method declaration and after a closing right brace that ends a class declaration. For example, line 11

```
} // end method main
```

specifies the closing right brace (}) of method `main`, and line 13

```
} // end class Welcome1
```

specifies the closing right brace (}) of class `Welcome1`. Each comment indicates the method or class that the right brace terminates.

Good Programming Practice 2.8

Following the closing right brace (}) of a method body or class declaration with an end-of-line comment indicating the method or class declaration to which the brace belongs improves program readability.

Compiling and Executing Your First Java Application

We are now ready to compile and execute our program. For this purpose, we assume you are using the Sun Microsystems' Java SE Development Kit 6.0 (JDK 6.0). In our Java Re-

44 Chapter 2 Introduction to Java Applications

source Centers at www.deitel.com/ResourceCenters.html, we provide links to tutorials that help you get started with several popular Java development tools.

To prepare to compile the program, open a command window and change to the directory where the program is stored. Most operating systems use the command `cd` to [change directories](#). For example,

```
cd c:\examples\ch02\fig02_01
```

changes to the `fig02_01` directory on Windows. The command

```
cd ~/examples/ch02/fig02_01
```

changes to the `fig02_01` directory on UNIX/Linux/Max OS X.

To compile the program, type

```
javac Welcome1.java
```

If the program contains no syntax errors, the preceding command creates a new file called `Welcome1.class` (known as the [class file](#) for `Welcome1`) containing the Java bytecodes that represent our application. When we use the `java` command to execute the application, these bytecodes will be executed by the JVM.

Error-Prevention Tip 2.3

When attempting to compile a program, if you receive a message such as “bad command or file-name,” “javac: command not found” or “‘javac’ is not recognized as an internal or external command, operable program or batch file,” then your Java software installation was not completed properly. If you are using the JDK, this indicates that the system’s PATH environment variable was not set properly. Please review the installation instructions in the Before You Begin section of this book carefully. On some systems, after correcting the PATH, you may need to reboot your computer or open a new command window for these settings to take effect.

Error-Prevention Tip 2.4

The Java compiler generates syntax-error messages when the syntax of a program is incorrect. Each error message contains the file name and line number where the error occurred. For example, `Welcome1.java:6` indicates that an error occurred in the file `Welcome1.java` at line 6. The remainder of the error message provides information about the syntax error.

Error-Prevention Tip 2.5

The compiler error message “Public class `ClassName` must be defined in a file called `ClassName.java`” indicates that the file name does not exactly match the name of the public class in the file or that you typed the class name incorrectly when compiling the class.

Figure 2.2 shows the program of Fig. 2.1 executing in a Microsoft® Windows® XP **Command Prompt** window. To execute the program, type `java Welcome1`. This launches the JVM, which loads the `.class` file for class `Welcome1`. Note that the `.class` file-name extension is omitted from the preceding command; otherwise, the JVM will not execute the program. The JVM calls method `main`. Next, the statement at line 9 of `main` displays “Welcome to Java Programming!” [Note: Many environments show command prompts with black backgrounds and white text. We adjusted these settings in our environment to make our screen captures more readable.]

2.3 Modifying Our First Java Program 45

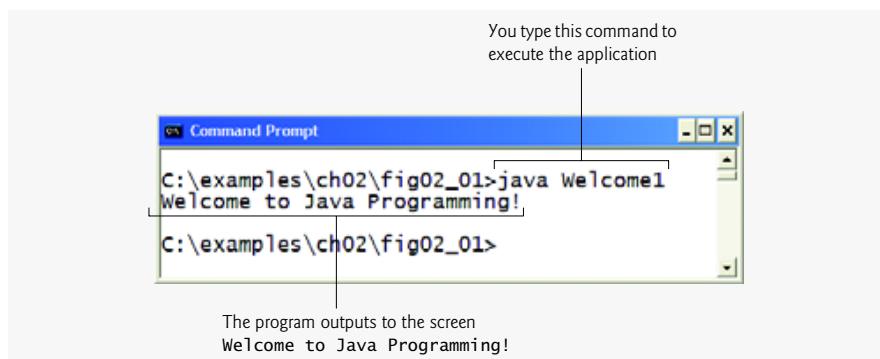

Fig. 2.2 | Executing `Welcome1` in a Microsoft Windows XP **Command Prompt** window.

Error-Prevention Tip 2.6

When attempting to run a Java program, if you receive a message such as “Exception in thread “main” java.lang.NoClassDefFoundError: Welcome1,” your CLASSPATH environment variable has not been set properly. Please review the installation instructions in the Before You Begin section of this book carefully. On some systems, you may need to reboot your computer or open a new command window after configuring the CLASSPATH.

2.3 Modifying Our First Java Program

This section continues our introduction to Java programming with two examples that modify the example in Fig. 2.1 to print text on one line by using multiple statements and to print text on several lines by using a single statement.

Displaying a Single Line of Text with Multiple Statements

`Welcome to Java Programming!` can be displayed several ways. Class `Welcome2`, shown in Fig. 2.3, uses two statements to produce the same output as that shown in Fig. 2.1. From this point forward, we highlight the new and key features in each code listing, as shown in lines 9–10 of this program.

```

1 // Fig. 2.3: Welcome2.java
2 // Printing a line of text with multiple statements.
3
4 public class Welcome2
5 {
6     // main method begins execution of Java application
7     public static void main( String args[] )
8     {
9         System.out.print( "Welcome to " );
10        System.out.println( "Java Programming!" );
11    }
12 } // end method main
13
14 } // end class Welcome2

```

Fig. 2.3 | Printing a line of text with multiple statements. (Part I of 2.)

46 Chapter 2 Introduction to Java Applications

Welcome to Java Programming!

Fig. 2.3 | Printing a line of text with multiple statements. (Part 2 of 2.)

The program is similar to Fig. 2.1, so we discuss only the changes here. Line 2

```
// Printing a line of text with multiple statements.
```

is an end-of-line comment stating the purpose of this program. Line 4 begins the `Welcome2` class declaration.

Lines 9–10 of method `main`

```
System.out.print( "Welcome to " );
System.out.println( "Java Programming!" );
```

display one line of text in the command window. The first statement uses `System.out`'s method `print` to display a string. Unlike `println`, after displaying its argument, `print` does not position the output cursor at the beginning of the next line in the command window—the next character the program displays will appear immediately after the last character that `print` displays. Thus, line 10 positions the first character in its argument (the letter “J”) immediately after the last character that line 9 displays (the space character before the string’s closing double-quote character). Each `print` or `println` statement resumes displaying characters from where the last `print` or `println` statement stopped displaying characters.

Displaying Multiple Lines of Text with a Single Statement

A single statement can display multiple lines by using **newline characters**, which indicate to `System.out`'s `print` and `println` methods when they should position the output cursor at the beginning of the next line in the command window. Like blank lines, space characters and tab characters, newline characters are white-space characters. Figure 2.4 outputs four lines of text, using newline characters to determine when to begin each new line. Most of the program is identical to those in Fig. 2.1 and Fig. 2.3, so we discuss only the changes here.

```

1 // Fig. 2.4: Welcome3.java
2 // Printing multiple lines of text with a single statement.
3
4 public class Welcome3
5 {
6     // main method begins execution of Java application
7     public static void main( String args[] )
8     {
9         System.out.println( "Welcome\ninto\nJava\nProgramming!" );
10    }
11 } // end method main
12
13 } // end class Welcome3
```

Fig. 2.4 | Printing multiple lines of text with a single statement. (Part 1 of 2.)

2.3 Modifying Our First Java Program **47**

```
Welcome
to
Java
Programming!
```

Fig. 2.4 | Printing multiple lines of text with a single statement. (Part 2 of 2.)

Line 2

```
// Printing multiple lines of text with a single statement.
```

is a comment stating the program's purpose. Line 4 begins the `Welcome3` class declaration.

Line 9

```
System.out.println( "Welcome\n to\n Java\n Programming!" );
```

displays four separate lines of text in the command window. Normally, the characters in a string are displayed exactly as they appear in the double quotes. Note, however, that the two characters `\` and `n` (repeated three times in the statement) do not appear on the screen. The `backslash (\)` is called an *escape character*. It indicates to `System.out`'s `print` and `println` methods that a “special character” is to be output. When a backslash appears in a string of characters, Java combines the next character with the backslash to form an *escape sequence*. The escape sequence `\n` represents the newline character. When a newline character appears in a string being output with `System.out`, the newline character causes the screen’s output cursor to move to the beginning of the next line in the command window. Figure 2.5 lists several common escape sequences and describes how they affect the display of characters in the command window. For the complete list of escape sequences, visit java.sun.com/docs/books/jls/third_edition/html/lexical.html#3.10.6.

Escape sequence	Description
<code>\n</code>	Newline. Position the screen cursor at the beginning of the next line.
<code>\t</code>	Horizontal tab. Move the screen cursor to the next tab stop.
<code>\r</code>	Carriage return. Position the screen cursor at the beginning of the current line—do not advance to the next line. Any characters output after the carriage return overwrite the characters previously output on that line.
<code>\\"</code>	Backslash. Used to print a backslash character.
<code>\\"</code>	Double quote. Used to print a double-quote character. For example, <code>System.out.println("\"in quotes\"");</code> displays " in quotes"

Fig. 2.5 | Some common escape sequences.

48 Chapter 2 Introduction to Java Applications

2.4 Displaying Text with `printf`

Java SE 5.0 added the `System.out.printf` method for displaying formatted data—the `f` in the name `printf` stands for “formatted.” Figure 2.6 outputs the strings “Welcome to” and “Java Programming!” with `System.out.printf`.

Lines 9–10

```
System.out.printf( "%s\n%s\n",
    "Welcome to", "Java Programming!" );
```

call method `System.out.printf` to display the program’s output. The method call specifies three arguments. When a method requires multiple arguments, the arguments are separated with commas (,)—this is known as a [comma-separated list](#).

Good Programming Practice 2.9

Place a space after each comma (,) in an argument list to make programs more readable.

Remember that all statements in Java end with a semicolon (;). Therefore, lines 9–10 represent only one statement. Java allows large statements to be split over many lines. However, you cannot split a statement in the middle of an identifier or in the middle of a string.

Common Programming Error 2.7

Splitting a statement in the middle of an identifier or a string is a syntax error.

Method `printf`’s first argument is a [format string](#) that may consist of [fixed text](#) and [format specifiers](#). Fixed text is output by `printf` just as it would be output by `print` or `println`. Each format specifier is a placeholder for a value and specifies the type of data to output. Format specifiers also may include optional formatting information.

```
1 // Fig. 2.6: Welcome4.java
2 // Printing multiple lines in a dialog box.
3
4 public class Welcome4
5 {
6     // main method begins execution of Java application
7     public static void main( String args[] )
8     {
9         System.out.printf( "%s\n%s\n",
10             "Welcome to", "Java Programming!" );
11
12     } // end method main
13
14 } // end class Welcome4
```

Welcome to
Java Programming!

Fig. 2.6 | Displaying multiple lines with method `System.out.printf`.

2.5 Another Java Application: Adding Integers 49

Format specifiers begin with a percent sign (%) and are followed by a character that represents the data type. For example, the format specifier %s is a placeholder for a string. The format string in line 9 specifies that printf should output two strings and that each string should be followed by a newline character. At the first format specifier's position, printf substitutes the value of the first argument after the format string. At each subsequent format specifier's position, printf substitutes the value of the next argument in the argument list. So this example substitutes "Welcome to" for the first %s and "Java Programming!" for the second %s. The output shows that two lines of text were displayed.

We introduce various formatting features as they are needed in our examples. Chapter 29 presents the details of formatting output with printf.

2.5 Another Java Application: Adding Integers

Our next application reads (or inputs) two **integers** (whole numbers, like -22, 7, 0 and 1024) typed by a user at the keyboard, computes the sum of the values and displays the result. This program must keep track of the numbers supplied by the user for the calculation later in the program. Programs remember numbers and other data in the computer's memory and access that data through program elements called **variables**. The program of Fig. 2.7 demonstrates these concepts. In the sample output, we use highlighting to differentiate between the user's input and the program's output.

```

1 // Fig. 2.7: Addition.java
2 // Addition program that displays the sum of two numbers.
3 import java.util.Scanner; // program uses class Scanner
4
5 public class Addition
6 {
7     // main method begins execution of Java application
8     public static void main( String args[] )
9     {
10        // create Scanner to obtain input from command window
11        Scanner input = new Scanner( System.in );
12
13        int number1; // first number to add
14        int number2; // second number to add
15        int sum; // sum of number1 and number2
16
17        System.out.print( "Enter first integer: " ); // prompt
18        number1 = input.nextInt(); // read first number from user
19
20        System.out.print( "Enter second integer: " ); // prompt
21        number2 = input.nextInt(); // read second number from user
22
23        sum = number1 + number2; // add numbers
24
25        System.out.printf( "Sum is %d\n", sum ); // display sum
26
27    } // end method main
28
29 } // end class Addition

```

Fig. 2.7 | Addition program that displays the sum of two numbers. (Part I of 2.)

50 Chapter 2 Introduction to Java Applications

```
Enter first integer: 45
Enter second integer: 72
Sum is 117
```

Fig. 2.7 | Addition program that displays the sum of two numbers. (Part 2 of 2.)

Lines 1–2

```
// Fig. 2.7: Addition.java
// Addition program that displays the sum of two numbers.
```

state the figure number, file name and purpose of the program. Line 3

```
import java.util.Scanner; // program uses class Scanner
```

is an **import declaration** that helps the compiler locate a class that is used in this program. A great strength of Java is its rich set of predefined classes that you can reuse rather than “reinventing the wheel.” These classes are grouped into **packages**—named collections of related classes—and are collectively referred to as the **Java class library**, or the **Java Application Programming Interface (Java API)**. Programmers use import declarations to identify the predefined classes used in a Java program. The import declaration in line 3 indicates that this example uses Java’s predefined Scanner class (discussed shortly) from package **java.util**. Then the compiler attempts to ensure that you use class Scanner correctly.

**Common Programming Error 2.8**

All import declarations must appear before the first class declaration in the file. Placing an import declaration inside a class declaration’s body or after a class declaration is a syntax error.

**Error-Prevention Tip 2.7**

Forgetting to include an import declaration for a class used in your program typically results in a compilation error containing a message such as “cannot resolve symbol.” When this occurs, check that you provided the proper import declarations and that the names in the import declarations are spelled correctly, including proper use of uppercase and lowercase letters.

Line 5

```
public class Addition
```

begins the declaration of class **Addition**. The file name for this **public** class must be **Addition.java**. Remember that the body of each class declaration starts with an opening left brace (line 6), **{**, and ends with a closing right brace (line 29), **}**.

The application begins execution with method **main** (lines 8–27). The left brace (line 9) marks the beginning of **main**’s body, and the corresponding right brace (line 27) marks the end of **main**’s body. Note that method **main** is indented one level in the body of class **Addition** and that the code in the body of **main** is indented another level for readability.

Line 11

```
Scanner input = new Scanner( System.in );
```

is a **variable declaration statement** (also called a **declaration**) that specifies the name (**input**) and type (**Scanner**) of a variable that is used in this program. A **variable** is a location in the computer’s memory where a value can be stored for use later in a program. All

2.5 Another Java Application: Adding Integers 51

variables must be declared with a **name** and a **type** before they can be used. A variable's name enables the program to access the value of the variable in memory. A variable's name can be any valid identifier. (See Section 2.2 for identifier naming requirements.) A variable's type specifies what kind of information is stored at that location in memory. Like other statements, declaration statements end with a semicolon (;).

The declaration in line 11 specifies that the variable named **input** is of type **Scanner**. A **Scanner** enables a program to read data (e.g., numbers) for use in a program. The data can come from many sources, such as a file on disk or the user at the keyboard. Before using a **Scanner**, the program must create it and specify the source of the data.

The equal sign (=) in line 11 indicates that **Scanner** variable **input** should be **initialized** (i.e., prepared for use in the program) in its declaration with the result of the expression **new Scanner(System.in)** to the right of the equal sign. This expression creates a **Scanner** object that reads data typed by the user at the keyboard. Recall that the standard output object, **System.out**, allows Java applications to display characters in the command window. Similarly, the **standard input object**, **System.in**, enables Java applications to read information typed by the user. So, line 11 creates a **Scanner** that enables the application to read information typed by the user at the keyboard.

The variable declaration statements at lines 13–15

```
int number1; // first number to add
int number2; // second number to add
int sum; // sum of number1 and number2
```

declare that variables **number1**, **number2** and **sum** hold data of type **int**—these variables can hold **integer** values (whole numbers such as 7, -11, 0 and 31,914). These variables are not yet initialized. The range of values for an **int** is -2,147,483,648 to +2,147,483,647. We'll soon discuss types **float** and **double**, for holding real numbers, and type **char**, for holding character data. Real numbers are numbers that contain decimal points, such as 3.4, 0.0 and -11.19. Variables of type **char** represent individual characters, such as an uppercase letter (e.g., **A**), a digit (e.g., **7**), a special character (e.g., * or %) or an escape sequence (e.g., the newline character, **\n**). Types such as **int**, **float**, **double** and **char** are called **primitive types** or **built-in types**. Primitive-type names are keywords and therefore must appear in all lowercase letters. Appendix D, Primitive Types, summarizes the characteristics of the eight primitive types (**boolean**, **byte**, **char**, **short**, **int**, **long**, **float** and **double**).

Variable declaration statements can be split over several lines, with the variable names separated by commas (i.e., a comma-separated list of variable names). Several variables of the same type may be declared in one declaration or in multiple declarations. For example, lines 13–15 can also be written as a single statement as follows:

```
int number1, // first number to add
    number2, // second number to add
    sum; // sum of number1 and number2
```

Note that we used end-of-line comments in lines 13–15. This use of comments is a common programming practice for indicating the purpose of each variable in the program.

Good Programming Practice 2.10

Declare each variable on a separate line. This format allows a descriptive comment to be easily inserted next to each declaration.

52 Chapter 2 Introduction to Java Applications

Good Programming Practice 2.11

*Choosing meaningful variable names helps a program to be **self-documenting** (i.e., one can understand the program simply by reading it rather than by reading manuals or viewing an excessive number of comments).*

Good Programming Practice 2.12

By convention, variable-name identifiers begin with a lowercase letter, and every word in the name after the first word begins with a capital letter. For example, variable-name identifier `firstNumber` has a capital N in its second word, Number.

Line 17

```
System.out.print( "Enter first integer: " ); // prompt
```

uses `System.out.print` to display the message "Enter first integer: ". This message is called a **prompt** because it directs the user to take a specific action. Recall from Section 2.2 that identifiers starting with capital letters represent class names. So, `System` is a class. Class `System` is part of package `java.lang`. Notice that class `System` is not imported with an `import` declaration at the beginning of the program.

Software Engineering Observation 2.1

By default, package `java.lang` is imported in every Java program; thus, classes in `java.lang` are the only ones in the Java API that do not require an import declaration.

Line 18

```
number1 = input.nextInt(); // read first number from user
```

uses `Scanner` object `input`'s `nextInt` method to obtain an integer from the user at the keyboard. At this point the program waits for the user to type the number and press the *Enter* key to submit the number to the program.

Technically, the user can type anything as the input value. Our program assumes that the user enters a valid integer value as requested. In this program, if the user types a non-integer value, a runtime logic error will occur and the program will terminate. Chapter 13, Exception Handling, discusses how to make your programs more robust by enabling them to handle such errors. This is also known as making your program **fault tolerant**.

In line 18, the result of the call to method `nextInt` (an `int` value) is placed in variable `number1` by using the **assignment operator**, `=`. The statement is read as "number1 gets the value of `input.nextInt()`." Operator `=` is called a **binary operator** because it has two **operands**—`number1` and the result of the method call `input.nextInt()`. This statement is called an **assignment statement** because it assigns a value to a variable. Everything to the right of the assignment operator, `=`, is always evaluated before the assignment is performed.

Good Programming Practice 2.13

Place spaces on either side of a binary operator to make it stand out and make the program more readable.

Line 20

```
System.out.print( "Enter second integer: " ); // prompt
```

prompts the user to input the second integer.

2.5 Another Java Application: Adding Integers 53

Line 21

```
number2 = input.nextInt(); // read second number from user
```

reads the second integer and assigns it to variable `number2`.

Line 23

```
sum = number1 + number2; // add numbers
```

is an assignment statement that calculates the sum of the variables `number1` and `number2` and assigns the result to variable `sum` by using the assignment operator, `=`. The statement is read as “`sum` gets the value of `number1 + number2`.” Most calculations are performed in assignment statements. When the program encounters the addition operation, it uses the values stored in the variables `number1` and `number2` to perform the calculation. In the preceding statement, the addition operator is a binary operator—its two operands are `number1` and `number2`. Portions of statements that contain calculations are called **expressions**. In fact, an expression is any portion of a statement that has a value associated with it. For example, the value of the expression `number1 + number2` is the sum of the numbers. Similarly, the value of the expression `input.nextInt()` is an integer typed by the user.

After the calculation has been performed, line 25

```
System.out.printf( "Sum is %d\n", sum ); // display sum
```

uses method `System.out.printf` to display the `sum`. The format specifier `%d` is a placeholder for an `int` value (in this case the value of `sum`)—the letter `d` stands for “decimal integer.” Note that other than the `%d` format specifier, the remaining characters in the format string are all fixed text. So method `printf` displays “`Sum is`”, followed by the value of `sum` (in the position of the `%d` format specifier) and a newline.

Note that calculations can also be performed inside `printf` statements. We could have combined the statements at lines 23 and 25 into the statement

```
System.out.printf( "Sum is %d\n", ( number1 + number2 ) );
```

The parentheses around the expression `number1 + number2` are not required—they are included to emphasize that the value of the expression is output in the position of the `%d` format specifier.

Java API Documentation

For each new Java API class we use, we indicate the package in which it is located. This package information is important because it helps you locate descriptions of each package and class in the [Java API documentation](#). A Web-based version of this documentation can be found at

java.sun.com/javase/6/docs/api/

Also, you can download this documentation to your own computer from

java.sun.com/javase/downloads/ea.jsp

The download is approximately 53 megabytes (MB). Appendix G, Using the Java API Documentation, describes how to use the Java API documentation.

54 Chapter 2 Introduction to Java Applications

2.6 Memory Concepts

Variable names such as `number1`, `number2` and `sum` actually correspond to **locations** in the computer's memory. Every variable has a **name**, a **type**, a **size** and a **value**.

In the addition program of Fig. 2.7, when the following statement (line 18) executes

```
number1 = input.nextInt(); // read first number from user
```

the number typed by the user is placed into a memory location to which the compiler assigned the name `number1`. Suppose that the user enters 45. The computer places that integer value into location `number1`, as shown in Fig. 2.8. Whenever a value is placed in a memory location, the value replaces the previous value in that location. The previous value is lost.

When the statement (line 21)

```
number2 = input.nextInt(); // read second number from user
```

executes, suppose that the user enters 72. The computer places that integer value into location `number2`. The memory now appears as shown in Fig. 2.9.

After the program of Fig. 2.7 obtains values for `number1` and `number2`, it adds the values and places the sum into variable `sum`. The statement (line 23)

```
sum = number1 + number2; // add numbers
```

performs the addition, then replaces `sum`'s previous value. After `sum` has been calculated, memory appears as shown in Fig. 2.10. Note that the values of `number1` and `number2` appear exactly as they did before they were used in the calculation of `sum`. These values were used, but not destroyed, as the computer performed the calculation. Thus, when a value is read from a memory location, the process is nondestructive.

Fig. 2.8 | Memory location showing the name and value of variable `number1`.

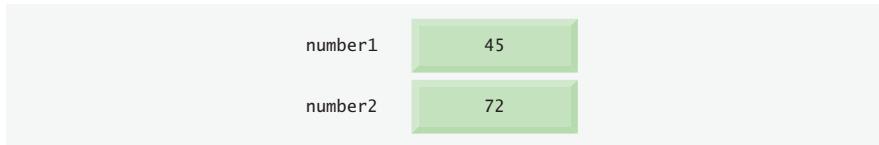

Fig. 2.9 | Memory locations after storing values for `number1` and `number2`.

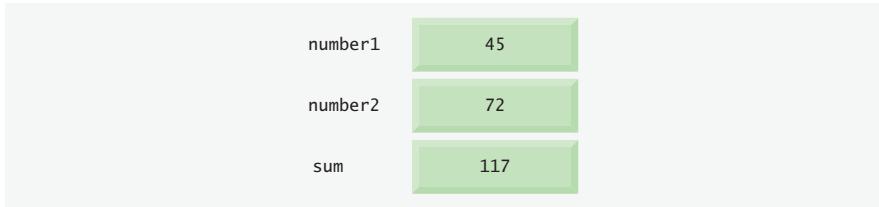

Fig. 2.10 | Memory locations after storing the sum of `number1` and `number2`.

2.7 Arithmetic

Most programs perform arithmetic calculations. The **arithmetic operators** are summarized in Fig. 2.11. Note the use of various special symbols not used in algebra. The **asterisk** (*) indicates multiplication, and the **percent sign** (%) is the **remainder operator** (called **modulus** in some languages), which we will discuss shortly. The arithmetic operators in Fig. 2.11 are binary operators because they each operate on two operands. For example, the expression $f + 7$ contains the binary operator + and the two operands f and 7.

Integer division yields an integer quotient—for example, the expression $7 / 4$ evaluates to 1, and the expression $17 / 5$ evaluates to 3. Any fractional part in integer division is simply discarded (i.e., truncated)—no rounding occurs. Java provides the remainder operator, %, which yields the remainder after division. The expression $x \% y$ yields the remainder after x is divided by y. Thus, $7 \% 4$ yields 3, and $17 \% 5$ yields 2. This operator is most commonly used with integer operands but can also be used with other arithmetic types. In this chapter's exercises and in later chapters, we consider several interesting applications of the remainder operator, such as determining whether one number is a multiple of another.

Arithmetic Expressions in Straight-Line Form

Arithmetic expressions in Java must be written in **straight-line form** to facilitate entering programs into the computer. Thus, expressions such as “a divided by b” must be written as a / b , so that all constants, variables and operators appear in a straight line. The following algebraic notation is generally not acceptable to compilers:

$$\frac{a}{b}$$

Parentheses for Grouping Subexpressions

Parentheses are used to group terms in Java expressions in the same manner as in algebraic expressions. For example, to multiply a times the quantity $b + c$, we write

$$a * (b + c)$$

If an expression contains **nested parentheses**, such as

$$((a + b) * c)$$

the expression in the innermost set of parentheses (a + b in this case) is evaluated first.

Java operation	Arithmetic operator	Algebraic expression	Java expression
Addition	+	$f + 7$	$f + 7$
Subtraction	-	$p - c$	$p - c$
Multiplication	*	bm	$b * m$
Division	/	x / y or $\frac{x}{y}$ or $x \div y$	x / y
Remainder	%	$r \bmod s$	$r \% s$

Fig. 2.11 | Arithmetic operators.

56 Chapter 2 Introduction to Java Applications

Rules of Operator Precedence

Java applies the operators in arithmetic expressions in a precise sequence determined by the following [rules of operator precedence](#), which are generally the same as those followed in algebra (Fig. 2.12):

1. Multiplication, division and remainder operations are applied first. If an expression contains several such operations, the operators are applied from left to right. Multiplication, division and remainder operators have the same level of precedence.
2. Addition and subtraction operations are applied next. If an expression contains several such operations, the operators are applied from left to right. Addition and subtraction operators have the same level of precedence.

These rules enable Java to apply operators in the correct order. When we say that operators are applied from left to right, we are referring to their [associativity](#). You will see that some operators associate from right to left. Figure 2.12 summarizes these rules of operator precedence. The table will be expanded as additional Java operators are introduced. A complete precedence chart is included in Appendix A, Operator Precedence Chart.

Sample Algebraic and Java Expressions

Now let us consider several expressions in light of the rules of operator precedence. Each example lists an algebraic expression and its Java equivalent. The following is an example of an arithmetic mean (average) of five terms:

$$\text{Algebra: } m = \frac{a + b + c + d + e}{5}$$

Java: `m = (a + b + c + d + e) / 5;`

The parentheses are required because division has higher precedence than addition. The entire quantity `(a + b + c + d + e)` is to be divided by 5. If the parentheses are erroneously omitted, we obtain `a + b + c + d + e / 5`, which evaluates as

$$a + b + c + d + \frac{e}{5}$$

Operator(s)	Operation(s)	Order of evaluation (precedence)
*	Multiplication	Evaluated first. If there are several operators of this type, they are evaluated from left to right.
/	Division	
%	Remainder	
+	Addition	Evaluated next. If there are several operators of this type, they are evaluated from left to right.
-	Subtraction	

Fig. 2.12 | Precedence of arithmetic operators.

2.7 Arithmetic 57

The following is an example of the equation of a straight line:

Algebra: $y = mx + b$

Java: $y = m * x + b;$

No parentheses are required. The multiplication operator is applied first because multiplication has a higher precedence than addition. The assignment occurs last because it has a lower precedence than multiplication or addition.

The following example contains remainder (%), multiplication, division, addition and subtraction operations:

Algebra: $z = pr \% q + w/x - y$

Java: $z = p * r \% q + w / x - y;$

The circled numbers under the statement indicate the order in which Java applies the operators. The multiplication, remainder and division operations are evaluated first in left-to-right order (i.e., they associate from left to right), because they have higher precedence than addition and subtraction. The addition and subtraction operations are evaluated next. These operations are also applied from left to right.

Evaluation of a Second-Degree Polynomial

To develop a better understanding of the rules of operator precedence, consider the evaluation of a second-degree polynomial ($y = ax^2 + bx + c$):

$y = a * x * x + b * x + c;$

The circled numbers indicate the order in which Java applies the operators. The multiplication operations are evaluated first in left-to-right order (i.e., they associate from left to right), because they have higher precedence than addition. The addition operations are evaluated next and are applied from left to right. There is no arithmetic operator for exponentiation in Java, so x^2 is represented as $x * x$. Section 5.4 shows an alternative for performing exponentiation in Java.

Suppose that a , b , c and x in the preceding second-degree polynomial are initialized (given values) as follows: $a = 2$, $b = 3$, $c = 7$ and $x = 5$. Figure 2.13 illustrates the order in which the operators are applied.

As in algebra, it is acceptable to place unnecessary parentheses in an expression to make the expression clearer. These are called **redundant parentheses**. For example, the preceding statement might be parenthesized as follows:

$y = (a * x * x) + (b * x) + c;$

Good Programming Practice 2.14

Using parentheses for complex arithmetic expressions, even when the parentheses are not necessary, can make the arithmetic expressions easier to read.

58 Chapter 2 Introduction to Java Applications

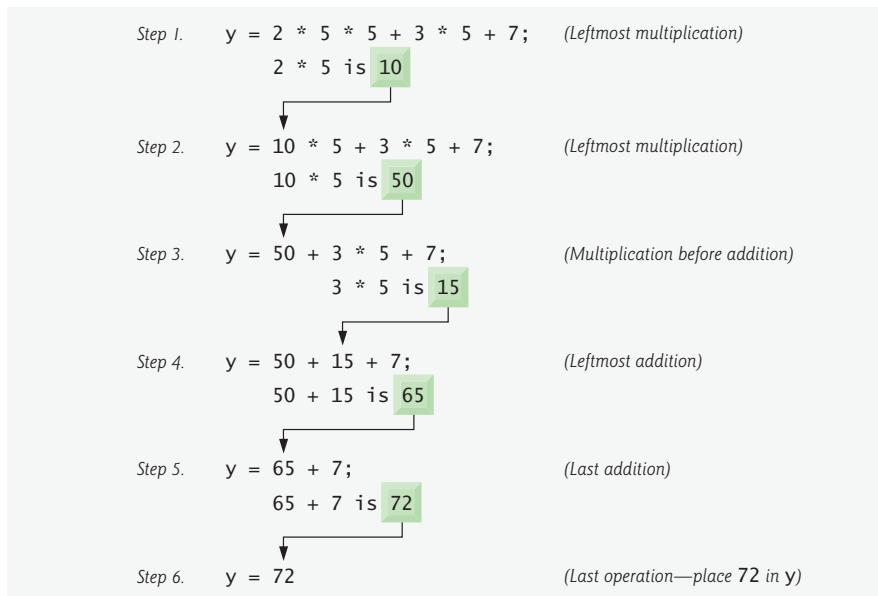

Fig. 2.13 | Order in which a second-degree polynomial is evaluated.

2.8 Decision Making: Equality and Relational Operators

A **condition** is an expression that can be either **true** or **false**. This section introduces Java's **if statement** that allows a program to make a **decision** based on a condition's value. For example, the condition "grade is greater than or equal to 60" determines whether a student passed a test. If the condition in an **if** statement is true, the body of the **if** statement executes. If the condition is false, the body does not execute. We will see an example shortly.

Conditions in **if** statements can be formed by using the **equality operators** (**==** and **!=**) and **relational operators** (**>**, **<**, **>=** and **<=**) summarized in Fig. 2.14. Both equality operators have the same level of precedence, which is lower than that of the relational operators. The equality operators associate from left to right. The relational operators all have the same level of precedence and also associate from left to right.

Standard algebraic equality or relational operator	Java equality or relational operator	Sample Java condition	Meaning of Java condition
<i>Equality operators</i>			
=	==	x == y	x is equal to y
≠	!=	x != y	x is not equal to y

Fig. 2.14 | Equality and relational operators. (Part I of 2.)

2.8 Decision Making: Equality and Relational Operators **59**

Standard algebraic equality or relational operator	Java equality or relational operator	Sample Java condition	Meaning of Java condition
<i>Relational operators</i>			
>	>	x > y	x is greater than y
<	<	x < y	x is less than y
≥	≥	x ≥ y	x is greater than or equal to y
≤	≤	x ≤ y	x is less than or equal to y

Fig. 2.14 | Equality and relational operators. (Part 2 of 2.)

The application of Fig. 2.15 uses six `if` statements to compare two integers input by the user. If the condition in any of these `if` statements is true, the assignment statement associated with that `if` statement executes. The program uses a `Scanner` to input the two integers from the user and store them in variables `number1` and `number2`. Then the program compares the numbers and displays the results of the comparisons that are true.

The declaration of class `Comparison` begins at line 6

```
public class Comparison
```

The class's `main` method (lines 9–41) begins the execution of the program. Line 12

```
Scanner input = new Scanner( System.in );
```

declares `Scanner` variable `input` and assigns it a `Scanner` that inputs data from the standard input (i.e., the keyboard).

```

1 // Fig. 2.15: Comparison.java
2 // Compare integers using if statements, relational operators
3 // and equality operators.
4 import java.util.Scanner; // program uses class Scanner
5
6 public class Comparison
7 {
8     // main method begins execution of Java application
9     public static void main( String args[] )
10    {
11        // create Scanner to obtain input from command window
12        Scanner input = new Scanner( System.in );
13
14        int number1; // first number to compare
15        int number2; // second number to compare
16
17        System.out.print( "Enter first integer: " ); // prompt
18        number1 = input.nextInt(); // read first number from user

```

Fig. 2.15 | Equality and relational operators. (Part 1 of 2.)

60 Chapter 2 Introduction to Java Applications

```

19      System.out.print( "Enter second integer: " ); // prompt
20      number2 = input.nextInt(); // read second number from user
21
22      if ( number1 == number2 )
23          System.out.printf( "%d == %d\n", number1, number2 );
24
25      if ( number1 != number2 )
26          System.out.printf( "%d != %d\n", number1, number2 );
27
28      if ( number1 < number2 )
29          System.out.printf( "%d < %d\n", number1, number2 );
30
31      if ( number1 > number2 )
32          System.out.printf( "%d > %d\n", number1, number2 );
33
34      if ( number1 <= number2 )
35          System.out.printf( "%d <= %d\n", number1, number2 );
36
37      if ( number1 >= number2 )
38          System.out.printf( "%d >= %d\n", number1, number2 );
39
40  } // end method main
41
42 } // end class Comparison

```

```

Enter first integer: 777
Enter second integer: 777
777 == 777
777 <= 777
777 >= 777

```

```

Enter first integer: 1000
Enter second integer: 2000
1000 != 2000
1000 < 2000
1000 <= 2000

```

```

Enter first integer: 2000
Enter second integer: 1000
2000 != 1000
2000 > 1000
2000 >= 1000

```

Fig. 2.15 | Equality and relational operators. (Part 2 of 2.)

Lines 14–15

```

int number1; // first number to compare
int number2; // second number to compare

```

declare the `int` variables used to store the values input from the user.

2.8 Decision Making: Equality and Relational Operators 61

Lines 17–18

```
System.out.print( "Enter first integer: " ); // prompt
number1 = input.nextInt(); // read first number from user
```

prompt the user to enter the first integer and input the value, respectively. The input value is stored in variable `number1`.

Lines 20–21

```
System.out.print( "Enter second integer: " ); // prompt
number2 = input.nextInt(); // read second number from user
```

prompt the user to enter the second integer and input the value, respectively. The input value is stored in variable `number2`.

Lines 23–24

```
if ( number1 == number2 )
    System.out.printf( "%d == %d\n", number1, number2 );
```

declare an `if` statement that compares the values of the variables `number1` and `number2` to determine whether they are equal. An `if` statement always begins with keyword `if`, followed by a condition in parentheses. An `if` statement expects one statement in its body. The indentation of the body statement shown here is not required, but it improves the program's readability by emphasizing that the statement in line 24 is part of the `if` statement that begins at line 23. Line 24 executes only if the numbers stored in variables `number1` and `number2` are equal (i.e., the condition is true). The `if` statements at lines 26–27, 29–30, 32–33, 35–36 and 38–39 compare `number1` and `number2` with the operators `!=`, `<`, `>`, `<=` and `>=`, respectively. If the condition in any of the `if` statements is true, the corresponding body statement executes.

Common Programming Error 2.9

Forgetting the left and/or right parentheses for the condition in an `if` statement is a syntax error—the parentheses are required.

Common Programming Error 2.10

Confusing the equality operator, `==`, with the assignment operator, `=`, can cause a logic error or a syntax error. The equality operator should be read as “is equal to,” and the assignment operator should be read as “gets” or “gets the value of.” To avoid confusion, some people read the equality operator as “double equals” or “equals equals.”

Common Programming Error 2.11

It is a syntax error if the operators `==`, `!=`, `>=` and `<=` contain spaces between their symbols, as in `= =`, `! =`, `> =` and `< =`, respectively.

Common Programming Error 2.12

Reversing the operators `!=`, `>=` and `<=`, as in `=!`, `=>` and `=<`, is a syntax error.

Good Programming Practice 2.15

Indent an `if` statement’s body to make it stand out and to enhance program readability.

62 Chapter 2 Introduction to Java Applications

Good Programming Practice 2.16

Place only one statement per line in a program. This format enhances program readability.

Note that there is no semicolon (;) at the end of the first line of each `if` statement. Such a semicolon would result in a logic error at execution time. For example,

```
if ( number1 == number2 ); // logic error
    System.out.printf( "%d == %d\n", number1, number2 );
```

would actually be interpreted by Java as

```
if ( number1 == number2 )
;
// empty statement

System.out.printf( "%d == %d\n", number1, number2 );
```

where the semicolon on the line by itself—called the `empty statement`—is the statement to execute if the condition in the `if` statement is true. When the empty statement executes, no task is performed in the program. The program then continues with the output statement, which always executes, regardless of whether the condition is true or false, because the output statement is not part of the `if` statement.

Common Programming Error 2.13

Placing a semicolon immediately after the right parenthesis of the condition in an if statement is normally a logic error.

Note the use of white space in Fig. 2.15. Recall that white-space characters, such as tabs, newlines and spaces, are normally ignored by the compiler. So statements may be split over several lines and may be spaced according to the programmer's preferences without affecting the meaning of a program. It is incorrect to split identifiers and strings. Ideally, statements should be kept small, but this is not always possible.

Good Programming Practice 2.17

A lengthy statement can be spread over several lines. If a single statement must be split across lines, choose breaking points that make sense, such as after a comma in a comma-separated list, or after an operator in a lengthy expression. If a statement is split across two or more lines, indent all subsequent lines until the end of the statement.

Figure 2.16 shows the precedence of the operators introduced in this chapter. The operators are shown from top to bottom in decreasing order of precedence. All these operators, with the exception of the assignment operator, `=`, associate from left to right. Addition is left associative, so an expression like `x + y + z` is evaluated as if it had been written as `(x + y) + z`. The assignment operator, `=`, associates from right to left, so an expression like `x = y = 0` is evaluated as if it had been written as `x = (y = 0)`, which, as we will soon see, first assigns the value 0 to variable `y` and then assigns the result of that assignment, 0, to `x`.

Good Programming Practice 2.18

Refer to the operator precedence chart (Appendix A) when writing expressions containing many operators. Confirm that the operations in the expression are performed in the order you expect. If you are uncertain about the order of evaluation in a complex expression, use parentheses to force the order, exactly as you would do in algebraic expressions. Observe that some operators, such as assignment, `=`, associate from right to left rather than from left to right.

2.9 Examining the Requirements Document **63**

Operators	Associativity				Type
*	/	%		left to right	multiplicative
+	-			left to right	additive
<	\leq	$>$	\geq	left to right	relational
\equiv	\neq			left to right	equality
=				right to left	assignment

Fig. 2.16 | Precedence and associativity of operations discussed.

2.9 (Optional) Software Engineering Case Study: Examining the Requirements Document

Now we begin our optional object-oriented design and implementation case study. The Software Engineering Case Study sections at the ends of this and the next several chapters will ease you into object orientation by examining an automated teller machine (ATM) case study. This case study will provide you with a concise, carefully paced, complete design and implementation experience. In Chapters 3–8 and 10, we will perform the various steps of an object-oriented design (OOD) process using the UML while relating these steps to the object-oriented concepts discussed in the chapters. Appendix J implements the ATM using the techniques of object-oriented programming (OOP) in Java. We present the complete case-study solution. This is not an exercise; rather, it is an end-to-end learning experience that concludes with a detailed walkthrough of the Java code that implements our design. It will acquaint you with the kinds of substantial problems encountered in industry and their potential solutions. We hope you enjoy this learning experience.

We begin our design process by presenting a [requirements document](#) that specifies the overall purpose of the ATM system and *what* it must do. Throughout the case study, we refer to the requirements document to determine precisely what functionality the system must include.

Requirements Document

A local bank intends to install a new automated teller machine (ATM) to allow users (i.e., bank customers) to perform basic financial transactions (Fig. 2.17). Each user can have only one account at the bank. ATM users should be able to view their account balance, withdraw cash (i.e., take money out of an account) and deposit funds (i.e., place money into an account). The user interface of the automated teller machine contains the following components:

- a screen that displays messages to the user
- a keypad that receives numeric input from the user
- a cash dispenser that dispenses cash to the user and
- a deposit slot that receives deposit envelopes from the user.

64 Chapter 2 Introduction to Java Applications

Fig. 2.17 | Automated teller machine user interface.

The cash dispenser begins each day loaded with 500 \$20 bills. [Note: Due to the limited scope of this case study, certain elements of the ATM described here do not accurately mimic those of a real ATM. For example, a real ATM typically contains a device that reads a user's account number from an ATM card, whereas this ATM asks the user to type the account number on the keypad. A real ATM also usually prints a receipt at the end of a session, but all output from this ATM appears on the screen.]

The bank wants you to develop software to perform the financial transactions initiated by bank customers through the ATM. The bank will integrate the software with the ATM's hardware at a later time. The software should encapsulate the functionality of the hardware devices (e.g., cash dispenser, deposit slot) within software components, but it need not concern itself with how these devices perform their duties. The ATM hardware has not been developed yet, so instead of writing your software to run on the ATM, you should develop a first version of the software to run on a personal computer. This version should use the computer's monitor to simulate the ATM's screen, and the computer's keyboard to simulate the ATM's keypad.

An ATM session consists of authenticating a user (i.e., proving the user's identity) based on an account number and personal identification number (PIN), followed by creating and executing financial transactions. To authenticate a user and perform transactions, the ATM must interact with the bank's account information database (i.e., an organized collection of data stored on a computer). For each bank account, the database stores an account number, a PIN and a balance indicating the amount of money in the account. [Note: We assume that the bank plans to build only one ATM, so we do not need to worry about multiple ATMs accessing this database at the same time. Furthermore, we assume that the bank does not make any changes to the information in the database while a user is accessing the ATM. Also, any business system like an ATM faces reasonably com-

2.9 Examining the Requirements Document 65

plicated security issues that are beyond the scope of a first or second programming course. We make the simplifying assumption, however, that the bank trusts the ATM to access and manipulate the information in the database without significant security measures.]

Upon first approaching the ATM (assuming no one is currently using it), the user should experience the following sequence of events (shown in Fig. 2.17):

1. The screen displays a welcome message and prompts the user to enter an account number.
2. The user enters a five-digit account number using the keypad.
3. The screen prompts the user to enter the PIN (personal identification number) associated with the specified account number.
4. The user enters a five-digit PIN using the keypad.
5. If the user enters a valid account number and the correct PIN for that account, the screen displays the main menu (Fig. 2.18). If the user enters an invalid account number or an incorrect PIN, the screen displays an appropriate message, then the ATM returns to *Step 1* to restart the authentication process.

After the ATM authenticates the user, the main menu (Fig. 2.18) should contain a numbered option for each of the three types of transactions: balance inquiry (option 1), withdrawal (option 2) and deposit (option 3). The main menu also should contain an option to allow the user to exit the system (option 4). The user then chooses either to perform a transaction (by entering 1, 2 or 3) or to exit the system (by entering 4).

If the user enters 1 to make a balance inquiry, the screen displays the user's account balance. To do so, the ATM must retrieve the balance from the bank's database.

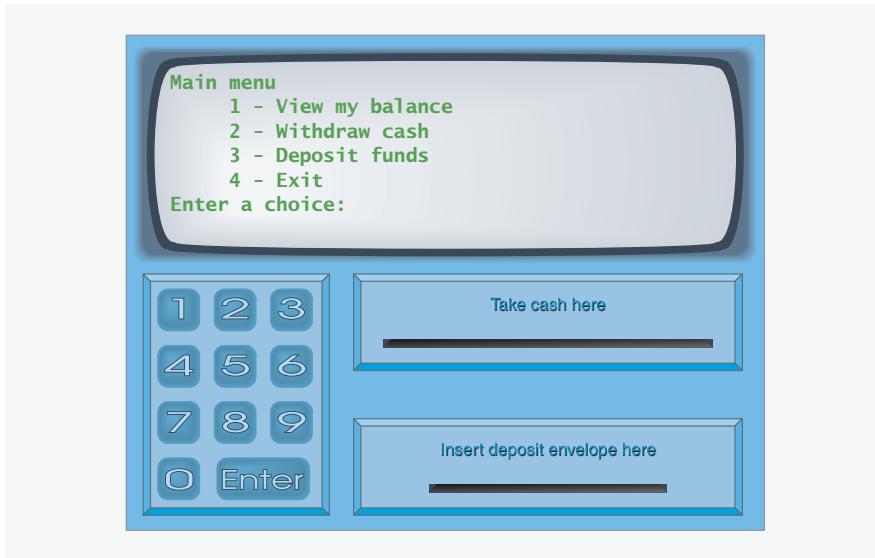

Fig. 2.18 | ATM main menu.

66 Chapter 2 Introduction to Java Applications

The following steps describe the actions that occur when the user enters 2 to make a withdrawal:

1. The screen displays a menu (shown in Fig. 2.19) containing standard withdrawal amounts: \$20 (option 1), \$40 (option 2), \$60 (option 3), \$100 (option 4) and \$200 (option 5). The menu also contains an option to allow the user to cancel the transaction (option 6).
2. The user enters a menu selection using the keypad.
3. If the withdrawal amount chosen is greater than the user's account balance, the screen displays a message stating this and telling the user to choose a smaller amount. The ATM then returns to *Step 1*. If the withdrawal amount chosen is less than or equal to the user's account balance (i.e., an acceptable amount), the ATM proceeds to *Step 4*. If the user chooses to cancel the transaction (option 6), the ATM displays the main menu and waits for user input.
4. If the cash dispenser contains enough cash to satisfy the request, the ATM proceeds to *Step 5*. Otherwise, the screen displays a message indicating the problem and telling the user to choose a smaller withdrawal amount. The ATM then returns to *Step 1*.
5. The ATM debits the withdrawal amount from the user's account in the bank's database (i.e., subtracts the withdrawal amount from the user's account balance).
6. The cash dispenser dispenses the desired amount of money to the user.
7. The screen displays a message reminding the user to take the money.

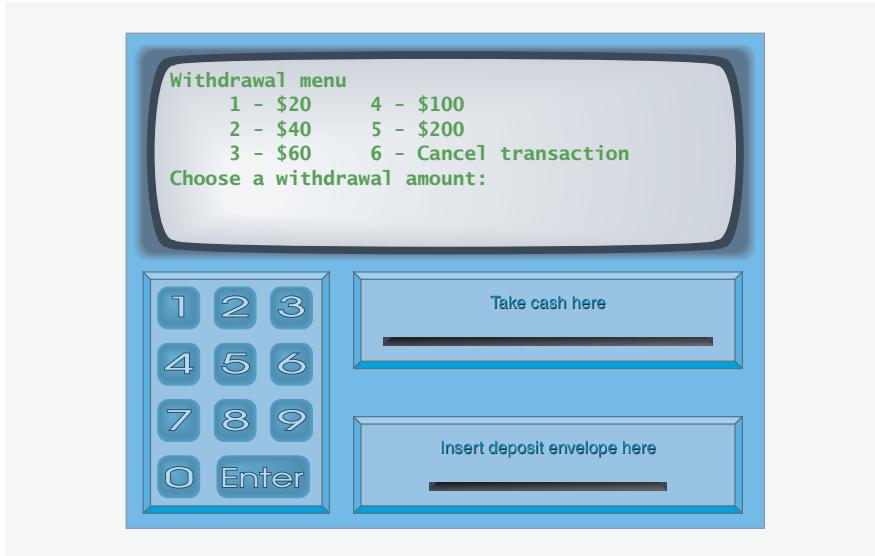

Fig. 2.19 | ATM withdrawal menu.

2.9 Examining the Requirements Document **67**

The following steps describe the actions that occur when the user enters 3 to make a deposit:

1. The screen prompts the user to enter a deposit amount or type 0 (zero) to cancel the transaction.
2. The user enters a deposit amount or 0 using the keypad. [Note: The keypad does not contain a decimal point or a dollar sign, so the user cannot type a real dollar amount (e.g., \$1.25). Instead, the user must enter a deposit amount as a number of cents (e.g., 125). The ATM then divides this number by 100 to obtain a number representing a dollar amount (e.g., $125 \div 100 = 1.25$).]
3. If the user specifies a deposit amount, the ATM proceeds to *Step 4*. If the user chooses to cancel the transaction (by entering 0), the ATM displays the main menu and waits for user input.
4. The screen displays a message telling the user to insert a deposit envelope into the deposit slot.
5. If the deposit slot receives a deposit envelope within two minutes, the ATM credits the deposit amount to the user's account in the bank's database (i.e., adds the deposit amount to the user's account balance). [Note: This money is not immediately available for withdrawal. The bank first must physically verify the amount of cash in the deposit envelope, and any checks in the envelope must clear (i.e., money must be transferred from the check writer's account to the check recipient's account). When either of these events occurs, the bank appropriately updates the user's balance stored in its database. This occurs independently of the ATM system.] If the deposit slot does not receive a deposit envelope within this time period, the screen displays a message that the system has canceled the transaction due to inactivity. The ATM then displays the main menu and waits for user input.

After the system successfully executes a transaction, it should return to the main menu so that the user can perform additional transactions. If the user chooses to exit the system, the screen should display a thank you message, then display the welcome message for the next user.

Analyzing the ATM System

The preceding statement is a simplified example of a requirements document. Typically, such a document is the result of a detailed process of **requirements gathering** that might include interviews with possible users of the system and specialists in fields related to the system. For example, a systems analyst who is hired to prepare a requirements document for banking software (e.g., the ATM system described here) might interview financial experts to gain a better understanding of what the software must do. The analyst would use the information gained to compile a list of **system requirements** to guide systems designers as they design the system.

The process of requirements gathering is a key task of the first stage of the software life cycle. The **software life cycle** specifies the stages through which software goes from the time it is first conceived to the time it is retired from use. These stages typically include: analysis, design, implementation, testing and debugging, deployment, maintenance and retirement. Several software life-cycle models exist, each with its own preferences and spec-

68 Chapter 2 Introduction to Java Applications

ifications for when and how often software engineers should perform each of these stages. **Waterfall models** perform each stage once in succession, whereas **iterative models** may repeat one or more stages several times throughout a product's life cycle.

The analysis stage of the software life cycle focuses on defining the problem to be solved. When designing any system, one must *solve the problem right*, but of equal importance, one must *solve the right problem*. Systems analysts collect the requirements that indicate the specific problem to solve. Our requirements document describes the requirements of our ATM system in sufficient detail that you do not need to go through an extensive analysis stage—it has been done for you.

To capture what a proposed system should do, developers often employ a technique known as **use case modeling**. This process identifies the **use cases** of the system, each of which represents a different capability that the system provides to its clients. For example, ATMs typically have several use cases, such as “View Account Balance,” “Withdraw Cash,” “Deposit Funds,” “Transfer Funds Between Accounts” and “Buy Postage Stamps.” The simplified ATM system we build in this case study allows only the first three use cases.

Each use case describes a typical scenario for which the user uses the system. You have already read descriptions of the ATM system's use cases in the requirements document; the lists of steps required to perform each transaction type (i.e., balance inquiry, withdrawal and deposit) actually described the three use cases of our ATM—“View Account Balance,” “Withdraw Cash” and “Deposit Funds,” respectively.

Use Case Diagrams

We now introduce the first of several UML diagrams in the case study. We create a **use case diagram** to model the interactions between a system's clients (in this case study, bank customers) and its use cases. The goal is to show the kinds of interactions users have with a system without providing the details—these are provided in other UML diagrams (which we present throughout this case study). Use case diagrams are often accompanied by informal text that describes the use cases in more detail—like the text that appears in the requirements document. Use case diagrams are produced during the analysis stage of the software life cycle. In larger systems, use case diagrams are indispensable tools that help system designers remain focused on satisfying the users' needs.

Figure 2.20 shows the use case diagram for our ATM system. The stick figure represents an **actor**, which defines the roles that an external entity—such as a person or another system—plays when interacting with the system. For our automated teller machine, the actor is a User who can view an account balance, withdraw cash and deposit funds from the ATM. The User is not an actual person, but instead comprises the roles that a real person—when playing the part of a User—can play while interacting with the ATM. Note that a use case diagram can include multiple actors. For example, the use case diagram for a real bank's ATM system might also include an actor named Administrator who refills the cash dispenser each day.

Our requirements document supplies the actors—“ATM users should be able to view their account balance, withdraw cash and deposit funds.” Therefore, the actor in each of the three use cases is the user who interacts with the ATM. An external entity—a real person—plays the part of the user to perform financial transactions. Figure 2.20 shows one actor, whose name, User, appears below the actor in the diagram. The UML models each use case as an oval connected to an actor with a solid line.

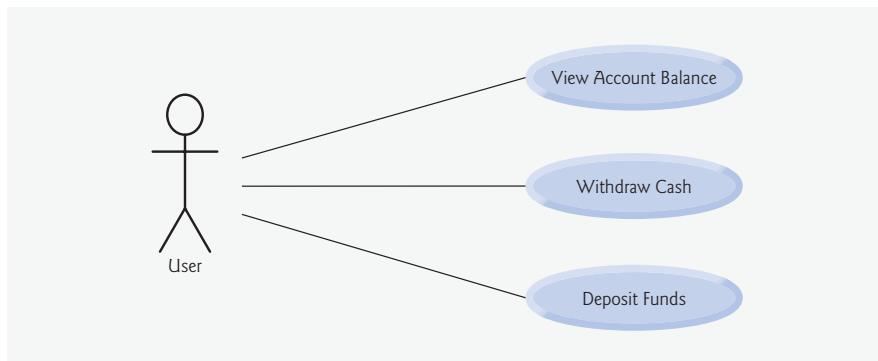

2.9 Examining the Requirements Document **69**

Fig. 2.20 | Use case diagram for the ATM system from the User's perspective.

Software engineers (more precisely, systems designers) must analyze the requirements document or a set of use cases and design the system before programmers implement it in a particular programming language. During the analysis stage, systems designers focus on understanding the requirements document to produce a high-level specification that describes *what* the system is supposed to do. The output of the design stage—a **design specification**—should specify clearly *how* the system should be constructed to satisfy these requirements. In the next several Software Engineering Case Study sections, we perform the steps of a simple object-oriented design (OOD) process on the ATM system to produce a design specification containing a collection of UML diagrams and supporting text. The UML is designed for use with any OOD process. Many such processes exist, the most well-known of which is the Rational Unified Process™ (RUP) developed by Rational Software Corporation. RUP is a rich process intended for designing “industrial strength” applications. For this case study, we present our own simplified design process, designed for students in first and second programming courses.

Designing the ATM System

We now begin the design stage of our ATM system. A **system** is a set of components that interact to solve a problem. For example, to perform the ATM system’s designated tasks, our ATM system has a user interface (Fig. 2.17), contains software that executes financial transactions and interacts with a database of bank account information. **System structure** describes the system’s objects and their interrelationships. **System behavior** describes how the system changes as its objects interact with one another. Every system has both structure and behavior—designers must specify both. There are several distinct types of system structures and behaviors. For example, the interactions among objects in the system differ from those between the user and the system, yet both constitute a portion of the system behavior.

The UML 2 specifies 13 diagram types for documenting the system models. Each models a distinct characteristic of a system’s structure or behavior—six diagrams relate to system structure; the remaining seven relate to system behavior. We list here only the six types used in our case study—one of these (class diagrams) models system structure, whereas the remaining five model system behavior. We overview the remaining seven UML diagram types in Appendix L, UML 2: Additional Diagram Types.

70 Chapter 2 Introduction to Java Applications

1. [Use case diagrams](#), such as the one in Fig. 2.20, model the interactions between a system and its external entities (actors) in terms of use cases (system capabilities, such as “View Account Balance,” “Withdraw Cash” and “Deposit Funds”).
2. [Class diagrams](#), which you will study in Section 3.10, model the classes, or “building blocks,” used in a system. Each noun or “thing” described in the requirements document is a candidate to be a class in the system (e.g., `Account`, `Keypad`). Class diagrams help us specify the structural relationships between parts of the system. For example, the ATM system class diagram will specify that the ATM is physically composed of a screen, a keypad, a cash dispenser and a deposit slot.
3. [State machine diagrams](#), which you will study in Section 5.11, model the ways in which an object changes state. An object’s [state](#) is indicated by the values of all the object’s attributes at a given time. When an object changes state, that object may behave differently in the system. For example, after validating a user’s PIN, the ATM transitions from the “user not authenticated” state to the “user authenticated” state, at which point the ATM allows the user to perform financial transactions (e.g., view account balance, withdraw cash, deposit funds).
4. [Activity diagrams](#), which you will also study in Section 5.11, model an object’s [activity](#)—the object’s workflow (sequence of events) during program execution. An activity diagram models the actions the object performs and specifies the order in which the object performs these actions. For example, an activity diagram shows that the ATM must obtain the balance of the user’s account (from the bank’s account information database) before the screen can display the balance to the user.
5. [Communication diagrams](#) (called [collaboration diagrams](#) in earlier versions of the UML) model the interactions among objects in a system, with an emphasis on *what* interactions occur. You will learn in Section 7.14 that these diagrams show which objects must interact to perform an ATM transaction. For example, the ATM must communicate with the bank’s account information database to retrieve an account balance.
6. [Sequence diagrams](#) also model the interactions among the objects in a system, but unlike communication diagrams, they emphasize *when* interactions occur. You will learn in Section 7.14 that these diagrams help show the order in which interactions occur in executing a financial transaction. For example, the screen prompts the user to enter a withdrawal amount before cash is dispensed.

In Section 3.10, we continue designing our ATM system by identifying the classes from the requirements document. We accomplish this by extracting key nouns and noun phrases from the requirements document. Using these classes, we develop our first draft of the class diagram that models the structure of our ATM system.

Software Engineering Case Study Self-Review Exercises

2.1 Suppose we enabled a user of our ATM system to transfer money between two bank accounts. Modify the use case diagram of Fig. 2.20 to reflect this change.

2.2 _____ model the interactions among objects in a system with an emphasis on *when* these interactions occur.

- a) Class diagrams
- b) Sequence diagrams
- c) Communication diagrams
- d) Activity diagrams

2.3 Which of the following choices lists stages of a typical software life cycle in sequential order?

- a) design, analysis, implementation, testing
- b) design, analysis, testing, implementation
- c) analysis, design, testing, implementation
- d) analysis, design, implementation, testing

Answers to Software Engineering Case Study Self-Review Exercises

2.1 Figure 2.21 contains a use case diagram for a modified version of our ATM system that also allows users to transfer money between accounts.

2.2 b.

2.3 d.

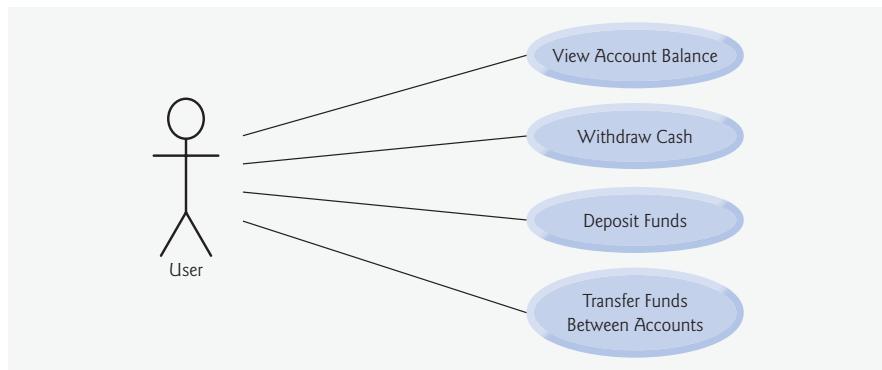

Fig. 2.21 | Use case diagram for a modified version of our ATM system that also allows users to transfer money between accounts.

2.10 Wrap-Up 73

2.10 Wrap-Up

You learned many important features of Java in this chapter, including displaying data on the screen in a Command Prompt, inputting data from the keyboard, performing calculations and making decisions. The applications presented here were meant to introduce you to basic programming concepts. As you will see in Chapter 3, Java applications typically contain just a few lines of code in method `main`—these statements normally create the objects that perform the work of the application. In Chapter 3, you will learn how to implement your own classes and use objects of those classes in applications.

Summary

Section 2.2 A First Program in Java: Printing a Line of Text

- Computer programmers create applications by writing computer programs. A Java application is a computer program that executes when you use the `java` command to launch the JVM.
- Programmers insert comments to document programs and improve their readability. The Java compiler ignores comments.
- A comment that begins with `//` is called an end-of-line (or single-line) comment because the comment terminates at the end of the line on which it appears.
- Traditional (multiple-line) comments can be spread over several lines and are delimited by `/*` and `*/`. All text between the delimiters is ignored by the compiler.
- Javadoc comments are delimited by `/**` and `*/`. Javadoc comments enable programmers to embed program documentation directly in their programs. The `javadoc` utility program generates HTML documentation based on Javadoc comments.
- A programming language's syntax specifies the rules for creating a proper program in that language.
- A syntax error (also called a compiler error, compile-time error or compilation error) occurs when the compiler encounters code that violates Java's language rules.
- Programmers use blank lines and space characters to make programs easier to read. Together, blank lines, space characters and tab characters are known as white space. Space characters and tabs are known specifically as white-space characters. White space is ignored by the compiler.
- Every program in Java consists of at least one class declaration that is defined by the programmer (also known as a programmer-defined class or a user-defined class).
- Keywords are reserved for use by Java and are always spelled with all lowercase letters.
- Keyword `class` introduces a class declaration and is immediately followed by the class name.
- By convention, all class names in Java begin with a capital letter and capitalize the first letter of each word they include (e.g., `SampleClassName`).
- A Java class name is an identifier—a series of characters consisting of letters, digits, underscores (`_`) and dollar signs (`$`) that does not begin with a digit and does not contain spaces. Normally, an identifier that does not begin with a capital letter is not the name of a Java class.
- Java is case sensitive—that is, uppercase and lowercase letters are distinct.
- The body of every class declaration is delimited by braces, `{` and `}`.
- A `public` class declaration must be saved in a file with the same name as the class followed by the `".java"` file-name extension.

74 Chapter 2 Introduction to Java Applications

- Method `main` is the starting point of every Java application and must begin with
`public static void main(String args[])`
otherwise, the JVM will not execute the application.
- Methods are able to perform tasks and return information when they complete their tasks. Keyword `void` indicates that a method will perform a task but will not return any information.
- Statements instruct the computer to perform actions.
- A sequence of characters in double quotation marks is called a string, a character string, a message or a string literal.
- `System.out`, the standard output object, allows Java applications to display characters in the command window.
- Method `System.out.println` displays its argument in the command window followed by a new-line character to position the output cursor to the beginning of the next line.
- Every statement ends with a semicolon.
- Most operating systems use the command `cd` to change directories in the command window.
- You compile a program with the command `javac`. If the program contains no syntax errors, a class file containing the Java bytecodes that represent the application is created. These bytecodes are interpreted by the JVM when we execute the program.

Section 2.3 Modifying Our First Java Program

- `System.out.print` displays its argument and positions the output cursor immediately after the last character displayed.
- A backslash (\) in a string is an escape character. It indicates that a “special character” is to be output. Java combines the next character with the backslash to form an escape sequence. The escape sequence `\n` represents the newline character, which positions the cursor on the next line.

Section 2.4 Displaying Text with `printf`

- `System.out.printf` method (f means “formatted”) displays formatted data.
- When a method requires multiple arguments, the arguments are separated with commas (,)—this is known as a comma-separated list.
- Method `printf`’s first argument is a format string that may consist of fixed text and format specifiers. Fixed text is output by `printf` just as it would be output by `print` or `println`. Each format specifier is a placeholder for a value and specifies the type of data to output.
- Format specifiers begin with a percent sign (%) and are followed by a character that represents the (-) data type. The format specifier `%s` is a placeholder for a string.
- At the first format specifier’s position, `printf` substitutes the value of the first argument after the format string. At each subsequent format specifier’s position, `printf` substitutes the value of the next argument in the argument list.

Section 2.5 Another Java Application: Adding Integers

- Integers are whole numbers, such as -22, 7, 0 and 1024.
- An `import` declaration helps the compiler locate a class that is used in a program.
- Java provides a rich set of predefined classes that programmers can reuse rather than “reinventing the wheel.” These classes are grouped into packages—named collections of classes.
- Collectively, Java’s packages are referred to as the Java class library, or the Java Application Programming Interface (Java API).
- A variable declaration statement specifies the name and type of a variable.

Summary 75

- A variable is a location in the computer's memory where a value can be stored for use later in a program. All variables must be declared with a name and a type before they can be used.
- A variable's name enables the program to access the value of the variable in memory. A variable name can be any valid identifier.
- Like other statements, variable declaration statements end with a semicolon (;).
- A Scanner (package `java.util`) enables a program to read data for use in a program. The data can come from many sources, such as a file on disk or the user at the keyboard. Before using a Scanner, the program must create it and specify the source of the data.
- Variables should be initialized to prepare them for use in a program.
- The expression `new Scanner(System.in)` creates a Scanner that reads from the keyboard. The standard input object, `System.in`, enables Java applications to read data typed by the user.
- Data type `int` is used to declare variables that will hold integer values. The range of values for an `int` is $-2,147,483,648$ to $+2,147,483,647$.
- Types `float` and `double` specify real numbers, and type `char` specifies character data. Real numbers are numbers that contain decimal points, such as `3.4`, `0.0` and `-11.19`. Variables of type `char` data represent individual characters, such as an uppercase letter (e.g., `A`), a digit (e.g., `7`), a special character (e.g., `*` or `%`) or an escape sequence (e.g., the newline character, `\n`).
- Types such as `int`, `float`, `double` and `char` are often called primitive types or built-in types. Primitive-type names are keywords; thus, they must appear in all lowercase letters.
- A prompt directs the user to take a specific action.
- Scanner method `nextInt` obtains an integer for use in a program.
- The assignment operator, `=`, enables the program to give a value to a variable. Operator `=` is called a binary operator because it has two operands. An assignment statement uses an assignment operator to assign a value to a variable.
- Portions of statements that have values are called expressions.
- The format specifier `%d` is a placeholder for an `int` value.

Section 2.6 Memory Concepts

- Variable names correspond to locations in the computer's memory. Every variable has a name, a type, a size and a value.
- Whenever a value is placed in a memory location, the value replaces the previous value in that location. The previous value is lost.

Section 2.7 Arithmetic

- Most programs perform arithmetic calculations. The arithmetic operators are `+` (addition), `-` (subtraction), `*` (multiplication), `/` (division) and `%` (remainder).
- Integer division yields an integer quotient.
- The remainder operator, `%`, yields the remainder after division.
- Arithmetic expressions in Java must be written in straight-line form.
- If an expression contains nested parentheses, the innermost set of parentheses is evaluated first.
- Java applies the operators in arithmetic expressions in a precise sequence determined by the rules of operator precedence.
- When we say that operators are applied from left to right, we are referring to their associativity. Some operators associate from right to left.
- Redundant parentheses in an expression can make an expression clearer.

76 Chapter 2 Introduction to Java Applications

Section 2.8 Decision Making: Equality and Relational Operators

- A condition is an expression that can be either true or false. Java's `if` statement allows a program to make a decision based on the value of a condition.
- Conditions in `if` statements can be formed by using the equality (`==` and `!=`) and relational (`>`, `<`, `>=` and `<=`) operators.
- An `if` statement always begins with keyword `if`, followed by a condition in parentheses, and expects one statement in its body.
- The empty statement is a statement that does not perform a task.

Terminology

addition operator (+)	equality operators == “is equal to” != “is not equal to”
application	escape character
argument	escape sequence
arithmetic operators (*, /, %, + and -)	<code>false</code>
assignment operator (=)	fault tolerant
assignment statement	fixed text in a format string
associativity of operators	<code>float</code> primitive type
backslash (\) escape character	format specifier
binary operator	format string
body of a class declaration	identifier
body of a method declaration	<code>if</code> statement
built-in type	<code>import</code> declaration
case sensitive	<code>int</code> (integer) primitive type
<code>cd</code> command to change directories	integer
<code>char</code> primitive type	integer division
character string	Java API documentation
class declaration	Java Application Programming Interface (API)
class file	Java class library
.class file extension	.java file extension
class keyword	<code>java</code> command
class name	Javadoc comment (/** */)
comma-separated list	javadoc utility program
command line	<code>java.lang</code> package
Command Prompt	left brace {)
command window	location of a variable
comment	<code>main</code> method
compilation error	memory location
compile-time error	message
compiler error	method
computer program	multiple-line comment /* */
condition	MS-DOS prompt
%d format specifier	multiplication operator (*)
decision	name of a variable
division operator (/)	nested parentheses
document a program	newline character (\n)
<code>double</code> primitive type	object
empty statement (;)	
end-of-line comment (//)	

Self-Review Exercises **77**

operand	standard input object (<code>System.in</code>)
operator	standard output object (<code>System.out</code>)
output cursor	statement
package	straight-line form
parentheses ()	string
perform an action	string literal
precedence	subtraction operator (-)
primitive type	syntax
programmer-defined class	syntax error
prompt	<code>System.in</code> (standard input) object
public keyword	<code>System.out</code> (standard output) object
redundant parentheses	<code>System.out.print</code> method
relational operators	<code>System.out.printf</code> method
< “is less than”	<code>System.out.println</code> method
<= “is less than or equal to”	terminal window
> “is greater than”	traditional comment /* */
>= “is greater than or equal to”	true
remainder operator (%)	type of a variable
reserved words	user-defined class
right brace ()	variable
rules of operator precedence	variable declaration
%s format specifier	variable declaration statement
Scanner class	variable name
self-documenting	variable value
semicolon ;	void keyword
shell	white space
single-line comment //	white-space characters
size of a variable	

Self-Review Exercises**2.1** Fill in the blanks in each of the following statements:

- a) A(n) _____ begins the body of every method, and a(n) _____ ends the body of every method.
- b) Every statement ends with a(n) _____.
- c) The _____ statement is used to make decisions.
- d) _____ begins an end-of-line comment.
- e) _____, _____, _____ and _____ are called white space.
- f) _____ are reserved for use by Java.
- g) Java applications begin execution at method _____.
- h) Methods _____, _____ and _____ display information in the command window.

2.2 State whether each of the following is *true* or *false*. If *false*, explain why.

- a) Comments cause the computer to print the text after the // on the screen when the program executes.
- b) All variables must be given a type when they are declared.
- c) Java considers the variables number and NuMbEr to be identical.
- d) The remainder operator (%) can be used only with integer operands.
- e) The arithmetic operators *, /, %, + and - all have the same level of precedence.

78 Chapter 2 Introduction to Java Applications

- 2.3** Write statements to accomplish each of the following tasks:
- Declare variables `c`, `thisIsAVariable`, `q76354` and `number` to be of type `int`.
 - Prompt the user to enter an integer.
 - Input an integer and assign the result to `int` variable `value`. Assume `Scanner` variable `input` can be used to read a value from the keyboard.
 - If the variable `number` is not equal to 7, display "The variable number is not equal to 7".
 - Print "This is a Java program" on one line in the command window.
 - Print "This is a Java program" on two lines in the command window. The first line should end with Java. Use method `System.out.println`.
 - Print "This is a Java program" on two lines in the command window. The first line should end with Java. Use method `System.out.printf` and two `%s` format specifiers.
- 2.4** Identify and correct the errors in each of the following statements:
- `if (c < 7);`
`System.out.println("c is less than 7");`
 - `if (c => 7)`
`System.out.println("c is equal to or greater than 7");`
- 2.5** Write declarations, statements or comments that accomplish each of the following tasks:
- State that a program will calculate the product of three integers.
 - Create a `Scanner` that reads values from the standard input.
 - Declare the variables `x`, `y`, `z` and `result` to be of type `int`.
 - Prompt the user to enter the first integer.
 - Read the first integer from the user and store it in the variable `x`.
 - Prompt the user to enter the second integer.
 - Read the second integer from the user and store it in the variable `y`.
 - Prompt the user to enter the third integer.
 - Read the third integer from the user and store it in the variable `z`.
 - Compute the product of the three integers contained in variables `x`, `y` and `z`, and assign the result to the variable `result`.
 - Display the message "Product is" followed by the value of the variable `result`.
- 2.6** Using the statements you wrote in Exercise 2.5, write a complete program that calculates and prints the product of three integers.

Answers to Self-Review Exercises

- 2.1** a) left brace (`{`), right brace (`}`). b) semicolon (`;`). c) `if`. d) `//`. e) Blank lines, space characters, newline characters and tab characters. f) Keywords. g) `main`. h) `System.out.print`, `System.out.println` and `System.out.printf`.
- 2.2** a) False. Comments do not cause any action to be performed when the program executes. They are used to document programs and improve their readability.
b) True.
c) False. Java is case sensitive, so these variables are distinct.
d) False. The remainder operator can also be used with noninteger operands in Java.
e) False. The operators `*`, `/` and `%` are on the same level of precedence, and the operators `+` and `-` are on a lower level of precedence.
- 2.3** a)
- ```
int c, thisIsAVariable, q76354, number;
or
int c;
int thisIsAVariable;
int q76354;
int number;
```

Answers to Self-Review Exercises **79**

- b) `System.out.print( "Enter an integer: " );`
- c) `value = input.nextInt();`
- d) `if ( number != 7 )  
 System.out.println( "The variable number is not equal to 7" );`
- e) `System.out.println( "This is a Java program" );`
- f) `System.out.println( "This is a Java\nprogram" );`
- g) `System.out.printf( "%s\n%s\n", "This is a Java", "program" );`

**2.4** The solutions to Self-Review Exercise 2.4 are as follows:

- a) Error: Semicolon after the right parenthesis of the condition (`c < 7`) in the `if`.  
Correction: Remove the semicolon after the right parenthesis. [Note: As a result, the output statement will execute regardless of whether the condition in the `if` is true.]
- b) Error: The relational operator `=>` is incorrect. Correction: Change `=>` to `>=`.

**2.5** `// Calculate the product of three integers`

- b) `Scanner input = new Scanner( System.in );`
- c) `int x, y, z, result;`  
or  
`int x;`  
`int y;`  
`int z;`  
`int result;`
- d) `System.out.print( "Enter first integer: " );`
- e) `x = input.nextInt();`
- f) `System.out.print( "Enter second integer: " );`
- g) `y = input.nextInt();`
- h) `System.out.print( "Enter third integer: " );`
- i) `z = input.nextInt();`
- j) `result = x * y * z;`
- k) `System.out.printf( "Product is %d\n", result );`

**2.6** The solution to Self-Review Exercise 2.6 is as follows:

```

1 // Ex. 2.6: Product.java
2 // Calculate the product of three integers.
3 import java.util.Scanner; // program uses Scanner
4
5 public class Product
6 {
7 public static void main(String args[])
8 {
9 // create Scanner to obtain input from command window
10 Scanner input = new Scanner(System.in);
11
12 int x; // first number input by user
13 int y; // second number input by user
14 int z; // third number input by user
15 int result; // product of numbers
16
17 System.out.print("Enter first integer: "); // prompt for input
18 x = input.nextInt(); // read first integer
19
20 System.out.print("Enter second integer: "); // prompt for input
21 y = input.nextInt(); // read second integer

```

**80** Chapter 2 Introduction to Java Applications

```

22
23 System.out.print("Enter third integer: "); // prompt for input
24 z = input.nextInt(); // read third integer
25
26 result = x * y * z; // calculate product of numbers
27
28 System.out.printf("Product is %d\n", result);
29
30 } // end method main
31
32 } // end class Product

```

```

Enter first integer: 10
Enter second integer: 20
Enter third integer: 30
Product is 6000

```

**Exercises**

- 2.7** Fill in the blanks in each of the following statements:
- \_\_\_\_\_ are used to document a program and improve its readability.
  - A decision can be made in a Java program with a(n) \_\_\_\_\_.
  - Calculations are normally performed by \_\_\_\_\_ statements.
  - The arithmetic operators with the same precedence as multiplication are \_\_\_\_\_ and \_\_\_\_\_.
  - When parentheses in an arithmetic expression are nested, the \_\_\_\_\_ set of parentheses is evaluated first.
  - A location in the computer's memory that may contain different values at various times throughout the execution of a program is called a(n) \_\_\_\_\_.
- 2.8** Write Java statements that accomplish each of the following tasks:
- Display the message "Enter an integer: ", leaving the cursor on the same line.
  - Assign the product of variables b and c to variable a.
  - State that a program performs a sample payroll calculation (i.e., use text that helps to document a program).
- 2.9** State whether each of the following is *true* or *false*. If *false*, explain why.
- Java operators are evaluated from left to right.
  - The following are all valid variable names: `_under_bar_`, `m928134`, `t5`, `j7`, `her_sales$`, `his$_account_total`, `a`, `b$`, `c`, `z` and `z2`.
  - A valid Java arithmetic expression with no parentheses is evaluated from left to right.
  - The following are all invalid variable names: `3g`, `87`, `67h2`, `h22` and `2h`.
- 2.10** Assuming that `x = 2` and `y = 3`, what does each of the following statements display?
- `System.out.printf( "x = %d\n", x );`
  - `System.out.printf( "Value of %d + %d is %d\n", x, x, ( x + x ) );`
  - `System.out.printf( "x =" );`
  - `System.out.printf( "%d = %d\n", ( x + y ), ( y + x ) );`
- 2.11** Which of the following Java statements contain variables whose values are modified?
- `p = i + j + k + 7;`
  - `System.out.println( "variables whose values are destroyed" );`
  - `System.out.println( "a = 5" );`
  - `value = input.nextInt();`

Exercises **81**

**2.12** Given that  $y = ax^3 + 7$ , which of the following are correct Java statements for this equation?

- a) `y = a * x * x * x + 7;`
- b) `y = a * x * x * (x + 7);`
- c) `y = (a * x) * x * (x + 7);`
- d) `y = (a * x) * x * x + 7;`
- e) `y = a * (x * x * x) + 7;`
- f) `y = a * x * (x * x + 7);`

**2.13** State the order of evaluation of the operators in each of the following Java statements, and show the value of `x` after each statement is performed:

- a) `x = 7 + 3 * 6 / 2 - 1;`
- b) `x = 2 % 2 + 2 * 2 - 2 / 2;`
- c) `x = (3 * 9 * (3 + (9 * 3 / (3))));`

**2.14** Write an application that displays the numbers 1 to 4 on the same line, with each pair of adjacent numbers separated by one space. Write the program using the following techniques:

- a) Use one `System.out.println` statement.
- b) Use four `System.out.print` statements.
- c) Use one `System.out.printf` statement.

**2.15** Write an application that asks the user to enter two integers, obtains them from the user and prints their sum, product, difference and quotient (division). Use the techniques shown in Fig. 2.7.

**2.16** Write an application that asks the user to enter two integers, obtains them from the user and displays the larger number followed by the words "is larger". If the numbers are equal, print the message "These numbers are equal". Use the techniques shown in Fig. 2.15.

**2.17** Write an application that inputs three integers from the user and displays the sum, average, product, smallest and largest of the numbers. Use the techniques shown in Fig. 2.15. [Note: The calculation of the average in this exercise should result in an integer representation of the average. So if the sum of the values is 7, the average should be 2, not 2.3333....]

**2.18** Write an application that displays a box, an oval, an arrow and a diamond using asterisks (\*), as follows:

```
***** *** * *
* * * * * *** * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
***** *** * *
```

**2.19** What does the following code print?

```
System.out.println("*\n**\n***\n****\n*****");
```

**2.20** What does the following code print?

```
System.out.println("**");
System.out.println("***");
System.out.println("****");
System.out.println("*****");
System.out.println("***");
```

**82** Chapter 2 Introduction to Java Applications**2.21** What does the following code print?

```
System.out.print("*");
System.out.print("***");
System.out.print("*****");
System.out.print("*****");
System.out.println("***");
```

**2.22** What does the following code print?

```
System.out.print("*");
System.out.println("***");
System.out.println("*****");
System.out.print("*****");
System.out.println("***");
```

**2.23** What does the following code print?

```
System.out.printf("%s\n%s\n%s\n", "*", "***", "*****");
```

**2.24** Write an application that reads five integers, determines and prints the largest and smallest integers in the group. Use only the programming techniques you learned in this chapter.**2.25** Write an application that reads an integer and determines and prints whether it is odd or even. [Hint: Use the remainder operator. An even number is a multiple of 2. Any multiple of 2 leaves a remainder of 0 when divided by 2.]**2.26** Write an application that reads two integers, determines whether the first is a multiple of the second and prints the result. [Hint: Use the remainder operator.]**2.27** Write an application that displays a checkerboard pattern, as follows:

```
* * * * * * *
* * * * * * *
* * * * * * *
* * * * * * *
* * * * * * *
* * * * * * *
* * * * * * *
```

**2.28** Here's a peek ahead. In this chapter, you have learned about integers and the type `int`. Java can also represent floating-point numbers that contain decimal points, such as 3.14159. Write an application that inputs from the user the radius of a circle as an integer and prints the circle's diameter, circumference and area using the floating-point value 3.14159 for  $\pi$ . Use the techniques shown in Fig. 2.7. [Note: You may also use the predefined constant `Math.PI` for the value of  $\pi$ . This constant is more precise than the value 3.14159. Class `Math` is defined in package `java.lang`. Classes in that package are imported automatically, so you do not need to `import` class `Math` to use it.] Use the following formulas ( $r$  is the radius):

$$\begin{aligned} \text{diameter} &= 2r \\ \text{circumference} &= 2\pi r \\ \text{area} &= \pi r^2 \end{aligned}$$

Do not store the results of each calculation in a variable. Rather, specify each calculation as the value that will be output in a `System.out.printf` statement. Note that the values produced by the circumference and area calculations are floating-point numbers. Such values can be output with the format specifier `%f` in a `System.out.printf` statement. You will learn more about floating-point numbers in Chapter 3.

Exercises **83**

**2.29** Here's another peek ahead. In this chapter, you have learned about integers and the type `int`. Java can also represent uppercase letters, lowercase letters and a considerable variety of special symbols. Every character has a corresponding integer representation. The set of characters a computer uses and the corresponding integer representations for those characters is called that computer's character set. You can indicate a character value in a program simply by enclosing that character in single quotes, as in '`A`'.

You can determine the integer equivalent of a character by preceding that character with `(int)`, as in

```
(int) 'A'
```

This form is called a cast operator. (You will learn about cast operators in Chapter 4.) The following statement outputs a character and its integer equivalent:

```
System.out.printf(
 "The character %c has the value %d\n", 'A', (int) 'A');
```

When the preceding statement executes, it displays the character `A` and the value 65 (from the Unicode® character set) as part of the string. Note that the format specifier `%c` is a placeholder for a character (in this case, the character '`A`').

Using statements similar to the one shown earlier in this exercise, write an application that displays the integer equivalents of some uppercase letters, lowercase letters, digits and special symbols. Display the integer equivalents of the following: `A B C a b c 0 1 2 $ * + /` and the blank character.

**2.30** Write an application that inputs one number consisting of five digits from the user, separates the number into its individual digits and prints the digits separated from one another by three spaces each. For example, if the user types in the number 42339, the program should print

|   |   |   |   |   |
|---|---|---|---|---|
| 4 | 2 | 3 | 3 | 9 |
|---|---|---|---|---|

Assume that the user enters the correct number of digits. What happens when you execute the program and type a number with more than five digits? What happens when you execute the program and type a number with fewer than five digits? [Hint: It is possible to do this exercise with the techniques you learned in this chapter. You will need to use both division and remainder operations to "pick off" each digit.]

**2.31** Using only the programming techniques you learned in this chapter, write an application that calculates the squares and cubes of the numbers from 0 to 10 and prints the resulting values in table format, as shown below. [Note: This program does not require any input from the user.]

| number | square | cube |
|--------|--------|------|
| 0      | 0      | 0    |
| 1      | 1      | 1    |
| 2      | 4      | 8    |
| 3      | 9      | 27   |
| 4      | 16     | 64   |
| 5      | 25     | 125  |
| 6      | 36     | 216  |
| 7      | 49     | 343  |
| 8      | 64     | 512  |
| 9      | 81     | 729  |
| 10     | 100    | 1000 |

**2.32** Write a program that inputs five numbers and determines and prints the number of negative numbers input, the number of positive numbers input and the number of zeros input.

# Introduction to Classes and Objects

## OBJECTIVES

In this chapter you will learn:

- What classes, objects, methods and instance variables are.
- How to declare a class and use it to create an object.
- How to declare methods in a class to implement the class's behaviors.
- How to declare instance variables in a class to implement the class's attributes.
- How to call an object's methods to make those methods perform their tasks.
- The differences between instance variables of a class and local variables of a method.
- How to use a constructor to ensure that an object's data is initialized when the object is created.
- The differences between primitive and reference types.

*You will see something new.  
Two things. And I call them  
Thing One and Thing Two.*

—Dr. Theodor Seuss Geisel

*Nothing can have value  
without being an object of  
utility.*

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 3.1 Introduction

We introduced the basic terminology and concepts of object-oriented programming in Section 1.16. In Chapter 2, you began to use those concepts to create simple applications that displayed messages to the user, obtained information from the user, performed calculations and made decisions. One common feature of every application in Chapter 2 was that all the statements that performed tasks were located in method `main`. Typically, the applications you develop in this book will consist of two or more classes, each containing one or more methods. If you become part of a development team in industry, you might work on applications that contain hundreds, or even thousands, of classes. In this chapter, we present a simple framework for organizing object-oriented applications in Java.

First, we motivate the notion of classes with a real-world example. Then we present five complete working applications to demonstrate creating and using your own classes. The first four of these examples begin our case study on developing a grade-book class that instructors can use to maintain student test scores. This case study is enhanced over the next several chapters, culminating with the version presented in Chapter 7, Arrays. The last example in the chapter introduces floating-point numbers—that is, numbers containing decimal points, such as 0.0345, -7.23 and 100.7—in the context of a bank account class that maintains a customer’s balance.

## 3.2 Classes, Objects, Methods and Instance Variables

Let’s begin with a simple analogy to help you understand classes and their contents. Suppose you want to drive a car and make it go faster by pressing down on its accelerator pedal. What must happen before you can do this? Well, before you can drive a car, someone has to design it. A car typically begins as engineering drawings, similar to the blueprints used to design a house. These engineering drawings include the design for an accelerator pedal to make the car go faster. The pedal “hides” from the driver the complex mechanisms that actually make the car go faster, just as the brake pedal “hides” the mechanisms that slow the car and the steering wheel “hides” the mechanisms that turn the car. This enables people with little or no knowledge of how engines work to drive a car easily.

**86**    [Chapter 3 Introduction to Classes and Objects](#)

Unfortunately, you cannot drive the engineering drawings of a car. Before you can drive a car, the car must be built from the engineering drawings that describe it. A completed car has an actual accelerator pedal to make the car go faster, but even that's not enough—the car won't accelerate on its own, so the driver must press the accelerator pedal.

Now let's use our car example to introduce the key programming concepts of this section. Performing a task in a program requires a method. The method describes the mechanisms that actually perform its tasks. The method hides from its user the complex tasks that it performs, just as the accelerator pedal of a car hides from the driver the complex mechanisms of making the car go faster. In Java, we begin by creating a program unit called a class to house a method, just as a car's engineering drawings house the design of an accelerator pedal. In a class, you provide one or more methods that are designed to perform the class's tasks. For example, a class that represents a bank account might contain one method to deposit money to an account, another to withdraw money from an account and a third to inquire what the current balance is.

Just as you cannot drive an engineering drawing of a car, you cannot "drive" a class. Just as someone has to build a car from its engineering drawings before you can actually drive a car, you must build an object of a class before you can get a program to perform the tasks the class describes how to do. That is one reason Java is known as an object-oriented programming language.

When you drive a car, pressing its gas pedal sends a message to the car to perform a task—that is, make the car go faster. Similarly, you send **messages** to an object—each message is known as a **method call** and tells a method of the object to perform its task.

Thus far, we've used the car analogy to introduce classes, objects and methods. In addition to a car's capabilities, a car also has many attributes, such as its color, the number of doors, the amount of gas in its tank, its current speed and its total miles driven (i.e., its odometer reading). Like the car's capabilities, these attributes are represented as part of a car's design in its engineering diagrams. As you drive a car, these attributes are always associated with the car. Every car maintains its own attributes. For example, each car knows how much gas is in its own gas tank, but not how much is in the tanks of other cars. Similarly, an object has attributes that are carried with the object as it is used in a program. These attributes are specified as part of the object's class. For example, a bank account object has a balance attribute that represents the amount of money in the account. Each bank account object knows the balance in the account it represents, but not the balances of the other accounts in the bank. Attributes are specified by the class's **instance variables**.

The remainder of this chapter presents examples that demonstrate the concepts we introduced in the context of the car analogy. The first four examples incrementally build a `GradeBook` class to demonstrate these concepts:

1. The first example presents a `GradeBook` class with one method that simply displays a welcome message when it is called. We then show how to create an object of that class and call the method so that it displays the welcome message.
2. The second example modifies the first by allowing the method to receive a course name as an argument and by displaying the name as part of the welcome message.
3. The third example shows how to store the course name in a `GradeBook` object. For this version of the class, we also show how to use methods to set the course name and obtain the course name.

### 3.3 Declaring a Class with a Method and Instantiating an Object of a Class 87

- The fourth example demonstrates how the data in a `GradeBook` object can be initialized when the object is created—the initialization is performed by the class's constructor.

The last example in the chapter presents an `Account` class that reinforces the concepts presented in the first four examples and introduces floating-point numbers. For this purpose, we present an `Account` class that represents a bank account and maintains its balance as a floating-point number. The class contains two methods—one that credits a deposit to the account, thus increasing the balance, and another that retrieves the balance. The class's constructor allows the balance of each `Account` object to be initialized as the object is created. We create two `Account` objects and make deposits into each to show that each object maintains its own balance. The example also demonstrates how to input and display floating-point numbers.

## 3.3 Declaring a Class with a Method and Instantiating an Object of a Class

We begin with an example that consists of classes `GradeBook` (Fig. 3.1) and `GradeBookTest` (Fig. 3.2). Class `GradeBook` (declared in file `GradeBook.java`) will be used to display a message on the screen (Fig. 3.2) welcoming the instructor to the grade-book application. Class `GradeBookTest` (declared in file `GradeBookTest.java`) is an application class in which the `main` method will use class `GradeBook`. Each class declaration that begins with keyword `public` must be stored in a file that has the same name as the class and ends with the `.java` file-name extension. Thus, classes `GradeBook` and `GradeBookTest` must be declared in separate files, because each class is declared `public`.

### Common Programming Error 3.1

*Declaring more than one `public` class in the same file is a compilation error.*

#### Class `GradeBook`

The `GradeBook` class declaration (Fig. 3.1) contains a `displayMessage` method (lines 7–10) that displays a message on the screen. Line 9 of the class performs the work of displaying the message. Recall that a class is like a blueprint—we'll need to make an object of this class and call its method to get line 9 to execute and display its message.

```

1 // Fig. 3.1: GradeBook.java
2 // Class declaration with one method.
3
4 public class GradeBook
5 {
6 // display a welcome message to the GradeBook user
7 public void displayMessage()
8 {
9 System.out.println("Welcome to the Grade Book!");
10 } // end method displayMessage
11
12 } // end class GradeBook

```

**Fig. 3.1** | Class declaration with one method.

3.3 Declaring a Class with a Method and Instantiating an Object of a Class **89**

```

1 // Fig. 3.2: GradeBookTest.java
2 // Create a GradeBook object and call its displayMessage method.
3
4 public class GradeBookTest
5 {
6 // main method begins program execution
7 public static void main(String args[])
8 {
9 // create a GradeBook object and assign it to myGradeBook
10 GradeBook myGradeBook = new GradeBook();
11
12 // call myGradeBook's displayMessage method
13 myGradeBook.displayMessage();
14 } // end main
15
16 } // end class GradeBookTest

```

Welcome to the Grade Book!

**Fig. 3.2** | Creating an object of class GradeBook and calling its displayMessage method.

and ends in line 16. The class contains only a `main` method, which is typical of many classes that begin an application’s execution.

Lines 7–14 declare method `main`. Recall from Chapter 2 that the `main` header must appear as shown in line 7; otherwise, the application will not execute. A key part of enabling the JVM to locate and call method `main` to begin the application’s execution is the `static` keyword (line 7), which indicates that `main` is a `static` method. A `static` method is special because it can be called without first creating an object of the class in which the method is declared. We thoroughly explain `static` methods in Chapter 6, Methods: A Deeper Look.

In this application, we’d like to call class `GradeBook`’s `displayMessage` method to display the welcome message in the command window. Typically, you cannot call a method that belongs to another class until you create an object of that class, as shown in line 10. We begin by declaring variable `myGradeBook`. Note that the variable’s type is `GradeBook`—the class we declared in Fig. 3.1. Each new class you create becomes a new type that can be used to declare variables and create objects. Programmers can declare new class types as needed; this is one reason why Java is known as an [extensible language](#).

Variable `myGradeBook` is initialized with the result of the [class instance creation expression](#) `new GradeBook()`. Keyword `new` creates a new object of the class specified to the right of the keyword (i.e., `GradeBook`). The parentheses to the right of `GradeBook` are required. As you will learn in Section 3.7, those parentheses in combination with a class name represent a call to a `constructor`, which is similar to a method, but is used only at the time an object is created to initialize the object’s data. In that section you will see that data can be placed in parentheses to specify initial values for the object’s data. For now, we simply leave the parentheses empty.

Just as we can use object `System.out` to call methods `print`, `printf` and `println`, we can use object `myGradeBook` to call method `displayMessage`. Line 13 calls the method `displayMessage` (lines 7–10 of Fig. 3.1) using `myGradeBook` followed by a [dot separator](#)

## 88 Chapter 3 Introduction to Classes and Objects

The class declaration begins in line 4. The keyword `public` is an [access modifier](#). For now, we will simply declare every class `public`. Every class declaration contains keyword `class` followed immediately by the class's name. Every class's body is enclosed in a pair of left and right braces (`{` and `}`), as in lines 5 and 12 of class `GradeBook`.

In Chapter 2, each class we declared had one method named `main`. Class `GradeBook` also has one method—`displayMessage` (lines 7–10). Recall that `main` is a special method that is always called automatically by the Java Virtual Machine (JVM) when you execute an application. Most methods do not get called automatically. As you will soon see, you must call method `displayMessage` to tell it to perform its task.

The method declaration begins with keyword `public` to indicate that the method is “available to the public”—that is, it can be called from outside the class declaration's body by methods of other classes. Keyword `void` indicates that this method will perform a task but will not return (i.e., give back) any information to its [calling method](#) when it completes its task. You have already used methods that return information—for example, in Chapter 2 you used `Scanner` method `nextInt` to input an integer typed by the user at the keyboard. When `nextInt` inputs a value, it returns that value for use in the program.

The name of the method, `displayMessage`, follows the return type. By convention, method names begin with a lowercase first letter and all subsequent words in the name begin with a capital letter. The parentheses after the method name indicate that this is a method. An empty set of parentheses, as shown in line 7, indicates that this method does not require additional information to perform its task. Line 7 is commonly referred to as the [method header](#). Every method's body is delimited by left and right braces (`{` and `}`), as in lines 8 and 10.

The body of a method contains statement(s) that perform the method's task. In this case, the method contains one statement (line 9) that displays the message “Welcome to the Grade Book!” followed by a newline in the command window. After this statement executes, the method has completed its task.

Next, we'd like to use class `GradeBook` in an application. As you learned in Chapter 2, method `main` begins the execution of every application. A class that contains method `main` is a Java application. Such a class is special because the JVM can use `main` as an entry point to begin execution. Class `GradeBook` is not an application because it does not contain `main`. Therefore, if you try to execute `GradeBook` by typing `java GradeBook` in the command window, you will receive an error message like:

```
Exception in thread "main" java.lang.NoSuchMethodError: main
```

This was not a problem in Chapter 2, because every class you declared had a `main` method. To fix this problem for the `GradeBook`, we must either declare a separate class that contains a `main` method or place a `main` method in class `GradeBook`. To help you prepare for the larger programs you will encounter later in this book and in industry, we use a separate class (`GradeBookTest` in this example) containing method `main` to test each new class we create in this chapter.

### **Class `GradeBookTest`**

The `GradeBookTest` class declaration (Fig. 3.2) contains the `main` method that will control our application's execution. Any class that contains `main` declared as shown in line 7 can be used to execute an application. The `GradeBookTest` class declaration begins in line 4

## 90 Chapter 3 Introduction to Classes and Objects

(.), the method name `displayMessage` and an empty set of parentheses. This call causes the `displayMessage` method to perform its task. This method call differs from those in Chapter 2 that displayed information in a command window—each of those method calls provided arguments that specified the data to display. At the beginning of line 13, “`myGradeBook.`” indicates that `main` should use the `myGradeBook` object that was created in line 10. Line 7 of Fig. 3.1 indicates that method `displayMessage` has an empty parameter list—that is, `displayMessage` does not require additional information to perform its task. For this reason, the method call (line 13 of Fig. 3.2) specifies an empty set of parentheses after the method name to indicate that no arguments are being passed to method `displayMessage`. When method `displayMessage` completes its task, method `main` continues executing in line 14. This is the end of method `main`, so the program terminates.

### *Compiling an Application with Multiple Classes*

You must compile the classes in Fig. 3.1 and Fig. 3.2 before you can execute the application. First, change to the directory that contains the application’s source-code files. Next, type the command

```
javac GradeBook.java GradeBookTest.java
```

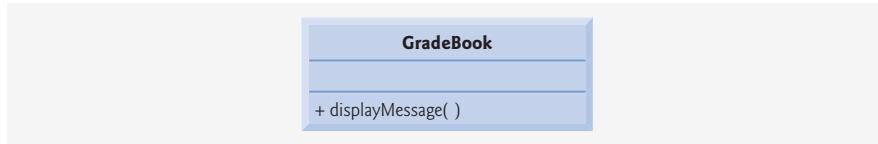

to compile both classes at once. If the directory containing the application includes only this application’s files, you can compile all the classes in the directory with the command

```
javac *.java
```

The asterisk (\*) in `*.java` indicates that all files in the current directory that end with the file name extension “`.java`” should be compiled.

### *UML Class Diagram for Class GradeBook*

Figure 3.3 presents a [UML class diagram](#) for class `GradeBook` of Fig. 3.1. Recall from Section 1.16 that the UML is a graphical language used by programmers to represent object-oriented systems in a standardized manner. In the UML, each class is modeled in a class diagram as a rectangle with three compartments. The top compartment contains the name of the class centered horizontally in boldface type. The middle compartment contains the class’s attributes, which correspond to instance variables in Java. In Fig. 3.3, the middle compartment is empty because the version of class `GradeBook` in Fig. 3.1 does not have any attributes. The bottom compartment contains the class’s operations, which correspond to methods in Java. The UML models operations by listing the operation name preceded by an access modifier and followed by a set of parentheses. Class `GradeBook` has one method, `displayMessage`, so the bottom compartment of Fig. 3.3 lists one operation with this name. Method `displayMessage` does not require additional information to per-

**Fig. 3.3** | UML class diagram indicating that class `GradeBook` has a `public` `displayMessage` operation.

3.4 Declaring a Method with a Parameter **91**

form its tasks, so the parentheses following the method name in the class diagram are empty, just as they were in the method's declaration in line 7 of Fig. 3.1. The plus sign (+) in front of the operation name indicates that `displayMessage` is a `public` operation in the UML (i.e., a `public` method in Java). We will often use UML class diagrams to summarize a class's attributes and operations.

### 3.4 Declaring a Method with a Parameter

In our car analogy from Section 3.2, we discussed the fact that pressing a car's gas pedal sends a message to the car to perform a task—make the car go faster. But how fast should the car accelerate? As you know, the farther down you press the pedal, the faster the car accelerates. So the message to the car actually includes the task to perform and additional information that helps the car perform the task. This additional information is known as a `parameter`—the value of the parameter helps the car determine how fast to accelerate. Similarly, a method can require one or more parameters that represent additional information it needs to perform its task. A method call supplies values—called arguments—for each of the method's parameters. For example, the method `System.out.println` requires an argument that specifies the data to output in a command window. Similarly, to make a deposit into a bank account, a `deposit` method specifies a parameter that represents the deposit amount. When the `deposit` method is called, an argument value representing the deposit amount is assigned to the method's parameter. The method then makes a deposit of that amount.

Our next example declares class `GradeBook` (Fig. 3.4) with a `displayMessage` method that displays the course name as part of the welcome message. (See the sample execution in Fig. 3.5.) The new `displayMessage` method requires a parameter that represents the course name to output.

Before discussing the new features of class `GradeBook`, let's see how the new class is used from the `main` method of class `GradeBookTest` (Fig. 3.5). Line 12 creates a `Scanner` named `input` for reading the course name from the user. Line 15 creates an object of class `GradeBook` and assigns it to variable `myGradeBook`. Line 18 prompts the user to enter a course name. Line 19 reads the name from the user and assigns it to the `nameOfCourse` variable, using `Scanner` method `nextLine` to perform the input. The user types the course name and presses *Enter* to submit the course name to the program. Note that pressing *Enter*

**CS101 Introduction to Java Programming**

Welcome to the grade book for  
**CS101 Introduction to Java Programming!**

**Fig. 3.5** | Creating a GradeBook object and passing a String to its displayMessage method.

inserts a newline character at the end of the characters typed by the user. Method `nextLine` reads characters typed by the user until the newline character is encountered, then returns a `String` containing the characters up to, but not including, the newline. The newline character is discarded. Class `Scanner` also provides a similar method—`next`—that reads individual words. When the user presses *Enter* after typing input, method `next` reads characters until a white-space character (such as a space, tab or newline) is encountered, then returns a `String` containing the characters up to, but not including, the white-space character (which is discarded). All information after the first white-space character is not lost—it can be read by other statements that call the `Scanner`'s methods later in the program.

Line 24 calls `myGradeBooks`'s `displayMessage` method. The variable `nameOfCourse` in parentheses is the argument that is passed to method `displayMessage` so that the method can perform its task. The value of variable `nameOfCourse` in `main` becomes the value of method `displayMessage`'s parameter `courseName` in line 7 of Fig. 3.4. When you execute this application, notice that method `displayMessage` outputs the name you type as part of the welcome message (Fig. 3.5).

3.4 Declaring a Method with a Parameter **93****Software Engineering Observation 3.1**

Normally, objects are created with new. One exception is a string literal that is contained in quotes, such as "hello". String literals are references to String objects that are implicitly created by Java.

**More on Arguments and Parameters**

When you declare a method, you must specify whether the method requires data to perform its task. To do so, you place additional information in the method's **parameter list**, which is located in the parentheses that follow the method name. The parameter list may contain any number of parameters, including none at all. Empty parentheses following the method name (as in Fig. 3.1, line 7) indicate that a method does not require any parameters. In Fig. 3.4, `displayMessage`'s parameter list (line 7) declares that the method requires one parameter. Each parameter must specify a type and an identifier. In this case, the type `String` and the identifier `courseName` indicate that method `displayMessage` requires a `String` to perform its task. At the time the method is called, the argument value in the call is assigned to the corresponding parameter (in this case, `courseName`) in the method header. Then, the method body uses the parameter `courseName` to access the value. Lines 9–10 of Fig. 3.4 display parameter `courseName`'s value, using the %s format specifier in `printf`'s format string. Note that the parameter variable's name (Fig. 3.4, line 7) can be the same or different from the argument variable's name (Fig. 3.5, line 24).

A method can specify multiple parameters by separating each parameter from the next with a comma (we'll see an example of this in Chapter 6). The number of arguments in a method call must match the number of parameters in the parameter list of the called method's declaration. Also, the argument types in the method call must be "consistent with" the types of the corresponding parameters in the method's declaration. (As you will learn in subsequent chapters, an argument's type and its corresponding parameter's type are not always required to be identical.) In our example, the method call passes one argument of type `String` (`nameOfCourse` is declared as a `String` in line 19 of Fig. 3.5) and the method declaration specifies one parameter of type `String` (line 7 in Fig. 3.4). So in this example the type of the argument in the method call exactly matches the type of the parameter in the method header.

**Common Programming Error 3.2**

A compilation error occurs if the number of arguments in a method call does not match the number of parameters in the method declaration.

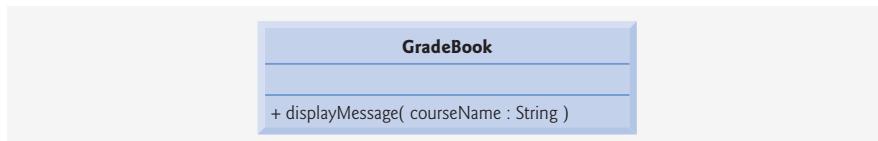

**Common Programming Error 3.3**

A compilation error occurs if the types of the arguments in a method call are not consistent with the types of the corresponding parameters in the method declaration.

**Updated UML Class Diagram for Class GradeBook**

The UML class diagram of Fig. 3.6 models class `GradeBook` of Fig. 3.4. Like Fig. 3.1, this `GradeBook` class contains `public` operation `displayMessage`. However, this version of `displayMessage` has a parameter. The UML models a parameter a bit differently from Java by listing the parameter name, followed by a colon and the parameter type in the parentheses following the operation name. The UML has its own data types similar to those of Java (but as you will see, not all the UML data types have the same names as the corresponding Java

## 94 Chapter 3 Introduction to Classes and Objects

**Fig. 3.6** | UML class diagram indicating that class GradeBook has a `displayMessage` operation with a `courseName` parameter of UML type `String`.

types). The UML type `String` does correspond to the Java type `String`. `GradeBook` method `displayMessage` (Fig. 3.4) has a `String` parameter named `courseName`, so Fig. 3.6 lists `courseName : String` between the parentheses following `displayMessage`.

### Notes on `import` Declarations

Notice the `import` declaration in Fig. 3.5 (line 4). This indicates to the compiler that the program uses class `Scanner`. Why do we need to import class `Scanner`, but not classes `System`, `String` or `GradeBook`? Most classes you will use in Java programs must be imported. Classes `System` and `String` are in package `java.lang`, which is implicitly imported into every Java program, so all programs can use package `java.lang`'s classes without explicitly importing them.

There is a special relationship between classes that are compiled in the same directory on disk, like classes `GradeBook` and `GradeBookTest`. By default, such classes are considered to be in the same package—known as the **default package**. Classes in the same package are implicitly imported into the source code files of other classes in the same package. Thus, an `import` declaration is not required when one class in a package uses another in the same package—such as when class `GradeBookTest` uses class `GradeBook`.

The `import` declaration in line 4 is not required if we always refer to class `Scanner` as `java.util.Scanner`, which includes the full package name and class name. This is known as the class's **fully qualified class name**. For example, line 12 could be written as

```
java.util.Scanner input = new java.util.Scanner(System.in);
```

### Software Engineering Observation 3.2

*The Java compiler does not require `import` declarations in a Java source code file if the fully qualified class name is specified every time a class name is used in the source code. But most Java programmers consider using fully qualified names to be cumbersome, and instead prefer to use `import` declarations.*

## 3.5 Instance Variables, set Methods and get Methods

In Chapter 2, we declared all of an application's variables in the application's main method. Variables declared in the body of a particular method are known as **local variables** and can be used only in that method. When that method terminates, the values of its local variables are lost. Recall from Section 3.2 that an object has attributes that are carried with the object as it is used in a program. Such attributes exist before a method is called on an object and after the method completes execution.

A class normally consists of one or more methods that manipulate the attributes that belong to a particular object of the class. Attributes are represented as variables in a class

3.5 Instance Variables, set Methods and get Methods **95**

declaration. Such variables are called **fields** and are declared inside a class declaration but outside the bodies of the class's method declarations. When each object of a class maintains its own copy of an attribute, the field that represents the attribute is also known as an instance variable—each object (instance) of the class has a separate instance of the variable in memory. The example in this section demonstrates a **GradeBook** class that contains a **courseName** instance variable to represent a particular **GradeBook** object's course name.

**GradeBook Class with an Instance Variable, a set Method and a get Method**

In our next application (Fig. 3.7–Fig. 3.8), class **GradeBook** (Fig. 3.7) maintains the course name as an instance variable so that it can be used or modified at any time during an application's execution. The class contains three methods—**setCourseName**, **getCourseName** and **displayMessage**. Method **setCourseName** stores a course name in a **GradeBook**. Method **getCourseName** obtains a **GradeBook**'s course name. Method **displayMessage**, which now specifies no parameters, still displays a welcome message that includes the course name; as you will see, the method now obtains the course name by calling another method in the same class—**getCourseName**.

```

```

**Fig. 3.8** | Creating and manipulating a GradeBook object.***set and get Methods***

A class's private fields can be manipulated only by methods of that class. So a **client of an object**—that is, any class that calls the object's methods—calls the class's public methods to manipulate the private fields of an object of the class. This is why the statements in method `main` (Fig. 3.8) call the `setCourseName`, `getCourseName` and `displayMessage` methods on a `GradeBook` object. Classes often provide public methods to allow clients of the class to *set* (i.e., assign values to) or *get* (i.e., obtain the values of) private instance variables. The names of these methods need not begin with *set* or *get*, but this naming convention is highly recommended in Java and is required for special Java software components called JavaBeans that can simplify programming in many Java integrated development environments.

## 96 Chapter 3 Introduction to Classes and Objects

A typical instructor teaches more than one course, each with its own course name. Line 7 declares that `courseName` is a variable of type `String`. Because the variable is declared in the body of the class but outside the bodies of the class's methods (lines 10–13, 16–19 and 22–28), line 7 is a declaration for an instance variable. Every instance (i.e., object) of class `GradeBook` contains one copy of each instance variable. For example, if there are two `GradeBook` objects, each object has its own copy of `courseName` (one per object). A benefit of making `courseName` an instance variable is that all the methods of the class (in this case, `GradeBook`) can manipulate any instance variables that appear in the class (in this case, `courseName`).

### **Access Modifiers `public` and `private`**

Most instance variable declarations are preceded with the keyword `private` (as in line 7). Like `public`, keyword `private` is an access modifier. Variables or methods declared with access modifier `private` are accessible only to methods of the class in which they are declared. Thus, variable `courseName` can be used only in methods `setCourseName`, `getCourseName` and `displayMessage` of (every object of) class `GradeBook`.

### **Software Engineering Observation 3.3**

*Precede every field and method declaration with an access modifier. As a rule of thumb, instance variables should be declared `private` and methods should be declared `public`. (We will see that it is appropriate to declare certain methods `private`, if they will be accessed only by other methods of the class.)*

### **Good Programming Practice 3.1**

*We prefer to list the fields of a class first, so that, as you read the code, you see the names and types of the variables before you see them used in the methods of the class. It is possible to list the class's fields anywhere in the class outside its method declarations, but scattering them tends to lead to hard-to-read code.*

### **Good Programming Practice 3.2**

*Place a blank line between method declarations to separate the methods and enhance program readability.*

Declaring instance variables with access modifier `private` is known as **data hiding**. When a program creates (instantiates) an object of class `GradeBook`, variable `courseName` is encapsulated (hidden) in the object and can be accessed only by methods of the object's class. In class `GradeBook`, methods `setCourseName` and `getCourseName` manipulate the instance variable `courseName`.

Method `setCourseName` (lines 10–13) does not return any data when it completes its task, so its return type is `void`. The method receives one parameter—`name`—which represents the course name that will be passed to the method as an argument. Line 12 assigns `name` to instance variable `courseName`.

Method `getCourseName` (lines 16–19) returns a particular `GradeBook` object's `courseName`. The method has an empty parameter list, so it does not require additional information to perform its task. The method specifies that it returns a `String`—this is known as the method's **return type**. When a method that specifies a return type is called and completes its task, the method returns a result to its calling method. For example,

3.5 Instance Variables, set Methods and get Methods **97**

when you go to an automated teller machine (ATM) and request your account balance, you expect the ATM to give you back a value that represents your balance. Similarly, when a statement calls method `getCourseName` on a `GradeBook` object, the statement expects to receive the `GradeBook`'s course name (in this case, a `String`, as specified in the method declaration's return type). If you have a method `square` that returns the square of its argument, you would expect the statement

```
int result = square(2);
```

to return 4 from method `square` and assign 4 to the variable `result`. If you have a method `maximum` that returns the largest of three integer arguments, you would expect the following statement

```
int biggest = maximum(27, 114, 51);
```

to return 114 from method `maximum` and assign 114 to variable `biggest`.

Note that the statements in lines 12 and 18 each use `courseName` even though it was not declared in any of the methods. We can use `courseName` in the methods of class `GradeBook` because `courseName` is a field of the class. Also note that the order in which methods are declared in a class does not determine when they are called at execution time. So method `getCourseName` could be declared before method `setCourseName`.

Method `displayMessage` (lines 22–28) does not return any data when it completes its task, so its return type is `void`. The method does not receive parameters, so the parameter list is empty. Lines 26–27 output a welcome message that includes the value of instance variable `courseName`. Once again, we need to create an object of class `GradeBook` and call its methods before the welcome message can be displayed.

#### ***GradeBookTest Class That Demonstrates Class GradeBook***

Class `GradeBookTest` (Fig. 3.8) creates one object of class `GradeBook` and demonstrates its methods. Line 11 creates a `Scanner` that will be used to obtain a course name from the user. Line 14 creates a `GradeBook` object and assigns it to local variable `myGradeBook` of type `GradeBook`. Lines 17–18 display the initial course name calling the object's `getCourseName` method. Note that the first line of the output shows the name "null." Unlike local variables, which are not automatically initialized, every field has a **default initial value**—a value provided by Java when the programmer does not specify the field's initial value. Thus, fields are not required to be explicitly initialized before they are used in a program—unless they must be initialized to values other than their default values. The default value for a field of type `String` (like `courseName` in this example) is `null`, which we say more about in Section 3.6.

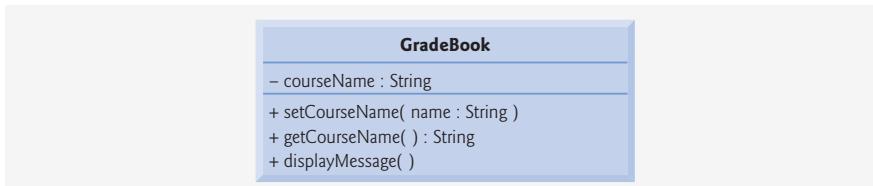

Line 21 prompts the user to enter a course name. Local `String` variable `theName` (declared in line 22) is initialized with the course name entered by the user, which is returned by the call to the `nextLine` method of the `Scanner` object `input`. Line 23 calls object `myGradeBook`'s `setCourseName` method and supplies `theName` as the method's argument. When the method is called, the argument's value is assigned to parameter `name` (line 10, Fig. 3.7) of method `setCourseName` (lines 10–13, Fig. 3.7). Then the parameter's value is assigned to instance variable `courseName` (line 12, Fig. 3.7). Line 24 (Fig. 3.8) skips a line in the output, then line 27 calls object `myGradeBook`'s `displayMessage` method to display the welcome message containing the course name.

### 3.6 Primitive Types vs. Reference Types 99

vironments (IDEs). The method that *sets* instance variable `courseName` in this example is called `setCourseName`, and the method that *gets* the value of instance variable `courseName` is called `getCourseName`.

***UML Class Diagram for class GradeBook with an Instance Variable and set and get Methods***

Figure 3.9 contains an updated UML class diagram for the version of class `GradeBook` in Fig. 3.7. This diagram models class `GradeBook`'s instance variable `courseName` as an attribute in the middle compartment of the class. The UML represents instance variables as attributes by listing the attribute name, followed by a colon and the attribute type. The UML type of attribute `courseName` is `String`. Instance variable `courseName` is *private* in Java, so the class diagram lists a minus sign (-) in front of the corresponding attribute's name. Class `GradeBook` contains three `public` methods, so the class diagram lists three operations in the third compartment. Recall that the plus (+) sign before each operation name indicates that the operation is `public`. Operation `setCourseName` has a `String` parameter called `name`. The UML indicates the return type of an operation by placing a colon and the return type after the parentheses following the operation name. Method `getCourseName` of class `GradeBook` (Fig. 3.7) has a `String` return type in Java, so the class diagram shows a `String` return type in the UML. Note that operations `setCourseName` and `displayMessage` do not return values (i.e., they return `void` in Java), so the UML class diagram does not specify a return type after the parentheses of these operations.

**Fig. 3.9** | UML class diagram indicating that class `GradeBook` has a `courseName` attribute of UML type `String` and three operations—`setCourseName` (with a `name` parameter of UML type `String`), `getCourseName` (which returns UML type `String`) and `displayMessage`.

### 3.6 Primitive Types vs. Reference Types

Data types in Java are divided into two categories—**primitive types** and **reference types** (sometimes called **nonprimitive types**). The primitive types are `boolean`, `byte`, `char`, `short`, `int`, `long`, `float` and `double`. All nonprimitive types are reference types, so classes, which specify the types of objects, are reference types.

A primitive-type variable can store exactly one value of its declared type at a time. For example, an `int` variable can store one whole number (such as 7) at a time. When another value is assigned to that variable, its initial value is replaced. Primitive-type instance variables are initialized by default—variables of types `byte`, `char`, `short`, `int`, `long`, `float` and `double` are initialized to 0, and variables of type `boolean` are initialized to `false`. You can specify your own initial values for primitive-type variables. Recall that local variables are *not* initialized by default.

**100** Chapter 3 Introduction to Classes and Objects**Error-Prevention Tip 3.1**

*Any attempt to use a local variable that has not been initialized results in a compilation error.*

Programs use variables of reference types (normally called **references**) to store the locations of objects in the computer’s memory. Such a variable is said to **refer to an object** in the program. Objects that are referenced may each contain many instance variables and methods. Line 14 of Fig. 3.8 creates an object of class GradeBook, and the variable myGradeBook contains a reference to that GradeBook object. Reference-type instance variables are initialized by default to the value `null`—a reserved word that represents a “reference to nothing.” This is why the first call to `getCourseName` in line 18 of Fig. 3.8 returned `null`—the value of `courseName` had not been set, so the default initial value `null` was returned. The complete list of reserved words and keywords is listed in Appendix C, **Keywords and Reserved Words**.

A reference to an object is required to **invoke** (i.e., call) the object’s methods. In the application of Fig. 3.8, the statements in method `main` use the variable `myGradeBook` to send messages to the `GradeBook` object. These messages are calls to methods (like `setCourseName` and `getCourseName`) that enable the program to interact with the `GradeBook` object. For example, the statement in line 23 uses `myGradeBook` to send the `setCourseName` message to the `GradeBook` object. The message includes the argument that `setCourseName` requires to perform its task. The `GradeBook` object uses this information to set the `courseName` instance variable. Note that primitive-type variables do not refer to objects, so such variables cannot be used to invoke methods.

**Software Engineering Observation 3.4**

*A variable’s declared type (e.g., `int`, `double` or `GradeBook`) indicates whether the variable is of a primitive or a reference type. If a variable’s type is not one of the eight primitive types, then it is a reference type. For example, `Account account1` indicates that `account1` is a reference to an `Account` object).*

**3.7 Initializing Objects with Constructors**

As mentioned in Section 3.5, when an object of class `GradeBook` (Fig. 3.7) is created, its instance variable `courseName` is initialized to `null` by default. What if you want to provide a course name when you create a `GradeBook` object? Each class you declare can provide a constructor that can be used to initialize an object of a class when the object is created. In fact, Java requires a constructor call for every object that is created. Keyword `new` calls the class’s constructor to perform the initialization. The constructor call is indicated by the class name followed by parentheses—the constructor *must* have the same name as the class. For example, line 14 of Fig. 3.8 first uses `new` to create a `GradeBook` object. The empty parentheses after “`new GradeBook`” indicate a call to the class’s constructor without arguments. By default, the compiler provides a **default constructor** with no parameters in any class that does not explicitly include a constructor. When a class has only the default constructor, its instance variables are initialized to their default values. Variables of types `char`, `byte`, `short`, `int`, `long`, `float` and `double` are initialized to 0, variables of type `boolean` are initialized to `false`, and reference-type variables are initialized to `null`.

3.7 Initializing Objects with Constructors 101

When you declare a class, you can provide your own constructor to specify custom initialization for objects of your class. For example, a programmer might want to specify a course name for a `GradeBook` object when the object is created, as in

```
GradeBook myGradeBook =
 new GradeBook("CS101 Introduction to Java Programming");
```

In this case, the argument "CS101 Introduction to Java Programming" is passed to the `GradeBook` object's constructor and used to initialize the `courseName`. The preceding statement requires that the class provide a constructor with a `String` parameter. Figure 3.10 contains a modified `GradeBook` class with such a constructor.

Lines 9–12 declare the constructor for class `GradeBook`. A constructor must have the same name as its class. Like a method, a constructor specifies in its parameter list the data it requires to perform its task. When you create a new object (as we will do in Fig. 3.11),

```
1 // Fig. 3.10: GradeBook.java
2 // GradeBook class with a constructor to initialize the course name.
3
4 public class GradeBook
5 {
6 private String courseName; // course name for this GradeBook
7
8 // constructor initializes courseName with String supplied as argument
9 public GradeBook(String name)
10 {
11 courseName = name; // initializes courseName
12 } // end constructor
13
14 // method to set the course name
15 public void setCourseName(String name)
16 {
17 courseName = name; // store the course name
18 } // end method setCourseName
19
20 // method to retrieve the course name
21 public String getCourseName()
22 {
23 return courseName;
24 } // end method getCourseName
25
26 // display a welcome message to the GradeBook user
27 public void displayMessage()
28 {
29 // this statement calls getCourseName to get the
30 // name of the course this GradeBook represents
31 System.out.printf("Welcome to the grade book for\n%s!\n",
32 getCourseName());
33 } // end method displayMessage
34
35 } // end class GradeBook
```

**Fig. 3.10** | GradeBook class with a constructor to initialize the course name.

**102** Chapter 3 Introduction to Classes and Objects

this data is placed in the parentheses that follow the class name. Line 9 indicates that class `GradeBook`'s constructor has a `String` parameter called `name`. The `name` passed to the constructor is assigned to instance variable `courseName` in line 11 of the constructor's body.

Figure 3.11 demonstrates initializing `GradeBook` objects using the constructor. Lines 11–12 create and initialize the `GradeBook` object `gradeBook1`. The constructor of class `GradeBook` is called with the argument "CS101 Introduction to Java Programming" to initialize the course name. The class instance creation expression to the right of the `=` in lines 11–12 returns a reference to the new object, which is assigned to the variable `gradeBook1`. Lines 13–14 repeat this process for another `GradeBook` object `gradeBook2`, this time passing the argument "CS102 Data Structures in Java" to initialize the course name for `gradeBook2`. Lines 17–20 use each object's `getCourseName` method to obtain the course names and show that they were indeed initialized when the objects were created. In the introduction to Section 3.5, you learned that each instance (i.e., object) of a class contains its own copy of the class's instance variables. The output confirms that each `GradeBook` maintains its own copy of instance variable `courseName`.

Like methods, constructors also can take arguments. However, an important difference between constructors and methods is that constructors cannot return values, so they cannot specify a return type (not even `void`). Normally, constructors are declared `public`. If a class does not include a constructor, the class's instance variables are initialized to their

```

1 // Fig. 3.11: GradeBookTest.java
2 // GradeBook constructor used to specify the course name at the
3 // time each GradeBook object is created.
4
5 public class GradeBookTest
6 {
7 // main method begins program execution
8 public static void main(String args[])
9 {
10 // create GradeBook object
11 GradeBook gradeBook1 = new GradeBook(
12 "CS101 Introduction to Java Programming");
13 GradeBook gradeBook2 = new GradeBook(
14 "CS102 Data Structures in Java");
15
16 // display initial value of courseName for each GradeBook
17 System.out.printf("gradeBook1 course name is: %s\n",
18 gradeBook1.getCourseName());
19 System.out.printf("gradeBook2 course name is: %s\n",
20 gradeBook2.getCourseName());
21 } // end main
22
23 } // end class GradeBookTest

```

```
gradeBook1 course name is: CS101 Introduction to Java Programming
gradeBook2 course name is: CS102 Data Structures in Java
```

**Fig. 3.11** | GradeBook constructor used to specify the course name at the time each GradeBook object is created.

3.8 Floating-Point Numbers and Type `double` 103

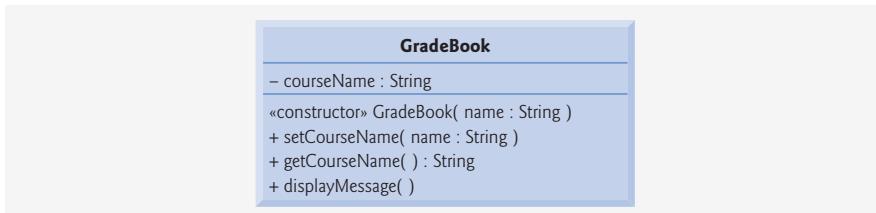

default values. If a programmer declares any constructors for a class, the Java compiler will not create a default constructor for that class.

**Error-Prevention Tip 3.2**

*Unless default initialization of your class's instance variables is acceptable, provide a constructor to ensure that your class's instance variables are properly initialized with meaningful values when each new object of your class is created.*

***Adding the Constructor to Class GradeBook's UML Class Diagram***

The UML class diagram of Fig. 3.12 models class `GradeBook` of Fig. 3.10, which has a constructor that has a `name` parameter of type `String`. Like operations, the UML models constructors in the third compartment of a class in a class diagram. To distinguish a constructor from a class's operations, the UML requires that the word "constructor" be placed between guillemets (« and ») before the constructor's name. It is customary to list constructors before other operations in the third compartment.

**Fig. 3.12** | UML class diagram indicating that class `GradeBook` has a constructor that has a `name` parameter of UML type `String`.

## 3.8 Floating-Point Numbers and Type `double`

In our next application, we depart temporarily from our `GradeBook` case study to declare a class called `Account` that maintains the balance of a bank account. Most account balances are not whole numbers (e.g., 0, -22 and 1024). For this reason, class `Account` represents the account balance as a **floating-point number** (i.e., a number with a decimal point, such as 7.33, 0.0975 or 1000.12345). Java provides two primitive types for storing floating-point numbers in memory—`float` and `double`. The primary difference between them is that `double` variables can store numbers with larger magnitude and finer detail (i.e., more digits to the right of the decimal point—also known as the number's **precision**) than `float` variables.

***Floating-Point Number Precision and Memory Requirements***

Variables of type `float` represent **single-precision floating-point numbers** and have seven significant digits. Variables of type `double` represent **double-precision floating-point numbers**. These require twice as much memory as `float` variables and provide 15 significant digits—approximately double the precision of `float` variables. For the range of values required by most programs, variables of type `float` should suffice, but you can use `double` to "play it safe." In some applications, even variables of type `double` will be inadequate—such applications are beyond the scope of this book. Most programmers repre-

## 104 Chapter 3 Introduction to Classes and Objects

sent floating-point numbers with type `double`. In fact, Java treats all floating-point numbers you type in a program's source code (such as 7.33 and 0.0975) as `double` values by default. Such values in the source code are known as [floating-point literals](#). See Appendix D, Primitive Types, for the ranges of values for `floats` and `doubles`.

Although floating-point numbers are not always 100% precise, they have numerous applications. For example, when we speak of a “normal” body temperature of 98.6, we do not need to be precise to a large number of digits. When we read the temperature on a thermometer as 98.6, it may actually be 98.5999473210643. Calling this number simply 98.6 is fine for most applications involving body temperatures. Due to the imprecise nature of floating-point numbers, type `double` is preferred over type `float` because `double` variables can represent floating-point numbers more accurately. For this reason, we use type `double` throughout the book.

Floating-point numbers also arise as a result of division. In conventional arithmetic, when we divide 10 by 3, the result is 3.333333..., with the sequence of 3s repeating infinitely. The computer allocates only a fixed amount of space to hold such a value, so clearly the stored floating-point value can be only an approximation.

### Common Programming Error 3.4

*Using floating-point numbers in a manner that assumes they are represented precisely can lead to logic errors.*

#### **Account Class with an Instance Variable of Type `double`**

Our next application (Figs. 3.13–3.14) contains a class named `Account` (Fig. 3.13) that maintains the balance of a bank account. A typical bank services many accounts, each with its own balance, so line 7 declares an instance variable named `balance` of type `double`. Variable `balance` is an instance variable because it is declared in the body of the class but outside the class's method declarations (lines 10–16, 19–22 and 25–28). Every instance (i.e., object) of class `Account` contains its own copy of `balance`.

```

1 // Fig. 3.13: Account.java
2 // Account class with a constructor to
3 // initialize instance variable balance.
4
5 public class Account
6 {
7 private double balance; // instance variable that stores the balance
8
9 // constructor
10 public Account(double initialBalance)
11 {
12 // validate that initialBalance is greater than 0.0;
13 // if it is not, balance is initialized to the default value 0.0
14 if (initialBalance > 0.0)
15 balance = initialBalance;
16 } // end Account constructor
17

```

**Fig. 3.13 |** Account class with an instance variable of type `double`. (Part 1 of 2.)

3.8 Floating-Point Numbers and Type `double` 105

```

18 // credit (add) an amount to the account
19 public void credit(double amount)
20 {
21 balance = balance + amount; // add amount to balance
22 } // end method credit
23
24 // return the account balance
25 public double getBalance()
26 {
27 return balance; // gives the value of balance to the calling method
28 } // end method getBalance
29
30 } // end class Account

```

**Fig. 3.13** | Account class with an instance variable of type `double`. (Part 2 of 2.)

Class `Account` contains a constructor and two methods. Since it is common for someone opening an account to place money in the account immediately, the constructor (lines 10–16) receives a parameter `initialBalance` of type `double` that represents the account's starting balance. Lines 14–15 ensure that `initialBalance` is greater than 0.0. If so, `initialBalance`'s value is assigned to instance variable `balance`. Otherwise, `balance` remains at 0.0—its default initial value.

Method `credit` (lines 19–22) does not return any data when it completes its task, so its return type is `void`. The method receives one parameter named `amount`—a `double` value that will be added to the balance. Line 21 adds `amount` to the current value of `balance`, then assigns the result to `balance` (thus replacing the prior balance amount).

Method `getBalance` (lines 25–28) allows clients of the class (i.e., other classes that use this class) to obtain the value of a particular `Account` object's balance. The method specifies return type `double` and an empty parameter list.

Once again, note that the statements in lines 15, 21 and 27 use instance variable `balance` even though it was not declared in any of the methods. We can use `balance` in these methods because it is an instance variable of the class.

#### ***AccountTest Class to Use Class Account***

Class `AccountTest` (Fig. 3.14) creates two `Account` objects (lines 10–11) and initializes them with 50.00 and -7.53, respectively. Lines 14–17 output the balance in each `Account` by calling the `Account`'s `getBalance` method. When method `getBalance` is called for `account1` from line 15, the value of `account1`'s `balance` is returned from line 27 of Fig. 3.13 and displayed by the `System.out.printf` statement (Fig. 3.14, lines 14–15). Similarly, when method `getBalance` is called for `account2` from line 17, the value of the `account2`'s `balance` is returned from line 27 of Fig. 3.13 and displayed by the `System.out.printf` statement (Fig. 3.14, lines 16–17). Note that the balance of `account2` is 0.00 because the constructor ensured that the account could not begin with a negative balance. The value is output by `printf` with the format specifier `% .2f`. The format specifier `f` is used to output values of type `float` or `double`. The `.2` between `%` and `f` represents the number of decimal places (2) that should be output to the right of the decimal point in the floating-point number—also known as the number's `precision`. Any floating-point

**106** Chapter 3 Introduction to Classes and Objects

value output with `%.2f` will be rounded to the hundredths position—for example, 123.457 would be rounded to 123.46, and 27.333 would be rounded to 27.33.

```

1 // Fig. 3.14: AccountTest.java
2 // Inputting and outputting floating-point numbers with Account objects.
3 import java.util.Scanner;
4
5 public class AccountTest
6 {
7 // main method begins execution of Java application
8 public static void main(String args[])
9 {
10 Account account1 = new Account(50.00); // create Account object
11 Account account2 = new Account(-7.53); // create Account object
12
13 // display initial balance of each object
14 System.out.printf("account1 balance: $%.2f\n",
15 account1.getBalance());
16 System.out.printf("account2 balance: $%.2f\n\n",
17 account2.getBalance());
18
19 // create Scanner to obtain input from command window
20 Scanner input = new Scanner(System.in);
21 double depositAmount; // deposit amount read from user
22
23 System.out.print("Enter deposit amount for account1: "); // prompt
24 depositAmount = input.nextDouble(); // obtain user input
25 System.out.printf("\nadding %.2f to account1 balance\n\n",
26 depositAmount);
27 account1.credit(depositAmount); // add to account1 balance
28
29 // display balances
30 System.out.printf("account1 balance: $%.2f\n",
31 account1.getBalance());
32 System.out.printf("account2 balance: $%.2f\n\n",
33 account2.getBalance());
34
35 System.out.print("Enter deposit amount for account2: "); // prompt
36 depositAmount = input.nextDouble(); // obtain user input
37 System.out.printf("\nadding %.2f to account2 balance\n\n",
38 depositAmount);
39 account2.credit(depositAmount); // add to account2 balance
40
41 // display balances
42 System.out.printf("account1 balance: $%.2f\n",
43 account1.getBalance());
44 System.out.printf("account2 balance: $%.2f\n",
45 account2.getBalance());
46 } // end main
47
48 } // end class AccountTest

```

**Fig. 3.14** | Inputting and outputting floating-point numbers with `Account` objects. (Part I of 2.)

3.8 Floating-Point Numbers and Type `double` **107**

```

account1 balance: $50.00
account2 balance: $0.00

Enter deposit amount for account1: 25.53
adding 25.53 to account1 balance

account1 balance: $75.53
account2 balance: $0.00

Enter deposit amount for account2: 123.45
adding 123.45 to account2 balance

account1 balance: $75.53
account2 balance: $123.45

```

**Fig. 3.14** | Inputting and outputting floating-point numbers with `Account` objects. (Part 2 of 2.)

Line 20 creates a `Scanner` that will be used to obtain deposit amounts from a user. Line 21 declares local variable `depositAmount` to store each deposit amount entered by the user. Unlike the instance variable `balance` in class `Account`, local variable `depositAmount` in `main` is not initialized to 0.0 by default. However, this variable does not need to be initialized here because its value will be determined by the user's input.

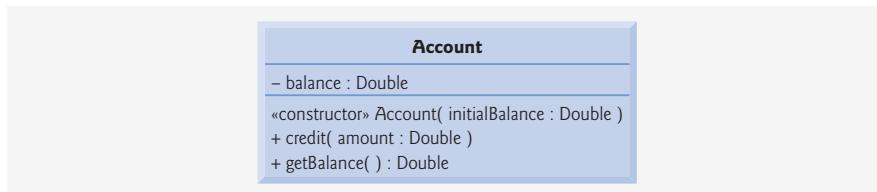

Line 23 prompts the user to enter a deposit amount for `account1`. Line 24 obtains the input from the user by calling `Scanner` object `input`'s `nextDouble` method, which returns a `double` value entered by the user. Lines 25–26 display the deposit amount. Line 27 calls object `account1`'s `credit` method and supplies `depositAmount` as the method's argument. When the method is called, the argument's value is assigned to parameter `amount` (line 19 of Fig. 3.13) of method `credit` (lines 19–22 of Fig. 3.13), then method `credit` adds that value to the `balance` (line 21 of Fig. 3.13). Lines 30–33 (Fig. 3.14) output the balances of both `Accounts` again to show that only `account1`'s balance changed.

Line 35 prompts the user to enter a deposit amount for `account2`. Line 36 obtains the input from the user by calling `Scanner` object `input`'s `nextDouble` method. Lines 37–38 display the deposit amount. Line 39 calls object `account2`'s `credit` method and supplies `depositAmount` as the method's argument, then method `credit` adds that value to the `balance`. Finally, lines 42–45 output the balances of both `Accounts` again to show that only `account2`'s balance changed.

#### *UML Class Diagram for Class Account*

The UML class diagram in Fig. 3.15 models class `Account` of Fig. 3.13. The diagram models the `private` attribute `balance` with UML type `Double` to correspond to the class's instance variable `balance` of Java type `double`. The diagram models class `Account`'s constructor with a parameter `initialBalance` of UML type `Double` in the third compartment of the class. The class's two `public` methods are modeled as operations in the third compartment as well. The diagram models operation `credit` with an `amount` parameter of UML type `Double` (because the corresponding method has an `amount` parameter of Java type `double`) and operation `getBalance` with a return type of `Double` (because the corresponding Java method returns a `double` value).

## 108 Chapter 3 Introduction to Classes and Objects

**Fig. 3.15** | UML class diagram indicating that class `Account` has a `private balance` attribute of UML type `Double`, a constructor (with a parameter of UML type `Double`) and two `public` operations—`credit` (with an `amount` parameter of UML type `Double`) and `getBalance` (returns UML type `Double`).

### 3.9 (Optional) GUI and Graphics Case Study: Using Dialog Boxes

This optional case study is designed for those who want to begin learning Java's powerful capabilities for creating graphical user interfaces (GUIs) and graphics earlier in the book than the main discussions of these topics in Chapter 11, GUI Components: Part 1, Chapter 12, Graphics and Java 2D™, and Chapter 22, GUI Components: Part 2.

The GUI and Graphics Case Study appears in 10 brief sections (Fig. 3.16). Each section introduces a few basic concepts and provides visual, graphical examples. In the first few sections, you create your first graphical applications. In the subsequent sections, you use the object-oriented programming concepts presented through Chapter 10 to create a drawing application that draws a variety of shapes. When we formally introduce GUIs in Chapter 11, we use the mouse to choose exactly which shapes to draw and where to draw them. In Chapter 12, we add capabilities of the Java 2D graphics API to draw the shapes with different line thicknesses and fills. We hope you find this case study informative and entertaining.

| Location       | Title—Exercise(s)                                                     |
|----------------|-----------------------------------------------------------------------|
| Section 3.9    | Using Dialog Boxes—Basic input and output with dialog boxes           |
| Section 4.14   | Creating Simple Drawings—Displaying and drawing lines on the screen   |
| Section 5.10   | Drawing Rectangles and Ovals—Using shapes to represent data           |
| Section 6.13   | Colors and Filled Shapes—Drawing a bull's-eye and random graphics     |
| Section 7.13   | Drawing Arcs—Drawing spirals with arcs                                |
| Section 8.18   | Using Objects with Graphics—Storing shapes as objects                 |
| Section 9.8    | Displaying Text and Images Using Labels—Providing status information  |
| Section 10.8   | Drawing with Polymorphism—Identifying the similarities between shapes |
| Exercise 11.18 | Expanding the Interface—Using GUI components and event handling       |
| Exercise 12.31 | Adding Java 2D—Using the Java 2D API to enhance drawings              |

**Fig. 3.16** | Summary of the GUI and Graphics Case Study in each chapter.

### 3.9 (Optional) GUI and Graphics Case Study: Using Dialog Boxes 109

#### *Displaying Text in a Dialog Box*

The programs presented thus far display output in the command window. Many applications use windows or **dialog boxes** (also called **dialogs**) to display output. For example, web browsers such as Firefox or Microsoft Internet Explorer display web pages in their own windows. E-mail programs allow you to type and read messages in a window. Typically, dialog boxes are windows in which programs display important messages to users. Class **JOptionPane** provides prepackaged dialog boxes that enable programs to display windows containing messages—such windows are called **message dialogs**. Figure 3.17 displays the String "Welcome\n to\n Java" in a message dialog.

Line 3 indicates that the program uses class **JOptionPane** from package **javax.swing**. This package contains many classes that help you create **graphical user interfaces (GUIs)** for applications. **GUI components** facilitate data entry by a program's user, and presenting data outputs to the user. Line 10 calls **JOptionPane** method **showMessageDialog** to display a dialog box containing a message. The method requires two arguments. The first argument helps the Java application determine where to position the dialog box. When the first argument is **null**, the dialog box appears in the center of the computer screen. The second argument is the **String** to display in the dialog box.

Method **showMessageDialog** is **static method** of class **JOptionPane**. **static** methods often define frequently used tasks that do not explicitly require creating an object. For example, many programs display dialog boxes. Rather than require you to create code that performs this task, the designers of Java's **JOptionPane** class declared a **static** method that performs this task for you. A **static** method typically is called by using its class name followed by a dot (.) and the method name, as in

```
ClassName.methodName(arguments)
```

Chapter 6, Methods: A Deeper Look, discusses **static** methods in detail.

```

1 // Fig. 3.17: Dialog1.java
2 // Printing multiple lines in dialog box.
3 import javax.swing.JOptionPane; // import class JOptionPane
4
5 public class Dialog1
6 {
7 public static void main(String args[])
8 {
9 // display a dialog with a message
10 JOptionPane.showMessageDialog(null, "Welcome\n to\n Java");
11 } // end main
12 } // end class Dialog1

```

**Fig. 3.17** | Using **JOptionPane** to display multiple lines in a dialog box.

**110** Chapter 3 Introduction to Classes and Objects***Entering Text in a Dialog Box***

The application of Fig. 3.18 uses another predefined `JOptionPane` dialog box called an **input dialog** that allows the user to enter data into the program. The program asks for the user's name, and responds with a message dialog containing a greeting and the name entered by the user.

Lines 10–11 use `JOptionPane` method `showInputDialog` to display an input dialog containing a prompt and a field (known as a **text field**) in which the user can enter text. Method `showInputDialog`'s argument is the prompt that indicates what the user should enter. The user types characters in the text field, then clicks the **OK** button or presses the *Enter* key to return the `String` to the program. Method `showInputDialog` (line 11) returns a `String` containing the characters typed by the user. We store the `String` in variable `name` (line 10). [Note: If you press the **Cancel** button in the dialog, the method returns `null` and the program displays the word "null" as the name.]

Lines 14–15 use static `String` method `format` to return a `String` containing a greeting with the user's name. Method `format` is similar to method `System.out.printf`, except that `format` returns the formatted `String` rather than displaying it in a command window. Line 18 displays the greeting in a message dialog.

```

1 // Fig. 3.18: NameDialog.java
2 // Basic input with a dialog box.
3 import javax.swing.JOptionPane;
4
5 public class NameDialog
6 {
7 public static void main(String args[])
8 {
9 // prompt user to enter name
10 String name =
11 JOptionPane.showInputDialog("What is your name?");
12
13 // create the message
14 String message =
15 String.format("Welcome, %s, to Java Programming!", name);
16
17 // display the message to welcome the user by name
18 JOptionPane.showMessageDialog(null, message);
19 } // end main
20 } // end class NameDialog

```

**Fig. 3.18** | Obtaining user input from a dialog.

### 3.10 Identifying the Classes in a Requirements Document III

#### *GUI and Graphics Case Study Exercise*

**3.1** Modify the addition program in Fig. 2.7 to use dialog-based input and output with the methods of class `JOptionPane`. Since method `showInputDialog` returns a `String`, you must convert the `String` the user enters to an `int` for use in calculations. The method

```
Integer.parseInt(String s)
```

takes a `String` argument representing an integer (e.g., the result of `JOptionPane.showInputDialog`) and returns the value as an `int`. Method `parseInt` is a static method of class `Integer` (from package `java.lang`). Note that if the `String` does not contain a valid integer, the program will terminate with an error.

## 3.10 (Optional) Software Engineering Case Study: Identifying the Classes in a Requirements Document

Now we begin designing the ATM system that we introduced in Chapter 2. In this section, we identify the classes that are needed to build the ATM system by analyzing the nouns and noun phrases that appear in the requirements document. We introduce UML class diagrams to model the relationships between these classes. This is an important first step in defining the structure of our system.

#### *Identifying the Classes in a System*

We begin our OOD process by identifying the classes required to build the ATM system. We will eventually describe these classes using UML class diagrams and implement these classes in Java. First, we review the requirements document of Section 2.9 and identify key nouns and noun phrases to help us identify classes that comprise the ATM system. We may decide that some of these nouns and noun phrases are attributes of other classes in the system. We may also conclude that some of the nouns do not correspond to parts of the system and thus should not be modeled at all. Additional classes may become apparent to us as we proceed through the design process.

Figure 3.19 lists the nouns and noun phrases found in the requirements document of Section 2.9. We list them from left to right in the order in which we first encounter them in the requirements document. We list only the singular form of each noun or noun phrase.

| Nouns and noun phrases in the ATM requirements document |                  |                 |
|---------------------------------------------------------|------------------|-----------------|
| bank                                                    | money / funds    | account number  |
| ATM                                                     | screen           | PIN             |
| user                                                    | keypad           | bank database   |
| customer                                                | cash dispenser   | balance inquiry |
| transaction                                             | \$20 bill / cash | withdrawal      |
| account                                                 | deposit slot     | deposit         |
| balance                                                 | deposit envelope |                 |

**Fig. 3.19** | Nouns and noun phrases in the ATM requirements document.

## 112 Chapter 3 Introduction to Classes and Objects

We create classes only for the nouns and noun phrases that have significance in the ATM system. We don't model "bank" as a class, because the bank is not a part of the ATM system—the bank simply wants us to build the ATM. "Customer" and "user" also represent outside entities—they are important because they interact with our ATM system, but we do not need to model them as classes in the ATM software. Recall that we modeled an ATM user (i.e., a bank customer) as the actor in the use case diagram of Fig. 2.20.

We do not model "\$20 bill" or "deposit envelope" as classes. These are physical objects in the real world, but they are not part of what is being automated. We can adequately represent the presence of bills in the system using an attribute of the class that models the cash dispenser. (We assign attributes to the ATM system's classes in Section 4.15.) For example, the cash dispenser maintains a count of the number of bills it contains. The requirements document does not say anything about what the system should do with deposit envelopes after it receives them. We can assume that simply acknowledging the receipt of an envelope—an operation performed by the class that models the deposit slot—is sufficient to represent the presence of an envelope in the system. (We assign operations to the ATM system's classes in Section 6.14.)

In our simplified ATM system, representing various amounts of "money," including an account's "balance," as attributes of classes seems most appropriate. Likewise, the nouns "account number" and "PIN" represent significant pieces of information in the ATM system. They are important attributes of a bank account. They do not, however, exhibit behaviors. Thus, we can most appropriately model them as attributes of an account class.

Though the requirements document frequently describes a "transaction" in a general sense, we do not model the broad notion of a financial transaction at this time. Instead, we model the three types of transactions (i.e., "balance inquiry," "withdrawal" and "deposit") as individual classes. These classes possess specific attributes needed for executing the transactions they represent. For example, a withdrawal needs to know the amount of money the user wants to withdraw. A balance inquiry, however, does not require any additional data. Furthermore, the three transaction classes exhibit unique behaviors. A withdrawal includes dispensing cash to the user, whereas a deposit involves receiving deposit envelopes from the user. [Note: In Section 10.9, we "factor out" common features of all transactions into a general "transaction" class using the object-oriented concept of inheritance.]

We determine the classes for our system based on the remaining nouns and noun phrases from Fig. 3.19. Each of these refers to one or more of the following:

- ATM
- screen
- keypad
- cash dispenser
- deposit slot
- account
- bank database
- balance inquiry
- withdrawal
- deposit

The elements of this list are likely to be classes we will need to implement our system.

3.10 Identifying the Classes in a Requirements Document **113**

We can now model the classes in our system based on the list we've created. We capitalize class names in the design process—a UML convention—as we'll do when we write the actual Java code that implements our design. If the name of a class contains more than one word, we run the words together and capitalize each word (e.g., `MultipleWordName`). Using this convention, we create classes `ATM`, `Screen`, `Keypad`, `CashDispenser`, `DepositSlot`, `Account`, `BankDatabase`, `BalanceInquiry`, `Withdrawal` and `Deposit`. We construct our system using these classes as building blocks. Before we begin building the system, however, we must gain a better understanding of how the classes relate to one another.

#### *Modeling Classes*

The UML enables us to model, via [class diagrams](#), the classes in the ATM system and their interrelationships. Figure 3.20 represents class `ATM`. In the UML, each class is modeled as a rectangle with three compartments. The top compartment contains the name of the class centered horizontally in boldface. The middle compartment contains the class's attributes. (We discuss attributes in Section 4.15 and Section 5.11.) The bottom compartment contains the class's operations (discussed in Section 6.14). In Fig. 3.20, the middle and bottom compartments are empty because we have not yet determined this class's attributes and operations.

Class diagrams also show the relationships between the classes of the system. Figure 3.21 shows how our classes `ATM` and `Withdrawal` relate to one another. For the moment, we choose to model only this subset of classes for simplicity. We present a more complete class diagram later in this section. Notice that the rectangles representing classes in this diagram are not subdivided into compartments. The UML allows the suppression of class attributes and operations in this manner to create more readable diagrams, when appropriate. Such a diagram is said to be an [elided diagram](#)—one in which some information, such as the contents of the second and third compartments, is not modeled. We will place information in these compartments in Section 4.15 and Section 6.14.

In Fig. 3.21, the solid line that connects the two classes represents an [association](#)—a relationship between classes. The numbers near each end of the line are [multiplicity](#) values, which indicate how many objects of each class participate in the association. In this case, following the line from one end to the other reveals that, at any given moment, one `ATM` object participates in an association with either zero or one `Withdrawal` objects—zero if the current user is not currently performing a transaction or has requested a different type of transaction, and one if the user has requested a withdrawal. The UML can model many types of multiplicity. Figure 3.22 lists and explains the multiplicity types.

An association can be named. For example, the word `Executes` above the line connecting classes `ATM` and `Withdrawal` in Fig. 3.21 indicates the name of that association. This part of the diagram reads “one object of class `ATM` executes zero or one objects of class

**Fig. 3.20** | Representing a class in the UML using a class diagram.

## 114 Chapter 3 Introduction to Classes and Objects

**Fig. 3.21** | Class diagram showing an association among classes.

| Symbol | Meaning                                 |
|--------|-----------------------------------------|
| 0      | None                                    |
| 1      | One                                     |
| $m$    | An integer value                        |
| 0..1   | Zero or one                             |
| $m, n$ | $m$ or $n$                              |
| $m..n$ | At least $m$ , but not more than $n$    |
| *      | Any non-negative integer (zero or more) |
| 0..*   | Zero or more (identical to *)           |
| 1..*   | One or more                             |

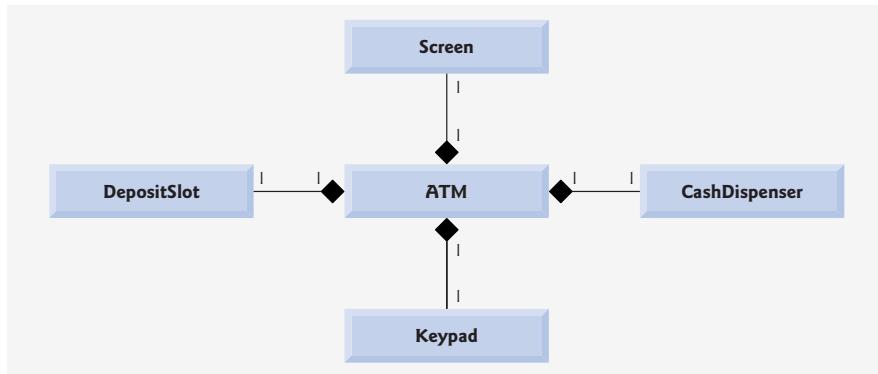

**Fig. 3.22** | Multiplicity types.

Withdrawal.” Note that association names are directional, as indicated by the filled arrowhead—so it would be improper, for example, to read the preceding association from right to left as “zero or one objects of class Withdrawal execute one object of class ATM.”

The word `currentTransaction` at the `Withdrawal` end of the association line in Fig. 3.21 is a **role name**, which identifies the role the `Withdrawal` object plays in its relationship with the `ATM`. A role name adds meaning to an association between classes by identifying the role a class plays in the context of an association. A class can play several roles in the same system. For example, in a school personnel system, a person may play the role of “professor” when relating to students. The same person may take on the role of “colleague” when participating in an association with another professor, and “coach” when coaching student athletes. In Fig. 3.21, the role name `currentTransaction` indicates that the `Withdrawal` object participating in the `Executes` association with an object of class `ATM` represents the transaction currently being processed by the `ATM`. In other contexts, a `Withdrawal` object may take on other roles (e.g., the previous transaction). Notice that we do not specify a role name for the `ATM` end of the `Executes` association. Role names in class diagrams are often omitted when the meaning of an association is clear without them.

In addition to indicating simple relationships, associations can specify more complex relationships, such as objects of one class being composed of objects of other classes. Consider a real-world automated teller machine. What “pieces” does a manufacturer put together to build a working `ATM`? Our requirements document tells us that the `ATM` is composed of a screen, a keypad, a cash dispenser and a deposit slot.

In Fig. 3.23, the **solid diamonds** attached to the association lines of class `ATM` indicate that class `ATM` has a **composition** relationship with classes `Screen`, `Keypad`, `CashDispenser`

3.10 Identifying the Classes in a Requirements Document **115**

**Fig. 3.23** | Class diagram showing composition relationships.

and `DepositSlot`. Composition implies a whole/part relationship. The class that has the composition symbol (the solid diamond) on its end of the association line is the whole (in this case, `ATM`), and the classes on the other end of the association lines are the parts—in this case, classes `Screen`, `Keypad`, `CashDispenser` and `DepositSlot`. The compositions in Fig. 3.23 indicate that an object of class `ATM` is formed from one object of class `Screen`, one object of class `CashDispenser`, one object of class `Keypad` and one object of class `DepositSlot`. The `ATM` “has-a” screen, a keypad, a cash dispenser and a deposit slot. The *has-a* relationship defines composition. (We will see in the Software Engineering Case Study section in Chapter 10 that the *is-a* relationship defines inheritance.)

According to the UML specification ([www.uml.org](http://www.uml.org)), composition relationships have the following properties:

1. Only one class in the relationship can represent the whole (i.e., the diamond can be placed on only one end of the association line). For example, either the screen is part of the `ATM` or the `ATM` is part of the screen, but the screen and the `ATM` cannot both represent the whole in the relationship.
2. The parts in the composition relationship exist only as long as the whole, and the whole is responsible for the creation and destruction of its parts. For example, the act of constructing an `ATM` includes manufacturing its parts. Also, if the `ATM` is destroyed, its screen, keypad, cash dispenser and deposit slot are also destroyed.
3. A part may belong to only one whole at a time, although the part may be removed and attached to another whole, which then assumes responsibility for the part.

The solid diamonds in our class diagrams indicate composition relationships that fulfill these three properties. If a *has-a* relationship does not satisfy one or more of these criteria, the UML specifies that hollow diamonds be attached to the ends of association lines to indicate *aggregation*—a weaker form of composition. For example, a personal computer and a computer monitor participate in an aggregation relationship—the computer “has-a” monitor, but the two parts can exist independently, and the same monitor can be attached to multiple computers at once, thus violating the second and third properties of composition.

## 116 Chapter 3 Introduction to Classes and Objects

Figure 3.24 shows a class diagram for the ATM system. This diagram models most of the classes that we identified earlier in this section, as well as the associations between them that we can infer from the requirements document. [Note: Classes `BalanceInquiry` and `Deposit` participate in associations similar to those of class `Withdrawal`, so we have chosen to omit them from this diagram to keep the diagram simple. In Chapter 10, we expand our class diagram to include all the classes in the ATM system.]

Figure 3.24 presents a graphical model of the structure of the ATM system. This class diagram includes classes `BankDatabase` and `Account`, and several associations that were not present in either Fig. 3.21 or Fig. 3.23. The class diagram shows that class `ATM` has a **one-to-one relationship** with class `BankDatabase`—one `ATM` object authenticates users against one `BankDatabase` object. In Fig. 3.24, we also model the fact that the bank’s database contains information about many accounts—one object of class `BankDatabase` participates in a composition relationship with zero or more objects of class `Account`. Recall from Fig. 3.22 that the multiplicity value `0..*` at the `Account` end of the association between class `BankDatabase` and class `Account` indicates that zero or more objects of class `Account` take part in the association. Class `BankDatabase` has a **one-to-many relationship** with class `Account`—the `BankDatabase` stores many `Accounts`. Similarly, class `Account` has a **many-to-one relationship** with class `BankDatabase`—there can be many `Accounts` stored in the `BankDatabase`. [Note: Recall from Fig. 3.22 that the multiplicity value `*` is identical to `0..*`. We include `0..*` in our class diagrams for clarity.]

Figure 3.24 also indicates that if the user is performing a withdrawal, “one object of class `Withdrawal` accesses/modifies an account balance through one object of class `BankDatabase`.” We could have created an association directly between class `Withdrawal` and class `Account`. The requirements document, however, states that the “ATM must interact with the bank’s account information database” to perform transactions. A bank account contains sensitive information, and systems engineers must always consider the security of personal data when designing a system. Thus, only the `BankDatabase` can access and manipulate an account directly. All other parts of the system must interact with the database to retrieve or update account information (e.g., an account balance).

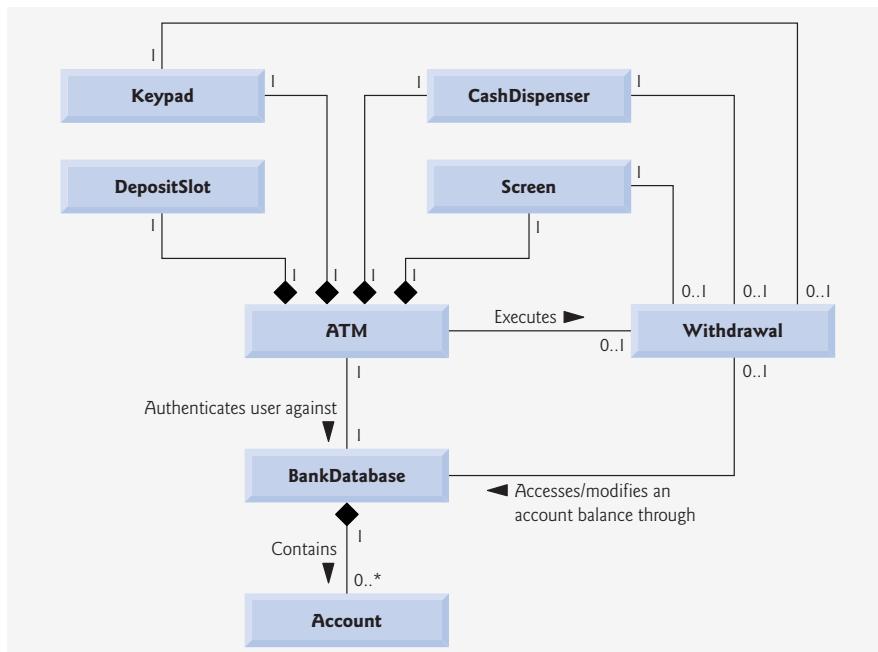

The class diagram in Fig. 3.24 also models associations between class `Withdrawal` and classes `Screen`, `CashDispenser` and `Keypad`. A withdrawal transaction includes prompting the user to choose a withdrawal amount and receiving numeric input. These actions require the use of the screen and the keypad, respectively. Furthermore, dispensing cash to the user requires access to the cash dispenser.

Classes `BalanceInquiry` and `Deposit`, though not shown in Fig. 3.24, take part in several associations with the other classes of the ATM system. Like class `Withdrawal`, each of these classes associates with classes `ATM` and `BankDatabase`. An object of class `BalanceInquiry` also associates with an object of class `Screen` to display the balance of an account to the user. Class `Deposit` associates with classes `Screen`, `Keypad` and `DepositSlot`. Like withdrawals, deposit transactions require use of the screen and the keypad to display prompts and receive input, respectively. To receive deposit envelopes, an object of class `Deposit` accesses the deposit slot.

We have now identified the classes in our ATM system (although we may discover others as we proceed with the design and implementation). In Section 4.15, we determine the attributes for each of these classes, and in Section 5.11, we use these attributes to examine how the system changes over time.

## 3.10 Identifying the Classes in a Requirements Document

117

**Fig. 3.24** | Class diagram for the ATM system model.

#### Software Engineering Case Study Self-Review Exercises

**3.1** Suppose we have a class `Car` that represents a car. Think of some of the different pieces that a manufacturer would put together to produce a whole car. Create a class diagram (similar to Fig. 3.23) that models some of the composition relationships of class `Car`.

**3.2** Suppose we have a class `File` that represents an electronic document in a standalone, non-networked computer represented by class `Computer`. What sort of association exists between class `Computer` and class `File`?

- Class `Computer` has a one-to-one relationship with class `File`.
- Class `Computer` has a many-to-one relationship with class `File`.
- Class `Computer` has a one-to-many relationship with class `File`.
- Class `Computer` has a many-to-many relationship with class `File`.

**3.3** State whether the following statement is *true* or *false*, and if *false*, explain why: A UML diagram in which a class's second and third compartments are not modeled is said to be an elided diagram.

**3.4** Modify the class diagram of Fig. 3.24 to include class `Deposit` instead of class `Withdrawal`.

#### Answers to Software Engineering Case Study Self-Review Exercises

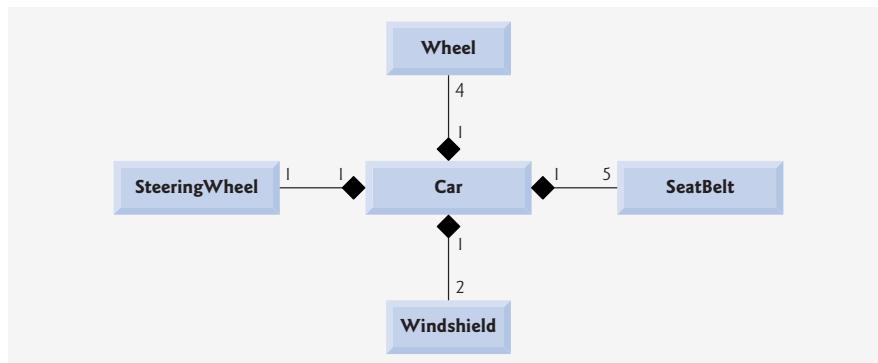

**3.1** [Note: Student answers may vary.] Figure 3.25 presents a class diagram that shows some of the composition relationships of a class `Car`.

**3.2** c. [Note: In a computer network, this relationship could be many-to-many.]

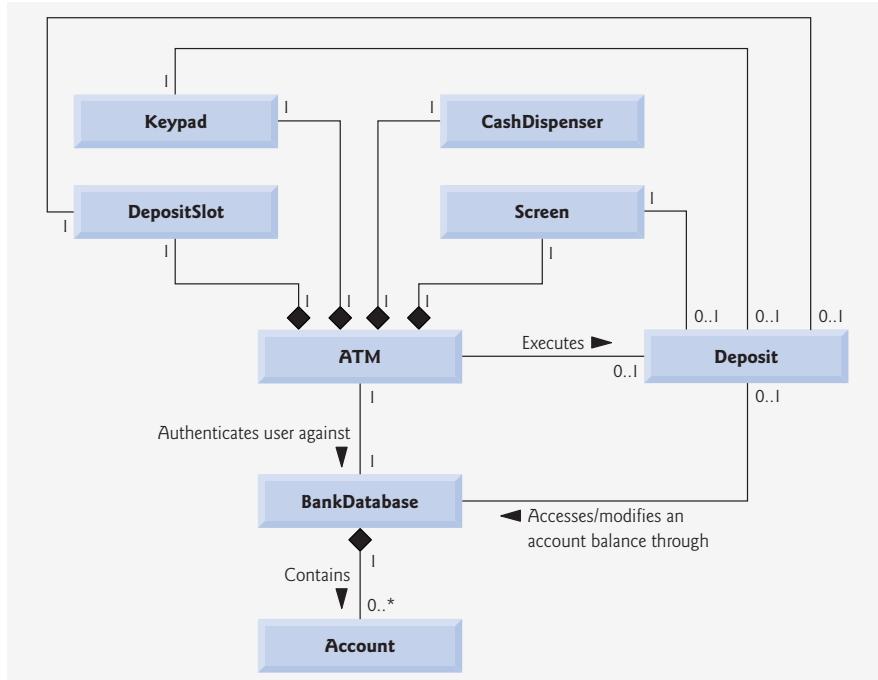

**118** Chapter 3 Introduction to Classes and Objects

**3.3** True.

**3.4** Figure 3.26 presents a class diagram for the ATM including class Deposit instead of class Withdrawal (as in Fig. 3.24). Note that Deposit does not access CashDispenser, but does access DepositSlot.

**Fig. 3.25** | Class diagram showing composition relationships of a class **Car**.

**Fig. 3.26** | Class diagram for the ATM system model including class **Deposit**.

### 3.11 Wrap-Up

In this chapter, you learned the basic concepts of classes, objects, methods and instance variables—these will be used in most Java applications you create. In particular, you learned how to declare instance variables of a class to maintain data for each object of the class, and how to declare methods that operate on that data. You learned how to call a method to tell it to perform its task and how to pass information to methods as arguments. You learned the difference between a local variable of a method and an instance variable of a class and that only instance variables are initialized automatically. You also learned how to use a class's constructor to specify the initial values for an object's instance variables. Throughout the chapter, you saw how the UML can be used to create class diagrams that model the constructors, methods and attributes of classes. Finally, you learned about floating-point numbers—how to store them with variables of primitive type `double`, how to input them with a `Scanner` object and how to format them with `printf` and format specifier `%f` for display purposes. In the next chapter we begin our introduction to control statements, which specify the order in which a program's actions are performed. You will use these in your methods to specify how they should perform their tasks.

### Summary

#### *Section 3.2 Classes, Objects, Methods and Instance Variables*

- Performing a task in a program requires a method. Inside the method you put the mechanisms that make the method do its tasks—that is, the method hides the implementation details of the tasks that it performs.
- The program unit that houses a method is called a class. A class may contain one or more methods that are designed to perform the class's tasks.
- A method can perform a task and return a result.
- A class can be used to create an instance of the class called an object. This is one of the reasons Java is known as an object-oriented programming language.
- Each message sent to an object is known as a method call and tells a method of the object to perform its task.
- Each method can specify parameters that represent additional information the method requires to perform its task correctly. A method call supplies values—called arguments—for the method's parameters.
- An object has attributes that are carried with the object as it is used in a program. These attributes are specified as part of the object's class. Attributes are specified in classes by fields.

#### *Section 3.3 Declaring a Class with a Method and Instantiating an Object of a Class*

- Each class declaration that begins with keyword `public` must be stored in a file that has exactly the same name as the class and ends with the `.java` file-name extension.
- Keyword `public` is an access modifier.
- Every class declaration contains keyword `class` followed immediately by the class's name.
- A method declaration that begins with keyword `public` indicates that the method is “available to the public”—that is, it can be called by other classes declared outside the class declaration.
- Keyword `void` indicates that a method will perform a task but will not return any information when it completes its task.

## 120 Chapter 3 Introduction to Classes and Objects

- By convention, method names begin with a lowercase first letter and all subsequent words in the name begin with a capital first letter.
- Empty parentheses following a method name indicate that the method does not require any parameters to perform its task.
- Every method's body is delimited by left and right braces ({ and }).
- The body of a method contains statements that perform the method's task. After the statements execute, the method has completed its task.
- When you attempt to execute a class, Java looks for the class's `main` method to begin execution.
- Any class that contains `public static void main(String args[])` can be used to execute an application.
- Typically, you cannot call a method that belongs to another class until you create an object of that class.
- Class instance creation expressions beginning with keyword `new` create new objects.
- To call a method of an object, follow the variable name with a dot separator (.), the method name and a set of parentheses containing the method's arguments.
- In the UML, each class is modeled in a class diagram as a rectangle with three compartments. The top compartment contains the name of the class centered horizontally in boldface. The middle compartment contains the class's attributes, which correspond to fields in Java. The bottom compartment contains the class's operations, which correspond to methods and constructors in Java.
- The UML models operations by listing the operation name followed by a set of parentheses. A plus sign (+) in front of the operation name indicates that the operation is a `public` operation in the UML (i.e., a `public` method in Java).

### *Section 3.4 Declaring a Method with a Parameter*

- Methods often require additional information to perform their tasks. Such additional information is provided to methods via arguments in method calls.
- Scanner method `nextLine` reads characters until a newline character is encountered, then returns the characters as a `String`.
- Scanner method `next` reads characters until any white-space character is encountered, then returns the characters as a `String`.
- A method that requires data to perform its task must specify this in its declaration by placing additional information in the method's parameter list.
- Each parameter must specify both a type and an identifier.
- At the time a method is called, its arguments are assigned to its parameters. Then the method body uses the parameter variables to access the argument values.
- A method can specify multiple parameters by separating each parameter from the next with a comma.
- The number of arguments in the method call must match the number of parameters in the method declaration's parameter list. Also, the argument types in the method call must be consistent with the types of the corresponding parameters in the method's declaration.
- Class `String` is in package `java.lang`, which is imported implicitly into all source-code files.
- There is a special relationship between classes that are compiled in the same directory on disk. By default, such classes are considered to be in the same package—known as the default package. Classes in the same package are implicitly imported into the source code files of other classes in

[Summary](#) **121**

the same package. Thus, an `import` declaration is not required when one class in a package uses another in the same package.

- An `import` declaration is not required if you always refer to a class with its fully qualified class name.
- The UML models a parameter of an operation by listing the parameter name, followed by a colon and the parameter type between the parentheses following the operation name.
- The UML has its own data types similar to those of Java. Not all the UML data types have the same names as the corresponding Java types.
- The UML type `String` corresponds to the Java type `String`.

### **Section 3.5 Instance Variables, set Methods and get Methods**

- Variables declared in the body of a particular method are known as local variables and can be used only in that method.
- A class normally consists of one or more methods that manipulate the attributes (data) that belong to a particular object of the class. Attributes are represented as fields in a class declaration. Such variables are called fields and are declared inside a class declaration but outside the bodies of the class's method declarations.
- When each object of a class maintains its own copy of an attribute, the field that represents the attribute is also known as an instance variable. Each object (instance) of the class has a separate instance of the variable in memory.
- Most instance variable declarations are preceded with the `private` access modifier. Variables or methods declared with access modifier `private` are accessible only to methods of the class in which they are declared.
- Declaring instance variables with access modifier `private` is known as data hiding.
- A benefit of fields is that all the methods of the class can use the fields. Another distinction between a field and a local variable is that a field has a default initial value provided by Java when the programmer does not specify the field's initial value, but a local variable does not.
- The default value for a field of type `String` is `null`.
- When a method that specifies a return type is called and completes its task, the method returns a result to its calling method.
- Classes often provide `public` methods to allow clients of the class to *set* or *get* private instance variables. The names of these methods need not begin with `set` or `get`, but this naming convention is highly recommended in Java and is required for special Java software components called JavaBeans.
- The UML represents instance variables as attributes by listing the attribute name, followed by a colon and the attribute type.
- Private attributes are preceded by a minus sign (-) in the UML.
- The UML indicates the return type of an operation by placing a colon and the return type after the parentheses following the operation name.
- UML class diagrams do not specify return types for operations that do not return values.

### **Section 3.6 Primitive Types vs. Reference Types**

- Types in Java are divided into two categories—primitive types and reference types (sometimes called nonprimitive types). The primitive types are `boolean`, `byte`, `char`, `short`, `int`, `long`, `float` and `double`. All other types are reference types, so classes, which specify the types of objects, are reference types.

## 122 Chapter 3 Introduction to Classes and Objects

- A primitive-type variable can store exactly one value of its declared type at a time.
- Primitive-type instance variables are initialized by default. Variables of types `byte`, `char`, `short`, `int`, `long`, `float` and `double` are initialized to 0. Variables of type `boolean` are initialized to `false`.
- Programs use variables of reference types (called references) to store the location of an object in the computer's memory. Such variables refer to objects in the program. The object that is referenced may contain many instance variables and methods.
- Reference-type fields are initialized by default to the value `null`.
- A reference to an object is required to invoke an object's instance methods. A primitive-type variable does not refer to an object and therefore cannot be used to invoke a method.

### *Section 3.7 Initializing Objects with Constructors*

- A constructor can be used to initialize an object of a class when the object is created.
- Constructors can specify parameters but cannot specify return types.
- If no constructor is provided for a class, the compiler provides a default constructor with no parameters.
- When a class has only the default constructor, its instance variables are initialized to their default values. Variables of types `char`, `byte`, `short`, `int`, `long`, `float` and `double` are initialized to 0, variables of type `boolean` are initialized to `false`, and reference-type variables are initialized to `null`.
- Like operations, the UML models constructors in the third compartment of a class diagram. To distinguish a constructor from a class's operations, the UML places the word "constructor" between guillemets (« and ») before the constructor's name.

### *Section 3.8 Floating-Point Numbers and Type `double`*

- A floating-point number is a number with a decimal point, such as 7.33, 0.0975 or 1000.12345. Java provides two primitive types for storing floating-point numbers in memory—`float` and `double`. The primary difference between these types is that `double` variables can store numbers with larger magnitude and finer detail (known as the number's precision) than `float` variables.
- Variables of type `float` represent single-precision floating-point numbers and have seven significant digits. Variables of type `double` represent double-precision floating-point numbers. These require twice as much memory as `float` variables and provide 15 significant digits—approximately double the precision of `float` variables.
- Floating-point values that appear in source code are known as floating-point literals and are type `double` by default.
- Scanner method `nextDouble` returns a `double` value.
- The format specifier `%f` is used to output values of type `float` or `double`. A precision can be specified between `%` and `f` to represent the number of decimal places that should be output to the right of the decimal point in the floating-point number.
- The default value for a field of type `double` is 0.0, and the default value for a field of type `int` is 0.

## Terminology

|                                  |                                      |
|----------------------------------|--------------------------------------|
| <code>%f</code> format specifier | class declaration                    |
| access modifier                  | class instance                       |
| aggregation (UML)                | <code>class</code> keyword           |
| attribute (UML)                  | class instance creation expression   |
| calling method                   | client of an object or a class       |

**Self-Review Exercises**

- 3.1** Fill in the blanks in each of the following:
- A house is to a blueprint as a(n) \_\_\_\_\_ is to a class.
  - Each class declaration that begins with keyword \_\_\_\_\_ must be stored in a file that has exactly the same name as the class and ends with the .java file-name extension.
  - Every class declaration contains keyword \_\_\_\_\_ followed immediately by the class's name.
  - Keyword \_\_\_\_\_ creates an object of the class specified to the right of the keyword.
  - Each parameter must specify both a(n) \_\_\_\_\_ and a(n) \_\_\_\_\_.
  - By default, classes that are compiled in the same directory are considered to be in the same package, known as the \_\_\_\_\_.
  - When each object of a class maintains its own copy of an attribute, the field that represents the attribute is also known as a(n) \_\_\_\_\_.

**124 Chapter 3 Introduction to Classes and Objects**

- h) Java provides two primitive types for storing floating-point numbers in memory: \_\_\_\_\_ and \_\_\_\_\_.
- i) Variables of type `double` represent \_\_\_\_\_ floating-point numbers.
- j) Scanner method \_\_\_\_\_ returns a `double` value.
- k) Keyword `public` is a(n) \_\_\_\_\_.
- l) Return type \_\_\_\_\_ indicates that a method will perform a task but will not return any information when it completes its task.
- m) Scanner method \_\_\_\_\_ reads characters until a newline character is encountered, then returns those characters as a `String`.
- n) Class `String` is in package \_\_\_\_\_.
- o) A(n) \_\_\_\_\_ is not required if you always refer to a class with its fully qualified class name.
- p) A(n) \_\_\_\_\_ is a number with a decimal point, such as 7.33, 0.0975 or 1000.12345.
- q) Variables of type `float` represent \_\_\_\_\_ floating-point numbers.
- r) The format specifier \_\_\_\_\_ is used to output values of type `float` or `double`.
- s) Types in Java are divided into two categories—\_\_\_\_\_ types and \_\_\_\_\_ types.

**3.2**

- State whether each of the following is *true* or *false*. If *false*, explain why.
- a) By convention, method names begin with an uppercase first letter and all subsequent words in the name begin with a capital first letter.
  - b) An `import` declaration is not required when one class in a package uses another in the same package.
  - c) Empty parentheses following a method name in a method declaration indicate that the method does not require any parameters to perform its task.
  - d) Variables or methods declared with access modifier `private` are accessible only to methods of the class in which they are declared.
  - e) A primitive-type variable can be used to invoke a method.
  - f) Variables declared in the body of a particular method are known as instance variables and can be used in all methods of the class.
  - g) Every method's body is delimited by left and right braces (`{` and `}`).
  - h) Primitive-type local variables are initialized by default.
  - i) Reference-type instance variables are initialized by default to the value `null`.
  - j) Any class that contains `public static void main(String args[])` can be used to execute an application.
  - k) The number of arguments in the method call must match the number of parameters in the method declaration's parameter list.
  - l) Floating-point values that appear in source code are known as floating-point literals and are type `float` by default.

**3.3** What is the difference between a local variable and a field?**3.4** Explain the purpose of a method parameter. What is the difference between a parameter and an argument?**Answers to Self-Review Exercises**

- 3.1** a) object. b) `public`. c) class. d) new. e) type, name. f) default package. g) instance variable. h) `float`, `double`. i) double-precision. j) `nextDouble`. k) access modifier. l) `void`. m) `nextLine`. n) `java.lang`. o) `import` declaration. p) floating-point number. q) single-precision. r) `%f`. s) primitive, reference.

- 3.2** a) False. By convention, method names begin with a lowercase first letter and all subsequent words in the name begin with a capital first letter. b) True. c) True. d) True. e) False. A

**Exercises 125**

primitive-type variable cannot be used to invoke a method—a reference to an object is required to invoke the object's methods. f) False. Such variables are called local variables and can be used only in the method in which they are declared. g) True. h) False. Primitive-type instance variables are initialized by default. Each local variable must explicitly be assigned a value. i) True. j) True. k) True. l) False. Such literals are of type `double` by default.

**3.3** A local variable is declared in the body of a method and can be used only from the point at which it is declared through the end of the method declaration. A field is declared in a class, but not in the body of any of the class's methods. Every object (instance) of a class has a separate copy of the class's fields. Also, fields are accessible to all methods of the class. (We will see an exception to this in Chapter 8, Classes and Objects: A Deeper Look.)

**3.4** A parameter represents additional information that a method requires to perform its task. Each parameter required by a method is specified in the method's declaration. An argument is the actual value for a method parameter. When a method is called, the argument values are passed to the method so that it can perform its task.

### Exercises

**3.5** What is the purpose of keyword `new`? Explain what happens when this keyword is used in an application.

**3.6** What is a default constructor? How are an object's instance variables initialized if a class has only a default constructor?

**3.7** Explain the purpose of an instance variable.

**3.8** Most classes need to be imported before they can be used in an application. Why is every application allowed to use classes `System` and `String` without first importing them?

**3.9** Explain how a program could use class `Scanner` without importing the class from package `java.util`.

**3.10** Explain why a class might provide a `set` method and a `get` method for an instance variable.

**3.11** Modify class `GradeBook` (Fig. 3.10) as follows:

- a) Include a second `String` instance variable that represents the name of the course's instructor.
- b) Provide a `set` method to change the instructor's name and a `get` method to retrieve it.
- c) Modify the constructor to specify two parameters—one for the course name and one for the instructor's name.
- d) Modify method `displayMessage` such that it first outputs the welcome message and course name, then outputs "This course is presented by: " followed by the instructor's name.

Use your modified class in a test application that demonstrates the class's new capabilities.

**3.12** Modify class `Account` (Fig. 3.13) to provide a method called `debit` that withdraws money from an `Account`. Ensure that the debit amount does not exceed the `Account`'s balance. If it does, the balance should be left unchanged and the method should print a message indicating "Debit amount exceeded account balance." Modify class `AccountTest` (Fig. 3.14) to test method `debit`.

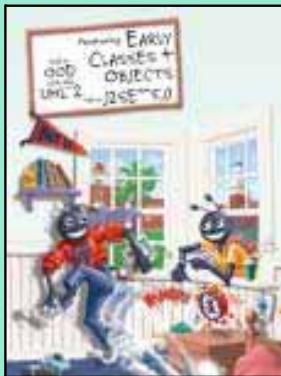

**3.13** Create a class called `Invoice` that a hardware store might use to represent an invoice for an item sold at the store. An `Invoice` should include four pieces of information as instance variables—a part number (type `String`), a part description (type `String`), a quantity of the item being purchased (type `int`) and a price per item (`double`). Your class should have a constructor that initializes the four instance variables. Provide a `set` and a `get` method for each instance variable. In addition, provide a method named `getInvoiceAmount` that calculates the invoice amount (i.e., multiplies the

**126**    [Chapter 3](#) [Introduction to Classes and Objects](#)

quantity by the price per item), then returns the amount as a `double` value. If the quantity is not positive, it should be set to 0. If the price per item is not positive, it should be set to 0.0. Write a test application named `InvoiceTest` that demonstrates class `Invoice`'s capabilities.

**3.14** Create a class called `Employee` that includes three pieces of information as instance variables—a first name (type `String`), a last name (type `String`) and a monthly salary (`double`). Your class should have a constructor that initializes the three instance variables. Provide a `set` and a `get` method for each instance variable. If the monthly salary is not positive, set it to 0.0. Write a test application named `EmployeeTest` that demonstrates class `Employee`'s capabilities. Create two `Employee` objects and display each object's *yearly* salary. Then give each `Employee` a 10% raise and display each `Employee`'s yearly salary again.

**3.15** Create a class called `Date` that includes three pieces of information as instance variables—a month (type `int`), a day (type `int`) and a year (type `int`). Your class should have a constructor that initializes the three instance variables and assumes that the values provided are correct. Provide a `set` and a `get` method for each instance variable. Provide a method `displayDate` that displays the month, day and year separated by forward slashes (/). Write a test application named `DateTest` that demonstrates class `Date`'s capabilities.

# Control Statements: Part I

## OBJECTIVES

In this chapter you will learn:

- To use basic problem-solving techniques.
- To develop algorithms through the process of top-down, stepwise refinement using pseudocode.
- To use the `if` and `if...else` selection statements to choose among alternative actions.
- To use the `while` repetition statement to execute statements in a program repeatedly.
- To use counter-controlled repetition and sentinel-controlled repetition.
- To use the compound assignment, increment and decrement operators.
- The primitive data types.

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 4.1 Introduction

Before writing a program to solve a problem, you must have a thorough understanding of the problem and a carefully planned approach to solving it. When writing a program, you also must understand the types of building blocks that are available and employ proven program-construction techniques. In this chapter and in Chapter 5, Control Statements: Part 2, we discuss these issues in our presentation of the theory and principles of structured programming. The concepts presented here are crucial in building classes and manipulating objects.

In this chapter, we introduce Java's `if...else` and `while` statements, three of the building blocks that allow programmers to specify the logic required for methods to perform their tasks. We devote a portion of this chapter (and Chapters 5 and 7) to further developing the `GradeBook` class introduced in Chapter 3. In particular, we add a method to the `GradeBook` class that uses control statements to calculate the average of a set of student grades. Another example demonstrates additional ways to combine control statements to solve a similar problem. We introduce Java's compound assignment operators and explore Java's increment and decrement operators. These additional operators abbreviate and simplify many program statements. Finally, we present an overview of the primitive data types available to programmers.

## 4.2 Algorithms

Any computing problem can be solved by executing a series of actions in a specific order. A procedure for solving a problem in terms of

1. the [actions](#) to execute and
2. the [order](#) in which these actions execute

is called an [algorithm](#). The following example demonstrates that correctly specifying the order in which the actions execute is important.

Consider the “rise-and-shine algorithm” followed by one executive for getting out of bed and going to work: (1) Get out of bed; (2) take off pajamas; (3) take a shower; (4) get dressed; (5) eat breakfast; (6) carpool to work. This routine gets the executive to work well prepared to make critical decisions. Suppose that the same steps are performed in a slightly different order: (1) Get out of bed; (2) take off pajamas; (3) get dressed; (4) take a shower; (5) eat breakfast; (6) carpool to work. In this case, our executive shows up for work soaking wet.

Specifying the order in which statements (actions) execute in a program is called [program control](#). This chapter investigates program control using Java’s [control statements](#).

### 4.3 Pseudocode

[Pseudocode](#) is an informal language that helps programmers develop algorithms without having to worry about the strict details of Java language syntax. The pseudocode we present is particularly useful for developing algorithms that will be converted to structured portions of Java programs. Pseudocode is similar to everyday English—it is convenient and user friendly, but it is not an actual computer programming language. We begin using pseudocode in Section 4.5, and a sample pseudocode program appears in Fig. 4.5.

Pseudocode does not execute on computers. Rather, it helps the programmer “think out” a program before attempting to write it in a programming language, such as Java. This chapter provides several examples of how to use pseudocode to develop Java programs.

The style of pseudocode we present consists purely of characters, so programmers can type pseudocode conveniently, using any [text-editor](#) program. A carefully prepared pseudocode program can easily be converted to a corresponding Java program. In many cases, this simply requires replacing pseudocode statements with Java equivalents.

Pseudocode normally describes only statements representing the actions that occur after a programmer converts a program from pseudocode to Java and the program is run on a computer. Such actions might include input, output or a calculation. We typically do not include variable declarations in our pseudocode, but some programmers choose to list variables and mention their purposes at the beginning of their pseudocode.

### 4.4 Control Structures

Normally, statements in a program are executed one after the other in the order in which they are written. This process is called [sequential execution](#). Various Java statements, which we will soon discuss, enable the programmer to specify that the next statement to execute is not necessarily the next one in sequence. This is called [transfer of control](#).

During the 1960s, it became clear that the indiscriminate use of transfers of control was the root of much difficulty experienced by software development groups. The blame was pointed at the [goto statement](#) (used in most programming languages of the time), which allows the programmer to specify a transfer of control to one of a very wide range of possible destinations in a program. The notion of so-called [structured programming](#) became almost synonymous with “[goto elimination](#).” [Note: Java does not have a [goto](#)

## 130 Chapter 4 Control Statements: Part I

statement; however, the word `goto` is reserved by Java and should not be used as an identifier in programs.]

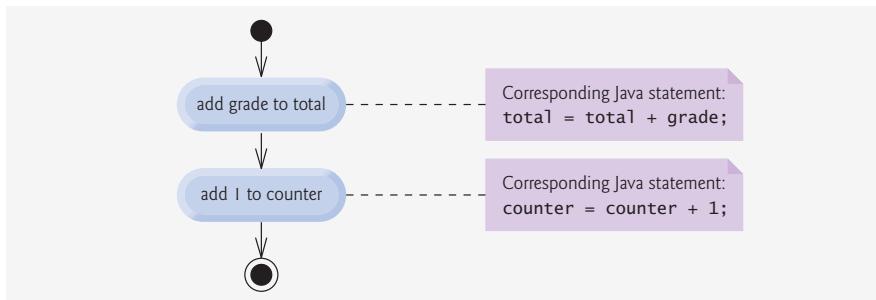

The research of Bohm and Jacopini<sup>1</sup> had demonstrated that programs could be written without any `goto` statements. The challenge of the era for programmers was to shift their styles to “`goto`-less programming.” Not until the 1970s did programmers start taking structured programming seriously. The results were impressive. Software development groups reported shorter development times, more frequent on-time delivery of systems and more frequent within-budget completion of software projects. The key to these successes was that structured programs were clearer, easier to debug and modify, and more likely to be bug free in the first place.

Bohm and Jacopini’s work demonstrated that all programs could be written in terms of only three control structures—the **sequence structure**, the **selection structure** and the **repetition structure**. The term “control structures” comes from the field of computer science. When we introduce Java’s implementations of control structures, we will refer to them in the terminology of the *Java Language Specification* as “control statements.”

### *Sequence Structure in Java*

The sequence structure is built into Java. Unless directed otherwise, the computer executes Java statements one after the other in the order in which they are written—that is, in sequence. The **activity diagram** in Fig. 4.1 illustrates a typical sequence structure in which two calculations are performed in order. Java lets us have as many actions as we want in a sequence structure. As we will soon see, anywhere a single action may be placed, we may place several actions in sequence.

Activity diagrams are part of the UML. An activity diagram models the **workflow** (also called the **activity**) of a portion of a software system. Such workflows may include a portion of an algorithm, such as the sequence structure in Fig. 4.1. Activity diagrams are composed of special-purpose symbols, such as **action-state symbols** (rectangles with their left and right sides replaced with arcs curving outward), **diamonds** and **small circles**. These symbols are connected by **transition arrows**, which represent the flow of the activity—that is, the order in which the actions should occur.

**Fig. 4.1** | Sequence structure activity diagram.

1. Bohm, C., and G. Jacopini, “Flow Diagrams, Turing Machines, and Languages with Only Two Formation Rules,” *Communications of the ACM*, Vol. 9, No. 5, May 1966, pp. 336–371.

4.4 Control Structures **131**

Like pseudocode, activity diagrams help programmers develop and represent algorithms, although many programmers prefer pseudocode. Activity diagrams clearly show how control structures operate.

Consider the activity diagram for the sequence structure in Fig. 4.1. It contains two **action states** that represent actions to perform. Each action state contains an **action expression**—for example, “add grade to total” or “add 1 to counter”—that specifies a particular action to perform. Other actions might include calculations or input/output operations. The arrows in the activity diagram represent **transitions**, which indicate the order in which the actions represented by the action states occur. The program that implements the activities illustrated by the diagram in Fig. 4.1 first adds grade to **total**, then adds 1 to **counter**.

The **solid circle** located at the top of the activity diagram represents the activity’s **initial state**—the beginning of the workflow before the program performs the modeled actions. The **solid circle surrounded by a hollow circle** that appears at the bottom of the diagram represents the **final state**—the end of the workflow after the program performs its actions.

Figure 4.1 also includes rectangles with the upper-right corners folded over. These are **UML notes** (like comments in Java)—explanatory remarks that describe the purpose of symbols in the diagram. Figure 4.1 uses UML notes to show the Java code associated with each action state in the activity diagram. A **dotted line** connects each note with the element that the note describes. Activity diagrams normally do not show the Java code that implements the activity. We use notes for this purpose here to illustrate how the diagram relates to Java code. For more information on the UML, see our optional case study, which appears in the Software Engineering Case Study sections at the ends of Chapters 1–8 and 10, or visit [www.uml.org](http://www.uml.org).

### *Selection Statements in Java*

Java has three types of **selection statements** (discussed in this chapter and Chapter 5). The **if** statement either performs (selects) an action, if a condition is true, or skips it, if the condition is false. The **if...else** statement performs an action if a condition is true and performs a different action if the condition is false. The **switch** statement (Chapter 5) performs one of many different actions, depending on the value of an expression.

The **if** statement is a **single-selection statement** because it selects or ignores a single action (or, as we will soon see, a single group of actions). The **if...else** statement is called a **double-selection statement** because it selects between two different actions (or groups of actions). The **switch** statement is called a **multiple-selection statement** because it selects among many different actions (or groups of actions).

### *Repetition Statements in Java*

Java provides three repetition statements (also called **looping statements**) that enable programs to perform statements repeatedly as long as a condition (called the **loop-continuation condition**) remains true. The repetition statements are the **while**, **do...while** and **for** statements. (Chapter 5 presents the **do...while** and **for** statements.) The **while** and **for** statements perform the action (or group of actions) in their bodies zero or more times—if the loop-continuation condition is initially false, the action (or group of actions) will not execute. The **do...while** statement performs the action (or group of actions) in its body one or more times.

## 132 Chapter 4 Control Statements: Part I

The words `if`, `else`, `switch`, `while`, `do` and `for` are Java keywords. Recall that keywords are used to implement various Java features, such as control statements. Keywords cannot be used as identifiers, such as variable names. A complete list of Java keywords appears in Appendix C.

### *Summary of Control Statements in Java*

Java has only three kinds of control structures, which from this point forward we refer to as control statements: the sequence statement, selection statements (three types) and repetition statements (three types). Every program is formed by combining as many sequence, selection and repetition statements as is appropriate for the algorithm the program implements. As with the sequence statement in Fig. 4.1, we can model each control statement as an activity diagram. Each diagram contains an initial state and a final state that represent a control statement's entry point and exit point, respectively. [Single-entry/single-exit control statements](#) make it easy to build programs—we “attach” the control statements to one another by connecting the exit point of one to the entry point of the next. This procedure is similar to the way in which a child stacks building blocks, so we call it [control-statement stacking](#). We will learn that there is only one other way in which control statements may be connected—[control-statement nesting](#)—in which one control statement appears inside another. Thus, algorithms in Java programs are constructed from only three kinds of control statements, combined in only two ways. This is the essence of simplicity.

## 4.5 `if` Single-Selection Statement

Programs use selection statements to choose among alternative courses of action. For example, suppose that the passing grade on an exam is 60. The pseudocode statement

```
If student's grade is greater than or equal to 60
 Print "Passed"
```

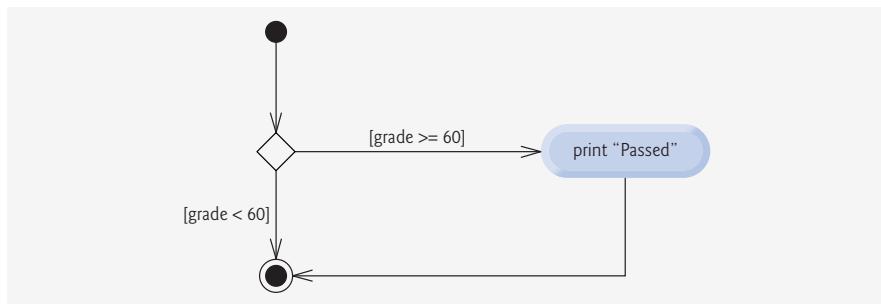

determines whether the condition “student’s grade is greater than or equal to 60” is true or false. If it is true, “Passed” is printed, and the next pseudocode statement in order is “performed.” (Remember that pseudocode is not a real programming language.) If the condition is false, the `Print` statement is ignored, and the next pseudocode statement in order is performed. The indentation of the second line of this selection statement is optional, but recommended, because it emphasizes the inherent structure of structured programs.

The preceding pseudocode `If` statement may be written in Java as

```
if (studentGrade >= 60)
 System.out.println("Passed");
```

Note that the Java code corresponds closely to the pseudocode. This is one of the properties of pseudocode that makes it such a useful program development tool.

Figure 4.2 illustrates the single-selection `if` statement. This figure contains what is perhaps the most important symbol in an activity diagram—the diamond, or [decision symbol](#), which indicates that a decision is to be made. The workflow will continue along a path determined by the symbol’s associated [guard conditions](#), which can be true or false. Each transition arrow emerging from a decision symbol has a guard condition (specified in square brackets next to the transition arrow). If a guard condition is true, the workflow enters the action state to which the transition arrow points. In Fig. 4.2, if the grade is

4.6 if...else Double-Selection Statement **133**

**Fig. 4.2** | if single-selection statement UML activity diagram.

greater than or equal to 60, the program prints “Passed,” then transitions to the final state of this activity. If the grade is less than 60, the program immediately transitions to the final state without displaying a message.

The `if` statement is a single-entry/single-exit control statement. We will see that the activity diagrams for the remaining control statements also contain initial states, transition arrows, action states that indicate actions to perform, decision symbols (with associated guard conditions) that indicate decisions to be made and final states. This is consistent with the [action/decision model of programming](#) we have been emphasizing.

Envision seven bins, each containing only one type of Java control statement. The control statements are all empty. Your task is to assemble a program from as many of each type of control statement as the algorithm demands, combining them in only two possible ways (stacking or nesting), then filling in the action states and decisions with action expressions and guard conditions appropriate for the algorithm. We will discuss the variety of ways in which actions and decisions can be written.

## 4.6 if...else Double-Selection Statement

The `if` single-selection statement performs an indicated action only when the condition is `true`; otherwise, the action is skipped. The `if...else` double-selection statement allows the programmer to specify an action to perform when the condition is `true` and a different action when the condition is `false`. For example, the pseudocode statement

```

If student's grade is greater than or equal to 60
 Print "Passed"
Else
 Print "Failed"

```

prints “Passed” if the student’s grade is greater than or equal to 60, but prints “Failed” if it is less than 60. In either case, after printing occurs, the next pseudocode statement in sequence is “performed.”

The preceding `If...Else` pseudocode statement can be written in Java as

```

if (grade >= 60)
 System.out.println("Passed");
else
 System.out.println("Failed");

```

**134** Chapter 4 Control Statements: Part I

Note that the body of the `else` is also indented. Whatever indentation convention you choose should be applied consistently throughout your programs. It is difficult to read programs that do not obey uniform spacing conventions.

**Good Programming Practice 4.1**

*Indent both body statements of an if...else statement.*

**Good Programming Practice 4.2**

*If there are several levels of indentation, each level should be indented the same additional amount of space.*

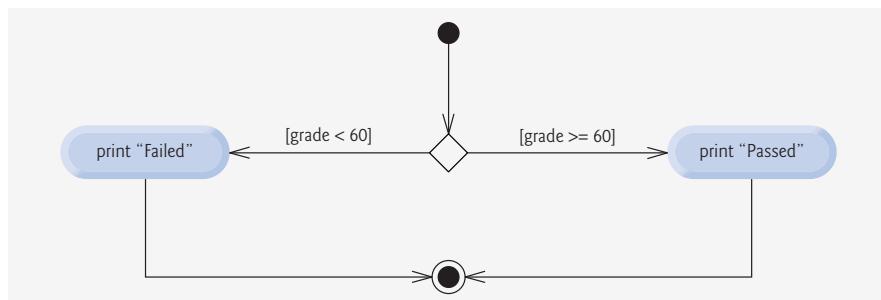

Figure 4.3 illustrates the flow of control in the `if...else` statement. Once again, the symbols in the UML activity diagram (besides the initial state, transition arrows and final state) represent action states and decisions. We continue to emphasize this action/decision model of computing. Imagine again a deep bin containing as many empty `if...else` statements as might be needed to build any Java program. Your job is to assemble these `if...else` statements (by stacking and nesting) with any other control statements required by the algorithm. You fill in the action states and decision symbols with action expressions and guard conditions appropriate to the algorithm you are developing.

**Conditional Operator (?:)**

Java provides the **conditional operator** (`?:`) that can be used in place of an `if...else` statement. This is Java's only **ternary operator**—this means that it takes three operands. Together, the operands and the `?:` symbol form a **conditional expression**. The first operand (to the left of the `?`) is a **boolean** expression (i.e., a condition that evaluates to a **boolean** value—`true` or `false`), the second operand (between the `?` and `:`) is the value of the conditional expression if the **boolean** expression is `true` and the third operand (to the right of the `:`) is the value of the conditional expression if the **boolean** expression evaluates to `false`. For example, the statement

```
System.out.println(studentGrade >= 60 ? "Passed" : "Failed");
```

prints the value of `println`'s conditional-expression argument. The conditional expression in this statement evaluates to the string "Passed" if the **boolean** expression `studentGrade >= 60` is `true` and evaluates to the string "Failed" if the **boolean** expression is `false`.

**Fig. 4.3** | `if...else` double-selection statement UML activity diagram.

4.6 if...else Double-Selection Statement **135**

Thus, this statement with the conditional operator performs essentially the same function as the if...else statement shown earlier in this section. The precedence of the conditional operator is low, so the entire conditional expression is normally placed in parentheses. We will see that conditional expressions can be used in some situations where if...else statements cannot.

**Good Programming Practice 4.3**

*Conditional expressions are more difficult to read than if...else statements and should be used to replace only simple if...else statements that choose between two values.*

**Nested if...else Statements**

A program can test multiple cases by placing if...else statements inside other if...else statements to create **nested if...else statements**. For example, the following pseudocode represents a nested if...else that prints A for exam grades greater than or equal to 90, B for grades in the range 80 to 89, C for grades in the range 70 to 79, D for grades in the range 60 to 69 and F for all other grades:

```
If student's grade is greater than or equal to 90
 Print "A"
else
 If student's grade is greater than or equal to 80
 Print "B"
 else
 If student's grade is greater than or equal to 70
 Print "C"
 else
 If student's grade is greater than or equal to 60
 Print "D"
 else
 Print "F"
```

This pseudocode may be written in Java as

```
if (studentGrade >= 90)
 System.out.println("A");
else
 if (studentGrade >= 80)
 System.out.println("B");
 else
 if (studentGrade >= 70)
 System.out.println("C");
 else
 if (studentGrade >= 60)
 System.out.println("D");
 else
 System.out.println("F");
```

If studentGrade is greater than or equal to 90, the first four conditions will be true, but only the statement in the if-part of the first if...else statement will execute. After that statement executes, the else-part of the “outermost” if...else statement is skipped. Most Java programmers prefer to write the preceding if...else statement as

**136** Chapter 4 Control Statements: Part I

```

if (studentGrade >= 90)
 System.out.println("A");
else if (studentGrade >= 80)
 System.out.println("B");
else if (studentGrade >= 70)
 System.out.println("C");
else if (studentGrade >= 60)
 System.out.println("D");
else
 System.out.println("F");

```

The two forms are identical except for the spacing and indentation, which the compiler ignores. The latter form is popular because it avoids deep indentation of the code to the right. Such indentation often leaves little room on a line of code, forcing lines to be split and decreasing program readability.

***Dangling-else Problem***

The Java compiler always associates an `else` with the immediately preceding `if` unless told to do otherwise by the placement of braces (`{` and `}`). This behavior can lead to what is referred to as the **dangling-else problem**. For example,

```

if (x > 5)
 if (y > 5)
 System.out.println("x and y are > 5");
else
 System.out.println("x is <= 5");

```

appears to indicate that if `x` is greater than 5, the nested `if` statement determines whether `y` is also greater than 5. If so, the string "`x and y are > 5`" is output. Otherwise, it appears that if `x` is not greater than 5, the `else` part of the `if...else` outputs the string "`x is <= 5`".

Beware! This nested `if...else` statement does not execute as it appears. The compiler actually interprets the statement as

```

if (x > 5)
 if (y > 5)
 System.out.println("x and y are > 5");
else
 System.out.println("x is <= 5");

```

in which the body of the first `if` is a nested `if...else`. The outer `if` statement tests whether `x` is greater than 5. If so, execution continues by testing whether `y` is also greater than 5. If the second condition is true, the proper string—"x and y are > 5"—is displayed. However, if the second condition is false, the string "`x is <= 5`" is displayed, even though we know that `x` is greater than 5. Equally bad, if the outer `if` statement's condition is false, the inner `if...else` is skipped and nothing is displayed.

To force the nested `if...else` statement to execute as it was originally intended, we must write it as follows:

```

if (x > 5)
{
 if (y > 5)
 System.out.println("x and y are > 5");
}
else
 System.out.println("x is <= 5");

```

## 4.6 if...else Double-Selection Statement 137

The braces ({} ) indicate to the compiler that the second `if` statement is in the body of the first `if` and that the `else` is associated with the *first if*. Exercises 4.27–4.28 investigate the dangling-`else` problem further.

### **Blocks**

The `if` statement normally expects only one statement in its body. To include several statements in the body of an `if` (or the body of an `else` for an `if...else` statement), enclose the statements in braces ({} and }). A set of statements contained within a pair of braces is called a **block**. A block can be placed anywhere in a program that a single statement can be placed.

The following example includes a block in the `else`-part of an `if...else` statement:

```

if (grade >= 60)
 System.out.println("Passed");
else
{
 System.out.println("Failed");
 System.out.println("You must take this course again.");
}

```

In this case, if `grade` is less than 60, the program executes both statements in the body of the `else` and prints

```

Failed.
You must take this course again.

```

Note the braces surrounding the two statements in the `else` clause. These braces are important. Without the braces, the statement

```

System.out.println("You must take this course again.");

```

would be outside the body of the `else`-part of the `if...else` statement and would execute regardless of whether the `grade` was less than 60.

Syntax errors (e.g., when one brace in a block is left out of the program) are caught by the compiler. A **logic error** (e.g., when both braces in a block are left out of the program) has its effect at execution time. A **fatal logic error** causes a program to fail and terminate prematurely. A **nonfatal logic error** allows a program to continue executing, but causes the program to produce incorrect results.

### Common Programming Error 4.1

*Forgetting one or both of the braces that delimit a block can lead to syntax errors or logic errors in a program.*

### Good Programming Practice 4.4

*Always using braces in an `if...else` (or other) statement helps prevent their accidental omission, especially when adding statements to the `if`-part or the `else`-part at a later time. To avoid omitting one or both of the braces, some programmers type the beginning and ending braces of blocks before typing the individual statements within the braces.*

Just as a block can be placed anywhere a single statement can be placed, it is also possible to have an empty statement. Recall from Section 2.8 that the empty statement is represented by placing a semicolon (;) where a statement would normally be.

### Common Programming Error 4.2

*Placing a semicolon after the condition in an if or if...else statement leads to a logic error in single-selection if statements and a syntax error in double-selection if...else statements (when the if-part contains an actual body statement).*

## 4.7 while Repetition Statement

A **repetition statement** (also called a **looping statement** or a **loop**) allows the programmer to specify that a program should repeat an action while some condition remains true. The pseudocode statement

*While there are more items on my shopping list  
Purchase next item and cross it off my list*

describes the repetition that occurs during a shopping trip. The condition “there are more items on my shopping list” may be true or false. If it is true, then the action “Purchase next item and cross it off my list” is performed. This action will be performed repeatedly while the condition remains true. The statement(s) contained in the *While* repetition statement constitute its body, which may be a single statement or a block. Eventually, the condition will become false (when the last item on the shopping list has been purchased and crossed off). At this point, the repetition terminates, and the first statement after the repetition statement executes.

As an example of Java’s `while` repetition statement, consider a program segment designed to find the first power of 3 larger than 100. Suppose that the `int` variable `product` is initialized to 3. When the following `while` statement finishes executing, `product` contains the result:

```
int product = 3;
while (product <= 100)
 product = 3 * product;
```

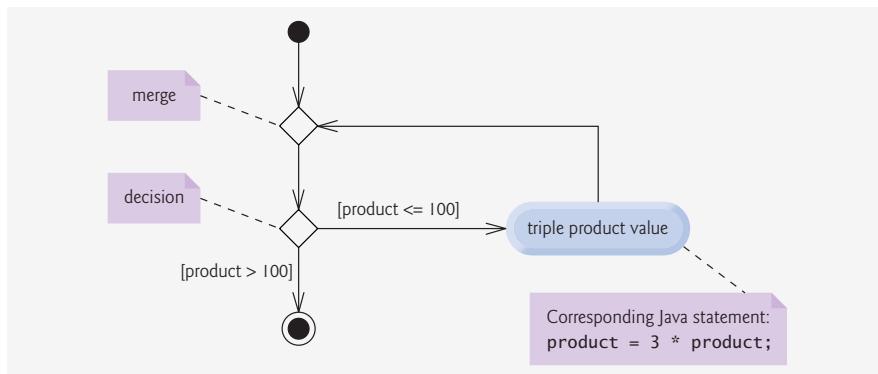

When this `while` statement begins execution, the value of variable `product` is 3. Each iteration of the `while` statement multiplies `product` by 3, so `product` takes on the values 9, 27, 81 and 243 successively. When variable `product` becomes 243, the `while` statement condition—`product <= 100`—becomes false. This terminates the repetition, so the final value of `product` is 243. At this point, program execution continues with the next statement after the `while` statement.

### Common Programming Error 4.3

*Not providing, in the body of a while statement, an action that eventually causes the condition in the while to become false normally results in a logic error called an infinite loop, in which the loop never terminates.*

The UML activity diagram in Fig. 4.4 illustrates the flow of control that corresponds to the preceding `while` statement. Once again, the symbols in the diagram (besides the initial state, transition arrows, a final state and three notes) represent an action state and a decision. This diagram also introduces the UML’s **merge symbol**. The UML represents both the merge symbol and the decision symbol as diamonds. The merge symbol joins two flows of activity into one. In this diagram, the merge symbol joins the transitions from the initial state and from the action state, so they both flow into the decision that determines

4.8 Formulating Algorithms: Counter-Controlled Repetition **139**

**Fig. 4.4** | `while` repetition statement UML activity diagram.

whether the loop should begin (or continue) executing. The decision and merge symbols can be distinguished by the number of “incoming” and “outgoing” transition arrows. A decision symbol has one transition arrow pointing to the diamond and two or more transition arrows pointing out from the diamond to indicate possible transitions from that point. In addition, each transition arrow pointing out of a decision symbol has a guard condition next to it. A merge symbol has two or more transition arrows pointing to the diamond and only one transition arrow pointing from the diamond, to indicate multiple activity flows merging to continue the activity. None of the transition arrows associated with a merge symbol has a guard condition.

Figure 4.4 clearly shows the repetition of the `while` statement discussed earlier in this section. The transition arrow emerging from the action state points back to the merge, from which program flow transitions back to the decision that is tested at the beginning of each iteration of the loop. The loop continues to execute until the guard condition `product > 100` becomes true. Then the `while` statement exits (reaches its final state), and control passes to the next statement in sequence in the program.

## 4.8 Formulating Algorithms: Counter-Controlled Repetition

To illustrate how algorithms are developed, we modify the `GradeBook` class of Chapter 3 to solve two variations of a problem that averages student grades. Consider the following problem statement:

*A class of ten students took a quiz. The grades (integers in the range 0 to 100) for this quiz are available to you. Determine the class average on the quiz.*

The class average is equal to the sum of the grades divided by the number of students. The algorithm for solving this problem on a computer must input each grade, keep track of the total of all grades input, perform the averaging calculation and print the result.

### Pseudocode Algorithm with Counter-Controlled Repetition

Let's use pseudocode to list the actions to execute and specify the order in which they should execute. We use **counter-controlled repetition** to input the grades one at a time.

## 140 Chapter 4 Control Statements: Part I

This technique uses a variable called a **counter** (or **control variable**) to control the number of times a set of statements will execute. Counter-controlled repetition is often called **definite repetition**, because the number of repetitions is known before the loop begins executing. In this example, repetition terminates when the counter exceeds 10. This section presents a fully developed pseudocode algorithm (Fig. 4.5) and a version of class **GradeBook** (Fig. 4.6) that implements the algorithm in a Java method. We then present an application (Fig. 4.7) that demonstrates the algorithm in action. In Section 4.9, we demonstrate how to use pseudocode to develop such an algorithm from scratch.

### Software Engineering Observation 4.1

*Experience has shown that the most difficult part of solving a problem on a computer is developing the algorithm for the solution. Once a correct algorithm has been specified, the process of producing a working Java program from the algorithm is usually straightforward.*

Note the references in the algorithm of Fig. 4.5 to a total and a counter. A **total** is a variable used to accumulate the sum of several values. A counter is a variable used to count—in this case, the grade counter indicates which of the 10 grades is about to be entered by the user. Variables used to store totals are normally initialized to zero before being used in a program.

#### Implementing Counter-Controlled Repetition in Class **GradeBook**

Class **GradeBook** (Fig. 4.6) contains a constructor (lines 11–14) that assigns a value to the class's instance variable **courseName** (declared in line 8). Lines 17–20, 23–26 and 29–34 declare methods **setCourseName**, **getCourseName** and **displayMessage**, respectively. Lines 37–66 declare method **determineClassAverage**, which implements the class-averaging algorithm described by the pseudocode in Fig. 4.5.

Line 40 declares and initializes **Scanner** variable **input**, which is used to read values entered by the user. Lines 42–45 declare local variables **total**, **gradeCounter**, **grade** and **average** to be of type **int**. Variable **grade** stores the user input.

Note that the declarations (in lines 42–45) appear in the body of method **determineClassAverage**. Recall that variables declared in a method body are local variables and can be used only from the line of their declaration in the method to the closing right brace **}**

- 1 Set total to zero
- 2 Set grade counter to one
- 3
- 4 While grade counter is less than or equal to ten
  - 5 Prompt the user to enter the next grade
  - 6 Input the next grade
  - 7 Add the grade into the total
  - 8 Add one to the grade counter
  - 9
- 10 Set the class average to the total divided by ten
- 11 Print the class average

**Fig. 4.5** | Pseudocode algorithm that uses counter-controlled repetition to solve the class-average problem.

4.8 Formulating Algorithms: Counter-Controlled Repetition **141**

```

1 // Fig. 4.6: GradeBook.java
2 // GradeBook class that solves class-average problem using
3 // counter-controlled repetition.
4 import java.util.Scanner; // program uses class Scanner
5
6 public class GradeBook
7 {
8 private String courseName; // name of course this GradeBook represents
9
10 // constructor initializes courseName
11 public GradeBook(String name)
12 {
13 courseName = name; // initializes courseName
14 } // end constructor
15
16 // method to set the course name
17 public void setCourseName(String name)
18 {
19 courseName = name; // store the course name
20 } // end method setCourseName
21
22 // method to retrieve the course name
23 public String getCourseName()
24 {
25 return courseName;
26 } // end method getCourseName
27
28 // display a welcome message to the GradeBook user
29 public void displayMessage()
30 {
31 // getCourseName gets the name of the course
32 System.out.printf("Welcome to the grade book for\n%s!\n\n",
33 getCourseName());
34 } // end method displayMessage
35
36 // determine class average based on 10 grades entered by user
37 public void determineClassAverage()
38 {
39 // create Scanner to obtain input from command window
40 Scanner input = new Scanner(System.in);
41
42 int total; // sum of grades entered by user
43 int gradeCounter; // number of the grade to be entered next
44 int grade; // grade value entered by user
45 int average; // average of grades
46
47 // initialization phase
48 total = 0; // initialize total
49 gradeCounter = 1; // initialize loop counter
50
51 // processing phase
52 while (gradeCounter <= 10) // loop 10 times
53 {

```

**Fig. 4.6** | Counter-controlled repetition: Class-average problem. (Part I of 2.)

**142** Chapter 4 Control Statements: Part I

```

54 System.out.print("Enter grade: "); // prompt
55 grade = input.nextInt(); // input next grade
56 total = total + grade; // add grade to total
57 gradeCounter = gradeCounter + 1; // increment counter by 1
58 } // end while
59
60 // termination phase
61 average = total / 10; // integer division yields integer result
62
63 // display total and average of grades
64 System.out.printf("\nTotal of all 10 grades is %d\n", total);
65 System.out.printf("Class average is %d\n", average);
66 } // end method determineClassAverage
67
68 } // end class GradeBook

```

**Fig. 4.6** | Counter-controlled repetition: Class-average problem. (Part 2 of 2.)

of the method declaration. A local variable's declaration must appear before the variable is used in that method. A local variable cannot be accessed outside the method in which it is declared.

In the versions of class `GradeBook` in this chapter, we simply read and process a set of grades. The averaging calculation is performed in method `determineClassAverage` using local variables—we do not preserve any information about student grades in instance variables of the class. In later versions of the class (in Chapter 7, Arrays), we maintain the grades in memory using an instance variable that refers to a data structure known as an array. This allows a `GradeBook` object to perform various calculations on the same set of grades without requiring the user to enter the grades multiple times.

**Good Programming Practice 4.5**

*Separate declarations from other statements in methods with a blank line for readability.*

The assignments (in lines 48–49) initialize `total` to 0 and `gradeCounter` to 1. Note that these initializations occur before the variables are used in calculations. Variables `grade` and `average` (for the user input and calculated average, respectively) need not be initialized here—their values will be assigned as they are input or calculated later in the method.

**Common Programming Error 4.4**

*Reading the value of a local variable before it is initialized results in a compilation error. All local variables must be initialized before their values are read in expressions.*

**Error-Prevention Tip 4.1**

*Initialize each counter and total, either in its declaration or in an assignment statement. Totals are normally initialized to 0. Counters are normally initialized to 0 or 1, depending on how they are used (we will show examples of when to use 0 and when to use 1).*

Line 52 indicates that the `while` statement should continue looping (also called **iterating**) as long as the value of `gradeCounter` is less than or equal to 10. While this condition

## 4.8 Formulating Algorithms: Counter-Controlled Repetition 143

remains true, the `while` statement repeatedly executes the statements between the braces that delimit its body (lines 54–57).

Line 54 displays the prompt "Enter grade: ". Line 55 reads the grade entered by the user and assigns it to variable `grade`. Then line 56 adds the new grade entered by the user to the `total` and assigns the result to `total`, which replaces its previous value.

Line 57 adds 1 to `gradeCounter` to indicate that the program has processed a grade and is ready to input the next grade from the user. Incrementing `gradeCounter` eventually causes `gradeCounter` to exceed 10. At that point the `while` loop terminates because its condition (line 52) becomes false.

When the loop terminates, line 61 performs the averaging calculation and assigns its result to the variable `average`. Line 64 uses `System.out`'s `printf` method to display the text "Total of all 10 grades is " followed by variable `total`'s value. Line 65 then uses `printf` to display the text "Class average is " followed by variable `average`'s value. After reaching line 66, method `determineClassAverage` returns control to the calling method (i.e., `main` in `GradeBookTest` of Fig. 4.7).

### **Class GradeBookTest**

Class `GradeBookTest` (Fig. 4.7) creates an object of class `GradeBook` (Fig. 4.6) and demonstrates its capabilities. Lines 10–11 of Fig. 4.7 create a new `GradeBook` object and assign it to variable `myGradeBook`. The `String` in line 11 is passed to the `GradeBook` constructor (lines 11–14 of Fig. 4.6). Line 13 calls `myGradeBook`'s `displayMessage` method to display a welcome message to the user. Line 14 then calls `myGradeBook`'s `determineClassAverage` method to allow the user to enter 10 grades, for which the method then calculates and prints the average—the method performs the algorithm shown in Fig. 4.5.

### **Notes on Integer Division and Truncation**

The averaging calculation performed by method `determineClassAverage` in response to the method call at line 14 in Fig. 4.7 produces an integer result. The program's output

```

1 // Fig. 4.7: GradeBookTest.java
2 // Create GradeBook object and invoke its determineClassAverage method.
3
4 public class GradeBookTest
5 {
6 public static void main(String args[])
7 {
8 // create GradeBook object myGradeBook and
9 // pass course name to constructor
10 GradeBook myGradeBook = new GradeBook(
11 "CS101 Introduction to Java Programming");
12
13 myGradeBook.displayMessage(); // display welcome message
14 myGradeBook.determineClassAverage(); // find average of 10 grades
15 } // end main
16
17 } // end class GradeBookTest

```

**Fig. 4.7 |** `GradeBookTest` class creates an object of class `GradeBook` (Fig. 4.6) and invokes its `determineClassAverage` method. (Part I of 2.)

**144** Chapter 4 Control Statements: Part I

```
Welcome to the grade book for
CS101 Introduction to Java Programming!

Enter grade: 67
Enter grade: 78
Enter grade: 89
Enter grade: 67
Enter grade: 87
Enter grade: 98
Enter grade: 93
Enter grade: 85
Enter grade: 82
Enter grade: 100

Total of all 10 grades is 846
Class average is 84
```

**Fig. 4.7** | GradeBookTest class creates an object of class GradeBook (Fig. 4.6) and invokes its `determineClassAverage` method. (Part 2 of 2.)

indicates that the sum of the grade values in the sample execution is 846, which, when divided by 10, should yield the floating-point number 84.6. However, the result of the calculation `total / 10` (line 61 of Fig. 4.6) is the integer 84, because `total` and 10 are both integers. Dividing two integers results in **integer division**—any fractional part of the calculation is lost (i.e., **truncated**). We will see how to obtain a floating-point result from the averaging calculation in the next section.

#### Common Programming Error 4.5

Assuming that integer division rounds (rather than truncates) can lead to incorrect results. For example,  $7 \div 4$ , which yields 1.75 in conventional arithmetic, truncates to 1 in integer arithmetic, rather than rounding to 2.

## 4.9 Formulating Algorithms: Sentinel-Controlled Repetition

Let us generalize Section 4.8's class-average problem. Consider the following problem:

*Develop a class-averaging program that processes grades for an arbitrary number of students each time it is run.*

In the previous class-average example, the problem statement specified the number of students, so the number of grades (10) was known in advance. In this example, no indication is given of how many grades the user will enter during the program's execution. The program must process an arbitrary number of grades. How can it determine when to stop the input of grades? How will it know when to calculate and print the class average?

One way to solve this problem is to use a special value called a **sentinel value** (also called a **signal value**, a **dummy value** or a **flag value**) to indicate “end of data entry.” The user enters grades until all legitimate grades have been entered. The user then types the sentinel value to indicate that no more grades will be entered. Sentinel-controlled repetition is often called **indefinite repetition** because the number of repetitions is not known before the loop begins executing.

## 4.9 Formulating Algorithms: Sentinel-Controlled Repetition 145

Clearly, a sentinel value must be chosen that cannot be confused with an acceptable input value. Grades on a quiz are nonnegative integers, so  $-1$  is an acceptable sentinel value for this problem. Thus, a run of the class-average program might process a stream of inputs such as 95, 96, 75, 74, 89 and  $-1$ . The program would then compute and print the class average for the grades 95, 96, 75, 74 and 89; since  $-1$  is the sentinel value, it should not enter into the averaging calculation.

### Common Programming Error 4.6

*Choosing a sentinel value that is also a legitimate data value is a logic error.*

#### *Developing the Pseudocode Algorithm with Top-Down, Stepwise Refinement: The Top and First Refinement*

We approach this class-average program with a technique called **top-down, stepwise refinement**, which is essential to the development of well-structured programs. We begin with a pseudocode representation of the **top**—a single statement that conveys the overall function of the program:

*Determine the class average for the quiz*

The top is, in effect, a *complete* representation of a program. Unfortunately, the top rarely conveys sufficient detail from which to write a Java program. So we now begin the refinement process. We divide the top into a series of smaller tasks and list these in the order in which they will be performed. This results in the following **first refinement**:

*Initialize variables*

*Input, sum and count the quiz grades*

*Calculate and print the class average*

This refinement uses only the sequence structure—the steps listed should execute in order, one after the other.

### Software Engineering Observation 4.2

*Each refinement, as well as the top itself, is a complete specification of the algorithm—only the level of detail varies.*

### Software Engineering Observation 4.3

*Many programs can be divided logically into three phases: an initialization phase that initializes the variables; a processing phase that inputs data values and adjusts program variables (e.g., counters and totals) accordingly; and a termination phase that calculates and outputs the final results.*

#### *Proceeding to the Second Refinement*

The preceding Software Engineering Observation is often all you need for the first refinement in the top-down process. To proceed to the next level of refinement—that is, the **second refinement**—we commit to specific variables. In this example, we need a running total of the numbers, a count of how many numbers have been processed, a variable to receive the value of each grade as it is input by the user and a variable to hold the calculated average. The pseudocode statement

*Initialize variables*

**146** Chapter 4 Control Statements: Part I

can be refined as follows:

*Initialize total to zero  
Initialize counter to zero*

Only the variables *total* and *counter* need to be initialized before they are used. The variables *average* and *grade* (for the calculated average and the user input, respectively) need not be initialized, because their values will be replaced as they are calculated or input.

The pseudocode statement

*Input, sum and count the quiz grades*

requires a repetition structure (i.e., a loop) that successively inputs each grade. We do not know in advance how many grades are to be processed, so we will use sentinel-controlled repetition. The user enters grades one at a time. After entering the last grade, the user enters the sentinel value. The program tests for the sentinel value after each grade is input and terminates the loop when the user enters the sentinel value. The second refinement of the preceding pseudocode statement is then

*Prompt the user to enter the first grade  
Input the first grade (possibly the sentinel)  
  
While the user has not yet entered the sentinel  
    Add this grade into the running total  
    Add one to the grade counter  
    Prompt the user to enter the next grade  
    Input the next grade (possibly the sentinel)*

In pseudocode, we do not use braces around the statements that form the body of the *While* structure. We simply indent the statements under the *While* to show that they belong to the *While*. Again, pseudocode is only an informal program development aid.

The pseudocode statement

*Calculate and print the class average*

can be refined as follows:

*If the counter is not equal to zero  
    Set the average to the total divided by the counter  
    Print the average  
else  
    Print "No grades were entered"*

We are careful here to test for the possibility of division by zero—normally a logic error that, if undetected, would cause the program to fail or produce invalid output. The complete second refinement of the pseudocode for the class-average problem is shown in Fig. 4.8.

### Error-Prevention Tip 4.2

*When performing division by an expression whose value could be zero, explicitly test for this possibility and handle it appropriately in your program (e.g., by printing an error message) rather than allow the error to occur.*

4.9 Formulating Algorithms: Sentinel-Controlled Repetition **147**

```

1 Initialize total to zero
2 Initialize counter to zero
3
4 Prompt the user to enter the first grade
5 Input the first grade (possibly the sentinel)
6
7 While the user has not yet entered the sentinel
8 Add this grade into the running total
9 Add one to the grade counter
10 Prompt the user to enter the next grade
11 Input the next grade (possibly the sentinel)
12
13 If the counter is not equal to zero
14 Set the average to the total divided by the counter
15 Print the average
16 else
17 Print "No grades were entered"

```

**Fig. 4.8** | Class-average problem pseudocode algorithm with sentinel-controlled repetition.

In Fig. 4.5 and Fig. 4.8, we included some blank lines and indentation in the pseudocode to make it more readable. The blank lines separate the pseudocode algorithms into their various phases and set off control statements; the indentation emphasizes the bodies of the control statements.

The pseudocode algorithm in Fig. 4.8 solves the more general class-averaging problem. This algorithm was developed after only two refinements. Sometimes more refinements are necessary.

#### Software Engineering Observation 4.4

Terminate the top-down, stepwise refinement process when you have specified the pseudocode algorithm in sufficient detail for you to convert the pseudocode to Java. Normally, implementing the Java program is then straightforward.

#### Software Engineering Observation 4.5

Some experienced programmers write programs without using program development tools like pseudocode. They feel that their ultimate goal is to solve the problem on a computer and that writing pseudocode merely delays the production of final outputs. Although this may work for simple and familiar problems, it can lead to serious errors and delays in large, complex projects.

#### Implementing Sentinel-Controlled Repetition in Class GradeBook

Figure 4.9 shows the Java class `GradeBook` containing method `determineClassAverage` that implements the pseudocode algorithm of Fig. 4.8. Although each grade is an integer, the averaging calculation is likely to produce a number with a decimal point—in other words, a real (i.e., floating-point) number. The type `int` cannot represent such a number, so this class uses type `double` to do so.

In this example, we see that control statements may be stacked on top of one another (in sequence) just as a child stacks building blocks. The `while` statement (lines 57–65) is

**148** Chapter 4 Control Statements: Part I

followed in sequence by an `if...else` statement (lines 69–80). Much of the code in this program is identical to that in Fig. 4.6, so we concentrate on the new concepts.

```

1 // Fig. 4.9: GradeBook.java
2 // GradeBook class that solves class-average program using
3 // sentinel-controlled repetition.
4 import java.util.Scanner; // program uses class Scanner
5
6 public class GradeBook
7 {
8 private String courseName; // name of course this GradeBook represents
9
10 // constructor initializes courseName
11 public GradeBook(String name)
12 {
13 courseName = name; // initializes courseName
14 } // end constructor
15
16 // method to set the course name
17 public void setCourseName(String name)
18 {
19 courseName = name; // store the course name
20 } // end method setCourseName
21
22 // method to retrieve the course name
23 public String getCourseName()
24 {
25 return courseName;
26 } // end method getCourseName
27
28 // display a welcome message to the GradeBook user
29 public void displayMessage()
30 {
31 // getCourseName gets the name of the course
32 System.out.printf("Welcome to the grade book for%n%s!\n\n",
33 getCourseName());
34 } // end method displayMessage
35
36 // determine the average of an arbitrary number of grades
37 public void determineClassAverage()
38 {
39 // create Scanner to obtain input from command window
40 Scanner input = new Scanner(System.in);
41
42 int total; // sum of grades
43 int gradeCounter; // number of grades entered
44 int grade; // grade value
45 double average; // number with decimal point for average
46
47 // initialization phase
48 total = 0; // initialize total
49 gradeCounter = 0; // initialize loop counter

```

**Fig. 4.9** | Sentinel-controlled repetition: Class-average problem. (Part I of 2.)

4.9 Formulating Algorithms: Sentinel-Controlled Repetition **149**

```

50 // processing phase
51 // prompt for input and read grade from user
52 System.out.print("Enter grade or -1 to quit: ");
53 grade = input.nextInt();
54
55 // loop until sentinel value read from user
56 while (grade != -1)
57 {
58 total = total + grade; // add grade to total
59 gradeCounter = gradeCounter + 1; // increment counter
60
61 // prompt for input and read next grade from user
62 System.out.print("Enter grade or -1 to quit: ");
63 grade = input.nextInt();
64 } // end while
65
66 // termination phase
67 // if user entered at least one grade...
68 if (gradeCounter != 0)
69 {
70 // calculate average of all grades entered
71 average = (double) total / gradeCounter;
72
73 // display total and average (with two digits of precision)
74 System.out.printf("\nTotal of the %d grades entered is %d\n",
75 gradeCounter, total);
76 System.out.printf("Class average is %.2f\n", average);
77 } // end if
78 else // no grades were entered, so output appropriate message
79 System.out.println("No grades were entered");
80 } // end method determineClassAverage
81 } // end class GradeBook

```

**Fig. 4.9** | Sentinel-controlled repetition: Class-average problem. (Part 2 of 2.)

Line 45 declares double variable `average`, which allows us to store the calculated class average as a floating-point number. Line 49 initializes `gradeCounter` to 0, because no grades have been entered yet. Remember that this program uses sentinel-controlled repetition to input the grades from the user. To keep an accurate record of the number of grades entered, the program increments `gradeCounter` only when the user enters a valid grade value.

**Program Logic for Sentinel-Controlled Repetition vs. Counter-Controlled Repetition**  
 Compare the program logic for sentinel-controlled repetition in this application with that for counter-controlled repetition in Fig. 4.6. In counter-controlled repetition, each iteration of the `while` statement (e.g., lines 52–58 of Fig. 4.6) reads a value from the user, for the specified number of iterations. In sentinel-controlled repetition, the program reads the first value (lines 53–54 of Fig. 4.9) before reaching the `while`. This value determines whether the program's flow of control should enter the body of the `while`. If the condition of the `while` is false, the user entered the sentinel value, so the body of the `while` does not

**150** Chapter 4 Control Statements: Part I

execute (i.e., no grades were entered). If, on the other hand, the condition is true, the body begins execution, and the loop adds the `grade` value to the `total` (line 59). Then lines 63–64 in the loop body input the next value from the user. Next, program control reaches the closing right brace `}` of the loop body at line 65, so execution continues with the test of the `while`'s condition (line 57). The condition uses the most recent `grade` input by the user to determine whether the loop body should execute again. Note that the value of variable `grade` is always input from the user immediately before the program tests the `while` condition. This allows the program to determine whether the value just input is the sentinel value *before* the program processes that value (i.e., adds it to the `total`). If the sentinel value is input, the loop terminates, and the program does not add  $-1$  to the `total`.

**Good Programming Practice 4.6**

*In a sentinel-controlled loop, the prompts requesting data entry should explicitly remind the user of the sentinel value.*

After the loop terminates, the `if...else` statement at lines 69–80 executes. The condition at line 69 determines whether any grades were input. If none were input, the `else` part (lines 79–80) of the `if...else` statement executes and displays the message "No grades were entered" and the method returns control to the calling method.

Notice the `while` statement's block in Fig. 4.9 (lines 58–65). Without the braces, the loop would consider its body to be only the first statement, which adds the `grade` to the `total`. The last three statements in the block would fall outside the loop body, causing the computer to interpret the code incorrectly as follows:

```
while (grade != -1)
 total = total + grade; // add grade to total
 gradeCounter = gradeCounter + 1; // increment counter

 // prompt for input and read next grade from user
 System.out.print("Enter grade or -1 to quit: ");
 grade = input.nextInt();
```

The preceding code would cause an infinite loop in the program if the user did not input the sentinel  $-1$  at line 54 (before the `while` statement).

**Common Programming Error 4.7**

*Omitting the braces that delimit a block can lead to logic errors, such as infinite loops. To prevent this problem, some programmers enclose the body of every control statement in braces, even if the body contains only a single statement.*

**Explicitly and Implicitly Converting Between Primitive Types**

If at least one grade was entered, line 72 of Fig. 4.9 calculates the average of the grades. Recall from Fig. 4.6 that integer division yields an integer result. Even though variable `average` is declared as a `double` (line 45), the calculation

```
average = total / gradeCounter;
```

loses the fractional part of the quotient before the result of the division is assigned to `average`. This occurs because `total` and `gradeCounter` are both integers, and integer division yields an integer result. To perform a floating-point calculation with integer values, we must temporarily treat these values as floating-point numbers for use in the calculation.

## 4.9 Formulating Algorithms: Sentinel-Controlled Repetition 151

Java provides the **unary cast operator** to accomplish this task. Line 72 uses the **(double)** cast operator—a unary operator—to create a *temporary* floating-point copy of its operand **total** (which appears to the right of the operator). Using a cast operator in this manner is called **explicit conversion**. The value stored in **total** is still an integer.

The calculation now consists of a floating-point value (the temporary **double** version of **total**) divided by the integer **gradeCounter**. Java knows how to evaluate only arithmetic expressions in which the operands' types are identical. To ensure that the operands are of the same type, Java performs an operation called **promotion** (or **implicit conversion**) on selected operands. For example, in an expression containing values of the types **int** and **double**, the **int** values are **promoted** to **double** values for use in the expression. In this example, the value of **gradeCounter** is promoted to type **double**, then the floating-point division is performed and the result of the calculation is assigned to **average**. As long as the **(double)** cast operator is applied to any variable in the calculation, the calculation will yield a **double** result. Later in this chapter, we discuss all the primitive types. You will learn more about the promotion rules in Section 6.7.

### Common Programming Error 4.8

*The cast operator can be used to convert between primitive numeric types, such as int and double, and between related reference types (as we discuss in Chapter 10, Object-Oriented Programming: Polymorphism). Casting to the wrong type may cause compilation errors or runtime errors.*

Cast operators are available for any type. The cast operator is formed by placing parentheses around the name of a type. The operator is a **unary operator** (i.e., an operator that takes only one operand). In Chapter 2, we studied the binary arithmetic operators. Java also supports unary versions of the plus (+) and minus (-) operators, so the programmer can write expressions like **-7** or **+5**. Cast operators associate from right to left and have the same precedence as other unary operators, such as unary + and unary -. This precedence is one level higher than that of the **multiplicative operators** **\***, **/** and **%**. (See the operator precedence chart in Appendix A.) We indicate the cast operator with the notation **(type)** in our precedence charts, to indicate that any type name can be used to form a cast operator.

Line 77 outputs the class average using **System.out**'s **printf** method. In this example, we display the class average rounded to the nearest hundredth. The format specifier **.2f** in **printf**'s format control string (line 77) indicates that variable **average**'s value should be displayed with two digits of precision to the right of the decimal point—indicated by **.2** in the format specifier. The three grades entered during the sample execution of class **GradeBookTest** (Fig. 4.10) total 257, which yields the average 85.666666.... Method **printf** uses the precision in the format specifier to round the value to the specified

```

number of digits. In this program, the average is rounded to the hundredths position and the average is displayed as 85.67.

## 4.10 Formulating Algorithms: Nested Control Statements

For the next example, we once again formulate an algorithm by using pseudocode and top-down, stepwise refinement, and write a corresponding Java program. We have seen that control statements can be stacked on top of one another (in sequence). In this case study, we examine the only other structured way control statements can be connected, namely, by **nesting** one control statement within another.

Consider the following problem statement:

*A college offers a course that prepares students for the state licensing exam for real estate brokers. Last year, ten of the students who completed this course took the exam. The college wants to know how well its students did on the exam. You have been asked to write a program to summarize the results. You have been given a list of these 10 students. Next to each name is written a 1 if the student passed the exam or a 2 if the student failed.*

*Your program should analyze the results of the exam as follows:*

1. *Input each test result (i.e., a 1 or a 2). Display the message “Enter result” on the screen each time the program requests another test result.*
2. *Count the number of test results of each type.*
3. *Display a summary of the test results indicating the number of students who passed and the number who failed.*
4. *If more than eight students passed the exam, print the message “Raise tuition.”*

4.10 Formulating Algorithms: Nested Control Statements **153**

After reading the problem statement carefully, we make the following observations:

1. The program must process test results for 10 students. A counter-controlled loop can be used because the number of test results is known in advance.
2. Each test result has a numeric value—either a 1 or a 2. Each time the program reads a test result, the program must determine whether the number is a 1 or a 2. We test for a 1 in our algorithm. If the number is not a 1, we assume that it is a 2. (Exercise 4.24 considers the consequences of this assumption.)
3. Two counters are used to keep track of the exam results—one to count the number of students who passed the exam and one to count the number of students who failed the exam.
4. After the program has processed all the results, it must decide whether more than eight students passed the exam.

Let us proceed with top-down, stepwise refinement. We begin with a pseudocode representation of the top:

*Analyze exam results and decide whether tuition should be raised*

Once again, the top is a *complete* representation of the program, but several refinements are likely to be needed before the pseudocode can evolve naturally into a Java program.

Our first refinement is

*Initialize variables*

*Input the 10 exam results, and count passes and failures*

*Print a summary of the exam results and decide whether tuition should be raised*

Here, too, even though we have a complete representation of the entire program, further refinement is necessary. We now commit to specific variables. Counters are needed to record the passes and failures, a counter will be used to control the looping process and a variable is needed to store the user input. The variable in which the user input will be stored is not initialized at the start of the algorithm, because its value is read from the user during each iteration of the loop.

The pseudocode statement

*Initialize variables*

can be refined as follows:

*Initialize passes to zero*

*Initialize failures to zero*

*Initialize student counter to one*

Notice that only the counters are initialized at the start of the algorithm.

The pseudocode statement

*Input the 10 exam results, and count passes and failures*

requires a loop that successively inputs the result of each exam. We know in advance that there are precisely 10 exam results, so counter-controlled looping is appropriate. Inside the loop (i.e., nested within the loop), a double-selection structure will determine whether each exam result is a pass or a failure and will increment the appropriate counter. The refinement of the preceding pseudocode statement is then

**154** Chapter 4 Control Statements: Part I

```

While student counter is less than or equal to 10
 Prompt the user to enter the next exam result
 Input the next exam result
 If the student passed
 Add one to passes
 Else
 Add one to failures
 Add one to student counter

```

We use blank lines to isolate the *If...Else* control structure, which improves readability.  
The pseudocode statement

*Print a summary of the exam results and decide whether tuition should be raised*  
can be refined as follows:

```

Print the number of passes
Print the number of failures
If more than eight students passed
 Print "Raise tuition"

```

#### **Complete Second Refinement of Pseudocode and Conversion to Class Analysis**

The complete second refinement appears in Fig. 4.11. Notice that blank lines are also used to set off the *While* structure for program readability. This pseudocode is now sufficiently refined for conversion to Java. The Java class that implements the pseudocode algorithm is shown in Fig. 4.12, and two sample executions appear in Fig. 4.13.

```

1 Initialize passes to zero
2 Initialize failures to zero
3 Initialize student counter to one
4
5 While student counter is less than or equal to 10
6 Prompt the user to enter the next exam result
7 Input the next exam result
8
9 If the student passed
10 Add one to passes
11 Else
12 Add one to failures
13
14 Add one to student counter
15
16 Print the number of passes
17 Print the number of failures
18
19 If more than eight students passed
20 Print "Raise tuition"

```

**Fig. 4.11** | Pseudocode for examination-results problem.

4.10 Formulating Algorithms: Nested Control Statements **155**

```

1 // Fig. 4.12: Analysis.java
2 // Analysis of examination results.
3 import java.util.Scanner; // class uses class Scanner
4
5 public class Analysis
6 {
7 public void processExamResults()
8 {
9 // create Scanner to obtain input from command window
10 Scanner input = new Scanner(System.in);
11
12 // initializing variables in declarations
13 int passes = 0; // number of passes
14 int failures = 0; // number of failures
15 int studentCounter = 1; // student counter
16 int result; // one exam result (obtains value from user)
17
18 // process 10 students using counter-controlled loop
19 while (studentCounter <= 10)
20 {
21 // prompt user for input and obtain value from user
22 System.out.print("Enter result (1 = pass, 2 = fail): ");
23 result = input.nextInt();
24
25 // if...else nested in while
26 if (result == 1) // if result 1,
27 passes = passes + 1; // increment passes;
28 else // else result is not 1, so
29 failures = failures + 1; // increment failures
30
31 // increment studentCounter so loop eventually terminates
32 studentCounter = studentCounter + 1;
33 } // end while
34
35 // termination phase; prepare and display results
36 System.out.printf("Passed: %d\nFailed: %d\n", passes, failures);
37
38 // determine whether more than 8 students passed
39 if (passes > 8)
40 System.out.println("Raise Tuition");
41 } // end method processExamResults
42
43 } // end class Analysis

```

**Fig. 4.12** | Nested control structures: Examination-results problem.

Lines 13–16 of Fig. 4.12 declare the variables that method `processExamResults` of class `Analysis` uses to process the examination results. Several of these declarations use Java's ability to incorporate variable initialization into declarations (`passes` is assigned 0, `failures` is assigned 0 and `studentCounter` is assigned 1). Looping programs may require initialization at the beginning of each repetition—such reinitialization would normally be performed by assignment statements rather than in declarations.

**156** Chapter 4 Control Statements: Part I

The `while` statement (lines 19–33) loops 10 times. During each iteration, the loop inputs and processes one exam result. Notice that the `if...else` statement (lines 26–29) for processing each result is nested in the `while` statement. If the `result` is 1, the `if...else` statement increments `passes`; otherwise, it assumes the `result` is 2 and increments `failures`. Line 32 increments `studentCounter` before the loop condition is tested again at line 19. After 10 values have been input, the loop terminates and line 36 displays the number of `passes` and `failures`. The `if` statement at lines 39–40 determines whether more than eight students passed the exam and, if so, outputs the message "Raise Tuition".

**Error-Prevention Tip 4.3**

*Initializing local variables when they are declared helps the programmer avoid any compilation errors that might arise from attempts to use uninitialized data. While Java does not require that local variable initializations be incorporated into declarations, it does require that local variables be initialized before their values are used in an expression.*

**AnalysisTest Class That Demonstrates Class Analysis**

Class `AnalysisTest` (Fig. 4.13) creates an `Analysis` object (line 8) and invokes the object's `processExamResults` method (line 9) to process a set of exam results entered by the user. Figure 4.13 shows the input and output from two sample executions of the program. During the first sample execution, the condition at line 39 of method `processExamResults` in Fig. 4.12 is true—more than eight students passed the exam, so the program outputs a message indicating that the tuition should be raised.

```

1 // Fig. 4.13: AnalysisTest.java
2 // Test program for class Analysis.
3
4 public class AnalysisTest
5 {
6 public static void main(String args[])
7 {
8 Analysis application = new Analysis(); // create Analysis object
9 application.processExamResults(); // call method to process results
10 } // end main
11
12 } // end class AnalysisTest

```

```

Enter result (1 = pass, 2 = fail): 1
Enter result (1 = pass, 2 = fail): 2
Enter result (1 = pass, 2 = fail): 1
Enter result (1 = pass, 2 = fail): 1
Enter result (1 = pass, 2 = fail): 1
Enter result (1 = pass, 2 = fail): 1

### 4.11 Compound Assignment Operators

Java provides several **compound assignment operators** for abbreviating assignment expressions. Any statement of the form

*variable* = *variable operator expression*;

where *operator* is one of the binary operators +, -, \*, / or % (or others we discuss later in the text) can be written in the form

*variable operator= expression*;

For example, you can abbreviate the statement

*c* = *c* + 3;

with the **addition compound assignment operator**, **+=**, as

*c* += 3;

The **+=** operator adds the value of the expression on the right of the operator to the value of the variable on the left of the operator and stores the result in the variable on the left of the operator. Thus, the assignment expression *c* += 3 adds 3 to *c*. Figure 4.14 shows the arithmetic compound assignment operators, sample expressions using the operators and explanations of what the operators do.

| Assignment operator                                                                       | Sample expression | Explanation             | Assigns        |
|-------------------------------------------------------------------------------------------|-------------------|-------------------------|----------------|
| <i>Assume:</i> int <i>c</i> = 3, <i>d</i> = 5, <i>e</i> = 4, <i>f</i> = 6, <i>g</i> = 12; |                   |                         |                |
| <b>+=</b>                                                                                 | <i>c</i> += 7     | <i>c</i> = <i>c</i> + 7 | 10 to <i>c</i> |
| <b>-=</b>                                                                                 | <i>d</i> -= 4     | <i>d</i> = <i>d</i> - 4 | 1 to <i>d</i>  |
| <b>*=</b>                                                                                 | <i>e</i> *= 5     | <i>e</i> = <i>e</i> * 5 | 20 to <i>e</i> |

**Fig. 4.14** | Arithmetic compound assignment operators. (Part 1 of 2.)

| Assignment operator | Sample expression   | Explanation            | Assigns             |
|---------------------|---------------------|------------------------|---------------------|
| <code>/=</code>     | <code>f /= 3</code> | <code>f = f / 3</code> | 2 to <code>f</code> |
| <code>%=</code>     | <code>g %= 9</code> | <code>g = g % 9</code> | 3 to <code>g</code> |

**Fig. 4.14** | Arithmetic compound assignment operators. (Part 2 of 2.)

## 4.12 Increment and Decrement Operators

Java provides two unary operators for adding 1 to or subtracting 1 from the value of a numeric variable. These are the unary **increment operator**, `++`, and the unary **decrement operator**, `--`, which are summarized in Fig. 4.15. A program can increment by 1 the value of a variable called `c` using the increment operator, `++`, rather than the expression `c = c + 1` or `c += 1`. An increment or decrement operator that is prefixed to (placed before) a variable is referred to as the **prefix increment** or **prefix decrement operator**, respectively. An increment or decrement operator that is postfixified to (placed after) a variable is referred to as the **postfix increment** or **postfix decrement operator**, respectively.

Using the prefix increment (or decrement) operator to add (or subtract) 1 from a variable is known as **preincrementing** (or **predecrementing**) the variable. Preincrementing (or predecrementing) a variable causes the variable to be incremented (decremented) by 1, and then the new value of the variable is used in the expression in which it appears. Using the postfix increment (or decrement) operator to add (or subtract) 1 from a variable is known as **postincrementing** (or **postdecrementing**) the variable. Postincrementing (or postdecrementing) the variable causes the current value of the variable to be used in the expression in which it appears, and then the variable's value is incremented (decremented) by 1.

### Good Programming Practice 4.7

*Unlike binary operators, the unary increment and decrement operators should be placed next to their operands, with no intervening spaces.*

| Operator        | Operator name     | Sample expression | Explanation                                                                                                                    |
|-----------------|-------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>++</code> | prefix increment  | <code>++a</code>  | Increment <code>a</code> by 1, then use the new value of <code>a</code> in the expression in which <code>a</code> resides.     |
| <code>++</code> | postfix increment | <code>a++</code>  | Use the current value of <code>a</code> in the expression in which <code>a</code> resides, then increment <code>a</code> by 1. |
| <code>--</code> | prefix decrement  | <code>--b</code>  | Decrement <code>b</code> by 1, then use the new value of <code>b</code> in the expression in which <code>b</code> resides.     |
| <code>--</code> | postfix decrement | <code>b--</code>  | Use the current value of <code>b</code> in the expression in which <code>b</code> resides, then decrement <code>b</code> by 1. |

**Fig. 4.15** | Increment and decrement operators.

4.12 Increment and Decrement Operators **159**

Figure 4.16 demonstrates the difference between the prefix increment and postfix increment versions of the `++` increment operator. The decrement operator (`--`) works similarly. Note that this example contains only one class, with method `main` performing all the class's work. In this chapter and in Chapter 3, you have seen examples consisting of two classes—one class containing methods that perform useful tasks and one containing method `main`, which creates an object of the other class and calls its methods. In this example, we simply want to show the mechanics of the `++` operator, so we use only one class declaration containing method `main`. Occasionally, when it does not make sense to try to create a reusable class to demonstrate a simple concept, we will use a “mechanical” example contained entirely within the `main` method of a single class.

Line 11 initializes the variable `c` to 5, and line 12 outputs `c`'s initial value. Line 13 outputs the value of the expression `c++`. This expression postincrements the variable `c`, so `c`'s original value (5) is output, then `c`'s value is incremented (to 6). Thus, line 13 outputs `c`'s

```

1 // Fig. 4.16: Increment.java
2 // Prefix increment and postfix increment operators.
3
4 public class Increment
5 {
6 public static void main(String args[])
7 {
8 int c;
9
10 // demonstrate postfix increment operator
11 c = 5; // assign 5 to c
12 System.out.println(c); // prints 5
13 System.out.println(c++); // prints 5 then postincrements
14 System.out.println(c); // prints 6
15
16 System.out.println(); // skip a line
17
18 // demonstrate prefix increment operator
19 c = 5; // assign 5 to c
20 System.out.println(c); // prints 5
21 System.out.println(++c); // preincrements then prints 6
22 System.out.println(c); // prints 6
23
24 } // end main
25
26 } // end class Increment

```

```

5
5
6

5
6
6

```

**Fig. 4.16** | Preincrementing and postincrementing.

**160** Chapter 4 Control Statements: Part I

initial value (5) again. Line 14 outputs c's new value (6) to prove that the variable's value was indeed incremented in line 13.

Line 19 resets c's value to 5, and line 20 outputs c's value. Line 21 outputs the value of the expression `++c`. This expression preincrements c, so its value is incremented, then the new value (6) is output. Line 22 outputs c's value again to show that the value of c is still 6 after line 21 executes.

The arithmetic compound assignment operators and the increment and decrement operators can be used to simplify program statements. For example, the three assignment statements in Fig. 4.12 (lines 27, 29 and 32)

```
passes = passes + 1;
failures = failures + 1;
studentCounter = studentCounter + 1;
```

can be written more concisely with compound assignment operators as

```
passes += 1;
failures += 1;
studentCounter += 1;
```

with prefix increment operators as

```
++passes;
++failures;
++studentCounter;
```

or with postfix increment operators as

```
passes++;
failures++;
studentCounter++;
```

When incrementing or decrementing a variable in a statement by itself, the prefix increment and postfix increment forms have the same effect, and the prefix decrement and postfix decrement forms have the same effect. It is only when a variable appears in the context of a larger expression that preincrementing and postincrementing the variable have different effects (and similarly for predecrementing and postdecrementing).

### Common Programming Error 4.9

*Attempting to use the increment or decrement operator on an expression other than one to which a value can be assigned is a syntax error. For example, writing `++(x + 1)` is a syntax error because `(x + 1)` is not a variable.*

Figure 4.17 shows the precedence and associativity of the operators we have introduced to this point. The operators are shown from top to bottom in decreasing order of precedence. The second column describes the associativity of the operators at each level of precedence. The conditional operator (`? :`); the unary operators increment (`++`), decrement (`--`), plus (`+`) and minus (`-`); the cast operators and the assignment operators `=`, `+=`, `-=`, `*=`, `/=` and `%=` associate from right to left. All the other operators in the operator precedence chart in Fig. 4.17 associate from left to right. The third column lists the type of each group of operators.

4.13 Primitive Types **161**

| Operators                                                                                      | Associativity | Type           |
|------------------------------------------------------------------------------------------------|---------------|----------------|
| <code>++</code> <code>--</code>                                                                | right to left | unary postfix  |
| <code>++</code> <code>--</code> <code>+</code> <code>-</code> <code>( type )</code>            | right to left | unary prefix   |
| <code>*</code> <code>/</code> <code>%</code>                                                   | left to right | multiplicative |
| <code>+</code> <code>-</code>                                                                  | left to right | additive       |
| <code>&lt;</code> <code>&lt;=</code> <code>&gt;</code> <code>&gt;=</code>                      | left to right | relational     |
| <code>==</code> <code>!=</code>                                                                | left to right | equality       |
| <code>?:</code>                                                                                | right to left | conditional    |
| <code>=</code> <code>+=</code> <code>-=</code> <code>*=</code> <code>/=</code> <code>%=</code> | right to left | assignment     |

**Fig. 4.17** | Precedence and associativity of the operators discussed so far.

## 4.13 Primitive Types

The table in Appendix D, Primitive Types, lists the eight primitive types in Java. Like its predecessor languages C and C++, Java requires all variables to have a type. For this reason, Java is referred to as a [strongly typed language](#).

In C and C++, programmers frequently have to write separate versions of programs to support different computer platforms, because the primitive types are not guaranteed to be identical from computer to computer. For example, an `int` value on one machine might be represented by 16 bits (2 bytes) of memory, and on another machine by 32 bits (4 bytes). In Java, `int` values are always 32 bits (4 bytes).

### Portability Tip 4.1

*Unlike C and C++, the primitive types in Java are portable across all computer platforms that support Java.*

Each type in Appendix D is listed with its size in bits (there are eight bits to a byte) and its range of values. Because the designers of Java want it to be maximally portable, they use internationally recognized standards for both character formats (Unicode; for more information, visit [www.unicode.org](http://www.unicode.org)) and floating-point numbers (IEEE 754; for more information, visit [grouper.ieee.org/groups/754/](http://grouper.ieee.org/groups/754/)).

Recall from Section 3.5 that variables of primitive types declared outside of a method as fields of a class are automatically assigned default values unless explicitly initialized. Instance variables of types `char`, `byte`, `short`, `int`, `long`, `float` and `double` are all given the value `0` by default. Instance variables of type `boolean` are given the value `false` by default. Reference-type instance variables are initialized by default to the value `null`.

## 4.14 (Optional) GUI and Graphics Case Study: Creating Simple Drawings

One of Java's appealing features is its graphics support that enables programmers to visually enhance their applications. This section introduces one of Java's graphical capabili-

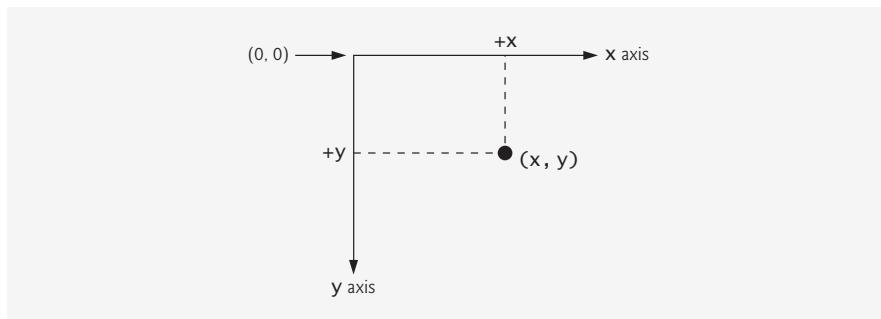

**162** Chapter 4 Control Statements: Part I

ties—drawing lines. It also covers the basics of creating a window to display a drawing on the computer screen.

To draw in Java, you must understand Java's **coordinate system** (Fig. 4.18), a scheme for identifying every point on the screen. By default, the upper-left corner of a GUI component has the coordinates (0, 0). A coordinate pair is composed of an **x-coordinate** (the **horizontal coordinate**) and a **y-coordinate** (the **vertical coordinate**). The **x**-coordinate is the horizontal location moving from left to right. The **y**-coordinate is the vertical location moving top to bottom. The **x-axis** describes every horizontal coordinate, and the **y-axis** every vertical coordinate.

Coordinates indicate where graphics should be displayed on a screen. Coordinate units are measured in **pixels**. A pixel is a display monitor's smallest unit of resolution. (The term pixel stands for “picture element.”)

Our first drawing application simply draws two lines. Class **DrawPanel1** (Fig. 4.19) performs the actual drawing, while class **DrawPanel1Test** (Fig. 4.20) creates a window to display the drawing. In class **DrawPanel1**, the **import** statements in lines 3–4 allow us to use class **Graphics** (from package **java.awt**), which provides various methods for drawing text and shapes onto the screen, and class **JPanel** (from package **javax.swing**), which provides an area on which we can draw.

**Fig. 4.18** | Java coordinate system. Units are measured in pixels.

```

1 // Fig. 4.19: DrawPanel.java
2 // Using drawLine to connect the corners of a panel.
3 import java.awt.Graphics;
4 import javax.swing.JPanel;
5
6 public class DrawPanel extends JPanel
7 {
8 // draws an X from the corners of the panel
9 public void paintComponent(Graphics g)
10 {
11 // call paintComponent to ensure the panel displays correctly
12 super.paintComponent(g);
13 }

```

**Fig. 4.19** | Using **drawLine** to connect the corners of a panel. (Part I of 2.)

4.14 (Optional) GUI and Graphics Case Study: Creating Simple Drawings **163**

```

14 int width = getWidth(); // total width
15 int height = getHeight(); // total height
16
17 // draw a line from the upper-left to the lower-right
18 g.drawLine(0, 0, width, height);
19
20 // draw a line from the lower-left to the upper-right
21 g.drawLine(0, height, width, 0);
22 } // end method paintComponent
23 } // end class DrawPanel

```

**Fig. 4.19** | Using `drawLine` to connect the corners of a panel. (Part 2 of 2.)

Line 6 uses the keyword `extends` to indicate that class `DrawPanel` is an enhanced type of `JPanel`. The keyword `extends` represents a so-called inheritance relationship in which our new class `DrawPanel` begins with the existing members (data and methods) from class `JPanel`. The class from which `DrawPanel` `inherits`, `JPanel`, appears to the right of keyword `extends`. In this inheritance relationship, `JPanel` is called the `superclass` and `DrawPanel` is called the `subclass`. This results in a `DrawPanel` class that has the attributes (data) and behaviors (methods) of class `JPanel` as well as the new features we are adding in our `DrawPanel` class declaration—specifically, the ability to draw two lines along the diagonals of the panel. Inheritance is explained in detail in Chapter 9.

Every `JPanel`, including our `DrawPanel`, has a `paintComponent` method (lines 9–22), which the system automatically calls every time it needs to display the `JPanel`. Method `paintComponent` must be declared as shown in line 9—otherwise, the system will not call the method. This method is called when a `JPanel` is first displayed on the screen, when it is covered then uncovered by a window on the screen and when the window in which it appears is resized. Method `paintComponent` requires one argument, a `Graphics` object, that is provided for you by the system when it calls `paintComponent`.

The first statement in every `paintComponent` method you create should always be

```
super.paintComponent(g);
```

which ensures that the panel is properly rendered on the screen before we begin drawing on it. Next, lines 14 and 15 call two methods that class `DrawPanel` inherits from class `JPanel`. Because `DrawPanel` extends `JPanel`, `DrawPanel` can use any `public` methods that are declared in `JPanel`. Methods `getWidth` and `getHeight` return the width and the height of the `JPanel` respectively. Lines 14–15 store these values in the local variables `width` and `height`. Finally, lines 18 and 21 use the `Graphics` reference `g` to call method `drawLine` to draw the two lines. Method `drawLine` draws a line between two points represented by its four arguments. The first two arguments are the *x*- and *y*-coordinates for one endpoint of the line, and the last two arguments are the coordinates for the other endpoint. If you resize the window, the lines will scale accordingly, because the arguments are based on the width and height of the panel. Resizing the window in this application causes the system to call `paintComponent` to redraw the `DrawPanel`'s contents.

To display the `DrawPanel` on the screen, we must place it in a window. You create a window with an object of class `JFrame`. In `DrawPanelTest.java` (Fig. 4.20), line 3 imports class `JFrame` from package `javax.swing`. Line 10 in the `main` method of class `DrawPanelTest` creates an instance of class `DrawPanel`, which contains our drawing, and line

**164** Chapter 4 Control Statements: Part I

```

1 // Fig. 4.20: DrawPanelTest.java
2 // Application to display a DrawPanel.
3 import javax.swing.JFrame;
4
5 public class DrawPanelTest
6 {
7 public static void main(String args[])
8 {
9 // create a panel that contains our drawing
10 DrawPanel panel = new DrawPanel();
11
12 // create a new frame to hold the panel
13 JFrame application = new JFrame();
14
15 // set the frame to exit when it is closed
16 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
17
18 application.add(panel); // add the panel to the frame
19 application.setSize(250, 250); // set the size of the frame
20 application.setVisible(true); // make the frame visible
21 } // end main
22 } // end class DrawPanelTest

```

**Fig. 4.20** | Creating JFrame to display DrawPanel.

Line 13 creates a new `JFrame` that can hold and display our panel. Line 16 calls method `setDefaultCloseOperation` with the argument `JFrame.EXIT_ON_CLOSE` to indicate that the application should terminate when the user closes the window. Line 18 uses `JFrame`'s `add` method to attach the `DrawPanel` containing our drawing to the `JFrame`. Line 19 sets the size of the `JFrame`. Method `setSize` takes two parameters—the width of the `JFrame`, and the height. Finally, line 20 displays the `JFrame`. When the `JFrame` is displayed, the `DrawPanel`'s `paintComponent` method (lines 9–22 of Fig. 4.19) is called, and the two lines are drawn (see the sample outputs in Fig. 4.20). Try resizing the window to see that the lines always draw based on the window's current width and height.

#### *GUI and Graphics Case Study Exercises*

- 4.1** Using loops and control statements to draw lines can lead to many interesting designs.  
 a) Create the design in the left screen capture of Fig. 4.21. This design draws lines from the top-left corner, fanning out the lines until they cover the upper-left half of the panel. One approach is to divide the width and height into an equal number of steps (we found

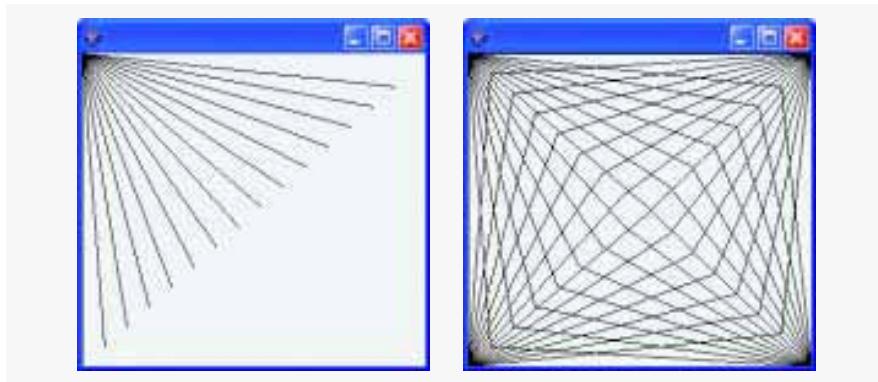

#### 4.14 (Optional) GUI and Graphics Case Study: Creating Simple Drawings **165**

15 steps worked well). The first endpoint of a line will always be in the top-left corner (0, 0). The second endpoint can be found by starting at the bottom-left corner and moving up one vertical step and right one horizontal step. Draw a line between the two endpoints. Continue moving up and to the right one step to find each successive endpoint. The figure should scale accordingly as you resize the window.

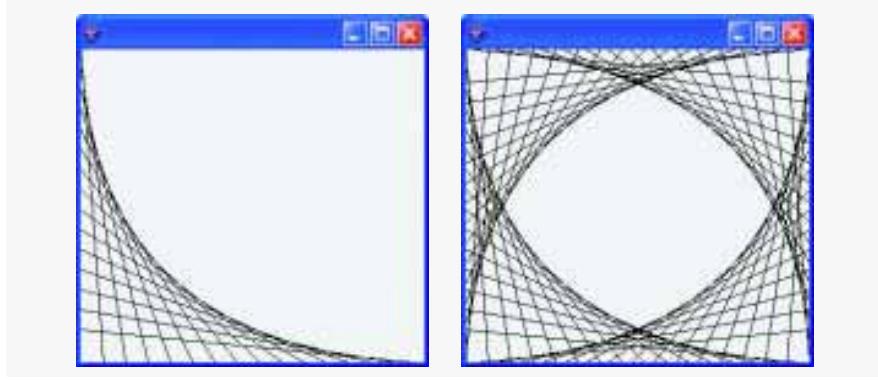

- Modify your answer in part (a) to have lines fan out from all four corners, as shown in the right screen capture of Fig. 4.21. Lines from opposite corners should intersect along the middle.

**4.2** Figure 4.22 displays two additional designs created using `while` loops and `drawLine`.

- Create the design in the left screen capture of Fig. 4.22. Begin by dividing each edge into an equal number of increments (we chose 15 again). The first line starts in the top-left corner and ends one step right on the bottom edge. For each successive line, move down one increment on the left edge and right one increment on the bottom edge. Continue drawing lines until you reach the bottom-right corner. The figure should scale as you resize the window so that the endpoints always touch the edges.
- Modify your answer in part (a) to mirror the design in all four corners, as shown in the right screen capture of Fig. 4.22.

**Fig. 4.21** | Lines fanning from a corner.

**Fig. 4.22** | Line art with loops and `drawLine`.

## 4.15 (Optional) Software Engineering Case Study: Identifying Class Attributes

In Section 3.10, we began the first stage of an object-oriented design (OOD) for our ATM system—analyzing the requirements document and identifying the classes needed to implement the system. We listed the nouns and noun phrases in the requirements document and identified a separate class for each one that plays a significant role in the ATM system. We then modeled the classes and their relationships in a UML class diagram (Fig. 3.24). Classes have attributes (data) and operations (behaviors). Class attributes are implemented in Java programs as fields, and class operations are implemented as methods. In this section, we determine many of the attributes needed in the ATM system. In Chapter 5, we examine how these attributes represent an object’s state. In Chapter 6, we determine class operations.

### *Identifying Attributes*

Consider the attributes of some real-world objects: A person’s attributes include height, weight and whether the person is left-handed, right-handed or ambidextrous. A radio’s attributes include its station setting, its volume setting and its AM or FM setting. A car’s attributes include its speedometer and odometer readings, the amount of gas in its tank and what gear it is in. A personal computer’s attributes include its manufacturer (e.g., Dell, Sun, Apple or IBM), type of screen (e.g., LCD or CRT), main memory size and hard disk size.

We can identify many attributes of the classes in our system by looking for descriptive words and phrases in the requirements document. For each one we find that plays a significant role in the ATM system, we create an attribute and assign it to one or more of the classes identified in Section 3.10. We also create attributes to represent any additional data that a class may need, as such needs become clear throughout the design process.

Figure 4.23 lists the words or phrases from the requirements document that describe each class. We formed this list by reading the requirements document and identifying any words or phrases that refer to characteristics of the classes in the system. For example, the requirements document describes the steps taken to obtain a “withdrawal amount,” so we list “amount” next to class `Withdrawal`.

| Class          | Descriptive words and phrases     |
|----------------|-----------------------------------|
| ATM            | user is authenticated             |
| BalanceInquiry | account number                    |
| Withdrawal     | account number<br>amount          |
| Deposit        | account number<br>amount          |
| BankDatabase   | [no descriptive words or phrases] |

**Fig. 4.23** | Descriptive words and phrases from the ATM requirements. (Part I of 2.)

4.15 Identifying Class Attributes **167**

| Class         | Descriptive words and phrases              |
|---------------|--------------------------------------------|
| Account       | account number<br>PIN<br>balance           |
| Screen        | [no descriptive words or phrases]          |
| Keypad        | [no descriptive words or phrases]          |
| CashDispenser | begins each day loaded with 500 \$20 bills |
| DepositSlot   | [no descriptive words or phrases]          |

**Fig. 4.23** | Descriptive words and phrases from the ATM requirements. (Part 2 of 2.)

Figure 4.23 leads us to create one attribute of class `ATM`. Class `ATM` maintains information about the state of the ATM. The phrase “user is authenticated” describes a state of the ATM (we introduce states in Section 5.11), so we include `userAuthenticated` as a **Boolean attribute** (i.e., an attribute that has a value of either `true` or `false`) in class `ATM`. Note that the Boolean attribute type in the UML is equivalent to the `boolean` type in Java. This attribute indicates whether the ATM has successfully authenticated the current user—`userAuthenticated` must be `true` for the system to allow the user to perform transactions and access account information. This attribute helps ensure the security of the data in the system.

Classes `BalanceInquiry`, `Withdrawal` and `Deposit` share one attribute. Each transaction involves an “account number” that corresponds to the account of the user making the transaction. We assign an integer attribute `accountNumber` to each transaction class to identify the account to which an object of the class applies.

Descriptive words and phrases in the requirements document also suggest some differences in the attributes required by each transaction class. The requirements document indicates that to withdraw cash or deposit funds, users must input a specific “amount” of money to be withdrawn or deposited, respectively. Thus, we assign to classes `Withdrawal` and `Deposit` an attribute `amount` to store the value supplied by the user. The amounts of money related to a withdrawal and a deposit are defining characteristics of these transactions that the system requires for these transactions to take place. Class `BalanceInquiry`, however, needs no additional data to perform its task—it requires only an account number to indicate the account whose balance should be retrieved.

Class `Account` has several attributes. The requirements document states that each bank account has an “account number” and “PIN,” which the system uses for identifying accounts and authenticating users. We assign to class `Account` two integer attributes: `accountNumber` and `pin`. The requirements document also specifies that an account maintains a “balance” of the amount of money in the account and that money the user deposits does not become available for a withdrawal until the bank verifies the amount of cash in the deposit envelope, and any checks in the envelope clear. An account must still record the amount of money that a user deposits, however. Therefore, we decide that an account should represent a balance using two attributes: `availableBalance` and `totalBalance`.

## 168 Chapter 4 Control Statements: Part I

Attribute `availableBalance` tracks the amount of money that a user can withdraw from the account. Attribute `totalBalance` refers to the total amount of money that the user has “on deposit” (i.e., the amount of money available, plus the amount waiting to be verified or cleared). For example, suppose an ATM user deposits \$50.00 into an empty account. The `totalBalance` attribute would increase to \$50.00 to record the deposit, but the `availableBalance` attribute would remain at \$0. [Note: We assume that the bank updates the `availableBalance` attribute of an `Account` some length of time after the ATM transaction occurs, in response to confirming that \$50 worth of cash or checks was found in the deposit envelope. We assume that this update occurs through a transaction that a bank employee performs using some piece of bank software other than the ATM. Thus, we do not discuss this transaction in our case study.]

Class `CashDispenser` has one attribute. The requirements document states that the cash dispenser “begins each day loaded with 500 \$20 bills.” The cash dispenser must keep track of the number of bills it contains to determine whether enough cash is on hand to satisfy withdrawal requests. We assign to class `CashDispenser` an integer attribute `count`, which is initially set to 500.

For real problems in industry, there is no guarantee that requirements documents will be rich enough and precise enough for the object-oriented systems designer to determine all the attributes or even all the classes. The need for additional classes, attributes and behaviors may become clear as the design process proceeds. As we progress through this case study, we too will continue to add, modify and delete information about the classes in our system.

### ***Modeling Attributes***

The class diagram in Fig. 4.24 lists some of the attributes for the classes in our system—the descriptive words and phrases in Fig. 4.23 lead us to identify these attributes. For simplicity, Fig. 4.24 does not show the associations among classes—we showed these in Fig. 3.24. This is a common practice of systems designers when designs are being developed. Recall from Section 3.10 that in the UML, a class’s attributes are placed in the middle compartment of the class’s rectangle. We list each attribute’s name and type separated by a colon (:), followed in some cases by an equal sign (=) and an initial value.

Consider the `userAuthenticated` attribute of class `ATM`:

```
userAuthenticated : Boolean = false
```

This attribute declaration contains three pieces of information about the attribute. The **attribute name** is `userAuthenticated`. The **attribute type** is `Boolean`. In Java, an attribute can be represented by a primitive type, such as `boolean`, `int` or `double`, or a reference type like a class—as discussed in Chapter 3. We have chosen to model only primitive-type attributes in Fig. 4.24—we discuss the reasoning behind this decision shortly. [Note: The attribute types in Fig. 4.24 are in UML notation. We will associate the types `Boolean`, `Integer` and `Double` in the UML diagram with the primitive types `boolean`, `int` and `double` in Java, respectively.]

We can also indicate an initial value for an attribute. The `userAuthenticated` attribute in class `ATM` has an initial value of `false`. This indicates that the system initially does not consider the user to be authenticated. If an attribute has no initial value specified, only its name and type (separated by a colon) are shown. For example, the `accountNumber`

## 4.15 Identifying Class Attributes 169

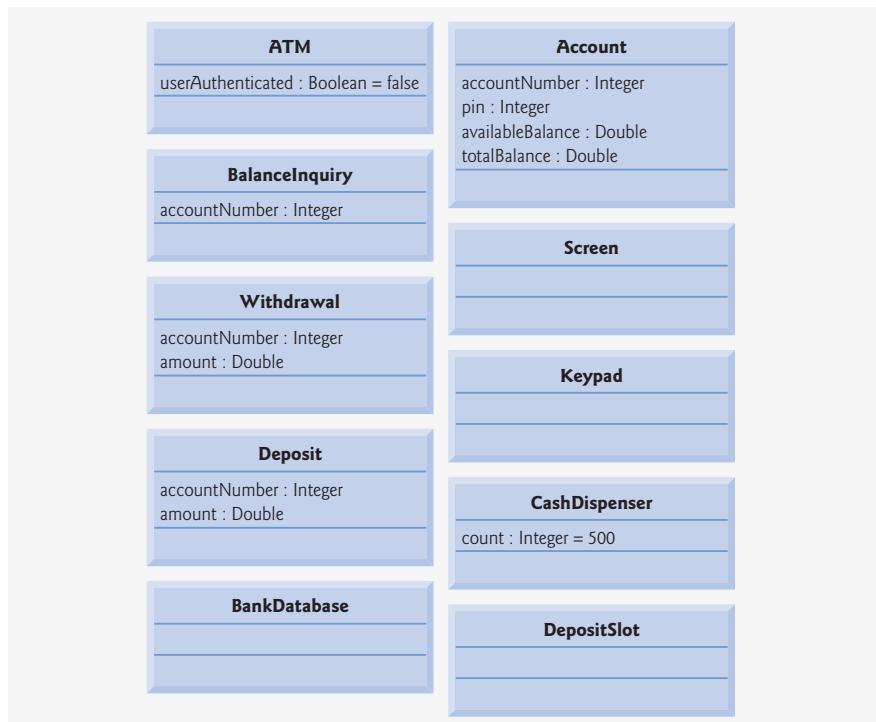

attribute of class `BalanceInquiry` is an integer. Here we show no initial value, because the value of this attribute is a number that we do not yet know. This number will be determined at execution time based on the account number entered by the current ATM user.

Figure 4.24 does not include any attributes for classes `Screen`, `Keypad` and `DepositSlot`. These are important components of our system, for which our design process simply has not yet revealed any attributes. We may still discover some, however, in the remaining phases of design or when we implement these classes in Java. This is perfectly normal.

**Software Engineering Observation 4.6**

*At early stages in the design process, classes often lack attributes (and operations). Such classes should not be eliminated, however, because attributes (and operations) may become evident in the later phases of design and implementation.*

Note that Fig. 4.24 also does not include attributes for class `BankDatabase`. Recall from Chapter 3 that in Java, attributes can be represented by either primitive types or reference types. We have chosen to include only primitive-type attributes in the class diagram in Fig. 4.24 (and in similar class diagrams throughout the case study). A reference-type attribute is modeled more clearly as an association (in particular, a composition) between the class holding the reference and the class of the object to which the reference points.

**Fig. 4.24** | Classes with attributes.

**170** Chapter 4 Control Statements: Part I

For example, the class diagram in Fig. 3.24 indicates that class `BankDatabase` participates in a composition relationship with zero or more `Account` objects. From this composition, we can determine that when we implement the ATM system in Java, we will be required to create an attribute of class `BankDatabase` to hold references to zero or more `Account` objects. Similarly, we can determine reference-type attributes of class `ATM` that correspond to its composition relationships with classes `Screen`, `Keypad`, `CashDispenser` and `DepositSlot`. These composition-based attributes would be redundant if modeled in Fig. 4.24, because the compositions modeled in Fig. 3.24 already convey the fact that the database contains information about zero or more accounts and that an ATM is composed of a screen, keypad, cash dispenser and deposit slot. Software developers typically model these whole/part relationships as compositions rather than as attributes required to implement the relationships.

The class diagram in Fig. 4.24 provides a solid basis for the structure of our model, but the diagram is not complete. In Section 5.11, we identify the states and activities of the objects in the model, and in Section 6.14 we identify the operations that the objects perform. As we present more of the UML and object-oriented design, we will continue to strengthen the structure of our model.

#### *Software Engineering Case Study Self-Review Exercises*

- 4.1** We typically identify the attributes of the classes in our system by analyzing the \_\_\_\_\_ in the requirements document.
- nouns and noun phrases
  - descriptive words and phrases
  - verbs and verb phrases
  - All of the above.
- 4.2** Which of the following is not an attribute of an airplane?
- length
  - wingspan
  - fly
  - number of seats
- 4.3** Describe the meaning of the following attribute declaration of class `CashDispenser` in the class diagram in Fig. 4.24:

```
count : Integer = 500
```

#### *Answers to Software Engineering Case Study Self-Review Exercises*

- 4.1** b.
- 4.2** c. Fly is an operation or behavior of an airplane, not an attribute.
- 4.3** This indicates that `count` is an `Integer` with an initial value of 500. This attribute keeps track of the number of bills available in the `CashDispenser` at any given time.

## 4.16 Wrap-Up

This chapter presented basic problem-solving strategies that programmers use in building classes and developing methods for these classes. We demonstrated how to construct an algorithm (i.e., an approach to solving a problem), then how to refine the algorithm through several phases of pseudocode development, resulting in Java code that can be ex-

## 4.16 Wrap-Up 171

ecuted as part of a method. The chapter showed how to use top-down, stepwise refinement to plan out the specific actions that a method must perform and the order in which the method must perform these actions.

Only three types of control structures—sequence, selection and repetition—are needed to develop any problem-solving algorithm. Specifically, this chapter demonstrated the `if` single-selection statement, the `if...else` double-selection statement and the `while` repetition statement. These are some of the building blocks used to construct solutions to many problems. We used control-statement stacking to total and compute the average of a set of student grades with counter- and sentinel-controlled repetition, and we used control-statement nesting to analyze and make decisions based on a set of exam results. We introduced Java's compound assignment operators, and its increment and decrement operators. Finally, we discussed the primitive types available to Java programmers. In Chapter 5, Control Statements: Part 2, we continue our discussion of control statements, introducing the `for`, `do...while` and `switch` statements.

## Summary

### Section 4.1 Introduction

- Before writing a program to solve a problem, you must have a thorough understanding of the problem and a carefully planned approach to solving it. You must also understand the building blocks that are available and to employ proven program-construction techniques.

### Section 4.2 Algorithms

- Any computing problem can be solved by executing a series of actions in a specific order.
- A procedure for solving a problem in terms of the actions to execute and the order in which they execute is called an algorithm.
- Specifying the order in which statements execute in a program is called program control.

### Section 4.3 Pseudocode

- Pseudocode is an informal language that helps programmers develop algorithms without having to worry about the strict details of Java language syntax.
- Pseudocode is similar to everyday English—it is convenient and user friendly, but it is not an actual computer programming language.
- Pseudocode helps the programmer “think out” a program before attempting to write it in a programming language, such as Java.
- Carefully prepared pseudocode can easily be converted to a corresponding Java program.

### Section 4.4 Control Structures

- Normally, statements in a program are executed one after the other in the order in which they are written. This process is called sequential execution.
- Various Java statements enable the programmer to specify that the next statement to execute is not necessarily the next one in sequence. This is called transfer of control.
- Bohm and Jacopini demonstrated that all programs could be written in terms of only three control structures—the sequence structure, the selection structure and the repetition structure.
- The term “control structures” comes from the field of computer science. The *Java Language Specification* refers to “control structures” as “control statements.”

**172**    [Chapter 4 Control Statements: Part I](#)

- The sequence structure is built into Java. Unless directed otherwise, the computer executes Java statements one after the other in the order in which they are written—that is, in sequence.
- Anywhere a single action may be placed, several actions may be placed in sequence.
- Activity diagrams are part of the UML. An activity diagram models the workflow (also called the activity) of a portion of a software system.
- Activity diagrams are composed of special-purpose symbols, such as action-state symbols, diamonds and small circles. These symbols are connected by transition arrows, which represent the flow of the activity.
- Action states represent actions to perform. Each action state contains an action expression that specifies a particular action to perform.
- The arrows in an activity diagram represent transitions, which indicate the order in which the actions represented by the action states occur.
- The solid circle located at the top of an activity diagram represents the activity's initial state—the beginning of the workflow before the program performs the modeled actions.
- The solid circle surrounded by a hollow circle that appears at the bottom of the diagram represents the final state—the end of the workflow after the program performs its actions.
- Rectangles with their upper-right corners folded over are UML notes—explanatory remarks that describe the purpose of symbols in the diagram.
- Java has three types of selection statements. The `if` statement either performs an action if a condition is true or skips the action if the condition is false. The `if...else` statement performs an action if a condition is true and a different action if the condition is false. The `switch` statement performs one of many different actions, depending on the value of an expression.
- The `if` statement is a single-selection statement because it selects or ignores a single action or a single group of actions.
- The `if...else` statement is called a double-selection statement because it selects between two different actions or groups of actions.
- The `switch` statement is called a multiple-selection statement because it selects among many different actions or groups of actions.
- Java provides the the `while`, `do...while` and `for` repetition (looping) statements that enable programs to perform statements repeatedly as long as a loop-continuation condition remains true.
- The `while` and `for` statements perform the action(s) in their bodies zero or more times—if the loop-continuation condition is initially false, the action(s) will not execute. The `do...while` statement performs the action(s) in its body one or more times.
- The words `if`, `else`, `switch`, `while`, `do` and `for` are Java keywords. Keywords cannot be used as identifiers, such as variable names.
- Every program is formed by combining as many sequence, selection and repetition statements as is appropriate for the algorithm the program implements.
- Single-entry/single-exit control statements make it easy to build programs—we “attach” the control statements to one another by connecting the exit point of one to the entry point of the next. This is known as control-statement stacking.
- There is only one other way in which control statements may be connected—control-statement nesting—in which a control statement appears inside another control statement.

**Section 4.5 `if` Single-Selection Statement**

- Programs use selection statements to choose among alternative courses of action.

[Summary](#) **173**

- The activity diagram for the single-selection `if` statement contains the diamond, or decision symbol, which indicates that a decision is to be made. The workflow will continue along a path determined by the symbol's associated guard conditions, which can be true or false. Each transition arrow emerging from a decision symbol has a guard condition. If a guard condition is true, the workflow enters the action state to which the transition arrow points.
- The `if` statement is a single-entry/single-exit control statement.

***Section 4.6 if...else Double-Selection Statement***

- The `if` single-selection statement performs an indicated action only when the condition is `true`.
- The `if...else` double-selection statement performs one action when the condition is `true` and a different action when the condition is `false`.
- The conditional operator (`? :`) can be used in place of an `if...else` statement. This is Java's only ternary operator—it takes three operands. Together, the operands and the `? :` symbol form a conditional expression.
- A program can test multiple cases by placing `if...else` statements inside other `if...else` statements to create nested `if...else` statements.
- The Java compiler always associates an `else` with the immediately preceding `if` unless told to do otherwise by the placement of braces (`{` and `}`). This behavior can lead to what is referred to as the *dangling-else* problem.
- The `if` statement normally expects only one statement in its body. To include several statements in the body of an `if` (or the body of an `else` for an `if...else` statement), enclose the statements in braces (`{` and `}`).
- A set of statements contained within a pair of braces is called a block. A block can be placed anywhere in a program that a single statement can be placed.
- Syntax errors are caught by the compiler.
- A logic error has its effect at execution time. A fatal logic error causes a program to fail and terminate prematurely. A nonfatal logic error allows a program to continue executing, but causes the program to produce incorrect results.
- Just as a block can be placed anywhere a single statement can be placed, you can also use an empty statement, represented by placing a semicolon (`;`) where a statement would normally be.

***Section 4.7 while Repetition Statement***

- The `while` repetition statement allows the programmer to specify that a program should repeat an action while some condition remains `true`.
- The UML's merge symbol joins two flows of activity into one.
- The decision and merge symbols can be distinguished by the number of “incoming” and “outgoing” transition arrows. A decision symbol has one transition arrow pointing to the diamond and two or more transition arrows pointing out from the diamond to indicate possible transitions from that point. Each transition arrow pointing out of a decision symbol has a guard condition. A merge symbol has two or more transition arrows pointing to the diamond and only one transition arrow pointing from the diamond, to indicate multiple activity flows merging to continue the activity. None of the transition arrows associated with a merge symbol has a guard condition.

***Section 4.8 Formulating Algorithms: Counter-Controlled Repetition***

- Counter-controlled repetition uses a variable called a counter (or control variable) to control the number of times a set of statements execute.

## 174 Chapter 4 Control Statements: Part I

- Counter-controlled repetition is often called definite repetition, because the number of repetitions is known before the loop begins executing.
- A total is a variable used to accumulate the sum of several values. Variables used to store totals are normally initialized to zero before being used in a program.
- A local variable's declaration must appear before the variable is used in that method. A local variable cannot be accessed outside the method in which it is declared.
- Dividing two integers results in integer division—the calculation's fractional part is truncated.

### **Section 4.9 Formulating Algorithms: Sentinel-Controlled Repetition**

- In sentinel-controlled repetition, a special value called a sentinel value (also called a signal value, a dummy value or a flag value) is used to indicate “end of data entry.”
- A sentinel value must be chosen that cannot be confused with an acceptable input value.
- Top-down, stepwise refinement is essential to the development of well-structured programs.
- Division by zero is normally a logic error that, if undetected, would cause the program to fail or produce invalid output.
- To perform a floating-point calculation with integer values, cast one of the integers to type `double`. Using a cast operator in this manner is called explicit conversion.
- Java knows how to evaluate only arithmetic expressions in which the operands' types are identical. To ensure that the operands are of the same type, Java performs an operation called promotion (or implicit conversion) on selected operands. In an expression containing values of the types `int` and `double`, the `int` values are promoted to `double` values for use in the expression.
- Cast operators are available for any type. The cast operator is formed by placing parentheses around the name of a type. The operator is a unary operator.

### **Section 4.11 Compound Assignment Operators**

- Java provides several compound assignment operators for abbreviating assignment expressions. Any statement of the form

`variable = variable operator expression;`

where `operator` is one of the binary operators `+`, `-`, `*`, `/` or `%` can be written in the form

`variable operator= expression;`

- The `+=` operator adds the value of the expression on the right of the operator to the value of the variable on the left of the operator and stores the result in the variable on the left of the operator.

### **Section 4.12 Increment and Decrement Operators**

- Java provides two unary operators for adding 1 to or subtracting 1 from the value of a numeric variable. These are the unary increment operator, `++`, and the unary decrement operator, `--`.
- An increment or decrement operator that is prefixed to a variable is the prefix increment or prefix decrement operator, respectively. An increment or decrement operator that is postfixified to a variable is the postfix increment or postfix decrement operator, respectively.
- Using the prefix increment or decrement operator to add or subtract 1 is known as preincrementing or predecrementing, respectively.
- Preincrementing or predecrementing a variable causes the variable to be incremented or decremented by 1, and then the new value of the variable is used in the expression in which it appears.

[Summary](#)    **175**

- Using the postfix increment or decrement operator to add or subtract 1 is known as postincrementing or postdecrementing, respectively.
- Postincrementing or postdecrementing the variable causes the current value of the variable to be used in the expression in which it appears, and then the variable's value is incremented or decremented by 1.
- When incrementing or decrementing a variable in a statement by itself, the prefix and postfix increment forms have the same effect, and the prefix and postfix decrement forms have the same effect.

***Section 4.13 Primitive Types***

- Java requires all variables to have a type. Thus, Java is referred to as a strongly typed language.
- Because the designers of Java want it to be maximally portable, they use internationally recognized standards for both character formats (Unicode) and floating-point numbers (IEEE 754).

***Section 4.14 (Optional) GUI and Graphics Case Study: Creating Simple Drawings***

- Java's coordinate system provides a scheme for identifying every point on the screen. By default, the upper-left corner of a GUI component has the coordinates (0, 0).
- A coordinate pair is composed of an *x*-coordinate (the horizontal coordinate) and a *y*-coordinate (the vertical coordinate). The *x*-coordinate is the horizontal location moving from left to right. The *y*-coordinate is the vertical location moving top to bottom.
- The *x*-axis describes every horizontal coordinate, and the *y*-axis every vertical coordinate.
- Coordinate units are measured in pixels. A pixel is a display monitor's smallest unit of resolution.
- Class `Graphics` (from package `java.awt`) provides various methods for drawing text and shapes onto the screen.
- Class `JPanel` (from package `javax.swing`) provides an area on which a program can draw.
- The keyword `extends` indicates that a class inherits from another class. The new class begins with the existing members (data and methods) from the existing class.
- The class from which the new class inherits is called the superclass and the new class is called the subclass.
- Every `JPanel` has a `paintComponent` method, which the system automatically calls every time it needs to display the `JPanel`—when a `JPanel` is first displayed on the screen, when it is covered then uncovered by a window on the screen and when the window in which it appears is resized.
- Method `paintComponent` requires one argument, a `Graphics` object, that is provided for you by the system when it calls `paintComponent`.
- The first statement in every `paintComponent` method you create should always be

```
super.paintComponent(g);
```

This ensures that the panel is properly rendered on the screen before you begin drawing on it.

- `JPanel` methods `getWidth` and `getHeight` return the width and height of a `JPanel`, respectively.
- `Graphics` method `drawLine` draws a line between two points represented by its four arguments. The first two arguments are the *x*- and *y*-coordinates for one endpoint of the line, and the last two arguments are the coordinates for the other endpoint of the line.
- To display a `JPanel` on the screen, you must place it in a window. You create a window with an object of class `JFrame` from package `javax.swing`.
- `JFrame` method `setDefaultCloseOperation` with the argument `JFrame.EXIT_ON_CLOSE` indicates that the application should terminate when the user closes the window.

## 176 Chapter 4 Control Statements: Part I

- `JFrame` method `add` attaches a GUI component to a `JFrame`.
- `JFrame` method `setSize` sets the width and height of the `JFrame`.

### Terminology

|                                                                                              |                                                                     |
|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <code>++</code> operator                                                                     | fatal logic error                                                   |
| <code>+=</code> operator                                                                     | final state (in the UML)                                            |
| <code>--</code> operator                                                                     | first refinement                                                    |
| <code>?:</code> operator                                                                     | flag value                                                          |
| action                                                                                       | <code>getHeight</code> method of class <code>JPanel</code> (GUI)    |
| action/decision model of programming                                                         | <code>getWidth</code> method of class <code>JPanel</code> (GUI)     |
| action expression (in the UML)                                                               | <code>goto</code> statement                                         |
| action state (in the UML)                                                                    | <code>Graphics</code> class (GUI)                                   |
| action-state symbol (in the UML)                                                             | guard condition (in the UML)                                        |
| activity (in the UML)                                                                        | horizontal coordinate (GUI)                                         |
| activity diagram (in the UML)                                                                | <code>if</code> single-selection statement                          |
| <code>add</code> method of class <code>JFrame</code> (GUI)                                   | <code>if...else</code> double-selection statement                   |
| addition compound assignment operator ( <code>+=</code> )                                    | implicit conversion                                                 |
| algorithm                                                                                    | increment operator ( <code>++</code> )                              |
| arithmetic compound assignment operators:<br><code>+=, -=, *=, /=</code> and <code>%=</code> | indefinite repetition                                               |
| block                                                                                        | infinite loop                                                       |

| small circle (in the UML)                   | y-coordinate                                  |
| solid circle (in the UML)                   |                                               |

**Self-Review Exercises**

**4.1** Fill in the blanks in each of the following statements:

- a) All programs can be written in terms of three types of control structures: \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.
- b) The \_\_\_\_\_ statement is used to execute one action when a condition is true and another when that condition is false.
- c) Repeating a set of instructions a specific number of times is called \_\_\_\_\_ repetition.
- d) When it is not known in advance how many times a set of statements will be repeated, a(n) \_\_\_\_\_ value can be used to terminate the repetition.
- e) The \_\_\_\_\_ structure is built into Java—by default, statements execute in the order they appear.
- f) Instance variables of types `char`, `byte`, `short`, `int`, `long`, `float` and `double` are all given the value \_\_\_\_\_ by default.
- g) Java is a(n) \_\_\_\_\_ language—it requires all variables to have a type.
- h) If the increment operator is \_\_\_\_\_ to a variable, the variable is incremented by 1 first, then its new value is used in the expression.

**4.2** State whether each of the following is *true* or *false*. If *false*, explain why.

- a) An algorithm is a procedure for solving a problem in terms of the actions to execute and the order in which they execute.
- b) A set of statements contained within a pair of parentheses is called a block.
- c) A selection statement specifies that an action is to be repeated while some condition remains true.

**178 Chapter 4 Control Statements: Part I**

- d) A nested control statement appears in the body of another control statement.
- e) Java provides the arithmetic compound assignment operators `+=`, `-=`, `*=`, `/=` and `%=` for abbreviating assignment expressions.
- f) The primitive types (`boolean`, `char`, `byte`, `short`, `int`, `long`, `float` and `double`) are portable across all Windows platforms.
- g) Specifying the order in which statements (actions) execute in a program is called program control.
- h) The unary cast operator (`double`) creates a temporary integer copy of its operand.
- i) Instance variables of type `boolean` are given the value `true` by default.
- j) Pseudocode helps a programmer think out a program before attempting to write it in a programming language.

**4.3** Write four different Java statements that each add 1 to integer variable `x`.

**4.4** Write Java statements to accomplish each of the following tasks:

- a) Assign the sum of `x` and `y` to `z`, and increment `x` by 1 after the calculation. Use only one statement.
- b) Test whether variable `count` is greater than 10. If it is, print "Count is greater than 10".
- c) Decrement the variable `x` by 1, then subtract it from the variable `total`. Use only one statement.
- d) Calculate the remainder after `q` is divided by `divisor`, and assign the result to `q`. Write this statement in two different ways.

**4.5** Write a Java statement to accomplish each of the following tasks:

- a) Declare variables `sum` and `x` to be of type `int`.
- b) Assign 1 to variable `x`.
- c) Assign 0 to variable `sum`.
- d) Add variable `x` to variable `sum`, and assign the result to variable `sum`.
- e) Print "The sum is: ", followed by the value of variable `sum`.

**4.6** Combine the statements that you wrote in Exercise 4.5 into a Java application that calculates and prints the sum of the integers from 1 to 10. Use a `while` statement to loop through the calculation and increment statements. The loop should terminate when the value of `x` becomes 11.

**4.7** Determine the value of the variables in the following statement after the calculation is performed. Assume that when the statement begins executing, all variables are type `int` and have the value 5.

```
product *= x++;
```

**4.8** Identify and correct the errors in each of the following sets of code:

- a) `while ( c <= 5 )`  
`{`  
 `product *= c;`  
 `++c;`
- b) `if ( gender == 1 )`  
 `System.out.println( "Woman" );`  
`else;`  
 `System.out.println( "Man" );`

**4.9** What is wrong with the following `while` statement?

```
while (z >= 0)
 sum += z;
```

**Answers to Self-Review Exercises 179****Answers to Self-Review Exercises**

**4.1** a) sequence, selection, repetition. b) `if...else`. c) counter-controlled (or definite). d) sentinel, signal, flag or dummy. e) sequence. f) 0 (zero). g) strongly typed. h) prefixed.

**4.2** a) True. b) False. A set of statements contained within a pair of braces (`{` and `}`) is called a block. c) False. A repetition statement specifies that an action is to be repeated while some condition remains true. d) True. e) True. f) False. The primitive types (`boolean`, `char`, `byte`, `short`, `int`, `long`, `float` and `double`) are portable across all computer platforms that support Java. g) True. h) False. The unary cast operator (`double`) creates a temporary floating-point copy of its operand. i) False. Instance variables of type `boolean` are given the value `false` by default. j) True.

**4.3**

```
x = x + 1;
x += 1;
++x;
x++;
```

**4.4** a) `z = x++ + y;`  
 b) `if ( count > 10 )
 System.out.println( "Count is greater than 10" );`  
 c) `total -= --x;`  
 d) `q %= divisor;
 q = q % divisor;`

**4.5** a) `int sum, x;`  
 b) `x = 1;`  
 c) `sum = 0;`  
 d) `sum += x; or sum = sum + x;`  
 e) `System.out.printf( "The sum is: %d\n", sum );`

**4.6** The program is as follows:

```
1 // Calculate the sum of the integers from 1 to 10
2 public class Calculate
3 {
4 public static void main(String args[])
5 {
6 int sum;
7 int x;
8
9 x = 1; // initialize x to 1 for counting
10 sum = 0; // initialize sum to 0 for totaling
11
12 while (x <= 10) // while x is less than or equal to 10
13 {
14 sum += x; // add x to sum
15 ++x; // increment x
16 } // end while
17
18 System.out.printf("The sum is: %d\n", sum);
19 } // end main
20
21 } // end class Calculate
```

The sum is: 55

**180** Chapter 4 Control Statements: Part I

- 4.7** product = 25, x = 6
- 4.8** a) Error: The closing right brace of the `while` statement's body is missing.  
Correction: Add a closing right brace after the statement `++c;`.  
b) Error: The semicolon after `else` results in a logic error. The second output statement will always be executed.  
Correction: Remove the semicolon after `else`.
- 4.9** The value of the variable `z` is never changed in the `while` statement. Therefore, if the loop-continuation condition (`z >= 0`) is true, an infinite loop is created. To prevent an infinite loop from occurring, `z` must be decremented so that it eventually becomes less than 0.

**Exercises**

- 4.10** Compare and contrast the `if` single-selection statement and the `while` repetition statement. How are these two statements similar? How are they different?
- 4.11** Explain what happens when a Java program attempts to divide one integer by another. What happens to the fractional part of the calculation? How can a programmer avoid that outcome?
- 4.12** Describe the two ways in which control statements can be combined.
- 4.13** What type of repetition would be appropriate for calculating the sum of the first 100 positive integers? What type of repetition would be appropriate for calculating the sum of an arbitrary number of positive integers? Briefly describe how each of these tasks could be performed.
- 4.14** What is the difference between preincrementing and postincrementing a variable?
- 4.15** Identify and correct the errors in each of the following pieces of code. [Note: There may be more than one error in each piece of code.]

- a) `if ( age >= 65 )  
 System.out.println( "Age greater than or equal to 65" );  
else  
 System.out.println( "Age is less than 65" );`
- b) `int x = 1, total;  
while ( x <= 10 )  
{  
 total += x;  
 ++x;  
}  
c) while ( x <= 100 )  
 total += x;  
 ++x;`
- d) `while ( y > 0 )  
{  
 System.out.println( y );  
 ++y;`

- 4.16** What does the following program print?

```
1 public class Mystery
2 {
3 public static void main(String args[])
4 {
5 int y;
6 int x = 1;
```

Exercises **181**

```

7 int total = 0;
8
9 while (x <= 10)
10 {
11 y = x * x;
12 System.out.println(y);
13 total += y;
14 ++x;
15 } // end while
16
17 System.out.printf("Total is %d\n", total);
18 } // end main
19
20 } // end class Mystery

```

For Exercise 4.17 through Exercise 4.20, perform each of the following steps:

- Read the problem statement.
- Formulate the algorithm using pseudocode and top-down, stepwise refinement.
- Write a Java program.
- Test, debug and execute the Java program.
- Process three complete sets of data.

**4.17** Drivers are concerned with the mileage their automobiles get. One driver has kept track of several tankfuls of gasoline by recording the miles driven and gallons used for each tankful. Develop a Java application that will input the miles driven and gallons used (both as integers) for each tankful. The program should calculate and display the miles per gallon obtained for each tankful and print the combined miles per gallon obtained for all tankfuls up to this point. All averaging calculations should produce floating-point results. Use class Scanner and sentinel-controlled repetition to obtain the data from the user.

**4.18** Develop a Java application that will determine whether any of several department-store customers has exceeded the credit limit on a charge account. For each customer, the following facts are available:

- account number
- balance at the beginning of the month
- total of all items charged by the customer this month
- total of all credits applied to the customer's account this month
- allowed credit limit.

The program should input all these facts as integers, calculate the new balance ( $= \text{beginning balance} + \text{charges} - \text{credits}$ ), display the new balance and determine whether the new balance exceeds the customer's credit limit. For those customers whose credit limit is exceeded, the program should display the message "Credit limit exceeded".

**4.19** A large company pays its salespeople on a commission basis. The salespeople receive \$200 per week plus 9% of their gross sales for that week. For example, a salesperson who sells \$5000 worth of merchandise in a week receives \$200 plus 9% of \$5000, or a total of \$650. You have been supplied with a list of the items sold by each salesperson. The values of these items are as follows:

| Item | Value  |
|------|--------|
| 1    | 239.99 |
| 2    | 129.75 |
| 3    | 99.95  |
| 4    | 350.89 |

**182** Chapter 4 Control Statements: Part I

Develop a Java application that inputs one salesperson's items sold for last week and calculates and displays that salesperson's earnings. There is no limit to the number of items that can be sold by a salesperson.

**4.20** Develop a Java application that will determine the gross pay for each of three employees. The company pays straight time for the first 40 hours worked by each employee and time and a half for all hours worked in excess of 40 hours. You are given a list of the employees of the company, the number of hours each employee worked last week and the hourly rate of each employee. Your program should input this information for each employee and should determine and display the employee's gross pay. Use class `Scanner` to input the data.

**4.21** The process of finding the largest value (i.e., the maximum of a group of values) is used frequently in computer applications. For example, a program that determines the winner of a sales contest would input the number of units sold by each salesperson. The salesperson who sells the most units wins the contest. Write a pseudocode program and then a Java application that inputs a series of 10 integers and determines and prints the largest integer. Your program should use at least the following three variables:

- counter: A counter to count to 10 (i.e., to keep track of how many numbers have been input and to determine when all 10 numbers have been processed).
- number: The integer most recently input by the user.
- largest: The largest number found so far.

**4.22** Write a Java application that uses looping to print the following table of values:

| N | 10*N | 100*N | 1000*N |
|---|------|-------|--------|
| 1 | 10   | 100   | 1000   |
| 2 | 20   | 200   | 2000   |
| 3 | 30   | 300   | 3000   |
| 4 | 40   | 400   | 4000   |
| 5 | 50   | 500   | 5000   |

**4.23** Using an approach similar to that for Exercise 4.21, find the *two* largest values of the 10 values entered. [Note: You may input each number only once.]

**4.24** Modify the program in Fig. 4.12 to validate its inputs. For any input, if the value entered is other than 1 or 2, keep looping until the user enters a correct value.

**4.25** What does the following program print?

```

1 public class Mystery2
2 {
3 public static void main(String args[])
4 {
5 int count = 1;
6
7 while (count <= 10)
8 {
9 System.out.println(count % 2 == 1 ? "*****" : "+++++++");
10 ++count;
11 } // end while
12 } // end main
13
14 } // end class Mystery2

```

[Exercises](#) **183**

**4.26** What does the following program print?

```

1 public class Mystery3
2 {
3 public static void main(String args[])
4 {
5 int row = 10;
6 int column;
7
8 while (row >= 1)
9 {
10 column = 1;
11
12 while (column <= 10)
13 {
14 System.out.print(row % 2 == 1 ? "<" : ">");
15 ++column;
16 } // end while
17
18 --row;
19 System.out.println();
20 } // end while
21 } // end main
22
23 } // end class Mystery3

```

**4.27** (*Dangling-else Problem*) Determine the output for each of the given sets of code when *x* is 9 and *y* is 11 and when *x* is 11 and *y* is 9. Note that the compiler ignores the indentation in a Java program. Also, the Java compiler always associates an *else* with the immediately preceding *if* unless told to do otherwise by the placement of braces ({}). On first glance, the programmer may not be sure which *if* an *else* matches—this situation is referred to as the “dangling-*else* problem.” We have eliminated the indentation from the following code to make the problem more challenging.

[Hint: Apply the indentation conventions you have learned.]

- a) 

```

if (x < 10)
 if (y > 10)
 System.out.println("*****");
 else
 System.out.println("#####");
 System.out.println("$$$$$");

```
- b) 

```

if (x < 10)
{
 if (y > 10)
 System.out.println("*****");
}
else
{
 System.out.println("#####");
 System.out.println("$$$$$");
}

```

**4.28** (*Another Dangling-else Problem*) Modify the given code to produce the output shown in each part of the problem. Use proper indentation techniques. Make no changes other than inserting braces and changing the indentation of the code. The compiler ignores indentation in a Java pro-

**184** Chapter 4 Control Statements: Part I

gram. We have eliminated the indentation from the given code to make the problem more challenging. [Note: It is possible that no modification is necessary for some of the parts.]

```
if (y == 8)
if (x == 5)
System.out.println("AAAAA");
else
System.out.println("#####");
System.out.println("$$$$$");
System.out.println("&&&&&");
```

- a) Assuming that  $x = 5$  and  $y = 8$ , the following output is produced:

```
AAAAA
$$$$$
&&&&
```

- b) Assuming that  $x = 5$  and  $y = 8$ , the following output is produced:

```
AAAAA
```

- c) Assuming that  $x = 5$  and  $y = 8$ , the following output is produced:

```
AAAAA
&&&&
```

- d) Assuming that  $x = 5$  and  $y = 7$ , the following output is produced. [Note: The last three output statements after the `else` are all part of a block.]

```
#####
$$$$$
```

**4.29** Write an application that prompts the user to enter the size of the side of a square, then displays a hollow square of that size made of asterisks. Your program should work for squares of all side lengths between 1 and 20.

**4.30** (*Palindromes*) A palindrome is a sequence of characters that reads the same backward as forward. For example, each of the following five-digit integers is a palindrome: 12321, 55555, 45554 and 11611. Write an application that reads in a five-digit integer and determines whether it is a palindrome. If the number is not five digits long, display an error message and allow the user to enter a new value.

**4.31** Write an application that inputs an integer containing only 0s and 1s (i.e., a binary integer) and prints its decimal equivalent. [Hint: Use the remainder and division operators to pick off the binary number's digits one at a time, from right to left. In the decimal number system, the rightmost digit has a positional value of 1 and the next digit to the left has a positional value of 10, then 100, then 1000, and so on. The decimal number 234 can be interpreted as  $4 * 1 + 3 * 10 + 2 * 100$ . In the binary number system, the rightmost digit has a positional value of 1, the next digit to the left has a positional value of 2, then 4, then 8, and so on. The decimal equivalent of binary 1101 is  $1 * 1 + 0 * 2 + 1 * 4 + 1 * 8$ , or  $1 + 0 + 4 + 8$  or, 13.]

**4.32** Write an application that uses only the output statements

```
System.out.print("x ");
System.out.print(" ");
System.out.println();
```

to display the checkerboard pattern that follows. Note that a `System.out.println` method call with no arguments causes the program to output a single newline character. [Hint: Repetition statements are required.]

Exercises **185**

```
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
```

**4.33** Write an application that keeps displaying in the command window the multiples of the integer 2—namely, 2, 4, 8, 16, 32, 64, and so on. Your loop should not terminate (i.e., create an infinite loop). What happens when you run this program?

**4.34** What is wrong with the following statement? Provide the correct statement to add one to the sum of *x* and *y*.

```
System.out.println(++(x + y));
```

**4.35** Write an application that reads three nonzero values entered by the user and determines and prints whether they could represent the sides of a triangle.

**4.36** Write an application that reads three nonzero integers and determines and prints whether they could represent the sides of a right triangle.

**4.37** A company wants to transmit data over the telephone but is concerned that its phones may be tapped. It has asked you to write a program that will encrypt the data so that it may be transmitted more securely. All the data is transmitted as four-digit integers. Your application should read a four-digit integer entered by the user and encrypt it as follows: Replace each digit with the result of adding 7 to the digit and getting the remainder after dividing the new value by 10. Then swap the first digit with the third, and swap the second digit with the fourth. Then print the encrypted integer. Write a separate application that inputs an encrypted four-digit integer and decrypts it to form the original number.

**4.38** The factorial of a nonnegative integer *n* is written as *n!* (pronounced “*n* factorial”) and is defined as follows:

$$n! = n \cdot (n - 1) \cdot (n - 2) \cdot \dots \cdot 1 \quad (\text{for values of } n \text{ greater than or equal to 1})$$

and

$$n! = 1 \quad (\text{for } n = 0)$$

For example,  $5! = 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1$ , which is 120.

a) Write an application that reads a nonnegative integer and computes and prints its factorial.

b) Write an application that estimates the value of the mathematical constant *e* by using the formula

$$e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \dots$$

c) Write an application that computes the value of  $e^x$  by using the formula

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$$

# Control Statements: Part 2

## OBJECTIVES

In this chapter you will learn:

- The essentials of counter-controlled repetition.
- To use the `for` and `do...while` repetition statements to execute statements in a program repeatedly.
- To understand multiple selection using the `switch` selection statement.
- To use the `break` and `continue` program control statements to alter the flow of control.
- To use the logical operators to form complex conditional expressions in control statements.

*Not everything that can be counted counts, and not every thing that counts can be counted.*

—Albert Einstein

*Who can control his fate?*

—William Shakespeare

*The used key is always bright.*

—Benjamin Franklin

*Intelligence ... is the faculty of making artificial objects, especially tools to make tools.*

—Henri Bergson

*Every advantage in the past is judged in the light of the final issue.*

## 5.1 Introduction

Chapter 4 began our introduction to the types of building blocks that are available for problem solving. We used those building blocks to employ proven program-construction techniques. This chapter continues our presentation of structured programming theory and principles by introducing Java's remaining control statements. The control statements we study here and in Chapter 4 are helpful in building and manipulating objects.

In this chapter, we demonstrate Java's `for`, `do...while` and `switch` statements. Through a series of short examples using `while` and `for`, we explore the essentials of counter-controlled repetition. We devote a portion of the chapter (and Chapter 7) to expanding the `GradeBook` class presented in Chapters 3–4. In particular, we create a version of class `GradeBook` that uses a `switch` statement to count the number of A, B, C, D and F grade equivalents in a set of numeric grades entered by the user. We introduce the `break` and `continue` program control statements. We discuss Java's logical operators, which enable you to use more complex conditional expressions in control statements. Finally, we summarize Java's control statements and the proven problem-solving techniques presented in this chapter and Chapter 4.

## 5.2 Essentials of Counter-Controlled Repetition

This section uses the `while` repetition statement introduced in Chapter 4 to formalize the elements required to perform counter-controlled repetition. Counter-controlled repetition requires

1. a **control variable** (or loop counter)
2. the **initial value** of the control variable
3. the **increment** (or **decrement**) by which the control variable is modified each time through the loop (also known as **each iteration of the loop**)
4. the **loop-continuation condition** that determines whether looping should continue.

**188** Chapter 5 Control Statements: Part 2

To see these elements of counter-controlled repetition, consider the application of Fig. 5.1, which uses a loop to display the numbers from 1 through 10. Note that Fig. 5.1 contains only one method, `main`, which does all of the class's work. For most applications in Chapters 3–4 we have encouraged the use of two separate files—one that declares a reusable class (e.g., `Account`) and one that instantiates one or more objects of that class (e.g., `AccountTest`) and demonstrates its (their) functionality. Occasionally, however, it is more appropriate simply to create one class whose `main` method concisely illustrates a basic concept. Throughout this chapter, we use several one-class examples like Fig. 5.1 to demonstrate the mechanics of Java's control statements.

In Fig. 5.1, the elements of counter-controlled repetition are defined in lines 8, 10 and 13. Line 8 declares the control variable (`counter`) as an `int`, reserves space for it in memory and sets its initial value to 1. Variable `counter` could also have been declared and initialized with the following local-variable declaration and assignment statements:

```
int counter; // declare counter
counter = 1; // initialize counter to 1
```

Line 12 displays control variable `counter`'s value during each iteration of the loop. Line 13 increments the control variable by 1 for each iteration of the loop. The loop-continuation condition in the `while` (line 10) tests whether the value of the control variable is less than or equal to 10 (the final value for which the condition is `true`). Note that the program performs the body of this `while` even when the control variable is 10. The loop terminates when the control variable exceeds 10 (i.e., `counter` becomes 11).

**Common Programming Error 5.1**

*Because floating-point values may be approximate, controlling loops with floating-point variables may result in imprecise counter values and inaccurate termination tests.*

```
1 // Fig. 5.1: WhileCounter.java
2 // Counter-controlled repetition with the while repetition statement.
3
4 public class WhileCounter
5 {
6 public static void main(String args[])
7 {
8 int counter = 1; // declare and initialize control variable
9
10 while (counter <= 10) // loop-continuation condition
11 {
12 System.out.printf("%d ", counter);
13 ++counter; // increment control variable by 1
14 } // end while
15
16 System.out.println(); // output a newline
17 } // end main
18 } // end class WhileCounter
```

```
1 2 3 4 5 6 7 8 9 10
```

**Fig. 5.1** | Counter-controlled repetition with the `while` repetition statement.

5.3 for Repetition Statement **189****Error-Prevention Tip 5.1***Control counting loops with integers.***Good Programming Practice 5.1***Place blank lines above and below repetition and selection control statements, and indent the statement bodies to enhance readability.*

The program in Fig. 5.1 can be made more concise by initializing counter to 0 in line 8 and preincrementing counter in the while condition as follows:

```
while (++counter <= 10) // Loop-continuation condition
 System.out.printf("%d ", counter);
```

This code saves a statement (and eliminates the need for braces around the loop's body), because the while condition performs the increment before testing the condition. (Recall from Section 4.12 that the precedence of `++` is higher than that of `<=`.) Coding in such a condensed fashion takes practice, might make code more difficult to read, debug, modify and maintain, and typically should be avoided.

**Software Engineering Observation 5.1***"Keep it simple" is good advice for most of the code you will write.*

## 5.3 for Repetition Statement

Section 5.2 presented the essentials of counter-controlled repetition. The `while` statement can be used to implement any counter-controlled loop. Java also provides the `for` repetition statement, which specifies the counter-controlled-repetition details in a single line of code. Figure 5.2 reimplements the application of Fig. 5.1 using `for`.

```
1 // Fig. 5.2: ForCounter.java
2 // Counter-controlled repetition with the for repetition statement.
3
4 public class ForCounter
5 {
6 public static void main(String args[])
7 {
8 // for statement header includes initialization,
9 // loop-continuation condition and increment
10 for (int counter = 1; counter <= 10; counter++)
11 System.out.printf("%d ", counter);
12
13 System.out.println(); // output a newline
14 } // end main
15 } // end class ForCounter
```

```
1 2 3 4 5 6 7 8 9 10
```

**Fig. 5.2** | Counter-controlled repetition with the `for` repetition statement.

**190** Chapter 5 Control Statements: Part 2

The application's `main` method operates as follows: When the `for` statement (lines 10–11) begins executing, the control variable `counter` is declared and initialized to 1. (Recall from Section 5.2 that the first two elements of counter-controlled repetition are the control variable and its initial value.) Next, the program checks the loop-continuation condition, `counter <= 10`, which is between the two required semicolons. Because the initial value of `counter` is 1, the condition initially is true. Therefore, the body statement (line 11) displays control variable `counter`'s value, namely 1. After executing the loop's body, the program increments `counter` in the expression `counter++`, which appears to the right of the second semicolon. Then the loop-continuation test is performed again to determine whether the program should continue with the next iteration of the loop. At this point, the control variable value is 2, so the condition is still true (the final value is not exceeded)—thus, the program performs the body statement again (i.e., the next iteration of the loop). This process continues until the numbers 1 through 10 have been displayed and the `counter`'s value becomes 11, causing the loop-continuation test to fail and repetition to terminate (after 10 repetitions of the loop body at line 11). Then the program performs the first statement after the `for`—in this case, line 13.

Note that Fig. 5.2 uses (in line 10) the loop-continuation condition `counter <= 10`. If you incorrectly specified `counter < 10` as the condition, the loop would iterate only nine times. This mistake is a common logic error called an [off-by-one error](#).

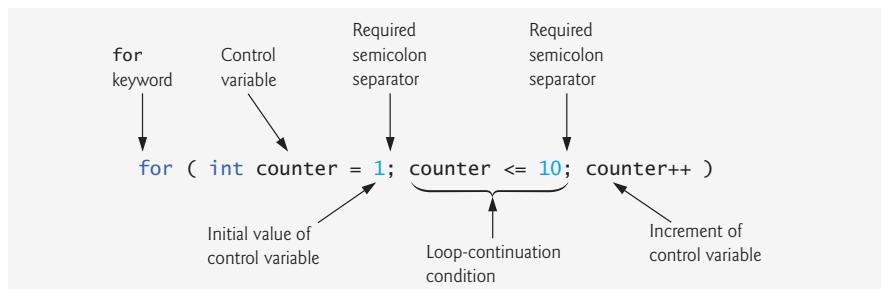

**Common Programming Error 5.2**

*Using an incorrect relational operator or an incorrect final value of a loop counter in the loop-continuation condition of a repetition statement can cause an off-by-one error.*

**Good Programming Practice 5.2**

*Using the final value in the condition of a `while` or `for` statement and using the `<=` relational operator helps avoid off-by-one errors. For a loop that prints the values 1 to 10, the loop-continuation condition should be `counter <= 10` rather than `counter < 10` (which causes an off-by-one error) or `counter < 11` (which is correct). Many programmers prefer so-called zero-based counting, in which to count 10 times, `counter` would be initialized to zero and the loop-continuation test would be `counter < 10`.*

Figure 5.3 takes a closer look at the `for` statement in Fig. 5.2. The `for`'s first line (including the keyword `for` and everything in parentheses after `for`)—line 10 in Fig. 5.2—is sometimes called the `for` [statement header](#), or simply the `for` [header](#). Note

**Fig. 5.3** | `for` statement header components.

5.3 **for** Repetition Statement **191**

that the **for** header “does it all”—it specifies each item needed for counter-controlled repetition with a control variable. If there is more than one statement in the body of the **for**, braces (**{** and **}**) are required to define the body of the loop.

The general format of the **for** statement is

```
for (initialization; loopContinuationCondition; increment)
 statement
```

where the *initialization* expression names the loop’s control variable and optionally provides its initial value, *loopContinuationCondition* is the condition that determines whether the loop should continue executing and *increment* modifies the control variable’s value (possibly an increment or decrement), so that the loop-continuation condition eventually becomes false. The two semicolons in the **for** header are required.

**Common Programming Error 5.3**

Using commas instead of the two required semicolons in a **for** header is a syntax error.

In most cases, the **for** statement can be represented with an equivalent **while** statement as follows:

```
initialization;
while (loopContinuationCondition)
{
 statement
 increment;
}
```

In Section 5.7, we show a case in which a **for** statement cannot be represented with an equivalent **while** statement.

Typically, **for** statements are used for counter-controlled repetition and **while** statements for sentinel-controlled repetition. However, **while** and **for** can each be used for either repetition type.

If the *initialization* expression in the **for** header declares the control variable (i.e., the control variable’s type is specified before the variable name, as in Fig. 5.2), the control variable can be used only in that **for** statement—it will not exist outside the **for** statement. This restricted use of the name of the control variable is known as the variable’s **scope**. The scope of a variable defines where it can be used in a program. For example, a local variable can be used only in the method that declares the variable and only from the point of declaration through the end of the method. Scope is discussed in detail in Chapter 6, Methods: A Deeper Look.

**Common Programming Error 5.4**

When a **for** statement’s control variable is declared in the initialization section of the **for**’s header, using the control variable after the **for**’s body is a compilation error.

All three expressions in a **for** header are optional. If the *loopContinuationCondition* is omitted, Java assumes that the loop-continuation condition is always true, thus creating an infinite loop. You might omit the *initialization* expression if the program initializes the control variable before the loop. You might omit the *increment* expression if the program

**192** Chapter 5 Control Statements: Part 2

calculates the increment with statements in the loop's body or if no increment is needed. The increment expression in a `for` acts as if it were a standalone statement at the end of the `for`'s body. Therefore, the expressions

```
counter = counter + 1
counter += 1
++counter
counter++
```

are equivalent increment expressions in a `for` statement. Many programmers prefer `counter++` because it is concise and because a `for` loop evaluates its increment expression after its body executes. Therefore, the postfix increment form seems more natural. In this case, the variable being incremented does not appear in a larger expression, so preincrementing and postincrementing actually have the same effect.

**Performance Tip 5.1**

*There is a slight performance advantage to preincrementing, but if you choose to postincrement because it seems more natural (as in a `for` header), optimizing compilers will generate Java bytecode that uses the more efficient form anyway.*

**Good Programming Practice 5.3**

*In most cases, preincrementing and postincrementing are both used to add 1 to a variable in a statement by itself. In these cases, the effect is exactly the same, except that preincrementing has a slight performance advantage. Given that the compiler typically optimizes your code to help you get the best performance, use the idiom with which you feel most comfortable in these situations.*

**Common Programming Error 5.5**

*Placing a semicolon immediately to the right of the right parenthesis of a `for` header makes that `for`'s body an empty statement. This is normally a logic error.*

**Error-Prevention Tip 5.2**

*Infinite loops occur when the loop-continuation condition in a repetition statement never becomes `false`. To prevent this situation in a counter-controlled loop, ensure that the control variable is incremented (or decremented) during each iteration of the loop. In a sentinel-controlled loop, ensure that the sentinel value is eventually input.*

The initialization, loop-continuation condition and increment portions of a `for` statement can contain arithmetic expressions. For example, assume that `x = 2` and `y = 10`. If `x` and `y` are not modified in the body of the loop, the statement

```
for (int j = x; j <= 4 * x * y; j += y / x)
```

is equivalent to the statement

```
for (int j = 2; j <= 80; j += 5)
```

The increment of a `for` statement may also be negative, in which case it is really a decrement, and the loop counts downward.

If the loop-continuation condition is initially `false`, the program does not execute the `for` statement's body. Instead, execution proceeds with the statement following the `for`.

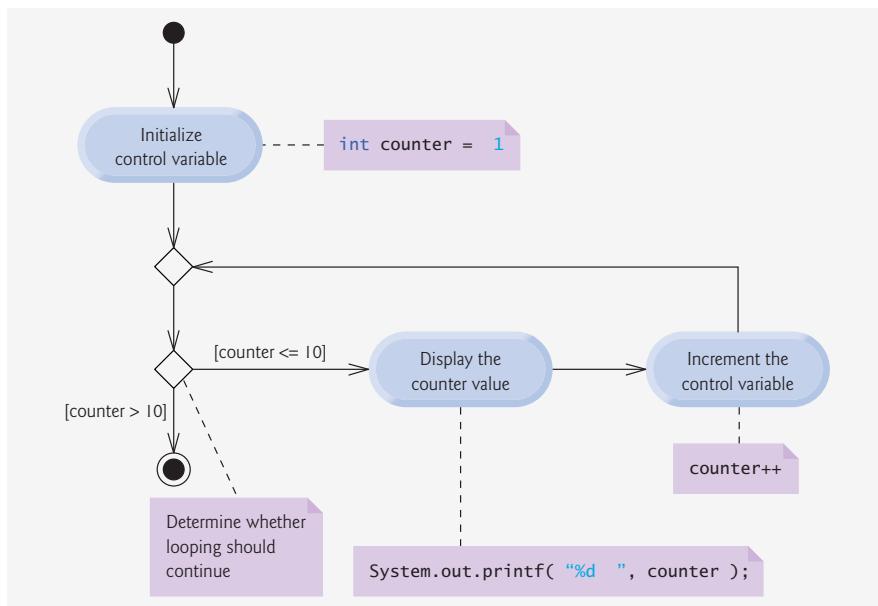

5.4 Examples Using the `for` Statement **193**

Programs frequently display the control variable value or use it in calculations in the loop body, but this use is not required. The control variable is commonly used to control repetition without mentioning the control variable in the body of the `for`.

**Error-Prevention Tip 5.3**

*Although the value of the control variable can be changed in the body of a `for` loop, avoid doing so, because this practice can lead to subtle errors.*

The `for` statement's UML activity diagram is similar to that of the `while` statement (Fig. 4.4). Figure 5.4 shows the activity diagram of the `for` statement in Fig. 5.2. The diagram makes it clear that initialization occurs once before the loop-continuation test is evaluated the first time, and that incrementing occurs each time through the loop after the body statement executes.

**Fig. 5.4** | UML activity diagram for the `for` statement in Fig. 5.2.

## 5.4 Examples Using the `for` Statement

The following examples show techniques for varying the control variable in a `for` statement. In each case, we write the appropriate `for` header. Note the change in the relational operator for loops that decrement the control variable.

- Vary the control variable from 1 to 100 in increments of 1.

```
for (int i = 1; i <= 100; i++)
```

- Vary the control variable from 100 to 1 in decrements of 1.

```
for (int i = 100; i >= 1; i--)
```

**194** Chapter 5 Control Statements: Part 2

- c) Vary the control variable from 7 to 77 in increments of 7.

```
for (int i = 7; i <= 77; i += 7)
```

- d) Vary the control variable from 20 to 2 in decrements of 2.

```
for (int i = 20; i >= 2; i -= 2)
```

- e) Vary the control variable over the following sequence of values: 2, 5, 8, 11, 14, 17, 20.

```
for (int i = 2; i <= 20; i += 3)
```

- f) Vary the control variable over the following sequence of values: 99, 88, 77, 66, 55, 44, 33, 22, 11, 0.

```
for (int i = 99; i >= 0; i -= 11)
```

**Common Programming Error 5.6**

*Not using the proper relational operator in the loop-continuation condition of a loop that counts downward (e.g., using `i <= 1` instead of `i >= 1` in a loop counting down to 1) is usually a logic error.*

**Application: Summing the Even Integers from 2 to 20**

We now consider two sample applications that demonstrate simple uses of `for`. The application in Fig. 5.5 uses a `for` statement to sum the even integers from 2 to 20 and store the result in an `int` variable called `total`.

The *initialization* and *increment* expressions can be comma-separated lists of expressions that enable you to use multiple initialization expressions or multiple increment expressions. For example, although this is discouraged, the body of the `for` statement in

```

1 // Fig. 5.5: Sum.java
2 // Summing integers with the for statement.
3
4 public class Sum
5 {
6 public static void main(String args[])
7 {
8 int total = 0; // initialize total
9
10 // total even integers from 2 through 20
11 for (int number = 2; number <= 20; number += 2)
12 total += number;
13
14 System.out.printf("Sum is %d\n", total); // display results
15 } // end main
16 } // end class Sum

```

Sum is 110

**Fig. 5.5** | Summing integers with the `for` statement.

5.4 Examples Using the `for` Statement **195**

lines 11–12 of Fig. 5.5 could be merged into the increment portion of the `for` header by using a comma as follows:

```
for (int number = 2; number <= 20; total += number, number += 2)
 ; // empty statement
```

**Good Programming Practice 5.4**

*Limit the size of control statement headers to a single line if possible.*

**Application: Compound-Interest Calculations**

The next application uses the `for` statement to compute compound interest. Consider the following problem:

*A person invests \$1000 in a savings account yielding 5% interest. Assuming that all the interest is left on deposit, calculate and print the amount of money in the account at the end of each year for 10 years. Use the following formula to determine the amounts:*

$$a = p (1 + r)^n$$

*where*

*p* is the original amount invested (i.e., the principal)

*r* is the annual interest rate (e.g., use 0.05 for 5%)

*n* is the number of years

*a* is the amount on deposit at the end of the *n*th year.

This problem involves a loop that performs the indicated calculation for each of the 10 years the money remains on deposit. The solution is the application shown in Fig. 5.6. Lines 8–10 in method `main` declare `double` variables `amount`, `principal` and `rate`, and initialize `principal` to 1000.0 and `rate` to 0.05. Java treats floating-point constants like 1000.0 and 0.05 as type `double`. Similarly, Java treats whole-number constants like 7 and -22 as type `int`.

Line 13 outputs the headers for this application's two columns of output. The first column displays the year, and the second column the amount on deposit at the end of that year. Note that we use the format specifier `%20s` to output the `String` "Amount on Deposit". The integer 20 between the % and the conversion character `s` indicates that the value output should be displayed with a **field width** of 20—that is, `printf` displays the value with at least 20 character positions. If the value to be output is less than 20 character positions wide (17 characters in this example), the value is **right justified** in the field by default. If the year value to be output were more than four character positions wide, the field width would be extended to the right to accommodate the entire value—this would push the amount field to the right, upsetting the neat columns of our tabular output. To indicate that values should be output **left justified**, simply precede the field width with the **minus sign (-) formatting flag**.

The `for` statement (lines 16–23) executes its body 10 times, varying control variable `year` from 1 to 10 in increments of 1. This loop terminates when control variable `year` becomes 11. (Note that `year` represents *n* in the problem statement.)

Classes provide methods that perform common tasks on objects. In fact, most methods must be called on a specific object. For example, to output text in Fig. 5.6, line

**196** Chapter 5 Control Statements: Part 2

```

1 // Fig. 5.6: Interest.java
2 // Compound-interest calculations with for.
3
4 public class Interest
5 {
6 public static void main(String args[])
7 {
8 double amount; // amount on deposit at end of each year
9 double principal = 1000.0; // initial amount before interest
10 double rate = 0.05; // interest rate
11
12 // display headers
13 System.out.printf("%s%20s\n", "Year", "Amount on deposit");
14
15 // calculate amount on deposit for each of ten years
16 for (int year = 1; year <= 10; year++)
17 {
18 // calculate new amount for specified year
19 amount = principal * Math.pow(1.0 + rate, year);
20
21 // display the year and the amount
22 System.out.printf("%4d%,20.2f\n", year, amount);
23 } // end for
24 } // end main
25 } // end class Interest

```

| Year | Amount on deposit |
|------|-------------------|
| 1    | 1,050.00          |
| 2    | 1,102.50          |
| 3    | 1,157.63          |
| 4    | 1,215.51          |
| 5    | 1,276.28          |
| 6    | 1,340.10          |
| 7    | 1,407.10          |
| 8    | 1,477.46          |
| 9    | 1,551.33          |
| 10   | 1,628.89          |

**Fig. 5.6** | Compound-interest calculations with for.

13 calls method `printf` on the `System.out` object. Many classes also provide methods that perform common tasks and do not require objects. Recall from Section 3.9 that these are called `static` methods. For example, Java does not include an exponentiation operator, so the designers of Java's `Math` class defined `static` method `pow` for raising a value to a power. You can call a `static` method by specifying the class name followed by a dot (.) and the method name, as in

`ClassName.methodName( arguments )`

In Chapter 6, you'll learn how to implement `static` methods in your own classes.

We use `static` method `pow` of class `Math` to perform the compound-interest calculation in Fig. 5.6. `Math.pow(x, y)` calculates the value of  $x$  raised to the  $y^{\text{th}}$  power. The

5.4 Examples Using the `for` Statement **197**

method receives two `double` arguments and returns a `double` value. Line 19 performs the calculation  $a = p(1 + r)^n$ , where  $a$  is `amount`,  $p$  is `principal`,  $r$  is `rate` and  $n$  is `year`.

After each calculation, line 22 outputs the year and the amount on deposit at the end of that year. The year is output in a field width of four characters (as specified by `%4d`). The amount is output as a floating-point number with the format specifier `%,20.2f`. The **comma (,)** **formatting flag** indicates that the floating-point value should be output with a grouping separator. The actual separator used is specific to the user's locale (i.e., country). For example, in the United States, the number will be output using commas to separate every three digits and a decimal point to separate the fractional part of the number, as in 1,234.45. The number 20 in the format specification indicates that the value should be output right justified in a field width of 20 characters. The .2 specifies the formatted number's precision—in this case, the number is rounded to the nearest hundredth and output with two digits to the right of the decimal point.

We declared variables `amount`, `principal` and `rate` to be of type `double` in this example. We are dealing with fractional parts of dollars and thus need a type that allows decimal points in its values. Unfortunately, floating-point numbers can cause trouble. Here is a simple explanation of what can go wrong when using `double` (or `float`) to represent dollar amounts (assuming that dollar amounts are displayed with two digits to the right of the decimal point): Two `double` dollar amounts stored in the machine could be 14.234 (which would normally be rounded to 14.23 for display purposes) and 18.673 (which would normally be rounded to 18.67 for display purposes). When these amounts are added, they produce the internal sum 32.907, which would normally be rounded to 32.91 for display purposes. Thus, your output could appear as

```
14.23
+
18.67

32.91
```

but a person adding the individual numbers as displayed would expect the sum to be 32.90. You have been warned!

**Good Programming Practice 5.5**

*Do not use variables of type `double` (or `float`) to perform precise monetary calculations. The imprecision of floating-point numbers can cause errors. In the exercises, we use integers to perform monetary calculations.*

Note that some third-party vendors provide for-sale class libraries that perform precise monetary calculations. In addition, the Java API provides class `java.math.BigDecimal` for performing calculations with arbitrary precision floating-point values.

Note that the body of the `for` statement contains the calculation `1.0 + rate`, which appears as an argument to the `Math.pow` method. In fact, this calculation produces the same result each time through the loop, so repeating the calculation every iteration of the loop is wasteful.

**Performance Tip 5.2**

*In loops, avoid calculations for which the result never changes—such calculations should typically be placed before the loop. [Note: Many of today's sophisticated optimizing compilers will place such calculations outside loops in the compiled code.]*

## 198 Chapter 5 Control Statements: Part 2

## 5.5 do...while Repetition Statement

The `do...while` repetition statement is similar to the `while` statement. In the `while`, the program tests the loop-continuation condition at the beginning of the loop, before executing the loop's body; if the condition is false, the body never executes. The `do...while` statement tests the loop-continuation condition *after* executing the loop's body; therefore, the body always executes at least once. When a `do...while` statement terminates, execution continues with the next statement in sequence. Figure 5.7 uses a `do...while` (lines 10–14) to output the numbers 1–10.

Line 8 declares and initializes control variable `counter`. Upon entering the `do...while` statement, line 12 outputs `counter`'s value and line 13 increments `counter`. Then the program evaluates the loop-continuation test at the bottom of the loop (line 14). If the condition is true, the loop continues from the first body statement in the `do...while` (line 12). If the condition is false, the loop terminates and the program continues with the next statement after the loop.

Figure 5.8 contains the UML activity diagram for the `do...while` statement. This diagram makes it clear that the loop-continuation condition is not evaluated until after the loop performs the action state at least once. Compare this activity diagram with that of the `while` statement (Fig. 4.4).

It is not necessary to use braces in the `do...while` repetition statement if there is only one statement in the body. However, most programmers include the braces, to avoid confusion between the `while` and `do...while` statements. For example,

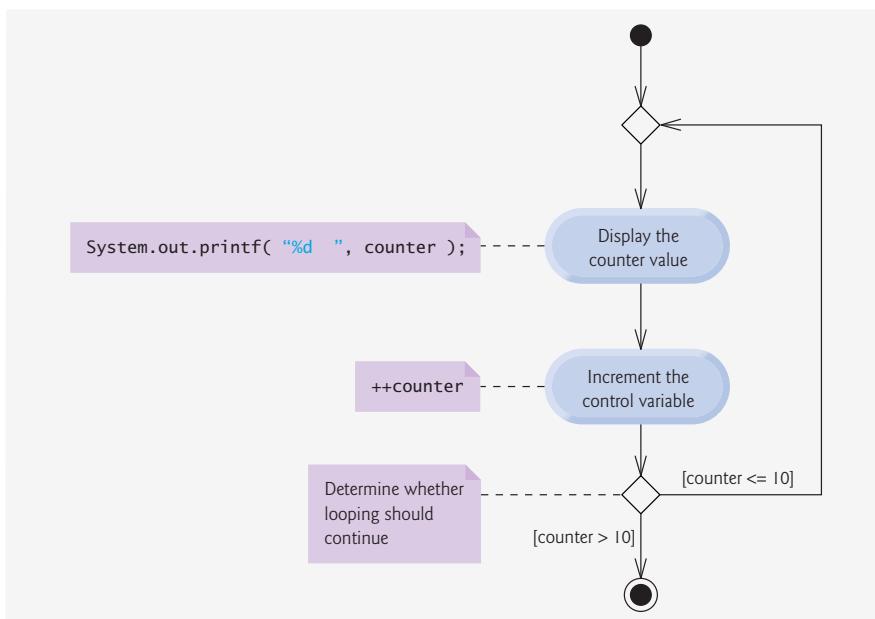

```
while (condition)
```

is normally the first line of a `while` statement. A `do...while` statement with no braces around a single-statement body appears as:

```
1 // Fig. 5.7: DoWhileTest.java
2 // do...while repetition statement.
3
4 public class DoWhileTest
5 {
6 public static void main(String args[])
7 {
8 int counter = 1; // initialize counter
9
10 do
11 {
12 System.out.printf("%d ", counter);
13 ++counter;
14 } while (counter <= 10); // end do...while
15
16 System.out.println(); // outputs a newline
17 } // end main
18 } // end class DoWhileTest
```

```
1 2 3 4 5 6 7 8 9 10
```

**Fig. 5.7 |** `do...while` repetition statement.

5.6 switch Multiple-Selection Statement **199**

**Fig. 5.8** | do...while repetition statement UML activity diagram.

```

do
 statement
 while (condition);

```

which can be confusing. A reader may misinterpret the last line—`while ( condition );`—as a `while` statement containing an empty statement (the semicolon by itself). Thus, the `do...while` statement with one body statement is usually written as follows:

```

do
{
 statement
} while (condition);

```

#### Good Programming Practice 5.6

*Always include braces in a do...while statement, even if they are not necessary. This helps eliminate ambiguity between the while statement and a do...while statement containing only one statement.*

## 5.6 switch Multiple-Selection Statement

We discussed the `if` single-selection statement and the `if...else` double-selection statement in Chapter 4. Java provides the `switch` multiple-selection statement to perform different actions based on the possible values of an integer variable or expression. Each action is associated with the value of a `constant integral expression` (i.e., a constant value of type

**200** Chapter 5 Control Statements: Part 2

byte, short, int or char, but not long) that the variable or expression on which the switch is based may assume.

***GradeBook Class with switch Statement to Count A, B, C, D and F Grades***

Figure 5.9 contains an enhanced version of the GradeBook class introduced in Chapter 3 and further developed in Chapter 4. The version of the class we now present not only calculates the average of a set of numeric grades entered by the user, but uses a switch statement to determine whether each grade is the equivalent of an A, B, C, D or F and to increment the appropriate grade counter. The class also displays a summary of the number of students who received each grade. Refer to Fig. 5.10 for sample input and output of the GradeBookTest application that uses class GradeBook to process a set of grades.

```

1 // Fig. 5.9: GradeBook.java
2 // GradeBook class uses switch statement to count A, B, C, D and F grades.
3 import java.util.Scanner; // program uses class Scanner
4
5 public class GradeBook
6 {
7 private String courseName; // name of course this GradeBook represents
8 private int total; // sum of grades
9 private int gradeCounter; // number of grades entered
10 private int aCount; // count of A grades
11 private int bCount; // count of B grades
12 private int cCount; // count of C grades
13 private int dCount; // count of D grades
14 private int fCount; // count of F grades
15
16 // constructor initializes courseName;
17 // int instance variables are initialized to 0 by default
18 public GradeBook(String name)
19 {
20 courseName = name; // initializes courseName
21 } // end constructor
22
23 // method to set the course name
24 public void setCourseName(String name)
25 {
26 courseName = name; // store the course name
27 } // end method setCourseName
28
29 // method to retrieve the course name
30 public String getCourseName()
31 {
32 return courseName;
33 } // end method getCourseName
34
35 // display a welcome message to the GradeBook user
36 public void displayMessage()
37 {

```

**Fig. 5.9** | GradeBook class uses switch statement to count A, B, C, D and F grades. (Part I of 3.)

## 5.6 switch Multiple-Selection Statement

```

38 // getCourseName gets the name of the course
39 System.out.printf("Welcome to the grade book for\n%s!\n\n",
40 getCourseName());
41 } // end method displayMessage
42
43 // input arbitrary number of grades from user
44 public void inputGrades()
45 {
46 Scanner input = new Scanner(System.in);
47
48 int grade; // grade entered by user
49
50 System.out.printf("%s\n%s\n %s\n %s\n",
51 "Enter the integer grades in the range 0-100.",
52 "Type the end-of-file indicator to terminate input:",
53 "On UNIX/Linux/Mac OS X type <ctrl> d then press Enter",
54 "On Windows type <ctrl> z then press Enter");
55
56 // loop until user enters the end-of-file indicator
57 while (input.hasNext())
58 {
59 grade = input.nextInt(); // read grade
60 total += grade; // add grade to total
61 ++gradeCounter; // increment number of grades
62
63 // call method to increment appropriate counter
64 incrementLetterGradeCounter(grade);
65 } // end while
66 } // end method inputGrades
67
68 // add 1 to appropriate counter for specified grade
69 public void incrementLetterGradeCounter(int Grade)
70 {
71 // determine which grade was entered
72 switch (grade / 10)
73 {
74 case 9: // grade was between 90
75 case 10: // and 100
76 ++aCount; // increment aCount
77 break; // necessary to exit switch
78
79 case 8: // grade was between 80 and 89
80 ++bCount; // increment bCount
81 break; // exit switch
82
83 case 7: // grade was between 70 and 79
84 ++cCount; // increment cCount
85 break; // exit switch
86
87 case 6: // grade was between 60 and 69
88 ++dCount; // increment dCount
89 break; // exit switch
90 }
}

```

**Fig. 5.9** | GradeBook class uses switch statement to count A, B, C, D and F grades. (Part 2 of 3.)

**202** Chapter 5 Control Statements: Part 2

```

91 default: // grade was less than 60
92 ++fCount; // increment fCount
93 break; // optional; will exit switch anyway
94 } // end switch
95 } // end method incrementLetterGradeCounter
96
97 // display a report based on the grades entered by user
98 public void displayGradeReport()
99 {
100 System.out.println("\nGrade Report:");
101
102 // if user entered at least one grade...
103 if (gradeCounter != 0)
104 {
105 // calculate average of all grades entered
106 double average = (double) total / gradeCounter;
107
108 // output summary of results
109 System.out.printf("Total of the %d grades entered is %d\n",
110 gradeCounter, total);
111 System.out.printf("Class average is %.2f\n", average);
112 System.out.printf("%s\n%s%d\n%s%d\n%s%d\n%s%d\n%s%d\n",
113 "Number of students who received each grade:",
114 "A: ", aCount, // display number of A grades
115 "B: ", bCount, // display number of B grades
116 "C: ", cCount, // display number of C grades
117 "D: ", dCount, // display number of D grades
118 "F: ", fCount); // display number of F grades
119 } // end if
120 else // no grades were entered, so output appropriate message
121 System.out.println("No grades were entered");
122 } // end method displayGradeReport
123 } // end class GradeBook

```

**Fig. 5.9** | GradeBook class uses switch statement to count A, B, C, D and F grades. (Part 3 of 3.)

Like earlier versions of the class, class `GradeBook` (Fig. 5.9) declares instance variable `courseName` (line 7) and contains methods `setCourseName` (lines 24–27), `getCourseName` (lines 30–33) and `displayMessage` (lines 36–41), which set the course name, store the course name and display a welcome message to the user, respectively. The class also contains a constructor (lines 18–21) that initializes the course name.

Class `GradeBook` also declares instance variables `total` (line 8) and `gradeCounter` (line 9), which keep track of the sum of the grades entered by the user and the number of grades entered, respectively. Lines 10–14 declare counter variables for each grade category. Class `GradeBook` maintains `total`, `gradeCounter` and the five letter-grade counters as instance variables so that these variables can be used or modified in any of the class's methods. Note that the class's constructor (lines 18–21) sets only the course name, because the remaining seven instance variables are `ints` and are initialized to 0 by default.

Class `GradeBook` (Fig. 5.9) contains three additional methods—`inputGrades`, `incrementLetterGradeCounter` and `displayGradeReport`. Method `inputGrades` (lines 44–66) reads an arbitrary number of integer grades from the user using sentinel-controlled repe-

5.6 switch Multiple-Selection Statement **205**

whether the user entered at least one grade—this helps us avoid dividing by zero. If so, line 106 calculates the average of the grades. Lines 109–118 then output the total of all the grades, the class average and the number of students who received each letter grade. If no grades were entered, line 121 outputs an appropriate message. The output in Fig. 5.10 shows a sample grade report based on 10 grades.

```

1 // Fig. 5.10: GradeBookTest.java
2 // Create GradeBook object, input grades and display grade report.
3
4 public class GradeBookTest
5 {
6 public static void main(String args[])
7 {
8 // create GradeBook object myGradeBook and
9 // pass course name to constructor
10 GradeBook myGradeBook = new GradeBook(
11 "CS101 Introduction to Java Programming");
12
13 myGradeBook.displayMessage(); // display welcome message
14 myGradeBook.inputGrades(); // read grades from user
15 myGradeBook.displayGradeReport(); // display report based on grades
16 } // end main
17 } // end class GradeBookTest

```

```

Welcome to the grade book for
CS101 Introduction to Java Programming!

Enter the integer grades in the range 0-100.

Grade Report:
Total of the 10 grades entered is 778
Class average is 77.80
Number of students who received each grade:
A: 4
B: 1
C: 2
D: 1
F: 2

```

**Fig. 5.10** | GradeBookTest creates a GradeBook object and invokes its methods.

5.6 switch Multiple-Selection Statement **203**

tion and updates instance variables `total` and `gradeCounter`. Method `inputGrades` calls method `incrementLetterGradeCounter` (lines 69–95) to update the appropriate letter-grade counter for each grade entered. Class `GradeBook` also contains method `displayGradeReport` (lines 98–122), which outputs a report containing the total of all grades entered, the average of the grades and the number of students who received each letter grade. Let's examine these methods in more detail.

Line 48 in method `inputGrades` declares variable `grade`, which will store the user's input. Lines 50–54 prompt the user to enter integer grades and to type the end-of-file indicator to terminate the input. The **end-of-file indicator** is a system-dependent keystroke combination which the user enters to indicate that there is no more data to input. In Chapter 14, Files and Streams, we will see how the end-of-file indicator is used when a program reads its input from a file.

On UNIX/Linux/Mac OS X systems, end-of-file is entered by typing the sequence

`<ctrl> d`

on a line by itself. This notation means to simultaneously press both the `ctrl` key and the `d` key. On Windows systems, end-of-file can be entered by typing

`<ctrl> z`

[*Note:* On some systems, you must press `Enter` after typing the end-of-file key sequence. Also, Windows typically displays the characters `^Z` on the screen when the end-of-file indicator is typed, as is shown in the output of Fig. 5.10.]

### Portability Tip 5.1

The keystroke combinations for entering end-of-file are system dependent.

The `while` statement (lines 57–65) obtains the user input. The condition at line 57 calls `Scanner` method `hasNext` to determine whether there is more data to input. This method returns the `boolean` value `true` if there is more data; otherwise, it returns `false`. The returned value is then used as the value of the condition in the `while` statement. As long as the end-of-file indicator has not been typed, method `hasNext` will return `true`.

Line 59 inputs a grade value from the user. Line 60 uses the `+=` operator to add `grade` to `total`. Line 61 increments `gradeCounter`. The class's `displayGradeReport` method uses these variables to compute the average of the grades. Line 64 calls the class's `incrementLetterGradeCounter` method (declared in lines 69–95) to increment the appropriate letter-grade counter based on the numeric grade entered.

Method `incrementLetterGradeCounter` contains a `switch` statement (lines 72–94) that determines which counter to increment. In this example, we assume that the user enters a valid grade in the range 0–100. A grade in the range 90–100 represents A, 80–89 represents B, 70–79 represents C, 60–69 represents D and 0–59 represents F. The `switch` statement consists of a block that contains a sequence of `case labels` and an optional `default case`. These are used in this example to determine which counter to increment based on the grade.

When the flow of control reaches the `switch`, the program evaluates the expression in the parentheses (`grade / 10`) following keyword `switch`. This is called the **controlling expression** of the `switch`. The program compares the value of the controlling expression

**204** Chapter 5 Control Statements: Part 2

(which must evaluate to an integral value of type `byte`, `char`, `short` or `int`) with each case label. The controlling expression in line 72 performs integer division, which truncates the fractional part of the result. Thus, when we divide any value for 0–100 by 10, the result is always a value from 0 to 10. We use several of these values in our case labels. For example, if the user enters the integer 85, the controlling expression evaluates to the `int` value 8. The `switch` compares 8 with each case label. If a match occurs (case 8: at line 79), the program executes the statements for that case. For the integer 8, line 80 increments `bCount`, because a grade in the 80s is a B. The `break` statement (line 81) causes program control to proceed with the first statement after the `switch`—in this program, we reach the end of method `incrementLetterGradeCounter`'s body, so control returns to line 65 in method `inputGrades` (the first line after the call to `incrementLetterGradeCounter`). This line marks the end of the body of the `while` loop that inputs grades (lines 57–65), so control flows to the `while`'s condition (line 57) to determine whether the loop should continue executing.

The cases in our `switch` explicitly test for the values 10, 9, 8, 7 and 6. Note the cases at lines 74–75 that test for the values 9 and 10 (both of which represent the grade A). Listing cases consecutively in this manner with no statements between them enables the cases to perform the same set of statements—when the controlling expression evaluates to 9 or 10, the statements in lines 76–77 will execute. The `switch` statement does not provide a mechanism for testing ranges of values, so every value that must be tested should be listed in a separate case label. Note that each case can have multiple statements. The `switch` statement differs from other control statements in that it does not require braces around multiple statements in a case.

Without `break` statements, each time a match occurs in the `switch`, the statements for that case and subsequent cases execute until a `break` statement or the end of the `switch` is encountered. This is often referred to as “falling through” to the statements in subsequent cases. (This feature is perfect for writing a concise program that displays the iterative song “The Twelve Days of Christmas” in Exercise 5.29.)

**Common Programming Error 5.7**

*Forgetting a `break` statement when one is needed in a `switch` is a logic error.*

If no match occurs between the controlling expression's value and a case label, the `default` case (lines 91–93) executes. We use the `default` case in this example to process all controlling-expression values that are less than 6—that is, all failing grades. If no match occurs and the `switch` does not contain a `default` case, program control simply continues with the first statement after the `switch`.

**GradeBookTest Class That Demonstrates Class GradeBook**

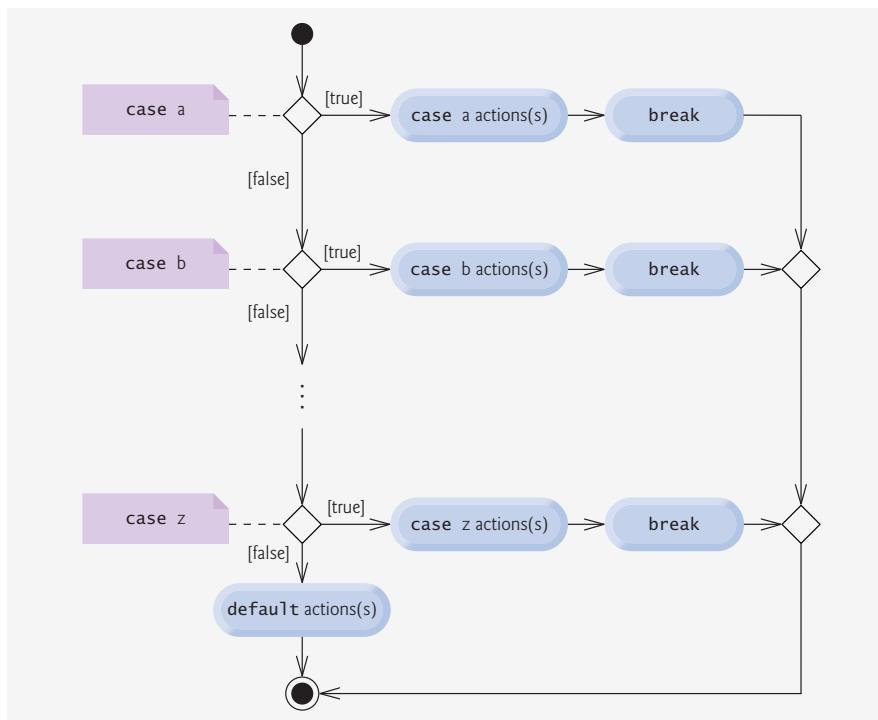

Class `GradeBookTest` (Fig. 5.10) creates a `GradeBook` object (lines 10–11). Line 13 invokes the object's `displayMessage` method to output a welcome message to the user. Line 14 invokes the object's `inputGrades` method to read a set of grades from the user and keep track of the sum of all the grades entered and the number of grades. Recall that method `inputGrades` also calls method `incrementLetterGradeCounter` to keep track of the number of students who received each letter grade. Line 15 invokes method `displayGradeReport` of class `GradeBook`, which outputs a report based on the grades entered (as in the input/output window in Fig. 5.10). Line 103 of class `GradeBook` (Fig. 5.9) determines

## 206 Chapter 5 Control Statements: Part 2

Note that class `GradeBookTest` (Fig. 5.10) does not directly call `GradeBook` method `incrementLetterGradeCounter` (lines 69–95 of Fig. 5.9). This method is used exclusively by method `inputGrades` of class `GradeBook` to update the appropriate letter-grade counter as each new grade is entered by the user. Method `incrementLetterGradeCounter` exists solely to support the operations of class `GradeBook`'s other methods and thus could be declared `private`. Recall from Chapter 3 that methods declared with access modifier `private` can be called only by other methods of the class in which the `private` methods are declared. Such methods are commonly referred to as **utility methods** or **helper methods** because they can be called only by other methods of that class and are used to support the operation of those methods.

### **switch Statement UML Activity Diagram**

Figure 5.11 shows the UML activity diagram for the general `switch` statement. Most `switch` statements use a `break` in each case to terminate the `switch` statement after processing the case. Figure 5.11 emphasizes this by including `break` statements in the activity diagram. The diagram makes it clear that the `break` statement at the end of a `case` causes control to exit the `switch` statement immediately.

**Fig. 5.11** | `switch` multiple-selection statement UML activity diagram with `break` statements.

## 5.7 break and continue Statements 207

The `break` statement is not required for the `switch`'s last case (or the optional `default` case, when it appears last), because execution continues with the next statement after the `switch`.

### **Software Engineering Observation 5.2**

*Provide a default case in switch statements. Including a default case focuses you on the need to process exceptional conditions.*

### **Good Programming Practice 5.7**

*Although each case and the default case in a switch can occur in any order, place the default case last. When the default case is listed last, the break for that case is not required. Some programmers include this break for clarity and symmetry with other cases.*

When using the `switch` statement, remember that the expression after each case must be a constant integral expression—that is, any combination of integer constants that evaluates to a constant integer value (e.g., `-7`, `0` or `221`). An integer constant is simply an integer value. In addition, you can use **character constants**—specific characters in single quotes, such as '`A`', '`7`' or '`$`'—which represent the integer values of characters. (Appendix B, ASCII Character Set, shows the integer values of the characters in the ASCII character set, which is a subset of the Unicode character set used by Java.)

The expression in each case also can be a **constant variable**—a variable that contains a value which does not change for the entire program. Such a variable is declared with keyword `final` (discussed in Chapter 6, Methods: A Deeper Look). Java has a feature called enumerations, which we also present in Chapter 6. Enumeration constants can also be used in `case` labels. In Chapter 10, Object-Oriented Programming: Polymorphism, we present a more elegant way to implement `switch` logic—we use a technique called polymorphism to create programs that are often clearer, easier to maintain and easier to extend than programs using `switch` logic.

## **5.7 break and continue Statements**

In addition to selection and repetition statements, Java provides statements `break` and `continue` (presented in this section and Appendix K, Labeled `break` and `continue` Statements) to alter the flow of control. The preceding section showed how `break` can be used to terminate a `switch` statement's execution. This section discusses how to use `break` in repetition statements.

Java also provides the labeled `break` and `continue` statements for use in cases in which you need to conveniently alter the flow of control in nested control statements. We discuss the labeled `break` and `continue` statements in Appendix K.

### ***break Statement***

The `break` statement, when executed in a `while`, `for`, `do...while` or `switch`, causes immediate exit from that statement. Execution continues with the first statement after the control statement. Common uses of the `break` statement are to escape early from a loop or to skip the remainder of a `switch` (as in Fig. 5.9). Figure 5.12 demonstrates a `break` statement exiting a `for`.

**208** Chapter 5 Control Statements: Part 2

```

1 // Fig. 5.12: BreakTest.java
2 // break statement exiting a for statement.
3 public class BreakTest
4 {
5 public static void main(String args[])
6 {
7 int count; // control variable also used after loop terminates
8
9 for (count = 1; count <= 10; count++) // loop 10 times
10 {
11 if (count == 5) // if count is 5,
12 break; // terminate loop
13
14 System.out.printf("%d ", count);
15 } // end for
16
17 System.out.printf("\nBroke out of loop at count = %d\n", count);
18 } // end main
19 } // end class BreakTest

```

```

1 2 3 4
Broke out of loop at count = 5

```

**Fig. 5.12** | break statement exiting a for statement.

When the `if` statement nested at line 11 in the `for` statement (lines 9–15) detects that `count` is 5, the `break` statement at line 12 executes. This terminates the `for` statement, and the program proceeds to line 17 (immediately after the `for` statement), which displays a message indicating the value of the control variable when the loop terminated. The loop fully executes its body only four times instead of 10.

***continue Statement***

The `continue` statement, when executed in a `while`, `for` or `do...while`, skips the remaining statements in the loop body and proceeds with the next iteration of the loop. In `while` and `do...while` statements, the program evaluates the loop-continuation test immediately after the `continue` statement executes. In a `for` statement, the increment expression executes, then the program evaluates the loop-continuation test.

Figure 5.13 uses the `continue` statement in a `for` to skip the statement at line 12 when the nested `if` (line 9) determines that the value of `count` is 5. When the `continue` statement executes, program control continues with the increment of the control variable in the `for` statement (line 7).

In Section 5.3, we stated that `while` could be used in most cases in place of `for`. The one exception occurs when the increment expression in the `while` follows a `continue` statement. In this case, the increment does not execute before the program evaluates the repetition-continuation condition, so the `while` does not execute in the same manner as the `for`.

**Software Engineering Observation 5.3**

*Some programmers feel that break and continue violate structured programming. Since the same effects are achievable with structured programming techniques, these programmers do not use break or continue.*

5.8 Logical Operators **209**

```

1 // Fig. 5.13: ContinueTest.java
2 // continue statement terminating an iteration of a for statement.
3 public class ContinueTest
4 {
5 public static void main(String args[])
6 {
7 for (int count = 1; count <= 10; count++) // loop 10 times
8 {
9 if (count == 5) // if count is 5,
10 continue; // skip remaining code in loop
11
12 System.out.printf("%d ", count);
13 } // end for
14
15 System.out.println("\nUsed continue to skip printing 5");
16 } // end main
17 } // end class ContinueTest

```

```

1 2 3 4 6 7 8 9 10
Used continue to skip printing 5

```

**Fig. 5.13** | continue statement terminating an iteration of a for statement.

#### Software Engineering Observation 5.4

*There is a tension between achieving quality software engineering and achieving the best-performing software. Often, one of these goals is achieved at the expense of the other. For all but the most performance-intensive situations, apply the following rule of thumb: First, make your code simple and correct; then make it fast and small, but only if necessary.*

## 5.8 Logical Operators

The `if`, `if...else`, `while`, `do...while` and `for` statements each require a condition to determine how to continue a program's flow of control. So far, we have studied only **simple conditions**, such as `count <= 10`, `number != sentinelValue` and `total > 1000`. Simple conditions are expressed in terms of the relational operators `>`, `<`, `>=` and `<=` and the equality operators `==` and `!=`, and each expression tests only one condition. To test multiple conditions in the process of making a decision, we performed these tests in separate statements or in nested `if` or `if...else` statements. Sometimes, control statements require more complex conditions to determine a program's flow of control.

Java provides **logical operators** to enable you to form more complex conditions by combining simple conditions. The logical operators are `&&` (conditional AND), `||` (conditional OR), `&` (boolean logical AND), `|` (boolean logical inclusive OR), `^` (boolean logical exclusive OR) and `!` (logical NOT).

### Conditional AND (`&&`) Operator

Suppose that we wish to ensure at some point in a program that two conditions are *both* true before we choose a certain path of execution. In this case, we can use the `&&` (**conditional AND**) operator, as follows:

**210** Chapter 5 Control Statements: Part 2

```
if (gender == FEMALE && age >= 65)
 ++seniorFemales;
```

This `if` statement contains two simple conditions. The condition `gender == FEMALE` compares variable `gender` to the constant `FEMALE`. This might be evaluated, for example, to determine whether a person is female. The condition `age >= 65` might be evaluated to determine whether a person is a senior citizen. The `if` statement considers the combined condition

```
gender == FEMALE && age >= 65
```

which is true if and only if both simple conditions are true. If the combined condition is true, the `if` statement's body increments `seniorFemales` by 1. If either or both of the simple conditions are false, the program skips the increment. Some programmers find that the preceding combined condition is more readable when redundant parentheses are added, as in:

```
(gender == FEMALE) && (age >= 65)
```

The table in Fig. 5.14 summarizes the `&&` operator. The table shows all four possible combinations of `false` and `true` values for `expression1` and `expression2`. Such tables are called **truth tables**. Java evaluates to `false` or `true` all expressions that include relational operators, equality operators or logical operators.

#### *Conditional OR (||) Operator*

Now suppose that we wish to ensure that either *or* both of two conditions are true before we choose a certain path of execution. In this case, we use the `||` (**conditional OR**) operator, as in the following program segment:

```
if ((semesterAverage >= 90) || (finalExam >= 90))
 System.out.println ("Student grade is A");
```

This statement also contains two simple conditions. The condition `semesterAverage >= 90` evaluates to determine whether the student deserves an A in the course because of a solid performance throughout the semester. The condition `finalExam >= 90` evaluates to determine whether the student deserves an A in the course because of an outstanding performance on the final exam. The `if` statement then considers the combined condition

```
(semesterAverage >= 90) || (finalExam >= 90)
```

| expression1 | expression2 | expression1 && expression2 |
|-------------|-------------|----------------------------|
| false       | false       | false                      |
| false       | true        | false                      |
| true        | false       | false                      |
| true        | true        | true                       |

**Fig. 5.14** | `&&` (conditional AND) operator truth table.

5.8 Logical Operators **211**

and awards the student an A if either or both of the simple conditions are true. The only time the message "Student grade is A" is *not* printed is when both of the simple conditions are false. Figure 5.15 is a truth table for operator conditional OR (`||`). Operator `&&` has a higher precedence than operator `||`. Both operators associate from left to right.

#### *Short-Circuit Evaluation of Complex Conditions*

The parts of an expression containing `&&` or `||` operators are evaluated only until it is known whether the condition is true or false. Thus, evaluation of the expression

```
(gender == FEMALE) && (age >= 65)
```

stops immediately if `gender` is not equal to `FEMALE` (i.e., the entire expression is `false`) and continues if `gender` is equal to `FEMALE` (i.e., the entire expression could still be `true` if the condition `age >= 65` is `true`). This feature of conditional AND and conditional OR expressions is called **short-circuit evaluation**.

#### Common Programming Error 5.8

*In expressions using operator `&&`, a condition—we will call this the dependent condition—may require another condition to be true for the evaluation of the dependent condition to be meaningful. In this case, the dependent condition should be placed after the other condition, or an error might occur. For example, in the expression `( i != 0 ) && ( 10 / i == 2 )`, the second condition must appear after the first condition, or a divide-by-zero error might occur.*

#### *Boolean Logical AND (`&`) and Boolean Logical Inclusive OR (`|`) Operators*

The **boolean logical AND (`&`)** and **boolean logical inclusive OR (`|`)** operators work identically to the `&&` (conditional AND) and `||` (conditional OR) operators, with one exception: The boolean logical operators always evaluate both of their operands (i.e., they do not perform short-circuit evaluation). Therefore, the expression

```
(gender == 1) & (age >= 65)
```

evaluates `age >= 65` regardless of whether `gender` is equal to 1. This is useful if the right operand of the boolean logical AND or boolean logical inclusive OR operator has a required **side effect**—a modification of a variable's value. For example, the expression

```
(birthday == true) | (++age >= 65)
```

guarantees that the condition `++age >= 65` will be evaluated. Thus, the variable `age` is incremented in the preceding expression, regardless of whether the overall expression is `true` or `false`.

| expression1 | expression2 | expression1    expression2 |
|-------------|-------------|----------------------------|
| false       | false       | false                      |
| false       | true        | true                       |
| true        | false       | true                       |
| true        | true        | true                       |

**Fig. 5.15** `| |` (conditional OR) operator truth table.

**212** Chapter 5 Control Statements: Part 2**Error-Prevention Tip 5.4**

*For clarity, avoid expressions with side effects in conditions. The side effects may look clever, but they can make it harder to understand code and can lead to subtle logic errors.*

**Boolean Logical Exclusive OR ( $\wedge$ )**

A simple condition containing the **boolean logical exclusive OR ( $\wedge$ )** operator is **true if and only if one of its operands is true and the other is false**. If both operands are **true** or both are **false**, the entire condition is **false**. Figure 5.16 is a truth table for the boolean logical exclusive OR operator ( $\wedge$ ). This operator is also guaranteed to evaluate both of its operands.

**Logical Negation (!) Operator**

The **!** (**logical NOT**, also called **logical negation** or **logical complement**) operator “reverses” the meaning of a condition. Unlike the logical operators **&&**, **||**, **&**, **|** and  **$\wedge$** , which are binary operators that combine two conditions, the logical negation operator is a unary operator that has only a single condition as an operand. The logical negation operator is placed before a condition to choose a path of execution if the original condition (without the logical negation operator) is **false**, as in the program segment

```
if (! (grade == sentinelValue))
 System.out.printf("The next grade is %d\n", grade);
```

which executes the **printf** call only if **grade** is not equal to **sentinelValue**. The parentheses around the condition **grade == sentinelValue** are needed because the logical negation operator has a higher precedence than the equality operator.

In most cases, you can avoid using logical negation by expressing the condition differently with an appropriate relational or equality operator. For example, the previous statement may also be written as follows:

```
if (grade != sentinelValue)
 System.out.printf("The next grade is %d\n", grade);
```

This flexibility can help you express a condition in a more convenient manner. Figure 5.17 is a truth table for the logical negation operator.

| expression1 | expression2 | expression1 $\wedge$ expression2 |
|-------------|-------------|----------------------------------|
| false       | false       | false                            |
| false       | true        | false                            |
| true        | false       | false                            |
| true        | true        | true                             |

**Fig. 5.16** |  $\wedge$  (boolean logical exclusive OR) operator truth table.

5.8 Logical Operators **213**

| expression | !expression |
|------------|-------------|
| false      | true        |
| true       | false       |

**Fig. 5.17** | ! (logical negation, or logical NOT) operator truth table.

#### *Logical Operators Example*

Figure 5.18 demonstrates the logical operators and boolean logical operators by producing their truth tables. The output shows the expression that was evaluated and the boolean result of that expression. The values of the boolean expressions are displayed with `printf` using the `%b` format specifier, which outputs the word “true” or the word “false” based on the expression’s value. Lines 9–13 produce the truth table for `&&`. Lines 16–20 produce the truth table for `||`. Lines 23–27 produce the truth table for `&`. Lines 30–35 produce the truth table for `|`. Lines 38–43 produce the truth table for `^`. Lines 46–47 produce the truth table for `!`.

5.9 Structured Programming Summary **215**

Figure 5.19 shows the precedence and associativity of the Java operators introduced so far. The operators are shown from top to bottom in decreasing order of precedence.

| Operators                          | Associativity | Type                         |
|------------------------------------|---------------|------------------------------|
| <code>++ --</code>                 | right to left | unary postfix                |
| <code>++ - + - ! (type)</code>     | right to left | unary prefix                 |
| <code>*</code> / %                 | left to right | multiplicative               |
| <code>+</code> -                   | left to right | additive                     |
| <code>&lt; &lt;= &gt; &gt;=</code> | left to right | relational                   |
| <code>== !=</code>                 | left to right | equality                     |
| <code>&amp;</code>                 | left to right | boolean logical AND          |
| <code>^</code>                     | left to right | boolean logical exclusive OR |
| <code> </code>                     | left to right | boolean logical inclusive OR |
| <code>&amp;&amp;</code>            | left to right | conditional AND              |
| <code>  </code>                    | left to right | conditional OR               |
| <code>?:</code>                    | right to left | conditional                  |
| <code>= += -= *= /= %=</code>      | right to left | assignment                   |

**Fig. 5.19** | Precedence/associativity of the operators discussed so far.

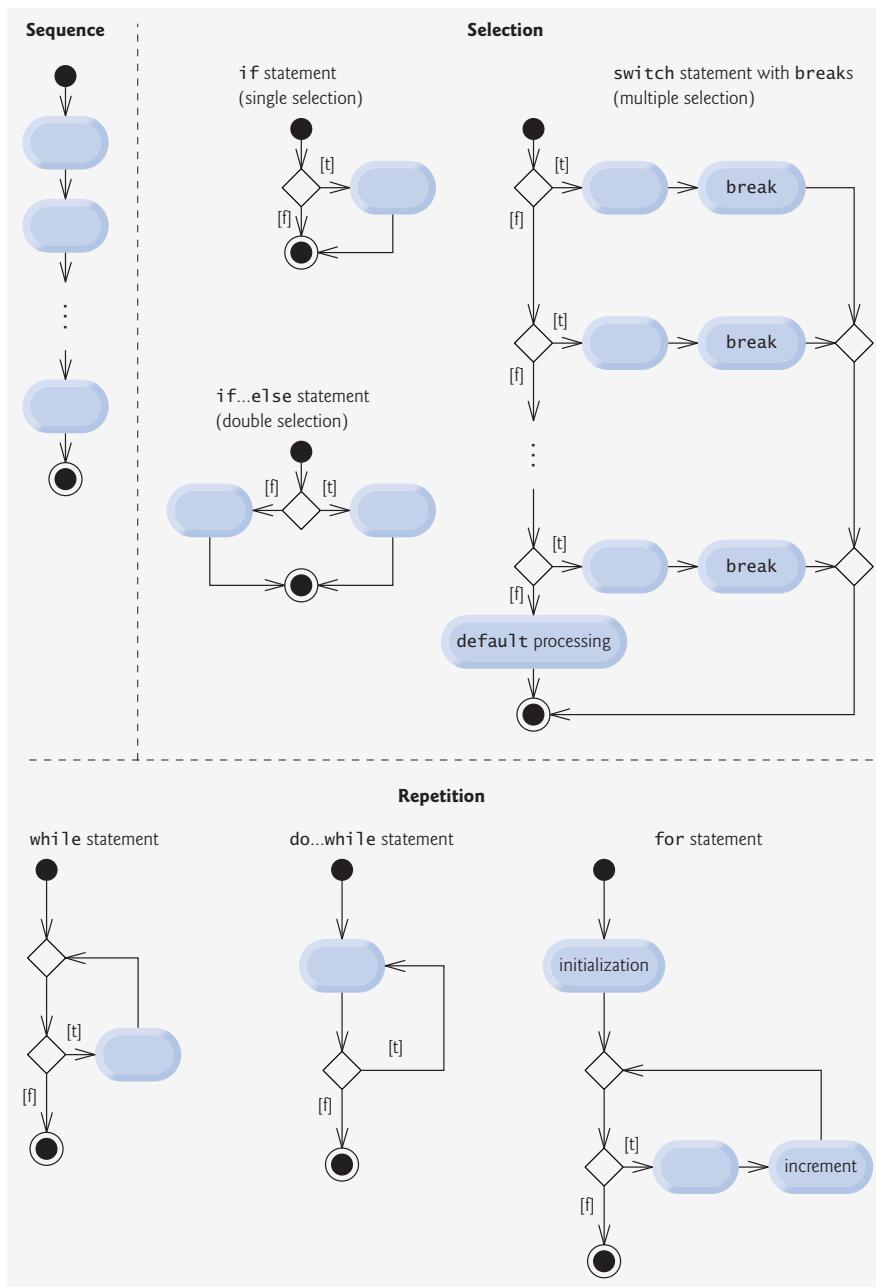

## 5.9 Structured Programming Summary

Just as architects design buildings by employing the collective wisdom of their profession, so should programmers design programs. Our field is much younger than architecture, and our collective wisdom is considerably sparser. We have learned that structured programming produces programs that are easier than unstructured programs to understand, test, debug, modify and even prove correct in a mathematical sense.

Figure 5.20 uses UML activity diagrams to summarize Java’s control statements. The initial and final states indicate the single entry point and the single exit point of each control statement. Arbitrarily connecting individual symbols in an activity diagram can lead to unstructured programs. Therefore, the programming profession has chosen a limited set of control statements that can be combined in only two simple ways to build structured programs.

For simplicity, only single-entry/single-exit control statements are used—there is only one way to enter and only one way to exit each control statement. Connecting control statements in sequence to form structured programs is simple. The final state of one control statement is connected to the initial state of the next control statement—that is, the control statements are placed one after another in a program in sequence. We call this “control-statement stacking.” The rules for forming structured programs also allow for control statements to be nested.

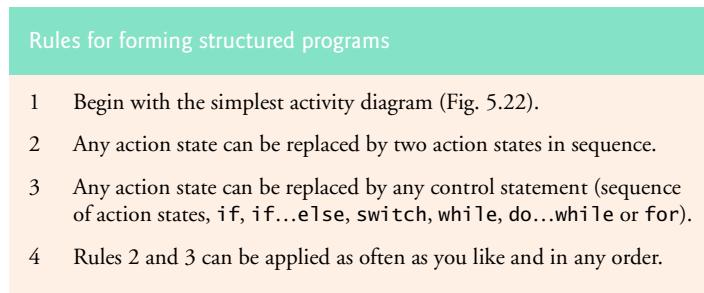

## 216 Chapter 5 Control Statements: Part 2

**Fig. 5.20** | Java's single-entry/single-exit sequence, selection and repetition statements.

## 5.9 Structured Programming Summary

217

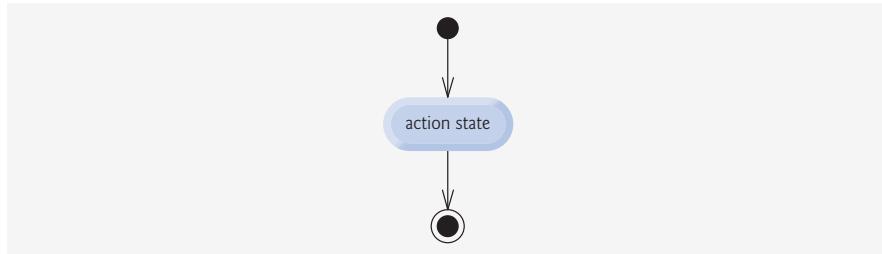

**Fig. 5.21** | Rules for forming structured programs.

Figure 5.21 shows the rules for forming structured programs. The rules assume that action states may be used to indicate any action. The rules also assume that we begin with the simplest activity diagram (Fig. 5.22) consisting of only an initial state, an action state, a final state and transition arrows.

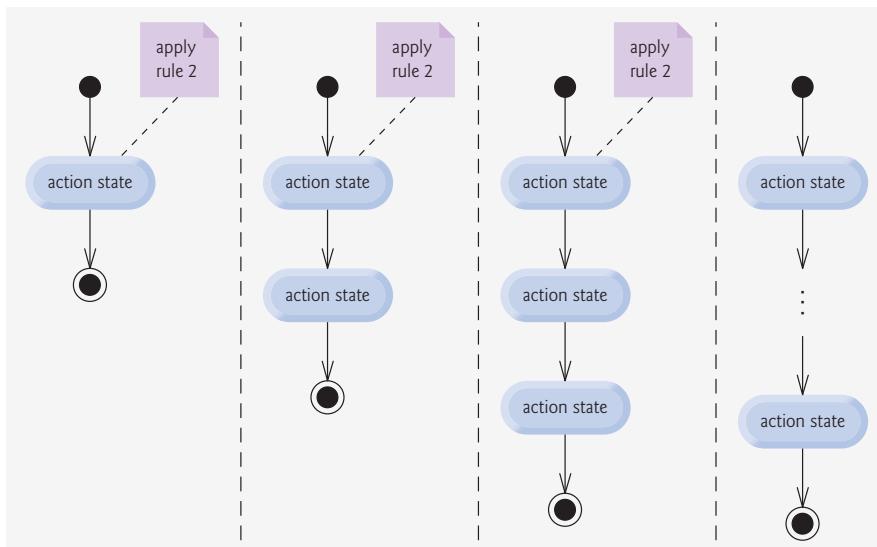

Applying the rules in Fig. 5.21 always results in a properly structured activity diagram with a neat, building-block appearance. For example, repeatedly applying rule 2 to the simplest activity diagram results in an activity diagram containing many action states in sequence (Fig. 5.23). Rule 2 generates a stack of control statements, so let us call rule 2 the **stacking rule**. [Note: The vertical dashed lines in Fig. 5.23 are not part of the UML. We use them to separate the four activity diagrams that demonstrate rule 2 of Fig. 5.21 being applied.]

Rule 3 is called the **nesting rule**. Repeatedly applying rule 3 to the simplest activity diagram results in an activity diagram with neatly nested control statements. For example, in Fig. 5.24, the action state in the simplest activity diagram is replaced with a double-selection (**if...else**) statement. Then rule 3 is applied again to the action states in the double-selection statement, replacing each with a double-selection statement. The dashed action-state symbol around each double-selection statement represents the action state that was replaced. [Note: The dashed arrows and dashed action-state symbols shown in Fig. 5.24 are not part of the UML. They are used here to illustrate that any action state can be replaced with a control statement.]

Rule 4 generates larger, more involved and more deeply nested statements. The diagrams that emerge from applying the rules in Fig. 5.21 constitute the set of all possible

**Fig. 5.22** | Simplest activity diagram.

**218** Chapter 5 Control Statements: Part 2

**Fig. 5.23** | Repeatedly applying the stacking rule (rule 2) of Fig. 5.21 to the simplest activity diagram.

structured activity diagrams and hence the set of all possible structured programs. The beauty of the structured approach is that we use only seven simple single-entry/single-exit control statements and assemble them in only two simple ways.

If the rules in Fig. 5.21 are followed, an “unstructured” activity diagram (like the one in Fig. 5.25) cannot be created. If you are uncertain about whether a particular diagram is structured, apply the rules of Fig. 5.21 in reverse to reduce the diagram to the simplest activity diagram. If you can reduce it, the original diagram is structured; otherwise, it is not.

Structured programming promotes simplicity. Bohm and Jacopini have given us the result that only three forms of control are needed to implement an algorithm:

- Sequence
- Selection
- Repetition

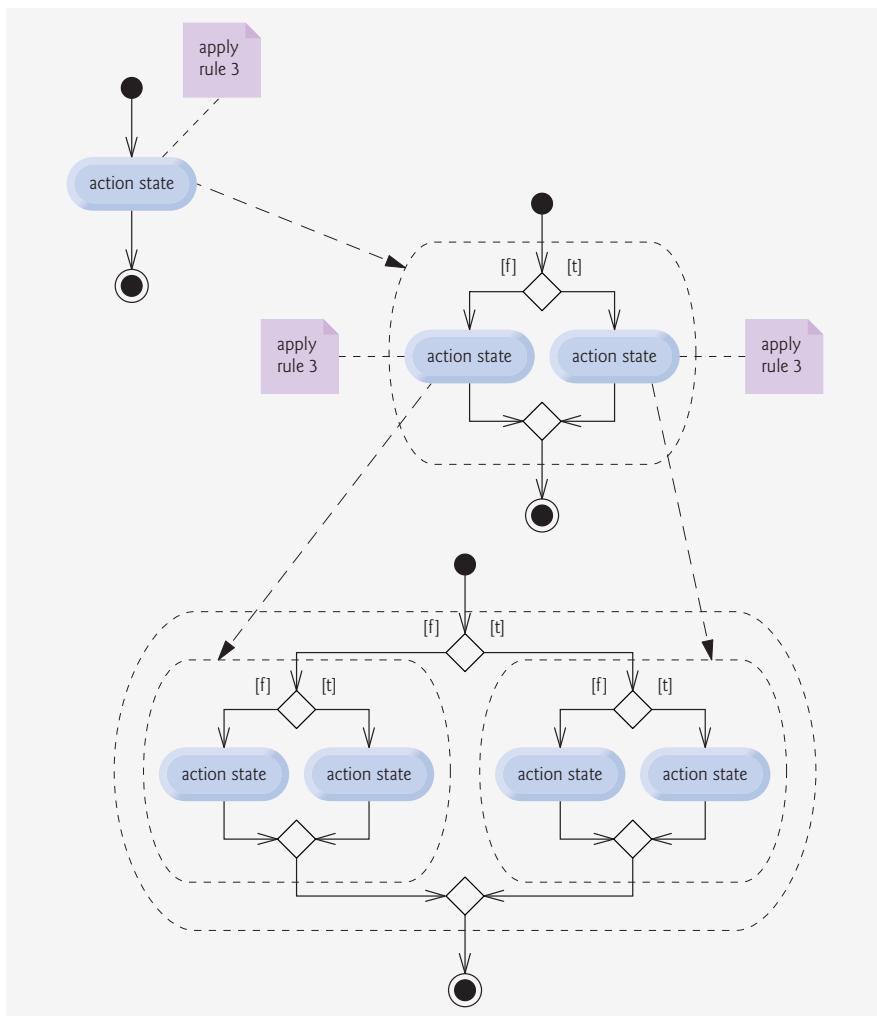

The sequence structure is trivial. Simply list the statements to execute in the order in which they should execute. Selection is implemented in one of three ways:

- `if` statement (single selection)
- `if...else` statement (double selection)
- `switch` statement (multiple selection)

In fact, it is straightforward to prove that the simple `if` statement is sufficient to provide any form of selection—everything that can be done with the `if...else` statement and the `switch` statement can be implemented by combining `if` statements (although perhaps not as clearly and efficiently).

## 5.9 Structured Programming Summary

219

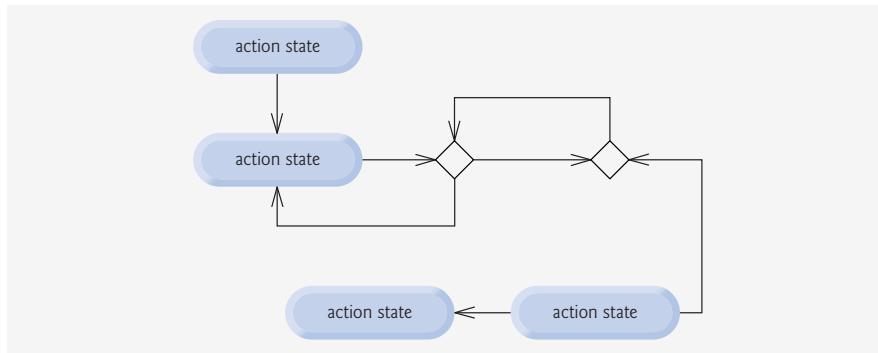

**Fig. 5.24** | Repeatedly applying the nesting rule (rule 3) of Fig. 5.21 to the simplest activity diagram.

Repetition is implemented in one of three ways:

- `while` statement
- `do...while` statement
- `for` statement

It is straightforward to prove that the `while` statement is sufficient to provide any form of repetition. Everything that can be done with the `do...while` statement and the `for` statement can be done with the `while` statement (although perhaps not as conveniently).

## 220 Chapter 5 Control Statements: Part 2

**Fig. 5.25** | “Unstructured” activity diagram.

Combining these results illustrates that any form of control ever needed in a Java program can be expressed in terms of

- sequence
- `if` statement (selection)
- `while` statement (repetition)

and that these can be combined in only two ways—stacking and nesting. Indeed, structured programming is the essence of simplicity.

## 5.10 (Optional) GUI and Graphics Case Study: Drawing Rectangles and Ovals

This section demonstrates drawing rectangles and ovals, using the `Graphics` methods `drawRect` and `drawOval`, respectively. These methods are demonstrated in Fig. 5.26.

Line 6 begins the class declaration for `Shapes`, which extends `JPanel`. Instance variable `choice`, declared in line 8, determines whether `paintComponent` should draw rectangles or ovals. The `Shapes` constructor at lines 11–14 initializes `choice` with the value passed in parameter `userChoice`.

Method `paintComponent` (lines 17–36) performs the actual drawing. Remember, the first statement in every `paintComponent` method should be a call to `super.paintComponent`, as in line 19. Lines 21–35 loop 10 times to draw 10 shapes. The `switch` statement (Lines 24–34) chooses between drawing rectangles and drawing ovals.

If `choice` is 1, then the program draws a rectangle. Lines 27–28 call `Graphics` method `drawRect`. Method `drawRect` requires four arguments. The first two represent the *x*- and *y*-coordinates of the upper-left corner of the rectangle; the next two represent the width and the height of the rectangle. In this example, we start at a position 10 pixels down and 10 pixels right of the top-left corner, and every iteration of the loop moves the upper-left corner another 10 pixels down and to the right. The width and the height of the rectangle start at 50 pixels and increase by 10 pixels in each iteration.

If `choice` is 2, the program draws an oval. When drawing an oval, an imaginary rectangle called a **bounding rectangle** is created, and an oval that touches the midpoints of all four sides of the bounding rectangle is placed inside. Method `drawOval` (lines 31–32)

## 5.10 (Optional) GUI and Graphics Case Study: Drawing Rectangles and Ovals

221

```

1 // Fig. 5.26: Shapes.java
2 // Demonstrates drawing different shapes.
3 import java.awt.Graphics;
4 import javax.swing.JPanel;
5
6 public class Shapes extends JPanel
7 {
8 private int choice; // user's choice of which shape to draw
9
10 // constructor sets the user's choice
11 public Shapes(int userChoice)
12 {
13 choice = userChoice;
14 } // end Shapes constructor
15
16 // draws a cascade of shapes starting from the top-left corner
17 public void paintComponent(Graphics g)
18 {
19 super.paintComponent(g);
20
21 for (int i = 0; i < 10; i++)
22 {
23 // pick the shape based on the user's choice
24 switch (choice)
25 {
26 case 1: // draw rectangles
27 g.drawRect(10 + i * 10, 10 + i * 10,
28 50 + i * 10, 50 + i * 10);
29 break;
30 case 2: // draw ovals
31 g.drawOval(10 + i * 10, 10 + i * 10,
32 50 + i * 10, 50 + i * 10);
33 break;
34 } // end switch
35 } // end for
36 } // end method paintComponent
37 } // end class Shapes

```

**Fig. 5.26** | Drawing a cascade of shapes based on the user's choice.

requires the same four arguments as method `drawRect`. The arguments specify the position and size of the bounding rectangle for the oval. The values passed to `drawOval` in this example are exactly the same as the values passed to `drawRect` in lines 27–28. Since the width and height of the bounding rectangle are identical in this example, lines 27–28 draw a circle. You may modify the program to draw both rectangles and ovals to see how `drawOval` and `drawRect` are related.

Figure 5.27 is responsible for handling input from the user and creating a window to display the appropriate drawing based on the user's response. Line 3 imports `JFrame` to handle the display, and Line 4 imports `JOptionPane` to handle the input.

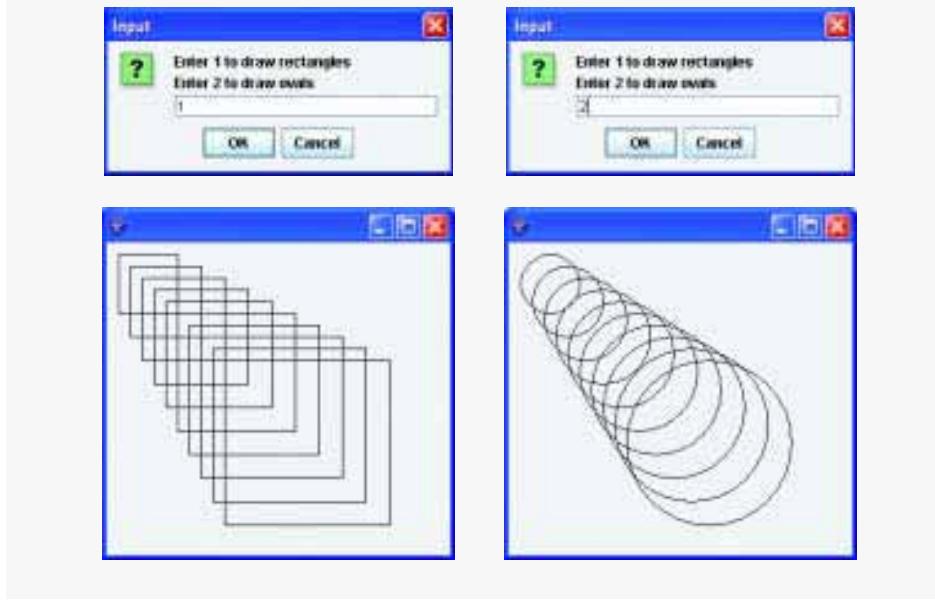

Lines 11–13 prompt the user with an input dialog and store the user's response in variable `input`. Line 15 uses `Integer` method `parseInt` to convert the `String` entered by the user to an `int` and stores the result in variable `choice`. An instance of class `Shapes` is

**222** Chapter 5 Control Statements: Part 2

created at line 18, with the user's choice passed to the constructor. Lines 20–25 perform the standard operations for creating and setting up a window—creating a frame, setting it to exit the application when closed, adding the drawing to the frame, setting the frame size and making it visible.

#### *GUI and Graphics Case Study Exercises*

**5.1** Draw 12 concentric circles in the center of a `JPanel` (Fig. 5.28). The innermost circle should have a radius of 10 pixels, and each successive circle should have a radius 10 pixels larger than the previous one. Begin by finding the center of the `JPanel`. To get the upper-left corner of a circle, move up one radius and to the left one radius from the center. The width and height of the bounding rectangle is the diameter of the circle (twice the radius).

**5.2** Modify Exercise 5.16 from the end-of-chapter exercises to read input using dialogs and to display the bar chart using rectangles of varying lengths.

**Fig. 5.28** | Drawing concentric circles.

## 5.11 (Optional) Software Engineering Case Study: Identifying Objects' States and Activities

In Section 4.15, we identified many of the class attributes needed to implement the ATM system and added them to the class diagram in Fig. 4.24. In this section, we show how these attributes represent an object's state. We identify some key states that our objects may occupy and discuss how objects change state in response to various events occurring in the system. We also discuss the workflow, or **activities**, that objects perform in the ATM system. We present the activities of `BalanceInquiry` and `Withdrawal` transaction objects in this section.

#### *State Machine Diagrams*

Each object in a system goes through a series of states. An object's current state is indicated by the values of the object's attributes at a given time. **State machine diagrams** (commonly called **state diagrams**) model several states of an object and show under what circumstances the object changes state. Unlike the class diagrams presented in earlier case study sections, which focused primarily on the structure of the system, state diagrams model some of the behavior of the system.

## 224 Chapter 5 Control Statements: Part 2

Figure 5.29 is a simple state diagram that models some of the states of an object of class ATM. The UML represents each state in a state diagram as a [rounded rectangle](#) with the name of the state placed inside it. A [solid circle](#) with an attached stick arrowhead designates the [initial state](#). Recall that we modeled this state information as the Boolean attribute `userAuthenticated` in the class diagram of Fig. 4.24. This attribute is initialized to `false`, or the “User not authenticated” state, according to the state diagram.

The arrows with stick arrowheads indicate [transitions](#) between states. An object can transition from one state to another in response to various events that occur in the system. The name or description of the event that causes a transition is written near the line that corresponds to the transition. For example, the ATM object changes from the “User not authenticated” to the “User authenticated” state after the database authenticates the user. Recall from the requirements document that the database authenticates a user by comparing the account number and PIN entered by the user with those of an account in the database. If the database indicates that the user has entered a valid account number and the correct PIN, the ATM object transitions to the “User authenticated” state and changes its `userAuthenticated` attribute to a value of `true`. When the user exits the system by choosing the “exit” option from the main menu, the ATM object returns to the “User not authenticated” state.

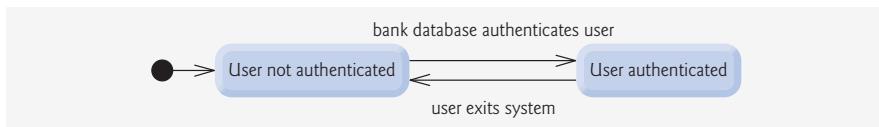

### Software Engineering Observation 5.5

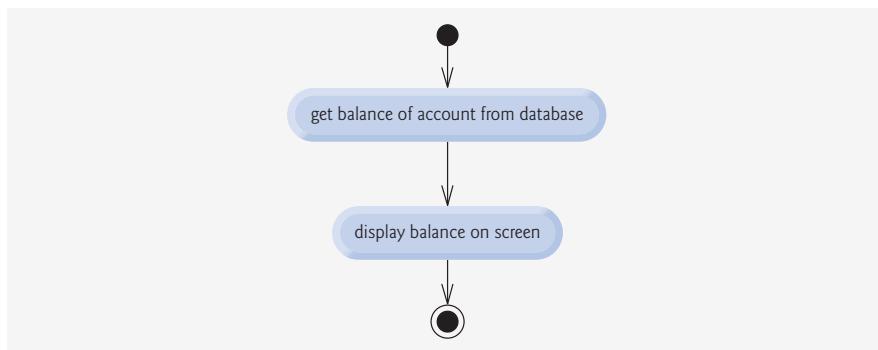

*Software designers do not generally create state diagrams showing every possible state and state transition for all attributes—there are simply too many of them. State diagrams typically show only key states and state transitions.*

### Activity Diagrams

Like a state diagram, an activity diagram models aspects of system behavior. Unlike a state diagram, an activity diagram models an object’s [workflow](#) (sequence of events) during program execution. An activity diagram models the [actions](#) the object will perform and in what order. The activity diagram in Fig. 5.30 models the actions involved in executing a balance-inquiry transaction. We assume that a `BalanceInquiry` object has already been initialized and assigned a valid account number (that of the current user), so the object knows which balance to retrieve. The diagram includes the actions that occur after the user selects a balance inquiry from the main menu and before the ATM returns the user to the main menu—a `BalanceInquiry` object does not perform or initiate these actions, so we do not model them here. The diagram begins with retrieving the balance of the account from the database. Next, the `BalanceInquiry` displays the balance on the screen. This action completes the execution of the transaction. Recall that we have chosen to represent an account balance as both the `availableBalance` and `totalBalance` attributes of class `Account`, so the actions modeled in Fig. 5.30 refer to the retrieval and display of both balance attributes.

**Fig. 5.29** | State diagram for the ATM object.

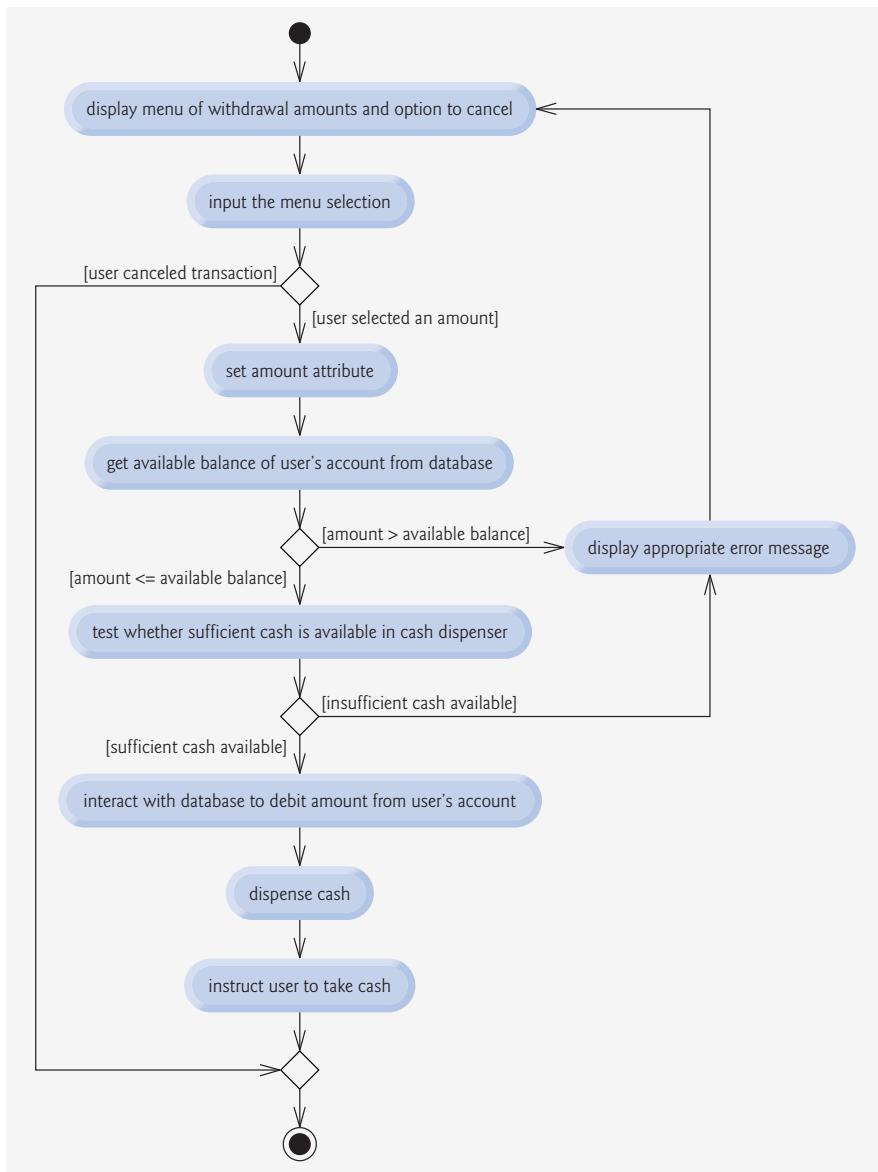

5.11 Identifying Objects' States and Activities **225**

**Fig. 5.30** | Activity diagram for a `BalanceInquiry` object.

The UML represents an action in an activity diagram as an action state modeled by a rectangle with its left and right sides replaced by arcs curving outward. Each action state contains an action expression—for example, “get balance of account from database”—that specifies an action to be performed. An arrow with a stick arrowhead connects two action states, indicating the order in which the actions represented by the action states occur. The solid circle (at the top of Fig. 5.30) represents the activity’s initial state—the beginning of the workflow before the object performs the modeled actions. In this case, the transaction first executes the “get balance of account from database” action expression. The transaction then displays both balances on the screen. The solid circle enclosed in an open circle (at the bottom of Fig. 5.30) represents the final state—the end of the workflow after the object performs the modeled actions. We used UML activity diagrams to illustrate the flow of control for the control statements presented in Chapters 4–5.

Figure 5.31 shows an activity diagram for a withdrawal transaction. We assume that a `Withdrawal` object has been assigned a valid account number. We do not model the user selecting a withdrawal from the main menu or the ATM returning the user to the main menu because these are not actions performed by a `Withdrawal` object. The transaction first displays a menu of standard withdrawal amounts (shown in Fig. 2.19) and an option to cancel the transaction. The transaction then receives a menu selection from the user. The activity flow now arrives at a decision (a fork indicated by the small diamond symbol). [Note: A decision was known as a branch in earlier versions of the UML.] This point determines the next action based on the associated guard condition (in square brackets next to the transition), which states that the transition occurs if this guard condition is met. If the user cancels the transaction by choosing the “cancel” option from the menu, the activity flow immediately skips to the final state. Note the merge (indicated by the small diamond symbol) where the cancellation flow of activity joins the main flow of activity before reaching the activity’s final state. If the user selects a withdrawal amount from the menu, `Withdrawal` sets `amount` (an attribute originally modeled in Fig. 4.24) to the value chosen by the user.

After setting the withdrawal amount, the transaction retrieves the available balance of the user’s account (i.e., the `availableBalance` attribute of the user’s `Account` object) from the database. The activity flow then arrives at another decision. If the requested withdrawal amount exceeds the user’s available balance, the system displays an appropriate

**226** Chapter 5 Control Statements: Part 2**Fig. 5.31** | Activity diagram for a withdrawal transaction.

error message informing the user of the problem, then returns to the beginning of the activity diagram and prompts the user to input a new amount. If the requested withdrawal amount is less than or equal to the user's available balance, the transaction proceeds. The transaction next tests whether the cash dispenser has enough cash remaining to satisfy the

**5.12 Wrap-Up 227**

withdrawal request. If it does not, the transaction displays an appropriate error message, then returns to the beginning of the activity diagram and prompts the user to choose a new amount. If sufficient cash is available, the transaction interacts with the database to debit the withdrawal amount from the user's account (i.e., subtract the amount from both the `availableBalance` and `totalBalance` attributes of the user's `Account` object). The transaction then dispenses the desired amount of cash and instructs the user to take the cash that is dispensed. Finally, the main flow of activity merges with the cancellation flow of activity before reaching the final state.

We have taken the first steps in modeling the behavior of the ATM system and have shown how an object's attributes participate in performing the object's activities. In Section 6.14, we investigate the behaviors for all classes to give a more accurate interpretation of the system behavior by "filling in" the third compartments of the classes in our class diagram.

#### *Software Engineering Case Study Self-Review Exercises*

**5.1** State whether the following statement is *true* or *false*, and if *false*, explain why: State diagrams model structural aspects of a system.

**5.2** An activity diagram models the \_\_\_\_\_ that an object performs and the order in which it performs them.

- a) actions
- b) attributes
- c) states
- d) state transitions

**5.3** Based on the requirements document, create an activity diagram for a deposit transaction.

#### *Answers to Software Engineering Case Study Self-Review Exercises*

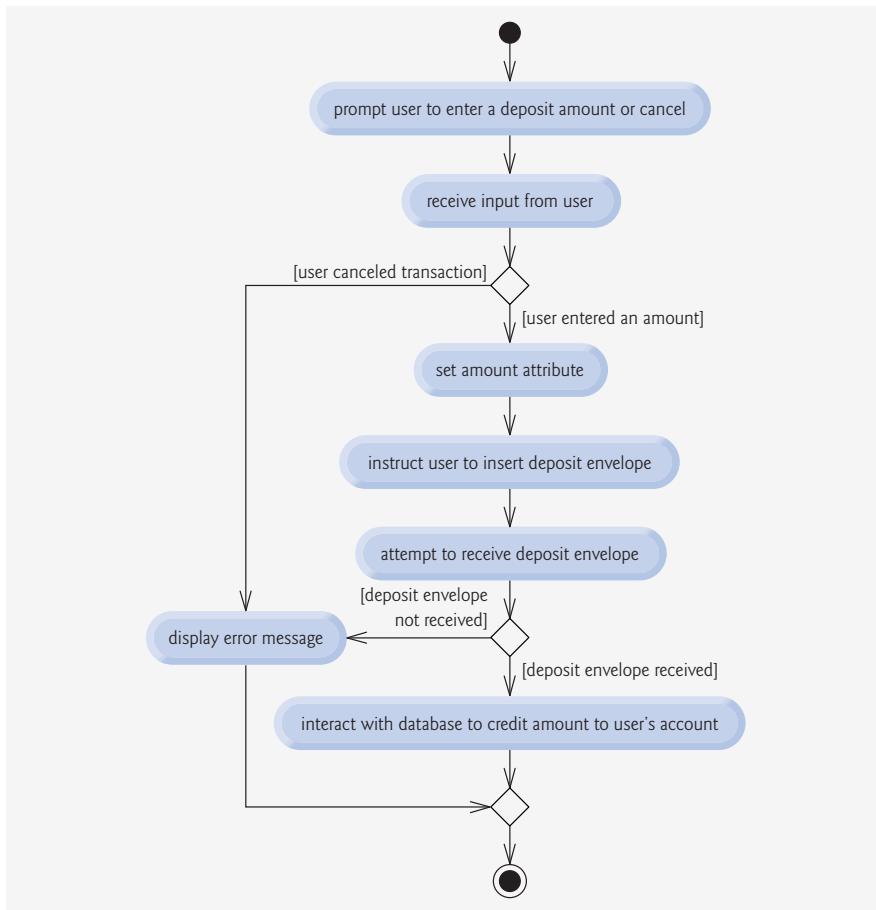

**5.1** False. State diagrams model some of the behavior of a system.

**5.2** a.

**5.3** Figure 5.32 presents an activity diagram for a deposit transaction. The diagram models the actions that occur after the user chooses the deposit option from the main menu and before the ATM returns the user to the main menu. Recall that part of receiving a deposit amount from the user involves converting an integer number of cents to a dollar amount. Also recall that crediting a deposit amount to an account involves increasing only the `totalBalance` attribute of the user's `Account` object. The bank updates the `availableBalance` attribute of the user's `Account` object only after confirming the amount of cash in the deposit envelope and after the enclosed checks clear—this occurs independently of the ATM system.

## 5.12 Wrap-Up

In this chapter, we completed our introduction to Java's control statements, which enable you to control the flow of execution in methods. Chapter 4 discussed Java's `if`, `if...else` and `while` statements. The current chapter demonstrated Java's remaining control statements—`for`, `do...while` and `switch`. We showed that any algorithm can be developed using combinations of the sequence structure (i.e., statements listed in the order in which they should execute), the three types of selection statements—`if`, `if...else` and `switch`—and the three types of repetition statements—`while`, `do...while` and `for`. In this chapter and Chapter 4, we discussed how you can combine these building blocks to utilize proven

**228** Chapter 5 Control Statements: Part 2**Fig. 5.32** | Activity diagram for a deposit transaction.

program-construction and problem-solving techniques. This chapter also introduced Java’s logical operators, which enable you to use more complex conditional expressions in control statements.

In Chapter 3, we introduced the basic concepts of objects, classes and methods. Chapter 4 and Chapter 5 introduced the types of control statements that you can use to specify program logic in methods. In Chapter 6, we examine methods in greater depth.

## Summary

### Section 5.2 Essentials of Counter-Controlled Repetition

- Counter-controlled repetition requires a control variable (or loop counter), the initial value of the control variable, the increment (or decrement) by which the control variable is modified each

[Summary](#)    **229**

time through the loop (also known as each iteration of the loop) and the loop-continuation condition that determines whether looping should continue.

- You can declare a variable and initialize it in the same statement.

### **Section 5.3 For Repetition Statement**

- The `while` statement can be used to implement any counter-controlled loop.
- The `for` repetition statement specifies the details of counter-controlled-repetition in a single line of code.
- When the `for` statement begins executing, its control variable is declared and initialized. Next, the program checks the loop-continuation condition. If the condition is initially true, the body executes. After executing the loop's body, the increment expression executes. Then the loop-continuation test is performed again to determine whether the program should continue with the next iteration of the loop.
- The general format of the `for` statement is

```
for (initialization; loopContinuationCondition; increment)
 statement
```

where the *initialization* expression names the loop's control variable and optionally provides its initial value, *loopContinuationCondition* is the condition that determines whether the loop should continue executing and *increment* modifies the control variable's value (possibly an increment or decrement), so that the loop-continuation condition eventually becomes false. The two semicolons in the `for` header are required.

- In most cases, the `for` statement can be represented with an equivalent `while` statement as follows:

```
initialization;
while (loopContinuationCondition)
{
 statement
 increment;
}
```

- Typically, `for` statements are used for counter-controlled repetition and `while` statements for sentinel-controlled repetition.
- If the *initialization* expression in the `for` header declares the control variable, the control variable can be used only in that `for` statement—it will not exist outside the `for` statement.
- All three expressions in a `for` header are optional. If the *loopContinuationCondition* is omitted, Java assumes that the loop-continuation condition is always true, thus creating an infinite loop. You might omit the *initialization* expression if the program initializes the control variable before the loop. You might omit the *increment* expression if the program calculates the increment with statements in the loop's body or if no increment is needed.
- The *increment* expression in a `for` acts as if it were a standalone statement at the end of the `for`'s body.
- The increment of a `for` statement may also be negative, in which case it is really a decrement, and the loop counts downward.
- If the loop-continuation condition is initially `false`, the program does not execute the `for` statement's body. Instead, execution proceeds with the statement following the `for`.

### **Section 5.4 Examples Using the For Statement**

- Java treats floating-point constants like `1000.0` and `0.05` as type `double`. Similarly, Java treats whole number constants like `7` and `-22` as type `int`.

**230**    [Chapter 5 Control Statements: Part 2](#)

- The format specifier `%20s` indicates that the `String` output should be displayed with a field width of 20—that is, `printf` displays the value with at least 20 character positions. If the value to be output is less than 20 character positions wide, the value is right justified in the field by default.
- `Math.pow(x, y)` calculates the value of  $x$  raised to the  $y^{\text{th}}$  power. The method receives two `double` arguments and returns a `double` value.
- The comma (,) formatting flag in a format specifier (e.g., `%,20.2f`) indicates that a floating-point value should be output with a grouping separator. The actual separator used is specific to the user's locale (i.e., country). For example, in the United States, the number will be output using commas to separate every three digits and a decimal point to separate the fractional part of the number, as in `1,234.45`.
- The `.2` specifies in a format specifier (e.g., `%,20.2f`) indicates a formatted number's precision—in this case, the number is rounded to the nearest hundredth and output with two digits to the right of the decimal point.

***Section 5.5 do...while Repetition Statement***

- The `do...while` repetition statement is similar to the `while` statement. In the `while`, the program tests the loop-continuation condition at the beginning of the loop, before executing the loop's body; if the condition is false, the body never executes. The `do...while` statement tests the loop-continuation condition *after* executing the loop's body; therefore, the body always executes at least once. When a `do...while` statement terminates, execution continues with the next statement in sequence.
- It is not necessary to use braces in the `do...while` repetition statement if there is only one statement in the body. However, most programmers include the braces, to avoid confusion between the `while` and `do...while` statements.

***Section 5.6 switch Multiple-Selection Statement***

- The `switch` multiple-selection statement performs different actions based on the possible values of an integer variable or expression. Each action is associated with the value of a constant integral expression (i.e., a constant value of type `byte`, `short`, `int` or `char`, but not `long`) that the variable or expression on which the `switch` is based may assume.
- The end-of-file indicator is a system-dependent keystroke combination which the user enters to indicate that there is no more data to input. On UNIX/Linux/Mac OS X systems, end-of-file is entered by typing the sequence `<ctrl>d` on a line by itself. This notation means to simultaneously press both the `ctrl` key and the `d` key. On Windows systems, end-of-file can be entered by typing `<ctrl>z`.
- `Scanner` method `hasNext` determines whether there is more data to input. This method returns the `boolean` value `true` if there is more data; otherwise, it returns `false`. As long as the end-of-file indicator has not been typed, method `hasNext` will return `true`.
- The `switch` statement consists of a block that contains a sequence of `case` labels and an optional `default` case.
- When the flow of control reaches the `switch`, the program evaluates the controlling expression of the `switch`. The program compares the value of the controlling expression (which must evaluate to an integral value of type `byte`, `char`, `short` or `int`) with each `case` label. If a match occurs, the program executes the statements for that `case`.
- Listing cases consecutively with no statements between them enables the cases to perform the same set of statements.
- The `switch` statement does not provide a mechanism for testing ranges of values, so every value that must be tested should be listed in a separate `case` label.

[Summary](#)    **23I**

- Each case can have multiple statements. The `switch` statement differs from other control statements in that it does not require braces around multiple statements in a `case`.
- Without `break` statements, each time a match occurs in the `switch`, the statements for that case and subsequent cases execute until a `break` statement or the end of the `switch` is encountered. This is often referred to as “falling through” to the statements in subsequent cases.
- If no match occurs between the controlling expression’s value and a `case` label, the optional `default` case executes. If no match occurs and the `switch` does not contain a `default` case, program control simply continues with the first statement after the `switch`.
- The `break` statement is not required for the `switch`’s last case (or the optional `default` case, when it appears last), because execution continues with the next statement after the `switch`.

**Section 5.7 break and continue Statements**

- In addition to selection and repetition statements, Java provides statements `break` and `continue` (presented in this section and Appendix K, Labeled `break` and `continue` Statements) to alter the flow of control. The preceding section showed how `break` can be used to terminate a `switch` statement’s execution. This section discusses how to use `break` in repetition statements.
- The `break` statement, when executed in a `while`, `for`, `do...while` or `switch`, causes immediate exit from that statement. Execution continues with the first statement after the control statement.
- The `continue` statement, when executed in a `while`, `for` or `do...while`, skips the remaining statements in the loop body and proceeds with the next iteration of the loop. In `while` and `do...while` statements, the program evaluates the loop-continuation test immediately after the `continue` statement executes. In a `for` statement, the increment expression executes, then the program evaluates the loop-continuation test.

**Section 5.8 Logical Operators**

- Simple conditions are expressed in terms of the relational operators `>`, `<`, `>=` and `<=` and the equality operators `==` and `!=`, and each expression tests only one condition.
- Logical operators to enable you to form more complex conditions by combining simple conditions. The logical operators are `&&` (conditional AND), `||` (conditional OR), `&` (boolean logical AND), `|` (boolean logical inclusive OR), `^` (boolean logical exclusive OR) and `!` (logical NOT).
- To ensure that two conditions are *both* true before choosing a certain path of execution, use the `&&` (conditional AND) operator. This operator yields true if and only if both of its simple conditions are true. If either or both of the simple conditions are false, the entire expression is false.
- To ensure that either *or* both of two conditions are true before choosing a certain path of execution, use the `||` (conditional OR) operator, which evaluates to true if either or both of its simple conditions are true.
- The parts of an expression containing `&&` or `||` operators are evaluated only until it is known whether the condition is true or false. This feature of conditional AND and conditional OR expressions is called short-circuit evaluation.
- The boolean logical AND (`&`) and boolean logical inclusive OR (`|`) operators work identically to the `&&` (conditional AND) and `||` (conditional OR) operators, with one exception: The boolean logical operators always evaluate both of their operands (i.e., they do not perform short-circuit evaluation).
- A simple condition containing the boolean logical exclusive OR (`^`) operator is *true if and only if one of its operands is true and the other is false*. If both operands are `true` or both are `false`, the entire condition is `false`. This operator is also guaranteed to evaluate both of its operands.

## 232 Chapter 5 Control Statements: Part 2

- The `!` (logical NOT, also called logical negation or logical complement) operator “reverses” the meaning of a condition. The logical negation operator is a unary operator that has only a single condition as an operand. The logical negation operator is placed before a condition to choose a path of execution if the original condition (without the logical negation operator) is `false`.
- In most cases, you can avoid using logical negation by expressing the condition differently with an appropriate relational or equality operator.

### *Section 5.10 (Optional) GUI and Graphics Case Study: Drawing Rectangles and Ovals*

- `Graphics` methods `drawRect` and `drawOval` draw rectangles and ovals, respectively.
- `Graphics` method `drawRect` requires four arguments. The first two represent the *x*- and *y*-coordinates of the upper-left corner of the rectangle; the next two represent the width and the height of the rectangle.
- When drawing an oval, an imaginary rectangle called a bounding rectangle is created, and an oval that touches the midpoints of all four sides of the bounding rectangle is placed inside. Method `drawOval` requires the same four arguments as method `drawRect`. The arguments specify the position and size of the bounding rectangle for the oval.

## Terminology

|                                                                   |                                                           |
|-------------------------------------------------------------------|-----------------------------------------------------------|
| !, logical not operator                                           | <code>final</code> keyword                                |
| %b format specifier                                               | <code>for</code> header                                   |
| &, boolean logical AND operator                                   | <code>for</code> repetition statement                     |
| &&, conditional AND operator                                      | <code>for</code> statement header                         |
| - (minus) format flag                                             | <code>hasNext</code> method of class <code>Scanner</code> |
| , (comma) format flag                                             | helper method                                             |
| , boolean logical OR operator                                     | increment a control variable                              |
| , conditional OR operator                                         | initial value                                             |
| ^, boolean logical exclusive OR operator                          | iteration of a loop                                       |
| boolean logical AND (&)                                           | left justify                                              |
| boolean logical exclusive OR (^)                                  | logical complement ( <code>!</code> )                     |
| boolean logical inclusive OR ( )                                  | logical negation ( <code>!</code> )                       |
| bounding rectangle of an oval (GUI)                               | logical operators                                         |
| <code>break</code> statement                                      | loop-continuation condition                               |
| <code>case</code> label                                           | multiple selection                                        |
| character constant                                                | nested control statements                                 |
| conditional AND (&&)                                              | nesting rule                                              |
| conditional OR (  )                                               | off-by-one error                                          |
| constant integral expression                                      | repetition statement                                      |
| constant variable                                                 | right justify                                             |
| <code>continue</code> statement                                   | scope of a variable                                       |
| control variable                                                  | short-circuit evaluation                                  |
| controlling expression of a <code>switch</code>                   | side effect                                               |
| decrement a control variable                                      | simple condition                                          |
| <code>default</code> case in <code>switch</code>                  | single-entry/single-exit control statements               |
| <code>do...while</code> repetition statement                      | stacked control statements                                |
| <code>drawOval</code> method of class <code>Graphics</code> (GUI) | stacking rule                                             |
| <code>drawRect</code> method of class <code>Graphics</code> (GUI) | <code>static</code> method                                |
| end-of-file indicator                                             | <code>switch</code> selection statement                   |
| field width                                                       | truth table                                               |

Self-Review Exercises **233****Self-Review Exercises**

- 5.1** Fill in the blanks in each of the following statements:
- Typically, \_\_\_\_\_ statements are used for counter-controlled repetition and \_\_\_\_\_ statements are used for sentinel-controlled repetition.
  - The `do...while` statement tests the loop-continuation condition \_\_\_\_\_ executing the loop's body; therefore, the body always executes at least once.
  - The \_\_\_\_\_ statement selects among multiple actions based on the possible values of an integer variable or expression.
  - The \_\_\_\_\_ statement, when executed in a repetition statement, skips the remaining statements in the loop body and proceeds with the next iteration of the loop.
  - The \_\_\_\_\_ operator can be used to ensure that two conditions are *both* true before choosing a certain path of execution.
  - If the loop-continuation condition in a `for` header is initially \_\_\_\_\_, the program does not execute the `for` statement's body.
  - Methods that perform common tasks and do not require objects are called \_\_\_\_\_ methods.
- 5.2** State whether each of the following is *true* or *false*. If *false*, explain why.
- The default case is required in the `switch` selection statement.
  - The `break` statement is required in the last case of a `switch` selection statement.
  - The expression `((x > y) && (a < b))` is true if either `x > y` is true or `a < b` is true.
  - An expression containing the `||` operator is true if either or both of its operands are true.
  - The comma (,) formatting flag in a format specifier (e.g., `%,20.2f`) indicates that a value should be output with a thousands separator.
  - To test for a range of values in a `switch` statement, use a hyphen (-) between the start and end values of the range in a case label.
  - Listing cases consecutively with no statements between them enables the cases to perform the same set of statements.
- 5.3** Write a Java statement or a set of Java statements to accomplish each of the following tasks:
- Sum the odd integers between 1 and 99, using a `for` statement. Assume that the integer variables `sum` and `count` have been declared.
  - Calculate the value of  $2.5$  raised to the power of 3, using the `pow` method.
  - Print the integers from 1 to 20, using a `while` loop and the counter variable `i`. Assume that the variable `i` has been declared, but not initialized. Print only five integers per line.  
[Hint: Use the calculation `i % 5`. When the value of this expression is 0, print a newline character; otherwise, print a tab character. Assume that this code is an application. Use the `System.out.println()` method to output the newline character, and use the `System.out.print('t')` method to output the tab character.]
  - Repeat part (c), using a `for` statement.
- 5.4** Find the error in each of the following code segments, and explain how to correct it:

```
a) i = 1;

while (i <= 10);
 i++;
}

b) for (k = 0.1; k != 1.0; k += 0.1)
 System.out.println(k);
```

**234 Chapter 5 Control Statements: Part 2**

- c) `switch ( n )`  
   {  
     case 1:  
       System.out.println( "The number is 1" );  
     case 2:  
       System.out.println( "The number is 2" );  
       break;  
     default:  
       System.out.println( "The number is not 1 or 2" );  
       break;  
   }
- d) The following code should print the values 1 to 10:  
`n = 1;`  
`while ( n < 10 )`  
`System.out.println( n++ );`

**Answers to Self-Review Exercises**

**5.1** a) for, while. b) after. c) switch. d) continue. e) `&&` (conditional AND). f) false. g) static.

**5.2** a) False. The default case is optional. If no default action is needed, then there is no need for a default case. b) False. The break statement is used to exit the switch statement. The break statement is not required for the last case in a switch statement. c) False. Both of the relational expressions must be true for the entire expression to be true when using the `&&` operator. d) True. e) True. f) False. The switch statement does not provide a mechanism for testing ranges of values, so every value that must be tested should be listed in a separate case label. g) True.

- 5.3** a) `sum = 0;`  
`for ( count = 1; count <= 99; count += 2 )`  
`sum += count;`
- b) `double result = Math.pow( 2.5, 3 );`
- c) `i = 1;`  
  
`while ( i <= 20 )`  
`{`  
`System.out.print( i );`  
  
`if ( i % 5 == 0 )`  
`System.out.println();`  
`else`  
`System.out.print( '\t' );`  
  
`++i;`  
`}`
- d) `for ( i = 1; i <= 20; i++ )`  
`{`  
`System.out.print( i );`  
  
`if ( i % 5 == 0 )`  
`System.out.println();`  
`else`  
`System.out.print( '\t' );`  
`}`

Exercises **235**

- 5.4** a) Error: The semicolon after the `while` header causes an infinite loop, and there is a missing left brace.  
 Correction: Replace the semicolon by a {, or remove both the ; and the }.
- b) Error: Using a floating-point number to control a `for` statement may not work, because floating-point numbers are represented only approximately by most computers.  
 Correction: Use an integer, and perform the proper calculation in order to get the values you desire:
- ```
for ( k = 1; k != 10; k++ )
    System.out.println( (double) k / 10 );
```
- c) Error: The missing code is the `break` statement in the statements for the first `case`.
 Correction: Add a `break` statement at the end of the statements for the first `case`. Note that this omission is not necessarily an error if you want the statement of `case 2`: to execute every time the `case 1`: statement executes.
- d) Error: An improper relational operator is used in the `while` repetition-continuation condition.
 Correction: Use <= rather than <, or change 10 to 11.

Exercises

- 5.5** Describe the four basic elements of counter-controlled repetition.
- 5.6** Compare and contrast the `while` and `for` repetition statements.
- 5.7** Discuss a situation in which it would be more appropriate to use a `do...while` statement than a `while` statement. Explain why.
- 5.8** Compare and contrast the `break` and `continue` statements.
- 5.9** Find and correct the error(s) in each of the following segments of code:
- `for (i = 100, i >= 1; i++)
 System.out.println(i);`
 - The following code should print whether integer value is odd or even:

```
switch ( value % 2 )
{
    case 0:
        System.out.println( "Even integer" );
    case 1:
        System.out.println( "Odd integer" );
}
```
 - The following code should output the odd integers from 19 to 1:

```
for ( i = 19; i >= 1; i += 2 )
    System.out.println( i );
```
 - The following code should output the even integers from 2 to 100:

```
counter = 2;
do
{
    System.out.println( counter );
    counter += 2;
} while ( counter < 100 );
```

236 Chapter 5 Control Statements: Part 2

5.10 What does the following program do?

```

1  public class Printing
2  {
3      public static void main( String args[] )
4      {
5          for ( int i = 1; i <= 10; i++ )
6          {
7              for ( int j = 1; j <= 5; j++ )
8                  System.out.print( '@' );
9
10             System.out.println();
11     } // end outer for
12 } // end main
13 } // end class Printing

```

5.11 Write an application that finds the smallest of several integers. Assume that the first value read specifies the number of values to input from the user.

5.12 Write an application that calculates the product of the odd integers from 1 to 15.

5.13 *Factorials* are used frequently in probability problems. The factorial of a positive integer n (written $n!$ and pronounced “ n factorial”) is equal to the product of the positive integers from 1 to n . Write an application that evaluates the factorials of the integers from 1 to 5. Display the results in tabular format. What difficulty might prevent you from calculating the factorial of 20?

5.14 Modify the compound-interest application of Fig. 5.6 to repeat its steps for interest rates of 5%, 6%, 7%, 8%, 9% and 10%. Use a *for* loop to vary the interest rate.

5.15 Write an application that displays the following patterns separately, one below the other. Use *for* loops to generate the patterns. All asterisks (*) should be printed by a single statement of the form `System.out.print('*')`; which causes the asterisks to print side by side. A statement of the form `System.out.println()`; can be used to move to the next line. A statement of the form `System.out.print(' ')`; can be used to display a space for the last two patterns. There should be no other output statements in the program. [Hint: The last two patterns require that each line begin with an appropriate number of blank spaces.]

(a)	(b)	(c)	(d)
*	*****	*****	*
**	*****	*****	**
***	*****	*****	***
****	*****	*****	****
*****	*****	*****	*****
*****	***	***	*****
*****	**	**	*****
*****	*	*	*****

5.16 One interesting application of computers is to display graphs and bar charts. Write an application that reads five numbers between 1 and 30. For each number that is read, your program should display the same number of adjacent asterisks. For example, if your program reads the number 7, it should display *****.

5.17 A mail-order house sells five products whose retail prices are as follows: Product 1, \$2.98; product 2, \$4.50; product 3, \$9.98; product 4, \$4.49 and product 5, \$6.87. Write an application that reads a series of pairs of numbers as follows:

[Exercises](#) **237**

- a) product number
- b) quantity sold

Your program should use a `switch` statement to determine the retail price for each product. It should calculate and display the total retail value of all products sold. Use a sentinel-controlled loop to determine when the program should stop looping and display the final results.

5.18 Modify the application in Fig. 5.6 to use only integers to calculate the compound interest. [Hint: Treat all monetary amounts as integral numbers of pennies. Then break the result into its dollars and cents portions by using the division and remainder operations, respectively. Insert a period between the dollars and the cents portions.]

5.19 Assume that $i = 1$, $j = 2$, $k = 3$ and $m = 2$. What does each of the following statements print?

- a) `System.out.println(i == 1);`
- b) `System.out.println(j == 3);`
- c) `System.out.println((i >= 1) && (j < 4));`
- d) `System.out.println((m <= 99) & (k < m));`
- e) `System.out.println((j >= i) || (k == m));`
- f) `System.out.println((k + m < j) | (3 - j >= k));`
- g) `System.out.println(!(k > m));`

5.20 Calculate the value of π from the infinite series

$$\pi = 4 - \frac{4}{3} + \frac{4}{5} - \frac{4}{7} + \frac{4}{9} - \frac{4}{11} + \dots$$

Print a table that shows the value of π approximated by computing one term of this series, by two terms, by three terms, and so on. How many terms of this series do you have to use before you first get 3.14? 3.141? 3.1415? 3.14159?

5.21 (*Pythagorean Triples*) A right triangle can have sides whose lengths are all integers. The set of three integer values for the lengths of the sides of a right triangle is called a Pythagorean triple. The lengths of the three sides must satisfy the relationship that the sum of the squares of two of the sides is equal to the square of the hypotenuse. Write an application to find all Pythagorean triples for `side1`, `side2` and the `hypotenuse`, all no larger than 500. Use a triple-nested `for` loop that tries all possibilities. This method is an example of “brute-force” computing. You will learn in more advanced computer science courses that for many interesting problems there is no known algorithmic approach other than using sheer brute force.

5.22 Modify Exercise 5.15 to combine your code from the four separate triangles of asterisks such that all four patterns print side by side. [Hint: Make clever use of nested `for` loops.]

5.23 (*De Morgan’s Laws*) In this chapter, we have discussed the logical operators `&&`, `&`, `||`, `|`, `^` and `!`. De Morgan’s Laws can sometimes make it more convenient for us to express a logical expression. These laws state that the expression `!(condition1 && condition2)` is logically equivalent to the expression `(!condition1 || !condition2)`. Also, the expression `!(condition1 || condition2)` is logically equivalent to the expression `(!condition1 && !condition2)`. Use De Morgan’s Laws to write equivalent expressions for each of the following, then write an application to show that both the original expression and the new expression in each case produce the same value:

- a) `!(x < 5) && !(y >= 7)`
- b) `!(a == b) || !(g != 5)`
- c) `!((x <= 8) && (y > 4))`
- d) `!((i > 4) || (j <= 6))`

5.24 Write an application that prints the following diamond shape. You may use output statements that print a single asterisk (*), a single space or a single newline character. Maximize your use of repetition (with nested `for` statements), and minimize the number of output statements.

238 Chapter 5 Control Statements: Part 2

```

*
 ***
 ****
 *****
 ******
 *****
 ****
 ***
 *

```

5.25 Modify the application you wrote in Exercise 5.24 to read an odd number in the range 1 to 19 to specify the number of rows in the diamond. Your program should then display a diamond of the appropriate size.

5.26 A criticism of the `break` statement and the `continue` statement is that each is unstructured. Actually, these statements can always be replaced by structured statements, although doing so can be awkward. Describe in general how you would remove any `break` statement from a loop in a program and replace it with some structured equivalent. [Hint: The `break` statement exits a loop from the body of the loop. The other way to exit is by failing the loop-continuation test. Consider using in the loop-continuation test a second test that indicates “early exit because of a ‘break’ condition.”] Use the technique you develop here to remove the `break` statement from the application in Fig. 5.12.

5.27 What does the following program segment do?

```

for ( i = 1; i <= 5; i++ )
{
    for ( j = 1; j <= 3; j++ )
    {
        for ( k = 1; k <= 4; k++ )
            System.out.print( '*' );

        System.out.println();
    } // end inner for

    System.out.println();
} // end outer for

```

5.28 Describe in general how you would remove any `continue` statement from a loop in a program and replace it with some structured equivalent. Use the technique you develop here to remove the `continue` statement from the program in Fig. 5.13.

5.29 (*“The Twelve Days of Christmas” Song*) Write an application that uses repetition and `switch` statements to print the song “The Twelve Days of Christmas.” One `switch` statement should be used to print the day (“first,” “second,” and so on). A separate `switch` statement should be used to print the remainder of each verse. Visit the website en.wikipedia.org/wiki/Twelvetide for the complete lyrics of the song.

The greatest invention of the nineteenth century was the invention of the method of invention.

—Alfred North Whitehead

Call me Ishmael.

—Herman Melville

When you call me that, smile!

—Owen Wister

Answer me in one word.

—William Shakespeare

O! call back yesterday, bid time return.

—William Shakespeare

There is a point at which methods devour themselves.

—Frantz Fanon

6

Methods: A Deeper Look

OBJECTIVES

In this chapter you will learn:

- How `static` methods and fields are associated with an entire class rather than specific instances of the class.
- To use common `Math` methods available in the Java API.
- To understand the mechanisms for passing information between methods.
- How the method call/return mechanism is supported by the method-call stack and activation records.
- How packages group related classes.
- How to use random-number generation to implement game-playing applications.
- How the visibility of declarations is limited to specific regions of programs.
- What method overloading is and how to create overloaded methods.

240 Chapter 6 Methods: A Deeper Look**Outline**

- 6.1** Introduction
- 6.2** Program Modules in Java
- 6.3** `static` Methods, `static` Fields and Class Math
- 6.4** Declaring Methods with Multiple Parameters
- 6.5** Notes on Declaring and Using Methods
- 6.6** Method-Call Stack and Activation Records
- 6.7** Argument Promotion and Casting
- 6.8** Java API Packages
- 6.9** Case Study: Random-Number Generation
 - 6.9.1** Generalized Scaling and Shifting of Random Numbers
 - 6.9.2** Random-Number Repeatability for Testing and Debugging
- 6.10** Case Study: A Game of Chance (Introducing Enumerations)
- 6.11** Scope of Declarations
- 6.12** Method Overloading
- 6.13** (Optional) GUI and Graphics Case Study: Colors and Filled Shapes
- 6.14** (Optional) Software Engineering Case Study: Identifying Class Operations
- 6.15** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

6.1 Introduction

Most computer programs that solve real-world problems are much larger than the programs presented in the first few chapters of this book. Experience has shown that the best way to develop and maintain a large program is to construct it from small, simple pieces, or **modules**. This technique is called **divide and conquer**. We introduced methods in Chapter 3. In Chapter 6, we study methods in more depth. We emphasize how to declare and use methods to facilitate the design, implementation, operation and maintenance of large programs.

You'll see that it is possible for certain methods, called **static** methods, to be called without the need for an object of the class to exist. You'll learn how to declare a method with more than one parameter. You'll also learn how Java is able to keep track of which method is currently executing, how local variables of methods are maintained in memory and how a method knows where to return after it completes execution.

We will take a brief diversion into simulation techniques with random-number generation and develop a version of the casino dice game called craps that uses most of the programming techniques you've used to this point in the book. In addition, you'll learn how to declare values that cannot change (i.e., constants) in your programs.

Many of the classes you'll use or create while developing applications will have more than one method of the same name. This technique, called **overloading**, is used to implement methods that perform similar tasks for arguments of different types or for different numbers of arguments.

We continue our discussion of methods in Chapter 15, Recursion. Recursion provides an entirely different way of thinking about methods and algorithms.

6.2 Program Modules in Java

Three kinds of modules exist in Java—methods, classes and packages. Java programs are written by combining new methods and classes that you write with predefined methods and classes available in the [Java Application Programming Interface](#) (also referred to as the [Java API](#) or [Java class library](#)) and in various other class libraries. Related classes are typically grouped into packages so that they can be imported into programs and reused. You'll learn how to group your own classes into packages in Chapter 8. The Java API provides a rich collection of predefined classes that contain methods for performing common mathematical calculations, string manipulations, character manipulations, input/output operations, database operations, networking operations, file processing, error checking and many other useful operations.

Good Programming Practice 6.1

Familiarize yourself with the rich collection of classes and methods provided by the Java API (java.sun.com/javase/6/docs/api/). In Section 6.8, we present an overview of several common packages. In Appendix G, we explain how to navigate the Java API documentation.

Software Engineering Observation 6.1

Don't try to reinvent the wheel. When possible, reuse Java API classes and methods. This reduces program development time and avoids introducing programming errors.

Methods (called [functions](#) or [procedures](#) in other languages) allow you to modularize a program by separating its tasks into self-contained units. You've declared methods in every program you have written—these methods are sometimes referred to as [programmer-declared methods](#). The statements in the method bodies are written only once, are reused from perhaps several locations in a program and are hidden from other methods.

One motivation for modularizing a program is the divide-and-conquer approach, which makes program development more manageable by constructing programs from small, simple pieces. Another is [software reusability](#)—using existing methods as building blocks to create new programs. Often, you can create programs mostly from standardized methods rather than by building customized code. For example, in earlier programs, we did not have to define how to read data values from the keyboard—Java provides these capabilities in class `Scanner`. A third motivation is to avoid repeating code. Dividing a program into meaningful methods makes the program easier to debug and maintain.

Software Engineering Observation 6.2

To promote software reusability, every method should be limited to performing a single, well-defined task, and the name of the method should express that task effectively. Such methods make programs easier to write, debug, maintain and modify.

Error-Prevention Tip 6.1

A small method that performs one task is easier to test and debug than a larger method that performs many tasks.

Software Engineering Observation 6.3

If you cannot choose a concise name that expresses a method's task, your method might be attempting to perform too many diverse tasks. It is usually best to break such a method into several smaller method declarations.

242 Chapter 6 Methods: A Deeper Look

As you know, a method is invoked by a method call, and when the called method completes its task, it returns either a result or simply control to the caller. An analogy to this program structure is the hierarchical form of management (Figure 6.1). A boss (the caller) asks a worker (the called method) to perform a task and report back (return) the results after completing the task. The boss method does not know how the worker method performs its designated tasks. The worker may also call other worker methods, unbeknown to the boss. This “hiding” of implementation details promotes good software engineering. Figure 6.1 shows the boss method communicating with several worker methods in a hierarchical manner. The boss method divides its responsibilities among the various worker methods. Note that worker1 acts as a “boss method” to worker4 and worker5.

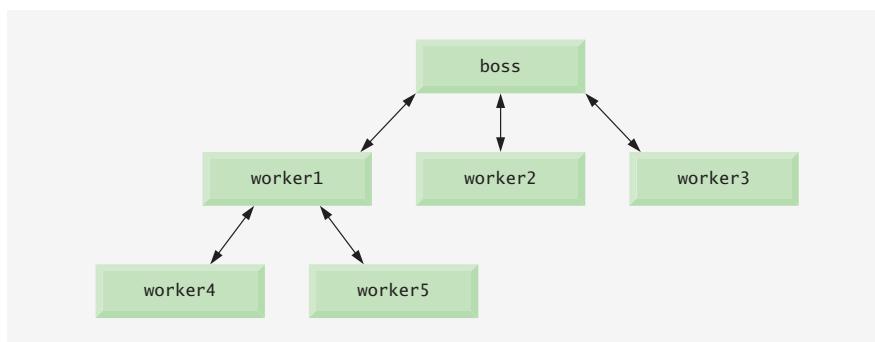

Fig. 6.1 | Hierarchical boss-method/worker-method relationship.

6.3 static Methods, static Fields and Class Math

As you know, every class provides methods that perform common tasks on objects of the class. For example, to input data from the keyboard, you have called methods on a `Scanner` object that was initialized in its constructor to obtain input from the standard input stream (`System.in`). As you'll learn in Chapter 14, Files and Streams, you can initialize a `Scanner` to obtain input from other sources, such as a file on disk. One program could have a `Scanner` object that inputs information from the standard input stream and a second `Scanner` that inputs information from a file. Each input method called on the standard input stream `Scanner` would obtain input from the keyboard, and each input method called on the file `Scanner` would obtain input from the specified file on disk.

Although most methods execute in response to method calls on specific objects, this is not always the case. Sometimes a method performs a task that does not depend on the contents of any object. Such a method applies to the class in which it is declared as a whole and is known as a **static** method or a **class method**. It is common for classes to contain convenient **static** methods to perform common tasks. For example, recall that we used **static** method `pow` of class `Math` to raise a value to a power in Fig. 5.6. To declare a method as **static**, place the keyword **static** before the return type in the method's declaration. You can call any **static** method by specifying the name of the class in which the method is declared, followed by a dot (.) and the method name, as in

`ClassName.methodName(arguments)`

6.3 static Methods, static Fields and Class Math 243

We use various `Math` class methods here to present the concept of `static` methods. Class `Math` provides a collection of methods that enable you to perform common mathematical calculations. For example, you can calculate the square root of `900.0` with the `static` method call

```
Math.sqrt( 900.0 )
```

The preceding expression evaluates to `30.0`. Method `sqrt` takes an argument of type `double` and returns a result of type `double`. To output the value of the preceding method call in the command window, you might write the statement

```
System.out.println( Math.sqrt( 900.0 ) );
```

In this statement, the value that `sqrt` returns becomes the argument to method `println`. Note that there was no need to create a `Math` object before calling method `sqrt`. Also note that *all* `Math` class methods are `static`—therefore, each is called by preceding the name of the method with the class name `Math` and the dot (.) separator.

Software Engineering Observation 6.4

Class `Math` is part of the `java.lang` package, which is implicitly imported by the compiler, so it is not necessary to import class `Math` to use its methods.

Method arguments may be constants, variables or expressions. If `c = 13.0`, `d = 3.0` and `f = 4.0`, then the statement

```
System.out.println( Math.sqrt( c + d * f ) );
```

calculates and prints the square root of $13.0 + 3.0 * 4.0 = 25.0$ —namely, `5.0`. Figure 6.2 summarizes several `Math` class methods. In the figure, `x` and `y` are of type `double`.

Method	Description	Example
<code>abs(x)</code>	absolute value of x	<code>abs(23.7)</code> is <code>23.7</code> <code>abs(0.0)</code> is <code>0.0</code> <code>abs(-23.7)</code> is <code>23.7</code>
<code>ceil(x)</code>	rounds x to the smallest integer not less than x	<code>ceil(9.2)</code> is <code>10.0</code> <code>ceil(-9.8)</code> is <code>-9.0</code>
<code>cos(x)</code>	trigonometric cosine of x (x in radians)	<code>cos(0.0)</code> is <code>1.0</code>
<code>exp(x)</code>	exponential method e^x	<code>exp(1.0)</code> is <code>2.71828</code> <code>exp(2.0)</code> is <code>7.38906</code>
<code>floor(x)</code>	rounds x to the largest integer not greater than x	<code>floor(9.2)</code> is <code>9.0</code> <code>floor(-9.8)</code> is <code>-10.0</code>
<code>log(x)</code>	natural logarithm of x (base e)	<code>log(Math.E)</code> is <code>1.0</code> <code>log(Math.E * Math.E)</code> is <code>2.0</code>

Fig. 6.2 | Math class methods. (Part 1 of 2.)

244 Chapter 6 Methods: A Deeper Look

Method	Description	Example
<code>max(x, y)</code>	larger value of x and y	<code>max(2.3, 12.7)</code> is 12.7 <code>max(-2.3, -12.7)</code> is -2.3
<code>min(x, y)</code>	smaller value of x and y	<code>min(2.3, 12.7)</code> is 2.3 <code>min(-2.3, -12.7)</code> is -12.7
<code>pow(x, y)</code>	x raised to the power y (i.e., x^y)	<code>pow(2.0, 7.0)</code> is 128.0 <code>pow(9.0, 0.5)</code> is 3.0
<code>sin(x)</code>	trigonometric sine of x (x in radians)	<code>sin(0.0)</code> is 0.0
<code>sqrt(x)</code>	square root of x	<code>sqrt(900.0)</code> is 30.0
<code>tan(x)</code>	trigonometric tangent of x (x in radians)	<code>tan(0.0)</code> is 0.0

Fig. 6.2 | Math class methods. (Part 2 of 2.)**Math Class Constants PI and E**

Class `Math` also declares two fields that represent commonly used mathematical constants: `Math.PI` and `Math.E`. The constant `Math.PI` (3.14159265358979323846) is the ratio of a circle's circumference to its diameter. The constant `Math.E` (2.7182818284590452354) is the base value for natural logarithms (calculated with static `Math` method `log`). These fields are declared in class `Math` with the modifiers `public`, `final` and `static`. Making them `public` allows other programmers to use these fields in their own classes. Any field declared with keyword `final` is constant—its value cannot be changed after the field is initialized. Both `PI` and `E` are declared `final` because their values never change. Making these fields `static` allows them to be accessed via the class name `Math` and a dot (.) separator, just like class `Math`'s methods. Recall from Section 3.5 that when each object of a class maintains its own copy of an attribute, the field that represents the attribute is also known as an instance variable—each object (instance) of the class has a separate instance of the variable in memory. There are fields for which each object of a class does not have a separate instance of the field. That is the case with `static` fields, which are also known as `class variables`. When objects of a class containing `static` fields are created, all the objects of that class share one copy of the class's `static` fields. Together the class variables (i.e., `static` variables) and instance variables represent the fields of a class. You'll learn more about `static` fields in Section 8.11.

Why Is Method `main` Declared `static`?

Why must `main` be declared `static`? When you execute the Java Virtual Machine (JVM) with the `java` command, the JVM attempts to invoke the `main` method of the class you specify—when no objects of the class have been created. Declaring `main` as `static` allows the JVM to invoke `main` without creating an instance of the class. Method `main` is declared with the header:

```
public static void main( String args[] )
```

When you execute your application, you specify its class name as an argument to the command `java`, as in

6.4 Declaring Methods with Multiple Parameters 245

```
java ClassName argument1 argument2 ...
```

The JVM loads the class specified by *ClassName* and uses that class name to invoke method `main`. In the preceding command, *ClassName* is a **command-line argument** to the JVM that tells it which class to execute. Following the *ClassName*, you can also specify a list of `Strings` (separated by spaces) as command-line arguments that the JVM will pass to your application. Such arguments might be used to specify options (e.g., a file name) to run the application. As you'll learn in Chapter 7, Arrays, your application can access those command-line arguments and use them to customize the application.

Additional Comments about Method main

In earlier chapters, every application had one class that contained only `main` and possibly a second class that was used by `main` to create and manipulate objects. Actually, any class can contain a `main` method. In fact, each of our two-class examples could have been implemented as one class. For example, in the application in Fig. 5.9 and Fig. 5.10, method `main` (lines 6–16 of Fig. 5.10) could have been taken as is and placed in class `GradeBook` (Fig. 5.9). You would then execute the application by typing the command `java GradeBook` in the command window—the application results would be identical to those of the two-class version. You can place a `main` method in every class you declare. The JVM invokes the `main` method only in the class used to execute the application. Some programmers take advantage of this to build a small test program into each class they declare.

6.4 Declaring Methods with Multiple Parameters

Chapters 3–5 presented classes containing simple methods that had at most one parameter. Methods often require more than one piece of information to perform their tasks. We now show how to write methods with multiple parameters.

The application in Fig. 6.3 and Fig. 6.4 uses a programmer-declared method called `maximum` to determine and return the largest of three `double` values that are input by the user. When the application begins execution, class `MaximumFinderTest`'s `main` method (lines 7–11 of Fig. 6.4) creates one object of class `MaximumFinder` (line 9) and calls the object's `determineMaximum` method (line 10) to produce the program's output. In class `MaximumFinder` (Fig. 6.3), lines 14–18 of method `determineMaximum` prompt the user to enter three `double` values, then read them from the user. Line 21 calls method `maximum` (declared in lines 28–41) to determine the largest of the three `double` values passed as arguments to the method. When method `maximum` returns the result to line 21, the program assigns `maximum`'s return value to local variable `result`. Then line 24 outputs the maximum value. At the end of this section, we'll discuss the use of operator `+` in line 24.

```
1 // Fig. 6.3: MaximumFinder.java
2 // Programmer-declared method maximum.
3 import java.util.Scanner;
4
5 public class MaximumFinder
6 {
```

Fig. 6.3 | Programmer-declared method `maximum` that has three `double` parameters. (Part I of 2.)

246 Chapter 6 Methods: A Deeper Look

```

7  // obtain three floating-point values and locate the maximum value
8  public void determineMaximum()
9  {
10     // create Scanner for input from command window
11     Scanner input = new Scanner( System.in );
12
13     // obtain user input
14     System.out.print(
15         "Enter three floating-point values separated by spaces: " );
16     double number1 = input.nextDouble(); // read first double
17     double number2 = input.nextDouble(); // read second double
18     double number3 = input.nextDouble(); // read third double
19
20     // determine the maximum value
21     double result = maximum( number1, number2, number3 );
22
23     // display maximum value
24     System.out.println( "Maximum is: " + result );
25 } // end method determineMaximum
26
27 // returns the maximum of its three double parameters
28 public double maximum( double x, double y, double z )
29 {
30     double maximumValue = x; // assume x is the largest to start
31
32     // determine whether y is greater than maximumValue
33     if ( y > maximumValue )
34         maximumValue = y;
35
36     // determine whether z is greater than maximumValue
37     if ( z > maximumValue )
38         maximumValue = z;
39
40     return maximumValue;
41 } // end method maximum
42 } // end class MaximumFinder

```

Fig. 6.3 | Programmer-declared method `maximum` that has three `double` parameters. (Part 2 of 2.)

```

1 // Fig. 6.4: MaximumFinderTest.java
2 // Application to test class MaximumFinder.
3
4 public class MaximumFinderTest
5 {
6     // application starting point
7     public static void main( String args[] )
8     {
9         MaximumFinder maximumFinder = new MaximumFinder();
10        maximumFinder.determineMaximum();
11    } // end main
12 } // end class MaximumFinderTest

```

Fig. 6.4 | Application to test class `MaximumFinder`. (Part 1 of 2.)

6.4 Declaring Methods with Multiple Parameters **247**

```
Enter three floating-point values separated by spaces: 9.35 2.74 5.1
Maximum is: 9.35
```

```
Enter three floating-point values separated by spaces: 5.8 12.45 8.32
Maximum is: 12.45
```

```
Enter three floating-point values separated by spaces: 6.46 4.12 10.54
Maximum is: 10.54
```

Fig. 6.4 | Application to test class `MaximumFinder`. (Part 2 of 2.)

Consider the declaration of method `maximum` (lines 28–41). Line 28 indicates that the method returns a `double` value, that the method's name is `maximum` and that the method requires three `double` parameters (`x`, `y` and `z`) to accomplish its task. When a method has more than one parameter, the parameters are specified as a comma-separated list. When `maximum` is called from line 21, the parameter `x` is initialized with the value of the argument `number1`, the parameter `y` is initialized with the value of the argument `number2` and the parameter `z` is initialized with the value of the argument `number3`. There must be one argument in the method call for each parameter (sometimes called a *formal parameter*) in the method declaration. Also, each argument must be consistent with the type of the corresponding parameter. For example, a parameter of type `double` can receive values like 7.35, 22 or -0.03456, but not `Strings` like "hello" nor the `boolean` values `true` or `false`. Section 6.7 discusses the argument types that can be provided in a method call for each parameter of a primitive type.

To determine the maximum value, we begin with the assumption that parameter `x` contains the largest value, so line 30 declares local variable `maximumValue` and initializes it with the value of parameter `x`. Of course, it is possible that parameter `y` or `z` contains the actual largest value, so we must compare each of these values with `maximumValue`. The `if` statement at lines 33–34 determines whether `y` is greater than `maximumValue`. If so, line 34 assigns `y` to `maximumValue`. The `if` statement at lines 37–38 determines whether `z` is greater than `maximumValue`. If so, line 38 assigns `z` to `maximumValue`. At this point the largest of the three values resides in `maximumValue`, so line 40 returns that value to line 21. When program control returns to the point in the program where `maximum` was called, `maximum`'s parameters `x`, `y` and `z` no longer exist in memory. Note that methods can return at most one value, but the returned value could be a reference to an object that contains many values.

Note that `result` is a local variable in `determineMaximum` because it is declared in the block that represents the method's body. Variables should be declared as fields of a class only if they are required for use in more than one method of the class or if the program should save their values between calls to the class's methods.

Common Programming Error 6.1

Declaring method parameters of the same type as `float x, y` instead of `float x, float y` is a syntax error—a type is required for each parameter in the parameter list.

248 Chapter 6 Methods: A Deeper Look**Software Engineering Observation 6.5**

A method that has many parameters may be performing too many tasks. Consider dividing the method into smaller methods that perform the separate tasks. As a guideline, try to fit the method header on one line if possible.

Implementing Method `maximum` by Reusing Method `Math.max`

Recall from Fig. 6.2 that class Math has a max method that can determine the larger of two values. The entire body of our maximum method could also be implemented with two calls to Math.max, as follows:

```
return Math.max( x, Math.max( y, z ) );
```

The first call to Math.max specifies arguments x and Math.max(y, z). Before any method can be called, its arguments must be evaluated to determine their values. If an argument is a method call, the method call must be performed to determine its return value. So, in the preceding statement, Math.max(y, z) is evaluated first to determine the maximum of y and z. Then the result is passed as the second argument to the other call to Math.max, which returns the larger of its two arguments. This is a good example of software reuse—we find the largest of three values by reusing Math.max, which finds the largest of two values. Note how concise this code is compared to lines 30–40 of Fig. 6.3.

Assembling Strings with String Concatenation

Java allows String objects to be created by assembling smaller strings into larger strings using operator + (or the compound assignment operator +=). This is known as **string concatenation**. When both operands of operator + are String objects, operator + creates a new String object in which the characters of the right operand are placed at the end of those in the left operand. For example, the expression "hello" + "there" creates the String "hello there".

In line 24 of Fig. 6.3, the expression "Maximum is: " + result uses operator + with operands of types String and double. Every primitive value and object in Java has a String representation. When one of the + operator's operands is a String, the other is converted to a String, then the two are concatenated. In line 24, the double value is converted to its String representation and placed at the end of the String "Maximum is: ". If there are any trailing zeros in a double value, these will be discarded when the number is converted to a String. Thus, the number 9.3500 would be represented as 9.35 in the resulting String.

For primitive values used in string concatenation, the primitive values are converted to Strings. If a boolean is concatenated with a String, the boolean is converted to the String "true" or "false". All objects have a method named `toString` that returns a String representation of the object. When an object is concatenated with a String, the object's `toString` method is implicitly called to obtain the String representation of the object. You will learn more about the method `toString` in Chapter 7, Arrays.

When a large String literal is typed into a program's source code, programmers sometimes prefer to break that String into several smaller Strings and place them on multiple lines of code for readability. In this case, the Strings can be reassembled using concatenation. We discuss the details of Strings in Chapter 30, Strings, Characters and Regular Expressions.

6.5 Notes on Declaring and Using Methods 249

Common Programming Error 6.2

It is a syntax error to break a String literal across multiple lines in a program. If a String does not fit on one line, split the String into several smaller Strings and use concatenation to form the desired String.

Common Programming Error 6.3

Confusing the + operator used for string concatenation with the + operator used for addition can lead to strange results. Java evaluates the operands of an operator from left to right. For example, if integer variable y has the value 5, the expression "y + 2 = " + y + 2 results in the string "y + 2 = 52", not "y + 2 = 7", because first the value of y (5) is concatenated with the string "y + 2 = ", then the value 2 is concatenated with the new larger string "y + 2 = 5". The expression "y + 2 = " + (y + 2) produces the desired result "y + 2 = 7".

6.5 Notes on Declaring and Using Methods

There are three ways to call a method:

1. Using a method name by itself to call another method of the same class—such as `maximum(number1, number2, number3)` in line 21 of Fig. 6.3.
2. Using a variable that contains a reference to an object, followed by a dot (.) and the method name to call a method of the referenced object—such as the method call in line 10 of Fig. 6.4, `maximumFinder.determineMaximum()`, which calls a method of class `MaximumFinder` from the `main` method of `MaximumFinderTest`.
3. Using the class name and a dot (.) to call a `static` method of a class—such as `Math.sqrt(900.0)` in Section 6.3.

Note that a `static` method can call only other `static` methods of the same class directly (i.e., using the method name by itself) and can manipulate only `static` fields in the same class directly. To access the class's non-`static` members, a `static` method must use a reference to an object of the class. Recall that `static` methods relate to a class as a whole, whereas non-`static` methods are associated with a specific instance (object) of the class and may manipulate the instance variables of that object. Many objects of a class, each with its own copies of the instance variables, may exist at the same time. Suppose a `static` method were to invoke a non-`static` method directly. How would the method know which object's instance variables to manipulate? What would happen if no objects of the class existed at the time the non-`static` method was invoked? Clearly, such a situation would be problematic. Thus, Java does not allow a `static` method to access non-`static` members of the same class directly.

There are three ways to return control to the statement that calls a method. If the method does not return a result, control returns when the program flow reaches the method-ending right brace or when the statement

```
return;
```

is executed. If the method returns a result, the statement

```
return expression;
```

evaluates the `expression`, then returns the result to the caller.

250 Chapter 6 Methods: A Deeper Look**Common Programming Error 6.4**

Declaring a method outside the body of a class declaration or inside the body of another method is a syntax error.

**Common Programming Error 6.5**

Omitting the return-value-type in a method declaration is a syntax error.

**Common Programming Error 6.6**

Placing a semicolon after the right parenthesis enclosing the parameter list of a method declaration is a syntax error.

**Common Programming Error 6.7**

Redeclaring a method parameter as a local variable in the method's body is a compilation error.

**Common Programming Error 6.8**

Forgetting to return a value from a method that should return a value is a compilation error. If a return-value-type other than void is specified, the method must contain a return statement that returns a value consistent with the method's return-value-type. Returning a value from a method whose return type has been declared void is a compilation error.

6.6 Method-Call Stack and Activation Records

To understand how Java performs method calls, we first need to consider a data structure (i.e., collection of related data items) known as a **stack**. Students can think of a stack as analogous to a pile of dishes. When a dish is placed on the pile, it is normally placed at the top (referred to as **pushing** the dish onto the stack). Similarly, when a dish is removed from the pile, it is always removed from the top (referred to as **popping** the dish off the stack). Stacks are known as **last-in, first-out (LIFO) data structures**—the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.

When a program calls a method, the called method must know how to return to its caller, so the return address of the calling method is pushed onto the **program execution stack** (sometimes referred to as the **method-call stack**). If a series of method calls occurs, the successive return addresses are pushed onto the stack in last-in, first-out order so that each method can return to its caller.

The program execution stack also contains the memory for the local variables used in each invocation of a method during a program's execution. This data, stored as a portion of the program execution stack, is known as the **activation record** or **stack frame** of the method call. When a method call is made, the activation record for that method call is pushed onto the program execution stack. When the method returns to its caller, the activation record for this method call is popped off the stack and those local variables are no longer known to the program. If a local variable holding a reference to an object is the only variable in the program with a reference to that object, when the activation record containing that local variable is popped off the stack, the object can no longer be accessed by the program and will eventually be deleted from memory by the JVM during “garbage collection.” We'll discuss garbage collection in Section 8.10.

6.7 Argument Promotion and Casting **251**

Of course, the amount of memory in a computer is finite, so only a certain amount of memory can be used to store activation records on the program execution stack. If more method calls occur than can have their activation records stored on the program execution stack, an error known as a [stack overflow](#) occurs.

6.7 Argument Promotion and Casting

Another important feature of method calls is [argument promotion](#)—converting an argument’s value to the type that the method expects to receive in its corresponding parameter. For example, a program can call Math method `sqrt` with an integer argument even though the method expects to receive a `double` argument (but, as we will soon see, not vice versa). The statement

```
System.out.println( Math.sqrt( 4 ) );
```

correctly evaluates `Math.sqrt(4)` and prints the value 2.0. The method declaration’s parameter list causes Java to convert the `int` value 4 to the `double` value 4.0 before passing the value to `sqrt`. Attempting these conversions may lead to compilation errors if Java’s [promotion rules](#) are not satisfied. The promotion rules specify which conversions are allowed—that is, which conversions can be performed without losing data. In the `sqrt` example above, an `int` is converted to a `double` without changing its value. However, converting a `double` to an `int` truncates the fractional part of the `double` value—thus, part of the value is lost. Converting large integer types to small integer types (e.g., `long` to `int`) may also result in changed values.

The promotion rules apply to expressions containing values of two or more primitive types and to primitive-type values passed as arguments to methods. Each value is promoted to the “highest” type in the expression. (Actually, the expression uses a temporary copy of each value—the types of the original values remain unchanged.) Figure 6.5 lists the primitive types and the types to which each can be promoted. Note that the valid promotions for a given type are always to a type higher in the table. For example, an `int` can be promoted to the higher types `long`, `float` and `double`.

Type	Valid promotions
<code>double</code>	None
<code>float</code>	<code>double</code>
<code>long</code>	<code>float</code> or <code>double</code>
<code>int</code>	<code>long</code> , <code>float</code> or <code>double</code>
<code>char</code>	<code>int</code> , <code>long</code> , <code>float</code> or <code>double</code>
<code>short</code>	<code>int</code> , <code>long</code> , <code>float</code> or <code>double</code> (but not <code>char</code>)
<code>byte</code>	<code>short</code> , <code>int</code> , <code>long</code> , <code>float</code> or <code>double</code> (but not <code>char</code>)
<code>boolean</code>	None (<code>boolean</code> values are not considered to be numbers in Java)

Fig. 6.5 | Promotions allowed for primitive types.

252 Chapter 6 Methods: A Deeper Look

Converting values to types lower in the table of Fig. 6.5 will result in different values if the lower type cannot represent the value of the higher type (e.g., the `int` value 2000000 cannot be represented as a `short`, and any floating-point number with digits after its decimal point cannot be represented in an integer type such as `long`, `int` or `short`). Therefore, in cases where information may be lost due to conversion, the Java compiler requires you to use a cast operator (introduced in Section 4.9) to explicitly force the conversion to occur—otherwise a compilation error occurs. This enables you to “take control” from the compiler. You essentially say, “I know this conversion might cause loss of information, but for my purposes here, that’s fine.” Suppose method `square` calculates the square of an integer and thus requires an `int` argument. To call `square` with a `double` argument named `doubleValue`, we would be required to write the method call as

```
square( (int) doubleValue )
```

This method call explicitly casts (converts) the value of `doubleValue` to an integer for use in method `square`. Thus, if `doubleValue`’s value is 4.5, the method receives the value 4 and returns 16, not 20.25.

**Common Programming Error 6.9**

Converting a primitive-type value to another primitive type may change the value if the new type is not a valid promotion. For example, converting a floating-point value to an integral value may introduce truncation errors (loss of the fractional part) into the result.

6.8 Java API Packages

As we have seen, Java contains many predefined classes that are grouped into categories of related classes called packages. Together, we refer to these packages as the Java Application Programming Interface (Java API), or the Java class library.

Throughout the text, `import` declarations specify the classes required to compile a Java program. For example, a program includes the declaration

```
import java.util.Scanner;
```

to specify that the program uses class `Scanner` from the `java.util` package. This allows you to use the simple class name `Scanner`, rather than the fully qualified class name `java.util.Scanner`, in the code. A great strength of Java is the large number of classes in the packages of the Java API. Some key Java API packages are described in Fig. 6.6, which represents only a small portion of the reusable components in the Java API. When learning Java, spend a portion of your time browsing the packages and classes in the Java API documentation (java.sun.com/javase/6/docs/api/).

The set of packages available in Java SE 6 is quite large. In addition to the packages summarized in Fig. 6.6, Java SE 6 includes packages for complex graphics, advanced graphical user interfaces, printing, advanced networking, security, database processing, multimedia, accessibility (for people with disabilities) and many other capabilities. For an overview of the packages in Java SE 6, visit

java.sun.com/javase/6/docs/api/overview-summary.html

Many other packages are also available for download at java.sun.com.

6.8 Java API Packages **253**

Package	Description
<code>java.applet</code>	The Java Applet Package contains a class and several interfaces required to create Java applets—programs that execute in Web browsers. (Applets are discussed in Chapter 20, Introduction to Java Applets; interfaces are discussed in Chapter 10, Object-Oriented Programming: Polymorphism.)
<code>java.awt</code>	The Java Abstract Window Toolkit Package contains the classes and interfaces required to create and manipulate GUIs in Java 1.0 and 1.1. In current versions of Java, the Swing GUI components of the <code>javax.swing</code> packages are often used instead. (Some elements of the <code>java.awt</code> package are discussed in Chapter 11, GUI Components: Part 1, Chapter 12, Graphics and Java 2D™, and Chapter 22, GUI Components: Part 2.)
<code>java.awt.event</code>	The Java Abstract Window Toolkit Event Package contains classes and interfaces that enable event handling for GUI components in both the <code>java.awt</code> and <code>javax.swing</code> packages. (You'll learn more about this package in Chapter 11, GUI Components: Part 1 and Chapter 22, GUI Components: Part 2.)
<code>java.io</code>	The Java Input/Output Package contains classes and interfaces that enable programs to input and output data. (You will learn more about this package in Chapter 14, Files and Streams.)
<code>java.lang</code>	The Java Language Package contains classes and interfaces (discussed throughout this text) that are required by many Java programs. This package is imported by the compiler into all programs, so you do not need to do so.
<code>java.net</code>	The Java Networking Package contains classes and interfaces that enable programs to communicate via computer networks like the Internet. (You will learn more about this in Chapter 24, Networking.)
<code>java.text</code>	The Java Text Package contains classes and interfaces that enable programs to manipulate numbers, dates, characters and strings. The package provides internationalization capabilities that enable a program to be customized to a specific locale (e.g., a program may display strings in different languages, based on the user's country).
<code>java.util</code>	The Java Utilities Package contains utility classes and interfaces that enable such actions as date and time manipulations, random-number processing (class <code>Random</code>), the storing and processing of large amounts of data and the breaking of strings into smaller pieces called tokens (class <code> StringTokenizer</code>). (You will learn more about the features of this package in Chapter 19, Collections.)

Fig. 6.6 | Java API packages (a subset). (Part 1 of 2.)

254 Chapter 6 Methods: A Deeper Look

Package	Description
<code>javax.swing</code>	The Java Swing GUI Components Package contains classes and interfaces for Java's Swing GUI components that provide support for portable GUIs. (You will learn more about this package in Chapter 11, GUI Components: Part 1 and Chapter 22, GUI Components: Part 2.)
<code>javax.swing.event</code>	The Java Swing Event Package contains classes and interfaces that enable event handling (e.g., responding to button clicks) for GUI components in package <code>javax.swing</code> . (You will learn more about this package in Chapter 11, GUI Components: Part 1 and Chapter 22, GUI Components: Part 2.)

Fig. 6.6 | Java API packages (a subset). (Part 2 of 2.)

You can locate additional information about a predefined Java class's methods in the Java API documentation at java.sun.com/javase/6/docs/api/. When you visit this site, click the **Index** link to see an alphabetical listing of all the classes and methods in the Java API. Locate the class name and click its link to see the online description of the class. Click the **METHOD** link to see a table of the class's methods. Each **static** method will be listed with the word "static" preceding the method's return type. For a more detailed overview of navigating the Java API documentation, see Appendix G, Using the Java API Documentation.

**Good Programming Practice 6.2**

The online Java API documentation is easy to search and provides many details about each class. As you learn a class in this book, you should get in the habit of looking at the class in the online documentation for additional information.

6.9 Case Study: Random-Number Generation

We now take a brief and, hopefully, entertaining diversion into a popular type of programming application—simulation and game playing. In this and the next section, we develop a nicely structured game-playing program with multiple methods. The program uses most of the control statements presented thus far in the book and introduces several new programming concepts.

There is something in the air of a casino that invigorates people—from the high rollers at the plush mahogany-and-felt craps tables to the quarter poppers at the one-armed bandits. It is the **element of chance**, the possibility that luck will convert a pocketful of money into a mountain of wealth. The element of chance can be introduced in a program via an object of class `Random` (package `java.util`) or via the `static` method `random` of class `Math`. Objects of class `Random` can produce random `boolean`, `byte`, `float`, `double`, `int`, `long` and Gaussian values, whereas `Math` method `random` can produce only `double` values in the range $0.0 \leq x < 1.0$, where x is the value returned by method `random`. In the next several examples, we use objects of class `Random` to produce random values.

6.9 Case Study: Random-Number Generation **255**

A new random-number generator object can be created as follows:

```
Random randomNumbers = new Random();
```

The random-number generator object can then be used to generate random `boolean`, `byte`, `float`, `double`, `int`, `long` and Gaussian values—we discuss only random `int` values here. For more information on the `Random` class, see java.sun.com/javase/6/docs/api/java/util/Random.html.

Consider the following statement:

```
int randomValue = randomNumbers.nextInt();
```

Method `nextInt` of class `Random` generates a random `int` value from $-2,147,483,648$ to $+2,147,483,647$. If the `nextInt` method truly produces values at random, then every value in that range should have an equal chance (or probability) of being chosen each time method `nextInt` is called. The values returned by `nextInt` are actually **pseudorandom numbers**—a sequence of values produced by a complex mathematical calculation. The calculation uses the current time of day (which, of course, changes constantly) to `seed` the random-number generator such that each execution of a program yields a different sequence of random values.

The range of values produced directly by method `nextInt` often differs from the range of values required in a particular Java application. For example, a program that simulates coin tossing might require only 0 for “heads” and 1 for “tails.” A program that simulates the rolling of a six-sided die might require random integers in the range 1–6. A program that randomly predicts the next type of spaceship (out of four possibilities) that will fly across the horizon in a video game might require random integers in the range 1–4. For cases like these, class `Random` provides another version of method `nextInt` that receives an `int` argument and returns a value from 0 up to, but not including, the argument’s value. For example, to simulate coin tossing, you might use the statement

```
int randomValue = randomNumbers.nextInt( 2 );
```

which returns 0 or 1.

Rolling a Six-Sided Die

To demonstrate random numbers, let us develop a program that simulates 20 rolls of a six-sided die and displays the value of each roll. We begin by using `nextInt` to produce random values in the range 0–5, as follows:

```
face = randomNumbers.nextInt( 6 );
```

The argument 6—called the **scaling factor**—represents the number of unique values that `nextInt` should produce (in this case six—0, 1, 2, 3, 4 and 5). This manipulation is called **scaling** the range of values produced by `Random` method `nextInt`.

A six-sided die has the numbers 1–6 on its faces, not 0–5. So we **shift** the range of numbers produced by adding a **shifting value**—in this case 1—to our previous result, as in

```
face = 1 + randomNumbers.nextInt( 6 );
```

The shifting value (1) specifies the first value in the desired set of random integers. The preceding statement assigns `face` a random integer in the range 1–6.

256 Chapter 6 Methods: A Deeper Look

Figure 6.7 shows two sample outputs which confirm that the results of the preceding calculation are integers in the range 1–6, and that each run of the program can produce a different sequence of random numbers. Line 3 imports class `Random` from the `java.util` package. Line 9 creates the `Random` object `randomNumbers` to produce random values. Line 16 executes 20 times in a loop to roll the die. The `if` statement (lines 21–22) in the loop starts a new line of output after every five numbers.

Rolling a Six-Sided Die 6000 Times

To show that the numbers produced by `nextInt` occur with approximately equal likelihood, let us simulate 6000 rolls of a die with the application in Fig. 6.8. Each integer from 1 to 6 should appear approximately 1000 times.

```

1 // Fig. 6.7: RandomIntegers.java
2 // Shifted and scaled random integers.
3 import java.util.Random; // program uses class Random
4
5 public class RandomIntegers
6 {
7     public static void main( String args[] )
8     {
9         Random randomNumbers = new Random(); // random number generator
10        int face; // stores each random integer generated
11
12        // Loop 20 times
13        for ( int counter = 1; counter <= 20; counter++ )
14        {
15            // pick random integer from 1 to 6
16            face = 1 + randomNumbers.nextInt( 6 );
17
18            System.out.printf( "%d ", face ); // display generated value
19
20            // if counter is divisible by 5, start a new line of output
21            if ( counter % 5 == 0 )
22                System.out.println();
23        } // end for
24    } // end main
25 } // end class RandomIntegers

```

```

1 5 3 6 2
5 2 6 5 2
4 4 4 2 6
3 1 6 2 2

```

```

6 5 4 2 6
1 2 5 1 3
6 3 2 2 1
6 4 2 6 4

```

Fig. 6.7 | Shifted and scaled random integers.

6.9 Case Study: Random-Number Generation **257**

As the two sample outputs show, scaling and shifting the values produced by method `nextInt` enables the program to realistically simulate rolling a six-sided die. The application uses nested control statements (the `switch` is nested inside the `for`) to determine the number of times each side of the die occurred. The `for` statement (lines 21–47) iterates 6000 times. During each iteration, line 23 produces a random value from 1 to 6. That value is then used as the controlling expression (line 26) of the `switch` statement (lines 26–46). Based on the face value, the `switch` statement increments one of the six counter variables during each iteration of the loop. When we study arrays in Chapter 7, we will show an elegant way to replace the entire `switch` statement in this program with a single statement! Note that the `switch` statement has no `default` case, because we have a case for every possible die value that the expression in line 23 could produce. Run the program several times, and observe the results. As you will see, every time you execute this program, it produces different results.

```

1 // Fig. 6.8: RollDie.java
2 // Roll a six-sided die 6000 times.
3 import java.util.Random;
4
5 public class RollDie
6 {
7     public static void main( String args[] )
8     {
9         Random randomNumbers = new Random(); // random number generator
10
11        int frequency1 = 0; // maintains count of 1s rolled
12        int frequency2 = 0; // count of 2s rolled
13        int frequency3 = 0; // count of 3s rolled
14        int frequency4 = 0; // count of 4s rolled
15        int frequency5 = 0; // count of 5s rolled
16        int frequency6 = 0; // count of 6s rolled
17
18        int face; // stores most recently rolled value
19
20        // summarize results of 6000 rolls of a die
21        for ( int roll = 1; roll <= 6000; roll++ )
22        {
23            face = 1 + randomNumbers.nextInt( 6 ); // number from 1 to 6
24
25            // determine roll value 1-6 and increment appropriate counter
26            switch ( face )
27            {
28                case 1:
29                    ++frequency1; // increment the 1s counter
30                    break;
31                case 2:
32                    ++frequency2; // increment the 2s counter
33                    break;
34                case 3:
35                    ++frequency3; // increment the 3s counter
36                    break;

```

6.9.1 Generalized Scaling and Shifting of Random Numbers

Previously, we demonstrated the statement

```
face = 1 + randomNumbers.nextInt( 6 );
```

which simulates the rolling of a six-sided die. This statement always assigns to variable `face` an integer in the range $1 \leq \text{face} \leq 6$. The width of this range (i.e., the number of consecutive integers in the range) is 6, and the starting number in the range is 1. Referring to the preceding statement, we see that the width of the range is determined by the number 6 that is passed as an argument to `Random` method `nextInt`, and the starting number of the range is the number 1 that is added to `randomNumberGenerator.nextInt(6)`. We can generalize this result as

```
number = shiftingValue + randomNumbers.nextInt( scalingFactor );
```

6.9 Case Study: Random-Number Generation 259

where *shiftingValue* specifies the first number in the desired range of consecutive integers and *scalingFactor* specifies how many numbers are in the range.

It is also possible to choose integers at random from sets of values other than ranges of consecutive integers. For example, to obtain a random value from the sequence 2, 5, 8, 11 and 14, you could use the statement

```
number = 2 + 3 * randomNumbers.nextInt( 5 );
```

In this case, `randomNumberGenerator.nextInt(5)` produces values in the range 0–4. Each value produced is multiplied by 3 to produce a number in the sequence 0, 3, 6, 9 and 12. We then add 2 to that value to shift the range of values and obtain a value from the sequence 2, 5, 8, 11 and 14. We can generalize this result as

```
number = shiftingValue +
    differenceBetweenValues * randomNumbers.nextInt( scalingFactor );
```

where *shiftingValue* specifies the first number in the desired range of values, *differenceBetweenValues* represents the difference between consecutive numbers in the sequence and *scalingFactor* specifies how many numbers are in the range.

6.9.2 Random-Number Repeatability for Testing and Debugging

As we mentioned earlier in Section 6.9, the methods of class `Random` actually generate pseudorandom numbers based on complex mathematical calculations. Repeatedly calling any of `Random`'s methods produces a sequence of numbers that appears to be random. The calculation that produces the pseudorandom numbers uses the time of day as a *seed value* to change the sequence's starting point. Each new `Random` object seeds itself with a value based on the computer system's clock at the time the object is created, enabling each execution of a program to produce a different sequence of random numbers.

When debugging an application, it is sometimes useful to repeat the exact same sequence of pseudorandom numbers during each execution of the program. This repeatability enables you to prove that your application is working for a specific sequence of random numbers before you test the program with different sequences of random numbers. When repeatability is important, you can create a `Random` object as follows:

```
Random randomNumbers = new Random( seedValue );
```

The `seedValue` argument (of type `long`) seeds the random-number calculation. If the same `seedValue` is used every time, the `Random` object produces the same sequence of random numbers. You can set a `Random` object's seed at any time during program execution by calling the object's `setSeed` method, as in

```
randomNumbers.setSeed( seedValue );
```

Error-Prevention Tip 6.2

While a program is under development, create the `Random` object with a specific seed value to produce a repeatable sequence of random numbers each time the program executes. If a logic error occurs, fix the error and test the program again with the same seed value—this allows you to reconstruct the same sequence of random numbers that caused the error. Once the logic errors have been removed, create the `Random` object without using a seed value, causing the `Random` object to generate a new sequence of random numbers each time the program executes.

260 Chapter 6 Methods: A Deeper Look

6.10 Case Study: A Game of Chance (Introducing Enumerations)

A popular game of chance is a dice game known as craps, which is played in casinos and back alleys throughout the world. The rules of the game are straightforward:

You roll two dice. Each die has six faces, which contain one, two, three, four, five and six spots, respectively. After the dice have come to rest, the sum of the spots on the two upward faces is calculated. If the sum is 7 or 11 on the first throw, you win. If the sum is 2, 3 or 12 on the first throw (called “craps”), you lose (i.e., the “house” wins). If the sum is 4, 5, 6, 8, 9 or 10 on the first throw, that sum becomes your “point.” To win, you must continue rolling the dice until you “make your point” (i.e., roll that same point value). You lose by rolling a 7 before making the point.

The application in Fig. 6.9 and Fig. 6.10 simulates the game of craps, using methods to define the logic of the game. In the `main` method of class `CrapsTest` (Fig. 6.10), line 8 creates an object of class `Craps` (Fig. 6.9) and line 9 calls its `play` method to start the game. The `play` method (Fig. 6.9, lines 21–65) calls the `rollDice` method (Fig. 6.9, lines 68–81) as necessary to roll the two dice and compute their sum. Four sample outputs in Fig. 6.10 show winning on the first roll, losing on the first roll, winning on a subsequent roll and losing on a subsequent roll, respectively.

```

1 // Fig. 6.9: Craps.java
2 // Craps class simulates the dice game craps.
3 import java.util.Random;
4
5 public class Craps
6 {
7     // create random number generator for use in method rollDice
8     private Random randomNumbers = new Random();
9
10    // enumeration with constants that represent the game status
11    private enum Status { CONTINUE, WON, LOST };
12
13    // constants that represent common rolls of the dice
14    private final static int SNAKE_EYES = 2;
15    private final static int TREY = 3;
16    private final static int SEVEN = 7;
17    private final static int YO_LEVEN = 11;
18    private final static int BOX_CARS = 12;
19
20    // plays one game of craps
21    public void play()
22    {
23        int myPoint = 0; // point if no win or loss on first roll
24        Status gameStatus; // can contain CONTINUE, WON or LOST
25
26        int sumOfDice = rollDice(); // first roll of the dice
27
28        // determine game status and point based on first roll
29        switch ( sumOfDice )
30        {

```

Fig. 6.9 | Craps class simulates the dice game craps. (Part I of 2.)

6.10 Case Study: A Game of Chance (Introducing Enumerations)

261

```

31     case SEVEN: // win with 7 on first roll
32     case YO_LEVEN: // win with 11 on first roll
33         gameStatus = Status.WON;
34         break;
35     case SNAKE_EYES: // lose with 2 on first roll
36     case TREY: // lose with 3 on first roll
37     case BOX_CARS: // lose with 12 on first roll
38         gameStatus = Status.LOST;
39         break;
40     default: // did not win or lose, so remember point
41         gameStatus = Status.CONTINUE; // game is not over
42         myPoint = sumOfDice; // remember the point
43         System.out.printf( "Point is %d\n", myPoint );
44         break; // optional at end of switch
45 } // end switch
46
47 // while game is not complete
48 while ( gameStatus == Status.CONTINUE ) // not WON or LOST
49 {
50     sumOfDice = rollDice(); // roll dice again
51
52     // determine game status
53     if ( sumOfDice == myPoint ) // win by making point
54         gameStatus = Status.WON;
55     else
56         if ( sumOfDice == SEVEN ) // lose by rolling 7 before point
57             gameStatus = Status.LOST;
58 } // end while
59
60 // display won or lost message
61 if ( gameStatus == Status.WON )
62     System.out.println( "Player wins" );
63 else
64     System.out.println( "Player loses" );
65 } // end method play
66
67 // roll dice, calculate sum and display results
68 public int rollDice()
69 {
70     // pick random die values
71     int die1 = 1 + randomNumbers.nextInt( 6 ); // first die roll
72     int die2 = 1 + randomNumbers.nextInt( 6 ); // second die roll
73
74     int sum = die1 + die2; // sum of die values
75
76     // display results of this roll
77     System.out.printf( "Player rolled %d + %d = %d\n",
78                         die1, die2, sum );
79
80     return sum; // return sum of dice
81 } // end method rollDice
82 } // end class Craps

```

Point is 8
Player rolled 5 + 1 = 6
Player rolled 2 + 1 = 3
Player rolled 1 + 6 = 7
Player loses

Fig. 6.10 | Application to test class Craps.

Let's discuss the declaration of class `Craps` in Fig. 6.9. In the rules of the game, the player must roll two dice on the first roll, and must do the same on all subsequent rolls. We declare method `rollDice` (lines 68–81) to roll the dice and compute and print their sum. Method `rollDice` is declared once, but it is called from two places (lines 26 and 50) in method `play`, which contains the logic for one complete game of craps. Method `rollDice` takes no arguments, so it has an empty parameter list. Each time it is called, `rollDice` returns the sum of the dice, so the return type `int` is indicated in the method header (line 68). Although lines 71 and 72 look the same (except for the die names), they do not necessarily produce the same result. Each of these statements produces a random value in the range 1–6. Note that `randomNumbers` (used in lines 71–72) is not declared in the method. Rather it is declared as a `private` instance variable of the class and initialized in line 8. This enables us to create one `Random` object that is reused in each call to `rollDice`.

6.10 Case Study: A Game of Chance (Introducing Enumerations)

263

The game is reasonably involved. The player may win or lose on the first roll, or may win or lose on any subsequent roll. Method `play` (lines 21–65) uses local variable `myPoint` (line 23) to store the “point” if the player does not win or lose on the first roll, local variable `gameStatus` (line 24) to keep track of the overall game status and local variable `sumOfDice` (line 26) to hold the sum of the dice for the most recent roll. Note that `myPoint` is initialized to 0 to ensure that the application will compile. If you do not initialize `myPoint`, the compiler issues an error, because `myPoint` is not assigned a value in every case of the `switch` statement, and thus the program could try to use `myPoint` before it is assigned a value. By contrast, `gameStatus` does not require initialization because it *is* assigned a value in every case of the `switch` statement—thus, it is guaranteed to be initialized before it is used.

Note that local variable `gameStatus` (line 24) is declared to be of a new type called `Status`, which we declared at line 11. Type `Status` is declared as a private member of class `Craps`, because `Status` will be used only in that class. `Status` is a programmer-declared type called an [enumeration](#), which, in its simplest form, declares a set of constants represented by identifiers. An enumeration is a special kind of class that is introduced by the keyword `enum` and a type name (in this case, `Status`). As with any class, braces {} and } delimit the body of an `enum` declaration. Inside the braces is a comma-separated list of [enumeration constants](#), each representing a unique value. The identifiers in an `enum` must be unique. (You will learn more about enumerations in Chapter 8.)

**Good Programming Practice 6.3**

Use only uppercase letters in the names of enumeration constants. This makes the constants stand out and reminds you that enumeration constants are not variables.

Variables of type `Status` can be assigned only one of the three constants declared in the enumeration (line 11) or a compilation error will occur. When the game is won, the program sets local variable `gameStatus` to `Status.WON` (lines 33 and 54). When the game is lost, the program sets local variable `gameStatus` to `Status.LOST` (lines 38 and 57). Otherwise, the program sets local variable `gameStatus` to `Status.CONTINUE` (line 41) to indicate that the game is not over and the dice must be rolled again.

**Good Programming Practice 6.4**

Using enumeration constants (like `Status.WON`, `Status.LOST` and `Status.CONTINUE`) rather than literal integer values (such as 0, 1 and 2) can make programs easier to read and maintain.

Line 26 in method `play` calls `rollDice`, which picks two random values from 1 to 6, displays the value of the first die, the value of the second die and the sum of the dice, and returns the sum of the dice. Method `play` next enters the `switch` statement at lines 29–45, which uses the `sumOfDice` value from line 26 to determine whether the game has been won or lost, or whether it should continue with another roll. The sums of the dice that would result in a win or loss on the first roll are declared as `public final static int` constants in lines 14–18. These are used in the cases of the `switch` statement. The identifier names use casino parlance for these sums. Note that these constants, like `enum` constants, are declared with all capital letters by convention, to make them stand out in the program. Lines 31–34 determine whether the player won on the first roll with `SEVEN` (7) or `YO_LEVEN` (11). Lines 35–39 determine whether the player lost on the first roll with `SNAKE_EYES` (2), `TREY` (3), or `BOX_CARS` (12). After the first roll, if the game is not over, the `default` case (lines 40–44) sets `gameStatus` to `Status.CONTINUE`, saves `sumOfDice` in `myPoint` and displays the point.

264 Chapter 6 Methods: A Deeper Look

If we are still trying to “make our point” (i.e., the game is continuing from a prior roll), the loop in lines 48–58 executes. Line 50 rolls the dice again. In line 53, if `sumOfDice` matches `myPoint`, line 54 sets `gameStatus` to `Status.WON`, then the loop terminates because the game is complete. In line 56, if `sumOfDice` is equal to `SEVEN` (7), line 57 sets `gameStatus` to `Status.LOST`, and the loop terminates because the game is complete. When the game completes, lines 61–64 display a message indicating whether the player won or lost, and the program terminates.

Note the use of the various program-control mechanisms we have discussed. The `Craps` class in concert with class `CrapsTest` uses two methods—`main`, `play` (called from `main`) and `rollDice` (called twice from `play`)—and the `switch`, `while`, `if...else` and nested `if` control statements. Note also the use of multiple case labels in the `switch` statement to execute the same statements for sums of `SEVEN` and `Y0_LEVEN` (lines 31–32) and for sums of `SNAKE_EYES`, `TREY` and `BOX_CARS` (lines 35–37).

You might be wondering why we declared the sums of the dice as `public final static int` constants rather than as `enum` constants. The answer lies in the fact that the program must compare the `int` variable `sumOfDice` (line 26) to these constants to determine the outcome of each roll. Suppose we were to declare `enum Sum` containing constants (e.g., `Sum.SNAKE_EYES`) representing the five sums used in the game, then use these constants in the cases of the `switch` statement (lines 29–45). Doing so would prevent us from using `sumOfDice` as the `switch` statement’s controlling expression, because Java does not allow an `int` to be compared to an enumeration constant. To achieve the same functionality as the current program, we would have to use a variable `currentSum` of type `Sum` as the `switch`’s controlling expression. Unfortunately, Java does not provide an easy way to convert an `int` value to a particular `enum` constant. Translating an `int` into an `enum` constant could be done with a separate `switch` statement. Clearly this would be cumbersome and not improve the readability of the program (thus defeating the purpose of using an `enum`).

6.11 Scope of Declarations

You have seen declarations of various Java entities, such as classes, methods, variables and parameters. Declarations introduce names that can be used to refer to such Java entities. The `scope` of a declaration is the portion of the program that can refer to the declared entity by its name. Such an entity is said to be “in scope” for that portion of the program. This section introduces several important scope issues. (For more scope information, see the *Java Language Specification, Section 6.3: Scope of a Declaration*, at java.sun.com/docs/books/jls/second_edition/html/names.doc.html#103228.)

The basic scope rules are as follows:

1. The scope of a parameter declaration is the body of the method in which the declaration appears.
2. The scope of a local-variable declaration is from the point at which the declaration appears to the end of that block.
3. The scope of a local-variable declaration that appears in the initialization section of a `for` statement’s header is the body of the `for` statement and the other expressions in the header.
4. The scope of a method or field of a class is the entire body of the class. This enables non-`static` methods of a class to use the class’s fields and other methods.

6.11 Scope of Declarations **265**

Any block may contain variable declarations. If a local variable or parameter in a method has the same name as a field, the field is “hidden” until the block terminates execution—this is called **shadowing**. In Chapter 8, we discuss how to access shadowed fields.

**Common Programming Error 6.10**

A compilation error occurs when a local variable is declared more than once in a method.

**Error-Prevention Tip 6.3**

Use different names for fields and local variables to help prevent subtle logic errors that occur when a method is called and a local variable of the method shadows a field of the same name in the class.

The application in Fig. 6.11 and Fig. 6.12 demonstrates scoping issues with fields and local variables. When the application begins execution, class `ScopeTest`'s `main` method (Fig. 6.12, lines 7–11) creates an object of class `Scope` (line 9) and calls the object's `begin` method (line 10) to produce the program's output (shown in Fig. 6.12).

```

1 // Fig. 6.11: Scope.java
2 // Scope class demonstrates field and local variable scopes.
3
4 public class Scope
5 {
6     // field that is accessible to all methods of this class
7     private int x = 1;
8
9     // method begin creates and initializes local variable x
10    // and calls methods useLocalVariable and useField
11    public void begin()
12    {
13        int x = 5; // method's local variable x shadows field x
14
15        System.out.printf("local x in method begin is %d\n", x);
16
17        useLocalVariable(); // useLocalVariable has local x
18        useField(); // useField uses class Scope's field x
19        useLocalVariable(); // useLocalVariable reinitializes local x
20        useField(); // class Scope's field x retains its value
21
22        System.out.printf("\nlocal x in method begin is %d\n", x);
23    } // end method begin
24
25    // create and initialize local variable x during each call
26    public void useLocalVariable()
27    {
28        int x = 25; // initialized each time useLocalVariable is called
29
30        System.out.printf(
31            "\nlocal x on entering method useLocalVariable is %d\n", x);
32        ++x; // modifies this method's local variable x

```

Fig. 6.11 | Scope class demonstrating scopes of a field and local variables. (Part I of 2.)

266 Chapter 6 Methods: A Deeper Look

```

33     System.out.printf(
34         "\nlocal x before exiting method useLocalVariable is %d\n", x );
35 } // end method useLocalVariable
36
37 // modify class Scope's field x during each call
38 public void useField()
39 {
40     System.out.printf(
41         "\nfield x on entering method useField is %d\n", x );
42     x *= 10; // modifies class Scope's field x
43     System.out.printf(
44         "field x before exiting method useField is %d\n", x );
45 } // end method useField
46 } // end class Scope

```

Fig. 6.11 | Scope class demonstrating scopes of a field and local variables. (Part 2 of 2.)

```

1 // Fig. 6.12: ScopeTest.java
2 // Application to test class Scope.
3
4 public class ScopeTest
5 {
6     // application starting point
7     public static void main( String args[] )
8     {
9         Scope testScope = new Scope();
10        testScope.begin();
11    } // end main
12 } // end class ScopeTest

local x in method begin is 5

local x on entering method useLocalVariable is 25
Local x before exiting method useLocalVariable is 26

field x on entering method useField is 1
field x before exiting method useField is 10

local x on entering method useLocalVariable is 25
Local x before exiting method useLocalVariable is 26

field x on entering method useField is 10
field x before exiting method useField is 100

local x in method begin is 5

```

Fig. 6.12 | Application to test class Scope.

In class Scope, line 7 declares and initializes the field x to 1. This field is shadowed (hidden) in any block (or method) that declares a local variable named x. Method begin (lines 11–23) declares a local variable x (line 13) and initializes it to 5. This local variable's

6.12 Method Overloading **267**

value is output to show that the field `x` (whose value is 1) is shadowed in method `begin`. The program declares two other methods—`useLocalVariable` (lines 26–35) and `useField` (lines 38–45)—that each take no arguments and do not return results. Method `begin` calls each method twice (lines 17–20). Method `useLocalVariable` declares local variable `x` (line 28). When `useLocalVariable` is first called (line 17), it creates local variable `x` and initializes it to 25 (line 28), outputs the value of `x` (lines 30–31), increments `x` (line 32) and outputs the value of `x` again (lines 33–34). When `useLocalVariable` is called a second time (line 19), it re-creates local variable `x` and re-initializes it to 25, so the output of each `useLocalVariable` call is identical.

Method `useField` does not declare any local variables. Therefore, when it refers to `x`, field `x` (line 7) of the class is used. When method `useField` is first called (line 18), it outputs the value (1) of field `x` (lines 40–41), multiplies the field `x` by 10 (line 42) and outputs the value (10) of field `x` again (lines 43–44) before returning. The next time method `useField` is called (line 20), the field has its modified value, 10, so the method outputs 10, then 100. Finally, in method `begin`, the program outputs the value of local variable `x` again (line 22) to show that none of the method calls modified `begin`'s local variable `x`, because the methods all referred to variables named `x` in other scopes.

6.12 Method Overloading

Methods of the same name can be declared in the same class, as long as they have different sets of parameters (determined by the number, types and order of the parameters)—this is called **method overloading**. When an overloaded method is called, the Java compiler selects the appropriate method by examining the number, types and order of the arguments in the call. Method overloading is commonly used to create several methods with the same name that perform the same or similar tasks, but on different types or different numbers of arguments. For example, `Math` methods `abs`, `min` and `max` (summarized in Section 6.3) are overloaded with four versions each:

1. One with two `double` parameters.
2. One with two `float` parameters.
3. One with two `int` parameters.
4. One with two `long` parameters.

Our next example demonstrates declaring and invoking overloaded methods. We present examples of overloaded constructors in Chapter 8.

Declaring Overloaded Methods

In our class `MethodOverload` (Fig. 6.13), we include two overloaded versions of a method called `square`—one that calculates the square of an `int` (and returns an `int`) and one that calculates the square of a `double` (and returns a `double`). Although these methods have the same name and similar parameter lists and bodies, you can think of them simply as *different* methods. It may help to think of the method names as “square of `int`” and “square of `double`,” respectively. When the application begins execution, class `MethodOverloadTest`'s `main` method (Fig. 6.14, lines 6–10) creates an object of class `MethodOverload` (line 8) and calls the object's method `testOverloadedMethods` (line 9) to produce the program's output (Fig. 6.14).

268 Chapter 6 Methods: A Deeper Look

```

1 // Fig. 6.13: MethodOverload.java
2 // Overloaded method declarations.
3
4 public class MethodOverload
5 {
6     // test overloaded square methods
7     public void testOverloadedMethods()
8     {
9         System.out.printf( "Square of integer 7 is %d\n", square( 7 ) );
10        System.out.printf( "Square of double 7.5 is %f\n", square( 7.5 ) );
11    } // end method testOverloadedMethods
12
13    // square method with int argument
14    public int square( int intValue )
15    {
16        System.out.printf( "\nCalled square with int argument: %d\n",
17                           intValue );
18        return intValue * intValue;
19    } // end method square with int argument
20
21    // square method with double argument
22    public double square( double doubleValue )
23    {
24        System.out.printf( "\nCalled square with double argument: %f\n",
25                           doubleValue );
26        return doubleValue * doubleValue;
27    } // end method square with double argument
28 } // end class MethodOverload

```

Fig. 6.13 | Overloaded method declarations.

```

1 // Fig. 6.14: MethodOverloadTest.java
2 // Application to test class MethodOverload.
3
4 public class MethodOverloadTest
5 {
6     public static void main( String args[] )
7     {
8         MethodOverload methodOverload = new MethodOverload();
9         methodOverload.testOverloadedMethods();
10    } // end main
11 } // end class MethodOverloadTest

```

```

Called square with int argument: 7
Square of integer 7 is 49

Called square with double argument: 7.500000
Square of double 7.5 is 56.250000

```

Fig. 6.14 | Application to test class MethodOverload.

6.12 Method Overloading **269**

In Fig. 6.13, line 9 invokes method `square` with the argument 7. Literal integer values are treated as type `int`, so the method call in line 9 invokes the version of `square` at lines 14–19 that specifies an `int` parameter. Similarly, line 10 invokes method `square` with the argument 7.5. Literal floating-point values are treated as type `double`, so the method call in line 10 invokes the version of `square` at lines 22–27 that specifies a `double` parameter. Each method first outputs a line of text to prove that the proper method was called in each case. Note that the values in lines 10 and 24 are displayed with the format specifier `%f` and that we did not specify a precision in either case. By default, floating-point values are displayed with six digits of precision if the precision is not specified in the format specifier.

Distinguishing Between Overloaded Methods

The compiler distinguishes overloaded methods by their *signature*—a combination of the method’s name and the number, types and order of its parameters. If the compiler looked only at method names during compilation, the code in Fig. 6.13 would be ambiguous—the compiler would not know how to distinguish between the two `square` methods (lines 14–19 and 22–27). Internally, the compiler uses longer method names that include the original method name, the types of each parameter and the exact order of the parameters to determine whether the methods in a class are unique in that class.

For example, in Fig. 6.13, the compiler might use the logical name “`square of int`” for the `square` method that specifies an `int` parameter and “`square of double`” for the `square` method that specifies a `double` parameter (the actual names the compiler uses are messier). If `method1`’s declaration begins as

```
void method1( int a, float b )
```

then the compiler might use the logical name “`method1 of int and float`.” If the parameters are specified as

```
void method1( float a, int b )
```

then the compiler might use the logical name “`method1 of float and int`.” Note that the order of the parameter types is important—the compiler considers the preceding two `method1` headers to be distinct.

Return Types of Overloaded Methods

In discussing the logical names of methods used by the compiler, we did not mention the return types of the methods. This is because method *calls* cannot be distinguished by return type. The program in Fig. 6.15 illustrates the compiler errors generated when two methods have the same signature and different return types. Overloaded methods can have different return types if the methods have different parameter lists. Also, overloaded methods need not have the same number of parameters.

```
1 // Fig. 6.15: MethodOverloadError.java
2 // Overloaded methods with identical signatures
3 // cause compilation errors, even if return types are different.
```

Fig. 6.15 | Overloaded method declarations with identical signatures cause compilation errors, even if the return types are different. (Part I of 2.)

270 Chapter 6 Methods: A Deeper Look

```

4  public class MethodOverloadError
5  {
6      // declaration of method square with int argument
7      public int square( int x )
8      {
9          return x * x;
10     }
11 }
12
13 // second declaration of method square with int argument
14 // causes compilation error even though return types are different
15 public double square( int y )
16 {
17     return y * y;
18 }
19 } // end class MethodOverloadError

```

```

MethodOverloadError.java:15: square(int) is already defined in
MethodOverloadError
    public double square( int y )
                           ^
1 error

```

Fig. 6.15 | Overloaded method declarations with identical signatures cause compilation errors, even if the return types are different. (Part 2 of 2.)

Common Programming Error 6.11

Declaring overloaded methods with identical parameter lists is a compilation error regardless of whether the return types are different.

6.13 (Optional) GUI and Graphics Case Study: Colors and Filled Shapes

Although you can create many interesting designs with just lines and basic shapes, class `Graphics` provides many more capabilities. The next two features we introduce are colors and filled shapes. Adding color brings another dimension to the drawings a user sees on the computer screen. Filled shapes fill entire regions with solid colors, rather than just drawing outlines.

Colors displayed on computer screens are defined by their red, green, and blue components. These components, called [RGB values](#), have integer values from 0 to 255. The higher the value of a particular component, the richer the particular shade will be in the final color. Java uses class `Color` in package `java.awt` to represent colors using their RGB values. For convenience, the `Color` object contains 13 predefined static `Color` objects—`Color.BLACK`, `Color.BLUE`, `Color.CYAN`, `Color.DARK_GRAY`, `Color.GRAY`, `Color.GREEN`, `Color.LIGHT_GRAY`, `Color.MAGENTA`, `Color.ORANGE`, `Color.PINK`, `Color.RED`, `Color.WHITE` and `Color.YELLOW`. Class `Color` also contains a constructor of the form:

```
public Color( int r, int g, int b )
```

6.13 (Optional) GUI and Graphics Case Study: Colors and Filled Shapes **271**

so you can create custom colors by specifying values for the individual red, green and blue components of a color.

Filled rectangles and filled ovals are drawn using `Graphics` methods `fillRect` and `fillOval`, respectively. These two methods have the same parameters as their unfilled counterparts `drawRect` and `drawOval`; the first two parameters are the coordinates for the upper-left corner of the shape, while the next two parameters determine its width and height. The example in Fig. 6.16 and Fig. 6.17 demonstrates colors and filled shapes by drawing and displaying a yellow smiley face on the screen.

```

1 // Fig. 6.16: DrawSmiley.java
2 // Demonstrates filled shapes.
3 import java.awt.Color;
4 import java.awt.Graphics;
5 import javax.swing.JPanel;
6
7 public class DrawSmiley extends JPanel
8 {
9     public void paintComponent( Graphics g )
10    {
11        super.paintComponent( g );
12
13        // draw the face
14        g.setColor( Color.YELLOW );
15        g.fillOval( 10, 10, 200, 200 );
16
17        // draw the eyes
18        g.setColor( Color.BLACK );
19        g.fillOval( 55, 65, 30, 30 );
20        g.fillOval( 135, 65, 30, 30 );
21
22        // draw the mouth
23        g.fillOval( 50, 110, 120, 60 );
24
25        // "touch up" the mouth into a smile
26        g.setColor( Color.YELLOW );
27        g.fillRect( 50, 110, 120, 30 );
28        g.fillOval( 50, 120, 120, 40 );
29    } // end method paintComponent
30 } // end class DrawSmiley

```

9   DrawSmiley panel = new DrawSmiley();
10  JFrame application = new JFrame();
11
12  application.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
13  application.add( panel );
14  application.setSize( 230, 250 );
15  application.setVisible( true );
16 } // end main
17 } // end class DrawSmileyTest

```

Fig. 6.17 | Creating `JFrame` to display a smiley face. (Part 2 of 2.)

The `import` statements in lines 3–5 of Fig. 6.16 import classes `Color`, `Graphics` and `JPanel`. Class `DrawSmiley` (lines 7–30) uses class `Color` to specify drawing colors, and uses class `Graphics` to draw. Class `JPanel` again provides the area in which we draw. Line 14 in method `paintComponent` uses `Graphics` method `setColor` to set the current drawing color to `Color.YELLOW`. Method `setColor` requires one argument, the `Color` to set as the drawing color. In this case, we use the predefined object `Color.YELLOW`. Line 15 draws a circle with diameter 200 to represent the face—when the width and height arguments are identical, method `fillOval` draws a circle. Next, line 18 sets the color to `Color.Black`, and lines 19–20 draw the eyes. Line 23 draws the mouth as an oval, but this is not quite what we want. To create a happy face, we will “touch up” the mouth. Line 26 sets the color to `Color.YELLOW`, so any shapes we draw will blend in with the face. Line 27 draws a rectangle that is half the mouth’s height. This “erases” the top half of the mouth, leaving just the bottom half. To create a better smile, line 28 draws another oval to slightly cover the upper portion of the mouth. Class `DrawSmileyTest` (Fig. 6.17) creates and displays a `JFrame` containing the drawing. When the `JFrame` is displayed, the system calls method `paintComponent` to draw the smiley face.

GUI and Graphics Case Study Exercises

6.1 Using method `fillOval`, draw a bull’s-eye that alternates between two random colors, as in Fig. 6.18. Use the constructor `Color(int r, int g, int b)` with random arguments to generate random colors.

6.2 Create a program that draws 10 random filled shapes in random colors, positions and sizes (Fig. 6.19). Method `paintComponent` should contain a loop that iterates 10 times. In each iteration, the loop should determine whether to draw a filled rectangle or an oval, create a random color and

6.14 Identifying Class Operations **273**

choose coordinates and dimensions at random. The coordinates should be chosen based on the panel's width and height. Lengths of sides should be limited to half the width or height of the window.

Fig. 6.18 | A bull's-eye with two alternating, random colors.

Fig. 6.19 | Randomly generated shapes.

6.14 (Optional) Software Engineering Case Study: Identifying Class Operations

In the Software Engineering Case Study sections at the ends of Chapters 3–5, we performed the first few steps in the object-oriented design of our ATM system. In Chapter 3, we identified the classes that we'll need to implement and created our first class diagram.

274 Chapter 6 Methods: A Deeper Look

In Chapter 4, we described some attributes of our classes. In Chapter 5, we examined objects' states and modeled objects' state transitions and activities. In this section, we determine some of the class operations (or behaviors) needed to implement the ATM system.

Identifying Operations

An operation is a service that objects of a class provide to clients (users) of the class. Consider the operations of some real-world objects. A radio's operations include setting its station and volume (typically invoked by a person adjusting the radio's controls). A car's operations include accelerating (invoked by the driver pressing the accelerator pedal), decelerating (invoked by the driver pressing the brake pedal or releasing the gas pedal), turning and shifting gears. Software objects can offer operations as well—for example, a software graphics object might offer operations for drawing a circle, drawing a line, drawing a square and the like. A spreadsheet software object might offer operations like printing the spreadsheet, totaling the elements in a row or column and graphing information in the spreadsheet as a bar chart or pie chart.

We can derive many of the operations of each class by examining the key verbs and verb phrases in the requirements document. We then relate each of these to particular classes in our system (Fig. 6.20). The verb phrases in Fig. 6.20 help us determine the operations of each class.

Modeling Operations

To identify operations, we examine the verb phrases listed for each class in Fig. 6.20. The “executes financial transactions” phrase associated with class `ATM` implies that class `ATM` instructs transactions to execute. Therefore, classes `BalanceInquiry`, `Withdrawal` and

Class	Verbs and verb phrases
<code>ATM</code>	executes financial transactions
<code>BalanceInquiry</code>	[none in the requirements document]
<code>Withdrawal</code>	[none in the requirements document]
<code>Deposit</code>	[none in the requirements document]
<code>BankDatabase</code>	authenticates a user, retrieves an account balance, credits a deposit amount to an account, debits a withdrawal amount from an account
<code>Account</code>	retrieves an account balance, credits a deposit amount to an account, debits a withdrawal amount from an account
<code>Screen</code>	displays a message to the user
<code>Keypad</code>	receives numeric input from the user
<code>CashDispenser</code>	dispenses cash, indicates whether it contains enough cash to satisfy a withdrawal request
<code>DepositSlot</code>	receives a deposit envelope

Fig. 6.20 | Verbs and verb phrases for each class in the ATM system.

6.14 Identifying Class Operations **275**

Deposit each need an operation to provide this service to the ATM. We place this operation (which we have named execute) in the third compartment of the three transaction classes in the updated class diagram of Fig. 6.21. During an ATM session, the ATM object will invoke these transaction operations as necessary.

The UML represents operations (which are implemented as methods in Java) by listing the operation name, followed by a comma-separated list of parameters in parentheses, a colon and the return type:

operationName(parameter1, parameter2, ..., parameterN) : return type

Each parameter in the comma-separated parameter list consists of a parameter name, followed by a colon and the parameter type:

parameterName : parameterType

For the moment, we do not list the parameters of our operations—we will identify and model the parameters of some of the operations shortly. For some of the operations,

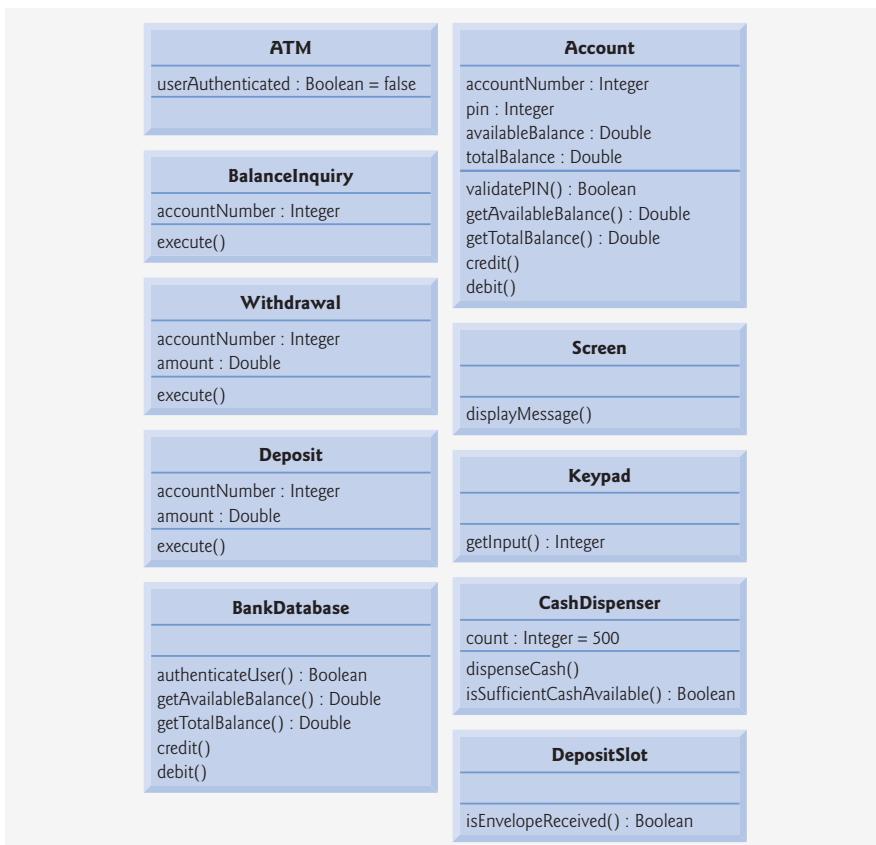

Fig. 6.21 | Classes in the ATM system with attributes and operations.

276 Chapter 6 Methods: A Deeper Look

we do not yet know the return types, so we also omit them from the diagram. These omissions are perfectly normal at this point. As our design and implementation proceed, we will add the remaining return types.

Figure 6.20 lists the phrase “authenticates a user” next to class `BankDatabase`—the database is the object that contains the account information necessary to determine whether the account number and PIN entered by a user match those of an account held at the bank. Therefore, class `BankDatabase` needs an operation that provides an authentication service to the ATM. We place the operation `authenticateUser` in the third compartment of class `BankDatabase` (Fig. 6.21). However, an object of class `Account`, not class `BankDatabase`, stores the account number and PIN that must be accessed to authenticate a user, so class `Account` must provide a service to validate a PIN obtained through user input against a PIN stored in an `Account` object. Therefore, we add a `validatePIN` operation to class `Account`. Note that we specify a return type of `Boolean` for the `authenticateUser` and `validatePIN` operations. Each operation returns a value indicating either that the operation was successful in performing its task (i.e., a return value of `true`) or that it was not (i.e., a return value of `false`).

Figure 6.20 lists several additional verb phrases for class `BankDatabase`: “retrieves an account balance,” “credits a deposit amount to an account” and “debits a withdrawal amount from an account.” Like “authenticates a user,” these remaining phrases refer to services that the database must provide to the ATM, because the database holds all the account data used to authenticate a user and perform ATM transactions. However, objects of class `Account` actually perform the operations to which these phrases refer. Thus, we assign an operation to both class `BankDatabase` and class `Account` to correspond to each of these phrases. Recall from Section 3.10 that, because a bank account contains sensitive information, we do not allow the ATM to access accounts directly. The database acts as an intermediary between the ATM and the account data, thus preventing unauthorized access. As we will see in Section 7.14, class `ATM` invokes the operations of class `BankDatabase`, each of which in turn invokes the operation with the same name in class `Account`.

The phrase “retrieves an account balance” suggests that classes `BankDatabase` and `Account` each need a `getBalance` operation. However, recall that we created two attributes in class `Account` to represent a balance—`availableBalance` and `totalBalance`. A balance inquiry requires access to both balance attributes so that it can display them to the user, but a withdrawal needs to check only the value of `availableBalance`. To allow objects in the system to obtain each balance attribute individually, we add operations `getAvailableBalance` and `getTotalBalance` to the third compartment of classes `BankDatabase` and `Account` (Fig. 6.21). We specify a return type of `Double` for these operations because the balance attributes which they retrieve are of type `Double`.

The phrases “credits a deposit amount to an account” and “debits a withdrawal amount from an account” indicate that classes `BankDatabase` and `Account` must perform operations to update an account during a deposit and withdrawal, respectively. We therefore assign `credit` and `debit` operations to classes `BankDatabase` and `Account`. You may recall that crediting an account (as in a deposit) adds an amount only to the `totalBalance` attribute. Debiting an account (as in a withdrawal), on the other hand, subtracts the amount from both balance attributes. We hide these implementation details inside class `Account`. This is a good example of encapsulation and information hiding.

6.14 Identifying Class Operations **277**

If this were a real ATM system, classes `BankDatabase` and `Account` would also provide a set of operations to allow another banking system to update a user's account balance after either confirming or rejecting all or part of a deposit. Operation `confirmDepositAmount`, for example, would add an amount to the `availableBalance` attribute, thus making deposited funds available for withdrawal. Operation `rejectDepositAmount` would subtract an amount from the `totalBalance` attribute to indicate that a specified amount, which had recently been deposited through the ATM and added to the `totalBalance`, was not found in the deposit envelope. The bank would invoke this operation after determining either that the user failed to include the correct amount of cash or that any checks did not clear (i.e., they "bounced"). While adding these operations would make our system more complete, we do not include them in our class diagrams or our implementation because they are beyond the scope of the case study.

Class `Screen` "displays a message to the user" at various times in an ATM session. All visual output occurs through the screen of the ATM. The requirements document describes many types of messages (e.g., a welcome message, an error message, a thank you message) that the screen displays to the user. The requirements document also indicates that the screen displays prompts and menus to the user. However, a prompt is really just a message describing what the user should input next, and a menu is essentially a type of prompt consisting of a series of messages (i.e., menu options) displayed consecutively. Therefore, rather than assign class `Screen` an individual operation to display each type of message, prompt and menu, we simply create one operation that can display any message specified by a parameter. We place this operation (`displayMessage`) in the third compartment of class `Screen` in our class diagram (Fig. 6.21). Note that we do not worry about the parameter of this operation at this time—we model the parameter later in this section.

From the phrase "receives numeric input from the user" listed by class `Keypad` in Fig. 6.20, we conclude that class `Keypad` should perform a `getInput` operation. Because the ATM's keypad, unlike a computer keyboard, contains only the numbers 0–9, we specify that this operation returns an integer value. Recall from the requirements document that in different situations the user may be required to enter a different type of number (e.g., an account number, a PIN, the number of a menu option, a deposit amount as a number of cents). Class `Keypad` simply obtains a numeric value for a client of the class—it does not determine whether the value meets any specific criteria. Any class that uses this operation must verify that the user entered an appropriate number in a given situation, then respond accordingly (i.e., display an error message via class `Screen`). [Note: When we implement the system, we simulate the ATM's keypad with a computer keyboard, and for simplicity we assume that the user does not enter non-numeric input using keys on the computer keyboard that do not appear on the ATM's keypad.]

Figure 6.20 lists "dispenses cash" for class `CashDispenser`. Therefore, we create operation `dispenseCash` and list it under class `CashDispenser` in Fig. 6.21. Class `CashDispenser` also "indicates whether it contains enough cash to satisfy a withdrawal request." Thus, we include `isSufficientCashAvailable`, an operation that returns a value of UML type `Boolean`, in class `CashDispenser`. Figure 6.20 also lists "receives a deposit envelope" for class `DepositSlot`. The deposit slot must indicate whether it received an envelope, so we place an operation `isEnvelopeReceived`, which returns a `Boolean` value, in the third compartment of class `DepositSlot`. [Note: A real hardware deposit slot would most likely send the ATM a signal to indicate that an envelope was received. We simulate this

278 Chapter 6 Methods: A Deeper Look

behavior, however, with an operation in class `DepositSlot` that class `ATM` can invoke to find out whether the deposit slot received an envelope.]

We do not list any operations for class `ATM` at this time. We are not yet aware of any services that class `ATM` provides to other classes in the system. When we implement the system with Java code, however, operations of this class, and additional operations of the other classes in the system, may emerge.

Identifying and Modeling Operation Parameters

So far, we have not been concerned with the parameters of our operations—we have attempted to gain only a basic understanding of the operations of each class. Let's now take a closer look at some operation parameters. We identify an operation's parameters by examining what data the operation requires to perform its assigned task.

Consider the `authenticateUser` operation of class `BankDatabase`. To authenticate a user, this operation must know the account number and PIN supplied by the user. Thus we specify that operation `authenticateUser` takes integer parameters `userAccountNumber` and `userPIN`, which the operation must compare to the account number and PIN of an `Account` object in the database. We prefix these parameter names with “user” to avoid confusion between the operation's parameter names and the attribute names that belong to class `Account`. We list these parameters in the class diagram in Fig. 6.22 that models only class `BankDatabase`. [Note: It is perfectly normal to model only one class in a class diagram. In this case, we are most concerned with examining the parameters of this one class in particular, so we omit the other classes. In class diagrams later in the case study, in which parameters are no longer the focus of our attention, we omit these parameters to save space. Remember, however, that the operations listed in these diagrams still have parameters.]

Recall that the UML models each parameter in an operation's comma-separated parameter list by listing the parameter name, followed by a colon and the parameter type (in UML notation). Figure 6.22 thus specifies that operation `authenticateUser` takes two parameters—`userAccountNumber` and `userPIN`, both of type `Integer`. When we implement the system in Java, we will represent these parameters with `int` values.

Class `BankDatabase` operations `getAvailableBalance`, `getTotalBalance`, `credit` and `debit` also each require a `userAccountNumber` parameter to identify the account to which the database must apply the operations, so we include these parameters in the class diagram of Fig. 6.22. In addition, operations `credit` and `debit` each require a `Double` parameter `amount` to specify the amount of money to be credited or debited, respectively.

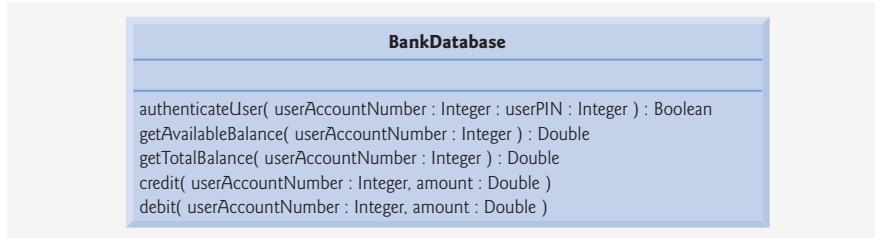

Fig. 6.22 | Class `BankDatabase` with operation parameters.

6.14 Identifying Class Operations **279**

The class diagram in Fig. 6.23 models the parameters of class `Account`'s operations. Operation `validatePIN` requires only a `userPIN` parameter, which contains the user-specified PIN to be compared with the PIN associated with the account. Like their counterparts in class `BankDatabase`, operations `credit` and `debit` in class `Account` each require a `Double` parameter `amount` that indicates the amount of money involved in the operation. Operations `getAvailableBalance` and `getTotalBalance` in class `Account` require no additional data to perform their tasks. Note that class `Account`'s operations do not require an account number parameter to distinguish between Accounts, because these operations can be invoked only on a specific `Account` object.

Figure 6.24 models class `Screen` with a parameter specified for operation `displayMessage`. This operation requires only a `String` parameter `message` that indicates the text to be displayed. Recall that the parameter types listed in our class diagrams are in UML notation, so the `String` type listed in Fig. 6.24 refers to the UML type. When we implement the system in Java, we will in fact use the Java class `String` to represent this parameter.

The class diagram in Fig. 6.25 specifies that operation `dispenseCash` of class `CashDispenser` takes a `Double` parameter `amount` to indicate the amount of cash (in dollars) to be dispensed. Operation `isSufficientCashAvailable` also takes a `Double` parameter `amount` to indicate the amount of cash in question.

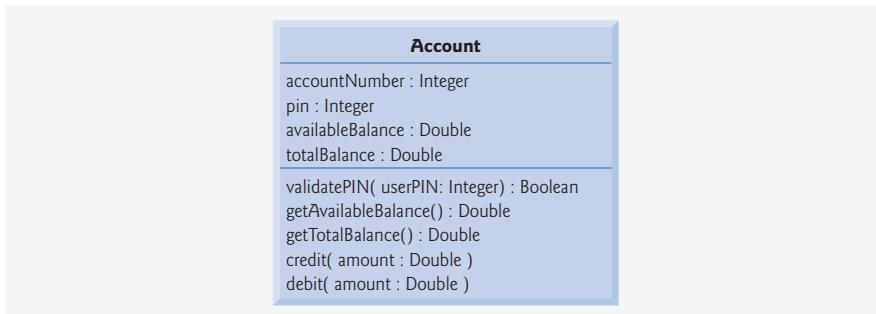

Fig. 6.23 | Class `Account` with operation parameters.

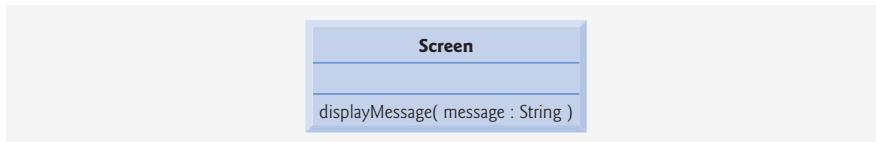

Fig. 6.24 | Class `Screen` with operation parameters.

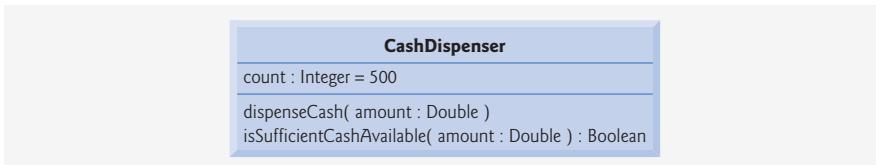

Fig. 6.25 | Class `CashDispenser` with operation parameters.

280 Chapter 6 Methods: A Deeper Look

Note that we do not discuss parameters for operation `execute` of classes `BalanceInquiry`, `Withdrawal` and `Deposit`, operation `getInput` of class `Keypad` and operation `isEnvelopeReceived` of class `DepositSlot`. At this point in our design process, we cannot determine whether these operations require additional data to perform their tasks, so we leave their parameter lists empty. As we progress through the case study, we may decide to add parameters to these operations.

In this section, we have determined many of the operations performed by the classes in the ATM system. We have identified the parameters and return types of some of the operations. As we continue our design process, the number of operations belonging to each class may vary—we might find that new operations are needed or that some current operations are unnecessary—and we might determine that some of our class operations need additional parameters and different return types.

Software Engineering Case Study Self-Review Exercises

6.1 Which of the following is not a behavior?

- a) reading data from a file
- b) printing output
- c) text output
- d) obtaining input from the user

6.2 If you were to add to the ATM system an operation that returns the `amount` attribute of class `Withdrawal`, how and where would you specify this operation in the class diagram of Fig. 6.21?

6.3 Describe the meaning of the following operation listing that might appear in a class diagram for an object-oriented design of a calculator:

```
add( x : Integer, y : Integer ) : Integer
```

Answers to Software Engineering Case Study Self-Review Exercises

6.1 c.

6.2 To specify an operation that retrieves the `amount` attribute of class `Withdrawal`, the following operation listing would be placed in the operation (i.e., third) compartment of class `Withdrawal`:

```
getAmount( ) : Double
```

6.3 This operation listing indicates an operation named `add` that takes integers `x` and `y` as parameters and returns an integer value.

6.15 Wrap-Up

In this chapter, you learned more about the details of method declarations. You also learned the difference between non-static and static methods and how to call static methods by preceding the method name with the name of the class in which it appears and the dot (.) separator. You learned how to use operator + to perform string concatenations. You learned how to declare named constants using both enum types and public final static variables. You saw how to use class Random to generate sets of random numbers that can be used for simulations. You also learned about the scope of fields and local variables in a class. Finally, you learned that multiple methods in one class can be overloaded by providing methods with the same name and different signatures. Such methods can be used to perform the same or similar tasks using different types or different numbers of parameters.

6.15 Wrap-Up **281**

In Chapter 7, you will learn how to maintain lists and tables of data in arrays. You will see a more elegant implementation of the application that rolls a die 6000 times and two enhanced versions of our GradeBook case study that you studied in Chapters 3–5. You will also learn how to access an application’s command-line arguments that are passed to method `main` when an application begins execution.

Summary

Section 6.1 Introduction

- Experience has shown that the best way to develop and maintain a large program is to construct it from small, simple pieces, or modules. This technique is called divide and conquer.

Section 6.2 Program Modules in Java

- There are three kinds of modules in Java—methods, classes and packages. Methods are declared within classes. Classes are typically grouped into packages so that they can be imported into programs and reused.
- Methods allow you to modularize a program by separating its tasks into self-contained units. The statements in a method are written only once and hidden from other methods.
- Using existing methods as building blocks to create new programs is a form of software reusability that allows you to avoid repeating code within a program.

Section 6.3 static Methods, static Fields and Class Math

- A method call specifies the name of the method to call and provides the arguments that the called method requires to perform its task. When the method call completes, the method returns either a result or simply control to its caller.
- A class may contain `static` methods to perform common tasks that do not require an object of the class. Any data a `static` method might require to perform its tasks can be sent to the method as arguments in a method call. A `static` method is called by specifying the name of the class in which the method is declared followed by a dot (.) and the method name, as in

ClassName.methodName(arguments)

- Method arguments may be constants, variables or expressions.
- Class `Math` provides `static` methods for performing common mathematical calculations. Class `Math` declares two fields that represent commonly used mathematical constants: `Math.PI` and `Math.E`. The constant `Math.PI` (3.14159265358979323846) is the ratio of a circle’s circumference to its diameter. The constant `Math.E` (2.7182818284590452354) is the base value for natural logarithms (calculated with `static` `Math` method `log`).
- `Math.PI` and `Math.E` are declared with the modifiers `public`, `final` and `static`. Making them `public` allows other programmers to use these fields in their own classes. Any field declared with keyword `final` is constant—its value cannot be changed after the field is initialized. Both `PI` and `E` are declared `final` because their values never change. Making these fields `static` allows them to be accessed via the class name `Math` and a dot (.) separator, just like class `Math`’s methods.
- When objects of a class containing `static` fields (class variables) are created, all the objects of that class share one copy of the class’s `static` fields. Together the class variables and instance variables represent the fields of a class. You will learn more about `static` fields in Section 8.11.
- When you execute the Java Virtual Machine (JVM) with the `java` command, the JVM attempts to invoke the `main` method of the class you specify. The JVM loads the class specified by `Class-`

282 Chapter 6 Methods: A Deeper Look

Name and uses that class name to invoke method `main`. You can specify an optional list of `String`s (separated by spaces) as command-line arguments that the JVM will pass to your application.

- You can place a `main` method in every class you declare—only the `main` method in the class you use to execute the application will be called. Some programmers take advantage of this to build a small test program into each class they declare.

Section 6.4 Declaring Methods with Multiple Parameters

- When a method is called, the program makes a copy of the method's argument values and assigns them to the method's corresponding parameters, which are created and initialized when the method is called. When program control returns to the point in the program where the method was called, the method's parameters are removed from memory.
- A method can return at most one value, but the returned value could be a reference to an object that contains many values.
- Variables should be declared as fields of a class only if they are required for use in more than one method of the class or if the program should save their values between calls to the class's methods.

Section 6.5 Notes on Declaring and Using Methods

- There are three ways to call a method—using a method name by itself to call another method of the same class; using a variable that contains a reference to an object, followed by a dot (.) and the method name to call a method of the referenced object; and using the class name and a dot (.) to call a `static` method of a class.
- There are three ways to return control to a statement that calls a method. If the method does not return a result, control returns when the program flow reaches the method-ending right brace or when the statement

```
return;
```

is executed. If the method returns a result, the statement

```
return expression;
```

evaluates the `expression`, then immediately returns the resulting value to the caller.

- When a method has more than one parameter, the parameters are specified as a comma-separated list. There must be one argument in the method call for each parameter in the method declaration. Also, each argument must be consistent with the type of the corresponding parameter. If a method does not accept arguments, the parameter list is empty.
- `String`s can be concatenated using operator `+`, which places the characters of the right operand at the end of those in the left operand.
- Every primitive value and object in Java has a `String` representation. When an object is concatenated with a `String`, the object is converted to a `String`, then the two `String`s are concatenated.
- For primitive values used in string concatenation, the JVM handles the conversion of the primitive values to `String`s. If a `boolean` is concatenated with a `String`, the word "true" or the word "false" is used to represent the `boolean` value. If there are any trailing zeros in a floating-point value, these will be discarded when the number is concatenated to a `String`.
- All objects in Java have a special method named `toString` that returns a `String` representation of the object's contents. When an object is concatenated with a `String`, the JVM implicitly calls the object's `toString` method to obtain the string representation of the object.
- When a large `String` literal is typed into a program's source code, programmers sometimes break that `String` into several smaller `String`s and place them on multiple lines of code for readability, then reassemble the `String`s using concatenation.

Section 6.6 Method-Call Stack and Activation Records

- Stacks are known as last-in, first-out (LIFO) data structures—the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.
- A called method must know how to return to its caller, so the return address of the calling method is pushed onto the program execution stack when the method is called. If a series of method calls occurs, the successive return addresses are pushed onto the stack in last-in, first-out order so that the last method to execute will be the first to return to its caller.
- The program execution stack contains the memory for the local variables used in each invocation of a method during a program's execution. This data is known as the activation record or stack frame of the method call. When a method call is made, the activation record for that method call is pushed onto the program execution stack. When the method returns to its caller, the activation record for this method call is popped off the stack and those local variables are no longer known to the program. If a local variable holding a reference to an object is the only variable in the program with a reference to that object, when the activation record containing that local variable is popped off the stack, the object can no longer be accessed by the program and will eventually be deleted from memory by the JVM during “garbage collection.”
- The amount of memory in a computer is finite, so only a certain amount of memory can be used to store activation records on the program execution stack. If there are more method calls than can have their activation records stored on the program execution stack, an error known as a stack overflow occurs. The application will compile correctly, but its execution causes a stack overflow.

Section 6.7 Argument Promotion and Casting

- An important feature of method calls is argument promotion—converting an argument's value to the type that the method expects to receive in its corresponding parameter.
- A set of promotion rules apply to expressions containing values of two or more primitive types and to primitive-type values passed as arguments to methods. Each value is promoted to the “highest” type in the expression. In cases where information may be lost due to conversion, the Java compiler requires you to use a cast operator to explicitly force the conversion to occur.

Section 6.9 Case Study: Random-Number Generation

- Objects of class `Random` (package `java.util`) can produce random `int`, `long`, `float` or `double` values. Math method `random` can produce `double` values in the range $0.0 \leq x < 1.0$, where x is the value returned by method `random`.
- `Random` method `nextInt` generates a random `int` value in the range $-2,147,483,648$ to $+2,147,483,647$. The values returned by `nextInt` are actually pseudorandom numbers—a sequence of values produced by a complex mathematical calculation. That calculation uses the current time of day to seed the random-number generator such that each execution of a program yields a different sequence of random values.
- Class `Random` provides another version of method `nextInt` that receives an `int` argument and returns a value from 0 up to, but not including, the argument's value.
- Random numbers in a range can be generated with

```
number = shiftingValue + randomNumbers.nextInt( scalingFactor );
```

where `shiftingValue` specifies the first number in the desired range of consecutive integers, and `scalingFactor` specifies how many numbers are in the range.

- Random numbers can be chosen from nonconsecutive integer ranges, as in

```
number = shiftingValue +
differenceBetweenValues * randomNumbers.nextInt( scalingFactor );
```

284 Chapter 6 Methods: A Deeper Look

where *shiftingValue* specifies the first number in the range of values, *differenceBetweenValues* represents the difference between consecutive numbers in the sequence and *scalingFactor* specifies how many numbers are in the range.

- For debugging, it is sometimes useful to repeat the same sequence of pseudorandom numbers during each program execution to prove that your application is working for a specific sequence of random numbers before testing the program with different sequences of random numbers. When repeatability is important, you can create a `Random` object by passing a `long` integer value to the constructor. If the same seed is used every time the program executes, the `Random` object produces the same sequence of random numbers. You can also set a `Random` object's seed at any time by calling the object's `setSeed` method.

Section 6.10 Case Study: A Game of Chance (Introducing Enumerations)

- An enumeration is introduced by the keyword `enum` and a type name. As with any class, braces (`{` and `}`) delimit the body of an `enum` declaration. Inside the braces is a comma-separated list of enumeration constants, each representing a unique value. The identifiers in an `enum` must be unique. Variables of an `enum` type can be assigned only constants of that `enum` type.
- Constants can also be declared as `public final static` variables. Such constants are declared with all capital letters by convention to make them stand out in the program.

Section 6.11 Scope of Declarations

- Scope is the portion of the program in which an entity, such as a variable or a method, can be referred to by its name. Such an entity is said to be “in scope” for that portion of the program.
- The scope of a parameter declaration is the body of the method in which the declaration appears.
- The scope of a local-variable declaration is from the point at which the declaration appears to the end of that block.
- The scope of a label in a labeled `break` or `continue` statement is the labeled statement’s body.
- The scope of a local-variable declaration that appears in the initialization section of a `for` statement’s header is the body of the `for` statement and the other expressions in the header.
- The scope of a method or field of a class is the entire body of the class. This enables a class’s methods to use simple names to call the class’s other methods and to access the class’s fields.
- Any block may contain variable declarations. If a local variable or parameter in a method has the same name as a field, the field is shadowed until the block terminates execution.

Section 6.12 Method Overloading

- Java allows several methods of the same name to be declared in a class, as long as the methods have different sets of parameters (determined by the number, order and types of the parameters). This technique is called method overloading.
- Overloaded methods are distinguished by their signatures—combinations of the methods’ names and the number, types and order of their parameters. Methods cannot be distinguished by return type.

Terminology

activation record	<code>Color</code> class
application programming interface (API)	comma-separated list of parameters
argument promotion	command-line argument
block	divide-and-conquer approach
class method	element of chance
class variable	<code>enum</code> keyword

Self-Review Exercises 285

enumeration	primitive-type promotions
enumeration constant	procedure
<code>fillOval</code> method of class <code>Graphics</code>	program execution stack
<code>fillRect</code> method of class <code>Graphics</code>	programmer-declared method
<code>final</code> keyword	promotion rules
formal parameter	pseudorandom number
function	pushing (onto a stack)
"hidden" fields	<code>Random</code> class
hide implementation details	<code>random</code> of class <code>Math</code>
hierarchical boss-method/worker-method relationship	random numbers
invoke a method	<code>return</code> keyword
Java API documentation	reusable software components
Java Application Programming Interface (API)	RGB values
last-in, first-out (LIFO) data structure	scaling factor (random numbers)
local variable	scope of a declaration
method call	seed value (random numbers)
method-call stack	<code>setColor</code> method of class <code>Graphics</code>
method declaration	<code>setSeed</code> method of class <code>Random</code>
method overloading	shadow a field
modularizing a program with methods	shift a range (random numbers)
module	shifting value (random numbers)
<code>nextInt</code> method of class <code>Random</code>	signature of a method
overload a method	simulation
package	software reuse
parameter	stack
parameter list	stack frame
popping (from a stack)	stack overflow
	string concatenation

Self-Review Exercises

6.1 Fill in the blanks in each of the following statements:

- a) A method is invoked with a(n) _____.
- b) A variable known only within the method in which it is declared is called a(n) _____.
- c) The _____ statement in a called method can be used to pass the value of an expression back to the calling method.
- d) The keyword _____ indicates that a method does not return a value.
- e) Data can be added or removed only from the _____ of a stack.
- f) Stacks are known as _____ data structures—the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.
- g) The three ways to return control from a called method to a caller are _____, _____ and _____.
- h) An object of class _____ produces random numbers.
- i) The program execution stack contains the memory for local variables on each invocation of a method during a program's execution. This data, stored as a portion of the program execution stack, is known as the _____ or _____ of the method call.
- j) If there are more method calls than can be stored on the program execution stack, an error known as a(n) _____ occurs.
- k) The _____ of a declaration is the portion of a program that can refer to the entity in the declaration by name.

286 Chapter 6 Methods: A Deeper Look

- l) In Java, it is possible to have several methods with the same name that each operate on different types or numbers of arguments. This feature is called method _____.
- m) The program execution stack is also referred to as the _____ stack.
- 6.2** For the class `Craps` in Fig. 6.9, state the scope of each of the following entities:
- the variable `randomNumbers`.
 - the variable `die1`.
 - the method `rollDice`.
 - the method `play`.
 - the variable `sumOfDice`.
- 6.3** Write an application that tests whether the examples of the `Math` class method calls shown in Fig. 6.2 actually produce the indicated results.
- 6.4** Give the method header for each of the following methods:
- Method `hypotenuse`, which takes two double-precision, floating-point arguments `side1` and `side2` and returns a double-precision, floating-point result.
 - Method `smallest`, which takes three integers `x`, `y` and `z` and returns an integer.
 - Method `instructions`, which does not take any arguments and does not return a value.
[Note: Such methods are commonly used to display instructions to a user.]
 - Method `intToFloat`, which takes an integer argument `number` and returns a floating-point result.
- 6.5** Find the error in each of the following program segments. Explain how to correct the error.
- ```
int g()
{
 System.out.println("Inside method g");
 int h()
 {
 System.out.println("Inside method h");
 }
}
```
  - ```
int sum( int x, int y )
{
    int result;
    result = x + y;
}
```
 - ```
void f(float a)
{
 float a;
 System.out.println(a);
}
```
  - ```
void product()
{
    int a = 6, b = 5, c = 4, result;
    result = a * b * c;
    System.out.printf( "Result is %d\n", result );
    return result;
}
```
- 6.6** Write a complete Java application to prompt the user for the `double` radius of a sphere, and call method `sphereVolume` to calculate and display the volume of the sphere. Use the following statement to calculate the volume:

```
double volume = ( 4.0 / 3.0 ) * Math.PI * Math.pow( radius, 3 )
```

Answers to Self-Review Exercises 287**Answers to Self-Review Exercises**

6.1 a) method call. b) local variable. c) `return`. d) `void`. e) top. f) last-in, first-out (LIFO).
 g) `return`; or `return expression`; or encountering the closing right brace of a method. h) `Random`.
 i) activation record, stack frame. j) stack overflow. k) scope. l) method overloading. m) method call.

6.2 a) class body. b) block that defines method `rollDice`'s body. c) class body. d) class body.
 e) block that defines method `play`'s body.

6.3 The following solution demonstrates the `Math` class methods in Fig. 6.2:

```

1 // Exercise 6.3: MathTest.java
2 // Testing the Math class methods.
3
4 public class MathTest
5 {
6     public static void main( String args[] )
7     {
8         System.out.printf( "Math.abs( 23.7 ) = %f\n", Math.abs( 23.7 ) );
9         System.out.printf( "Math.abs( 0.0 ) = %f\n", Math.abs( 0.0 ) );
10        System.out.printf( "Math.abs( -23.7 ) = %f\n", Math.abs( -23.7 ) );
11        System.out.printf( "Math.ceil( 9.2 ) = %f\n", Math.ceil( 9.2 ) );
12        System.out.printf( "Math.ceil( -9.8 ) = %f\n", Math.ceil( -9.8 ) );
13        System.out.printf( "Math.cos( 0.0 ) = %f\n", Math.cos( 0.0 ) );
14        System.out.printf( "Math.exp( 1.0 ) = %f\n", Math.exp( 1.0 ) );
15        System.out.printf( "Math.exp( 2.0 ) = %f\n", Math.exp( 2.0 ) );
16        System.out.printf( "Math.floor( 9.2 ) = %f\n", Math.floor( 9.2 ) );
17        System.out.printf( "Math.floor( -9.8 ) = %f\n",
18                           Math.floor( -9.8 ) );
19        System.out.printf( "Math.log( Math.E ) = %f\n",
20                           Math.log( Math.E ) );
21        System.out.printf( "Math.log( Math.E * Math.E ) = %f\n",
22                           Math.log( Math.E * Math.E ) );
23        System.out.printf( "Math.max( 2.3, 12.7 ) = %f\n",
24                           Math.max( 2.3, 12.7 ) );
25        System.out.printf( "Math.max( -2.3, -12.7 ) = %f\n",
26                           Math.max( -2.3, -12.7 ) );
27        System.out.printf( "Math.min( 2.3, 12.7 ) = %f\n",
28                           Math.min( 2.3, 12.7 ) );
29        System.out.printf( "Math.min( -2.3, -12.7 ) = %f\n",
30                           Math.min( -2.3, -12.7 ) );
31        System.out.printf( "Math.pow( 2.0, 7.0 ) = %f\n",
32                           Math.pow( 2.0, 7.0 ) );
33        System.out.printf( "Math.pow( 9.0, 0.5 ) = %f\n",
34                           Math.pow( 9.0, 0.5 ) );
35        System.out.printf( "Math.sin( 0.0 ) = %f\n", Math.sin( 0.0 ) );
36        System.out.printf( "Math.sqrt( 900.0 ) = %f\n",
37                           Math.sqrt( 900.0 ) );
38        System.out.printf( "Math.sqrt( 9.0 ) = %f\n", Math.sqrt( 9.0 ) );
39        System.out.printf( "Math.tan( 0.0 ) = %f\n", Math.tan( 0.0 ) );
40    } // end main
41 } // end class MathTest

```

288 Chapter 6 Methods: A Deeper Look

```

Math.abs( 23.7 ) = 23.700000
Math.abs( 0.0 ) = 0.000000
Math.abs( -23.7 ) = 23.700000
Math.ceil( 9.2 ) = 10.000000
Math.ceil( -9.8 ) = -9.000000

Math.tan( 0.0 ) = 0.000000

```

- 6.4** a) `double hypotenuse(double side1, double side2)`
 b) `int smallest(int x, int y, int z)`
 c) `void instructions()`
 d) `float intToFloat(int number)`
- 6.5** a) Error: Method `h` is declared within method `g`.
 Correction: Move the declaration of `h` outside the declaration of `g`.
 b) Error: The method is supposed to return an integer, but does not.
 Correction: Delete the variable `result`, and place the statement
`return x + y;`
 in the method, or add the following statement at the end of the method body:
`return result;`
 c) Error: The semicolon after the right parenthesis of the parameter list is incorrect, and
 the parameter `a` should not be redeclared in the method.
 Correction: Delete the semicolon after the right parenthesis of the parameter list, and
 delete the declaration `float a;`
 d) Error: The method returns a value when it is not supposed to.
 Correction: Change the return type from `void` to `int`.
- 6.6** The following solution calculates the volume of a sphere, using the radius entered by the user:

```

1 // Exercise 6.6: Sphere.java
2 // Calculate the volume of a sphere.
3 import java.util.Scanner;
4
5 public class Sphere
6 {
7     // obtain radius from user and display volume of sphere
8     public void determineSphereVolume()
9     {

```

[Exercises](#) **289**

```

10     Scanner input = new Scanner( System.in );
11
12     System.out.print( "Enter radius of sphere: " );
13     double radius = input.nextDouble();
14
15     System.out.printf( "Volume is %f\n", sphereVolume( radius ) );
16 } // end method determineSphereVolume
17
18 // calculate and return sphere volume
19 public double sphereVolume( double radius )
20 {
21     double volume = ( 4.0 / 3.0 ) * Math.PI * Math.pow( radius, 3 );
22     return volume;
23 } // end method sphereVolume
24 } // end class Sphere

1 // Exercise 6.6: SphereTest.java
2 // Calculate the volume of a sphere.
3
4 public class SphereTest
5 {
6     // application starting point
7     public static void main( String args[] )
8     {
9         Sphere mySphere = new Sphere();
10        mySphere.determineSphereVolume();
11    } // end main
12 } // end class SphereTest

```

Enter radius of sphere: 4
 Volume is 268.082573

Exercises

- 6.7** What is the value of *x* after each of the following statements is executed?

- a) *x* = Math.abs(7.5);
- b) *x* = Math.floor(7.5);
- c) *x* = Math.abs(0.0);
- d) *x* = Math.ceil(0.0);
- e) *x* = Math.abs(-6.4);
- f) *x* = Math.ceil(-6.4);
- g) *x* = Math.ceil(-Math.abs(-8 + Math.floor(-5.5)));

- 6.8** A parking garage charges a \$2.00 minimum fee to park for up to three hours. The garage charges an additional \$0.50 per hour for each hour *or part thereof* in excess of three hours. The maximum charge for any given 24-hour period is \$10.00. Assume that no car parks for longer than 24 hours at a time. Write an application that calculates and displays the parking charges for each customer who parked in the garage yesterday. You should enter the hours parked for each customer. The program should display the charge for the current customer and should calculate and display the running total of yesterday's receipts. The program should use the method calculateCharges to determine the charge for each customer.

290 Chapter 6 Methods: A Deeper Look

- 6.9** An application of method `Math.floor` is rounding a value to the nearest integer. The statement

```
y = Math.floor( x + 0.5 );
```

will round the number `x` to the nearest integer and assign the result to `y`. Write an application that reads `double` values and uses the preceding statement to round each of the numbers to the nearest integer. For each number processed, display both the original number and the rounded number.

- 6.10** `Math.floor` may be used to round a number to a specific decimal place. The statement

```
y = Math.floor( x * 10 + 0.5 ) / 10;
```

rounds `x` to the tenths position (i.e., the first position to the right of the decimal point). The statement

```
y = Math.floor( x * 100 + 0.5 ) / 100;
```

rounds `x` to the hundredths position (i.e., the second position to the right of the decimal point). Write an application that defines four methods for rounding a number `x` in various ways:

- `roundToInteger(number)`
- `roundToTenths(number)`
- `roundToHundreds(number)`
- `roundToThousands(number)`

For each value read, your program should display the original value, the number rounded to the nearest integer, the number rounded to the nearest tenth, the number rounded to the nearest hundredth and the number rounded to the nearest thousandth.

- 6.11** Answer each of the following questions:

- What does it mean to choose numbers “at random?”
- Why is the `nextInt` method of class `Random` useful for simulating games of chance?
- Why is it often necessary to scale or shift the values produced by a `Random` object?
- Why is computerized simulation of real-world situations a useful technique?

- 6.12** Write statements that assign random integers to the variable `n` in the following ranges:

- $1 \leq n \leq 2$.
- $1 \leq n \leq 100$.
- $0 \leq n \leq 9$.
- $1000 \leq n \leq 1112$.
- $-1 \leq n \leq 1$.
- $-3 \leq n \leq 11$.

- 6.13** For each of the following sets of integers, write a single statement that will display a number at random from the set:

- 2, 4, 6, 8, 10.
- 3, 5, 7, 9, 11.
- 6, 10, 14, 18, 22.

- 6.14** Write a method `integerPower(base, exponent)` that returns the value of

base exponent

For example, `integerPower(3, 4)` calculates 3^4 (or $3 * 3 * 3 * 3$). Assume that `exponent` is a positive, nonzero integer and that `base` is an integer. Method `integerPower` should use a `for` or `while` statement to control the calculation. Do not use any math library methods. Incorporate this method into an application that reads integer values for `base` and `exponent` and performs the calculation with the `integerPower` method.

Exercises **291**

6.15 Define a method `hypotenuse` that calculates the length of the hypotenuse of a right triangle when the lengths of the other two sides are given. (Use the sample data in Fig. 6.26.) The method should take two arguments of type `double` and return the hypotenuse as a `double`. Incorporate this method into an application that reads values for `side1` and `side2` and performs the calculation with the `hypotenuse` method. Determine the length of the hypotenuse for each of the triangles in Fig. 6.26.

6.16 Write a method `multiple` that determines, for a pair of integers, whether the second integer is a multiple of the first. The method should take two integer arguments and return `true` if the second is a multiple of the first and `false` otherwise. [Hint: Use the remainder operator.] Incorporate this method into an application that inputs a series of pairs of integers (one pair at a time) and determines whether the second value in each pair is a multiple of the first.

6.17 Write a method `isEven` that uses the remainder operator (%) to determine whether an integer is even. The method should take an integer argument and return `true` if the integer is even and `false` otherwise. Incorporate this method into an application that inputs a sequence of integers (one at a time) and determines whether each is even or odd.

6.18 Write a method `squareOfAsterisks` that displays a solid square (the same number of rows and columns) of asterisks whose side is specified in integer parameter `side`. For example, if `side` is 4, the method should display

```
*****
*****
*****
*****
```

Incorporate this method into an application that reads an integer value for `side` from the user and outputs the asterisks with the `squareOfAsterisks` method.

6.19 Modify the method created in Exercise 6.18 to form the square out of whatever character is contained in character parameter `fillCharacter`. Thus, if `side` is 5 and `fillCharacter` is “#”, the method should display

```
#####
#####
#####
#####
#####
```

6.20 Write an application that prompts the user for the radius of a circle and uses a method called `circleArea` to calculate the area of the circle.

6.21 Write program segments that accomplish each of the following tasks:

- Calculate the integer part of the quotient when integer `a` is divided by integer `b`.
- Calculate the integer remainder when integer `a` is divided by integer `b`.

Triangle	Side 1	Side 2
1	3.0	4.0
2	5.0	12.0
3	8.0	15.0

Fig. 6.26 | Values for the sides of triangles in Exercise 6.15.

292 Chapter 6 Methods: A Deeper Look

- c) Use the program pieces developed in parts (a) and (b) to write a method `displayDigits` that receives an integer between 1 and 99999 and displays it as a sequence of digits, separating each pair of digits by two spaces. For example, the integer 4562 should appear as

```
4 5 6 2
```

- d) Incorporate the method developed in part (c) into an application that inputs an integer and calls `displayDigits` by passing the method the integer entered. Display the results.

6.22 Implement the following integer methods:

- a) Method `celsius` returns the Celsius equivalent of a Fahrenheit temperature, using the calculation

```
celsius = 5.0 / 9.0 * ( fahrenheit - 32 );
```

- b) Method `fahrenheit` returns the Fahrenheit equivalent of a Celsius temperature, using the calculation

```
fahrenheit = 9.0 / 5.0 * celsius + 32;
```

- c) Use the methods from parts (a) and (b) to write an application that enables the user either to enter a Fahrenheit temperature and display the Celsius equivalent or to enter a Celsius temperature and display the Fahrenheit equivalent.

6.23 Write a method `minimum3` that returns the smallest of three floating-point numbers. Use the `Math.min` method to implement `minimum3`. Incorporate the method into an application that reads three values from the user, determines the smallest value and displays the result.

6.24 An integer number is said to be a *perfect number* if its factors, including 1 (but not the number itself), sum to the number. For example, 6 is a perfect number, because $6 = 1 + 2 + 3$. Write a method `perfect` that determines whether parameter `number` is a perfect number. Use this method in an application that determines and displays all the perfect numbers between 1 and 1000. Display the factors of each perfect number to confirm that the number is indeed perfect. Challenge the computing power of your computer by testing numbers much larger than 1000. Display the results.

6.25 An integer is said to be *prime* if it is divisible by only 1 and itself. For example, 2, 3, 5 and 7 are prime, but 4, 6, 8 and 9 are not.

- Write a method that determines whether a number is prime.
- Use this method in an application that determines and displays all the prime numbers less than 10,000. How many numbers up to 10,000 do you have to test to ensure that you have found all the primes?
- Initially, you might think that $n/2$ is the upper limit for which you must test to see whether a number is prime, but you need only go as high as the square root of n . Why? Rewrite the program, and run it both ways.

6.26 Write a method that takes an integer value and returns the number with its digits reversed. For example, given the number 7631, the method should return 1367. Incorporate the method into an application that reads a value from the user and displays the result.

6.27 The *greatest common divisor (GCD)* of two integers is the largest integer that evenly divides each of the two numbers. Write a method `gcd` that returns the greatest common divisor of two integers. [Hint: You might want to use Euclid's Algorithm. You can find information about the algorithm at en.wikipedia.org/wiki/Euclidean_algorithm.] Incorporate the method into an application that reads two values from the user and displays the result.

6.28 Write a method `qualityPoints` that inputs a student's average and returns 4 if the student's average is 90–100, 3 if the average is 80–89, 2 if the average is 70–79, 1 if the average is 60–69 and 0 if the average is lower than 60. Incorporate the method into an application that reads a value from the user and displays the result.

[Exercises](#) **293**

6.29 Write an application that simulates coin tossing. Let the program toss a coin each time the user chooses the “Toss Coin” menu option. Count the number of times each side of the coin appears. Display the results. The program should call a separate method `flip` that takes no arguments and returns `false` for tails and `true` for heads. [Note: If the program realistically simulates coin tossing, each side of the coin should appear approximately half the time.]

6.30 Computers are playing an increasing role in education. Write a program that will help an elementary school student learn multiplication. Use a `Random` object to produce two positive one-digit integers. The program should then prompt the user with a question, such as

How much is 6 times 7?

The student then inputs the answer. Next, the program checks the student’s answer. If it is correct, display the message “Very good!” and ask another multiplication question. If the answer is wrong, display the message “No. Please try again.” and let the student try the same question repeatedly until the student finally gets it right. A separate method should be used to generate each new question. This method should be called once when the application begins execution and each time the user answers the question correctly.

6.31 The use of computers in education is referred to as *computer-assisted instruction (CAI)*. One problem that develops in CAI environments is student fatigue. This problem can be eliminated by varying the computer’s responses to hold the student’s attention. Modify the program of Exercise 6.30 so that the various comments are displayed for each correct answer and each incorrect answer as follows:

Responses to a correct answer:

Very good!
Excellent!
Nice work!
Keep up the good work!

Responses to an incorrect answer:

No. Please try again.
Wrong. Try once more.
Don’t give up!
No. Keep trying.

Use random-number generation to choose a number from 1 to 4 that will be used to select an appropriate response to each answer. Use a `switch` statement to issue the responses.

6.32 More sophisticated computer-assisted instruction systems monitor the student’s performance over a period of time. The decision to begin a new topic is often based on the student’s success with previous topics. Modify the program of Exercise 6.31 to count the number of correct and incorrect responses typed by the student. After the student types 10 answers, your program should calculate the percentage of correct responses. If the percentage is lower than 75%, display `Please ask your instructor for extra help` and reset the program so another student can try it.

6.33 Write an application that plays “guess the number” as follows: Your program chooses the number to be guessed by selecting a random integer in the range 1 to 1000. The application displays the prompt `Guess a number between 1 and 1000.` The player inputs a first guess. If the player’s guess is incorrect, your program should display `Too high.` `Try again.` or `Too low.` `Try again.` to help the player “zero in” on the correct answer. The program should prompt the user for the next guess. When the user enters the correct answer, display `Congratulations. You guessed the number!`, and allow the user to choose whether to play again. [Note: The guessing technique employed in this problem is similar to a binary search, which is discussed in Chapter 16, Searching and Sorting.]

294 Chapter 6 Methods: A Deeper Look

6.34 Modify the program of Exercise 6.33 to count the number of guesses the player makes. If the number is 10 or fewer, display *Either you know the secret or you got lucky!* If the player guesses the number in 10 tries, display *Aha! You know the secret!* If the player makes more than 10 guesses, display *You should be able to do better!* Why should it take no more than 10 guesses? Well, with each “good guess,” the player should be able to eliminate half of the numbers, then half of the remaining numbers, and so on.

6.35 Exercise 6.30 through Exercise 6.32 developed a computer-assisted instruction program to teach an elementary school student multiplication. Perform the following enhancements:

- a) Modify the program to allow the user to enter a school grade-level capability. A grade level of 1 means that the program should use only single-digit numbers in the problems, a grade level of 2 means that the program should use numbers as large as two digits, and so on.
- b) Modify the program to allow the user to pick the type of arithmetic problems he or she wishes to study. An option of 1 means addition problems only, 2 means subtraction problems only, 3 means multiplication problems only, 4 means division problems only and 5 means a random mixture of problems of all these types.

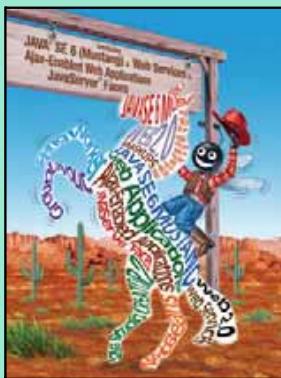

6.36 Write method `distance` to calculate the distance between two points $(x1, y1)$ and $(x2, y2)$. All numbers and return values should be of type `double`. Incorporate this method into an application that enables the user to enter the coordinates of the points.

6.37 Modify the craps program of Fig. 6.9 to allow wagering. Initialize variable `bankBalance` to 1000 dollars. Prompt the player to enter a wager. Check that `wager` is less than or equal to `bankBalance`, and if it is not, have the user reenter wager until a valid wager is entered. After a correct wager is entered, run one game of craps. If the player wins, increase `bankBalance` by `wager` and display the new `bankBalance`. If the player loses, decrease `bankBalance` by `wager`, display the new `bankBalance`, check whether `bankBalance` has become zero and, if so, display the message *“Sorry. You busted!”* As the game progresses, display various messages to create some “chatter,” such as *“Oh, you’re going for broke, huh?”* or *“Aw c’m’on, take a chance!”* or *“You’re up big. Now’s the time to cash in your chips!”*. Implement the “chatter” as a separate method that randomly chooses the string to display.

6.38 Write an application that displays a table of the binary, octal, and hexadecimal equivalents of the decimal numbers in the range 1 through 256. If you are not familiar with these number systems, read Appendix E first.

7

Arrays

*Now go, write it
before them in a table,
and note it in a book.*

—Isaiah 30:8

*To go beyond is as
wrong as to fall short.*

—Confucius

*Begin at the beginning. . .
and go on till you come to
the end: then stop.*

—Lewis Carroll

OBJECTIVES

In this chapter you will learn:

- What arrays are.
- To use arrays to store data in and retrieve data from lists and tables of values.
- To declare arrays, initialize arrays and refer to individual elements of arrays.
- To use the enhanced `for` statement to iterate through arrays.
- To pass arrays to methods.
- To declare and manipulate multidimensional arrays.
- To write methods that use variable-length argument lists.
- To read command-line arguments into a program.

[Special Section: Building Your Own Computer](#)

7.1 Introduction

This chapter introduces [data structures](#)—collections of related data items. [Arrays](#) are data structures consisting of related data items of the same type. Arrays are fixed-length entities—they remain the same length once they are created, although an array variable may be reassigned such that it refers to a new array of a different length. We study data structures in depth in Chapters 17–19.

After discussing how arrays are declared, created and initialized, we present a series of practical examples that demonstrate several common array manipulations. We also present a case study that examines how arrays can help simulate the shuffling and dealing of playing cards for use in an application that implements a card game. The chapter then introduces Java’s enhanced `for` statement, which allows a program to access the data in an array more easily than does the counter-controlled `for` statement presented in Section 5.3. Two sections of the chapter enhance the case study of class `GradeBook` in Chapters 3–5. In particular, we use arrays to enable the class to maintain a set of grades in memory and analyze student grades from multiple exams in a semester—two capabilities that were absent from previous versions of the class. These and other chapter examples demonstrate the ways in which arrays allow programmers to organize and manipulate data.

7.2 Arrays

An array is a group of variables (called [elements](#) or [components](#)) containing values that all have the same type. Recall that types are divided into two categories—primitive types and reference types. Arrays are objects, so they are considered reference types. As you will soon see, what we typically think of as an array is actually a reference to an array object in mem-

7.2 Arrays **297**

ory. The elements of an array can be either primitive types or reference types (including arrays, as we will see in Section 7.9). To refer to a particular element in an array, we specify the name of the reference to the array and the position number of the element in the array. The position number of the element is called the element's **index** or **subscript**.

Figure 7.1 shows a logical representation of an integer array called `c`. This array contains 12 elements. A program refers to any one of these elements with an **array-access expression** that includes the name of the array followed by the index of the particular element in **square brackets** (`[]`). The first element in every array has **index zero** and is sometimes called the **zeroth element**. Thus, the elements of array `c` are `c[0]`, `c[1]`, `c[2]` and so on. The highest index in array `c` is 11, which is 1 less than 12—the number of elements in the array. Array names follow the same conventions as other variable names.

An index must be a nonnegative integer. A program can use an expression as an index. For example, if we assume that variable `a` is 5 and variable `b` is 6, then the statement

```
c[ a + b ] += 2;
```

adds 2 to array element `c[11]`. Note that an indexed array name is an array-access expression. Such expressions can be used on the left side of an assignment to place a new value into an array element.

**Common Programming Error 7.1**

Using a value of type long as an array index results in a compilation error. An index must be an int value or a value of a type that can be promoted to int—namely, byte, short or char, but not long.

Let us examine array `c` in Fig. 7.1 more closely. The **name** of the array is `c`. Every array object knows its own length and maintains this information in a `length` field. The expression `c.length` accesses array `c`'s `length` field to determine the length of the array. Note that, even though the `length` member of an array is `public`, it cannot be changed because

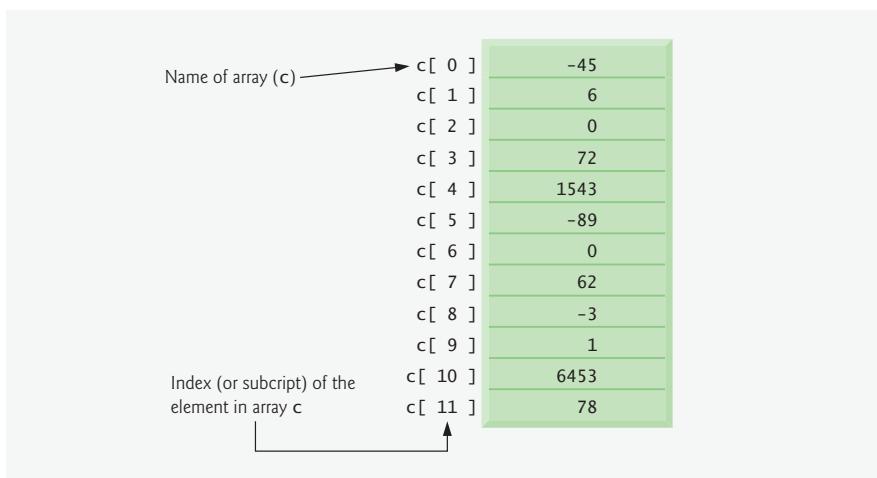

Fig. 7.1 | A 12-element array.

298 Chapter 7 Arrays

it is a `final` variable. This array's 12 elements are referred to as `c[0]`, `c[1]`, `c[2]`, ..., `c[11]`. The value of `c[0]` is -45, the value of `c[1]` is 6, the value of `c[2]` is 0, the value of `c[7]` is 62 and the value of `c[11]` is 78. To calculate the sum of the values contained in the first three elements of array `c` and store the result in variable `sum`, we would write

```
sum = c[ 0 ] + c[ 1 ] + c[ 2 ];
```

To divide the value of `c[6]` by 2 and assign the result to the variable `x`, we would write

```
x = c[ 6 ] / 2;
```

7.3 Declaring and Creating Arrays

Array objects occupy space in memory. Like other objects, arrays are created with keyword `new`. To create an array object, the programmer specifies the type of the array elements and the number of elements as part of an [array-creation expression](#) that uses keyword `new`. Such an expression returns a reference that can be stored in an array variable. The following declaration and array-creation expression create an array object containing 12 `int` elements and store the array's reference in variable `c`:

```
int c[] = new int[ 12 ];
```

This expression can be used to create the array shown in Fig. 7.1. This task also can be performed in two steps as follows:

```
int c[];           // declare the array variable
c = new int[ 12 ]; // create the array; assign to array variable
```

In the declaration, the square brackets following the variable name `c` indicate that `c` is a variable that will refer to an array (i.e., the variable will store an array reference). In the assignment statement, the array variable `c` receives the reference to a new array of 12 `int` elements. When an array is created, each element of the array receives a default value—zero for the numeric primitive-type elements, `false` for `boolean` elements and `null` for references (any nonprimitive type). As we will soon see, we can provide specific, nondefault initial element values when we create an array.

Common Programming Error 7.2

In an array declaration, specifying the number of elements in the square brackets of the declaration (e.g., `int c[12];`) is a syntax error.

A program can create several arrays in a single declaration. The following `String` array declaration reserves 100 elements for `b` and 27 elements for `x`:

```
String b[] = new String[ 100 ], x[] = new String[ 27 ];
```

In this case, the class name `String` applies to each variable in the declaration. For readability, we prefer to declare only one variable per declaration, as in:

```
String b[] = new String[ 100 ]; // create array b
String x[] = new String[ 27 ]; // create array x
```

7.4 Examples Using Arrays **299****Good Programming Practice 7.1**

For readability, declare only one variable per declaration. Keep each declaration on a separate line, and include a comment describing the variable being declared.

When an array is declared, the type of the array and the square brackets can be combined at the beginning of the declaration to indicate that all the identifiers in the declaration are array variables. For example, the declaration

```
double[] array1, array2;
```

indicates that `array1` and `array2` are each “array of `double`” variables. The preceding declaration is equivalent to:

```
double array1[];
double array2[];
```

or

```
double[] array1;
double[] array2;
```

The preceding pairs of declarations are equivalent—when only one variable is declared in each declaration, the square brackets can be placed either after the type or after the array variable name.

**Common Programming Error 7.3**

Declaring multiple array variables in a single declaration can lead to subtle errors. Consider the declaration `int[] a, b, c;`. If `a`, `b` and `c` should be declared as array variables, then this declaration is correct—placing square brackets directly following the type indicates that all the identifiers in the declaration are array variables. However, if only `a` is intended to be an array variable, and `b` and `c` are intended to be individual `int` variables, then this declaration is incorrect—the declaration `int a[], b, c;` would achieve the desired result.

A program can declare arrays of any type. Every element of a primitive-type array contains a value of the array’s declared type. Similarly, in an array of a reference type, every element is a reference to an object of the array’s declared type. For example, every element of an `int` array is an `int` value, and every element of a `String` array is a reference to a `String` object.

7.4 Examples Using Arrays

This section presents several examples that demonstrate declaring arrays, creating arrays, initializing arrays and manipulating array elements.

Creating and Initializing an Array

The application of Fig. 7.2 uses keyword `new` to create an array of 10 `int` elements, which are initially zero (the default for `int` variables).

Line 8 declares `array`—a reference capable of referring to an array of `int` elements. Line 10 creates the array object and assigns its reference to variable `array`. Line 12 outputs the column headings. The first column contains the index (0–9) of each array element, and the second column contains the default value (0) of each array element.

300 Chapter 7 Arrays

```

1 // Fig. 7.2: InitArray.java
2 // Creating an array.
3
4 public class InitArray
5 {
6     public static void main( String args[] )
7     {
8         int array[]; // declare array named array
9
10        array = new int[ 10 ]; // create the space for array
11
12        System.out.printf( "%s%8s\n", "Index", "Value" ); // column headings
13
14        // output each array element's value
15        for ( int counter = 0; counter < array.length; counter++ )
16            System.out.printf( "%5d%8d\n", counter, array[ counter ] );
17    } // end main
18 } // end class InitArray

```

Index	Value
0	0
1	0
2	0
3	0
4	0
5	0
6	0
7	0
8	0
9	0

Fig. 7.2 | Initializing the elements of an array to default values of zero.

The `for` statement in lines 15–16 outputs the index number (represented by `counter`) and the value of each array element (represented by `array[counter]`). Note that the loop control variable `counter` is initially 0—index values start at 0, so using zero-based counting allows the loop to access every element of the array. The `for`'s loop-continuation condition uses the expression `array.length` (line 15) to determine the length of the array. In this example, the length of the array is 10, so the loop continues executing as long as the value of control variable `counter` is less than 10. The highest index value of a 10-element array is 9, so using the less-than operator in the loop-continuation condition guarantees that the loop does not attempt to access an element beyond the end of the array (i.e., during the final iteration of the loop, `counter` is 9). We will soon see what Java does when it encounters such an out-of-range index at execution time.

Using an Array Initializer

A program can create an array and initialize its elements with an **array initializer**, which is a comma-separated list of expressions (called an **initializer list**) enclosed in braces (`{` and `}`); the array length is determined by the number of elements in the initializer list. For example, the declaration

```
int n[] = { 10, 20, 30, 40, 50 };
```

7.4 Examples Using Arrays **301**

creates a five-element array with index values 0, 1, 2, 3 and 4. Element `n[0]` is initialized to 10, `n[1]` is initialized to 20, and so on. This declaration does not require `new` to create the array object. When the compiler encounters an array declaration that includes an initializer list, it counts the number of initializers in the list to determine the size of the array, then sets up the appropriate `new` operation “behind the scenes.”

The application in Fig. 7.3 initializes an integer array with 10 values (line 9) and displays the array in tabular format. The code for displaying the array elements (lines 14–15) is identical to that in Fig. 7.2 (lines 15–16).

Calculating the Values to Store in an Array

The application in Fig. 7.4 creates a 10-element array and assigns to each element one of the even integers from 2 to 20 (2, 4, 6, ..., 20). Then the application displays the array in tabular format. The `for` statement at lines 12–13 calculates an array element’s value by multiplying the current value of the control variable counter by 2, then adding 2.

Line 8 uses the modifier `final` to declare the `constant variable` `ARRAY_LENGTH` with the value 10. Constant variables (also known as `final` variables) must be initialized before they are used and cannot be modified thereafter. If you attempt to modify a `final` variable after it is initialized in its declaration (as in line 8), the compiler issues the error message

cannot assign a value to final variable `variableName`

```

4	10
5	12
6	14
7	16
8	18
9	20

Fig. 7.4 | Calculating the values to be placed into the elements of an array.

If an attempt is made to access the value of a `final` variable before it is initialized, the compiler issues the error message

`variable variableName might not have been initialized`

Good Programming Practice 7.2

Constant variables also are called *named constants* or *read-only variables*. Such variables often make programs more readable than programs that use literal values (e.g., 10)—a named constant such as `ARRAY_LENGTH` clearly indicates its purpose, whereas a literal value could have different meanings based on the context in which it is used.

Common Programming Error 7.4

Assigning a value to a constant after the variable has been initialized is a compilation error.

Common Programming Error 7.5

Attempting to use a constant before it is initialized is a compilation error.

Summing the Elements of an Array

Often, the elements of an array represent a series of values to be used in a calculation. For example, if the elements of an array represent exam grades, a professor may wish to total the elements of the array and use that sum to calculate the class average for the exam. The examples using class `GradeBook` later in the chapter, namely Fig. 7.14 and Fig. 7.18, use this technique.

The application in Fig. 7.5 sums the values contained in a 10-element integer array. The program declares, creates and initializes the array at line 8. The `for` statement performs the calculations. [Note: The values supplied as array initializers are often read into a program rather than specified in an initializer list. For example, an application could input the values from a user or from a file on disk (as discussed in Chapter 14, Files and Streams). Reading the data into a program makes the program more reusable, because it can be used with different sets of data.]

Using Bar Charts to Display Array Data Graphically

Many programs present data to users in a graphical manner. For example, numeric values are often displayed as bars in a bar chart. In such a chart, longer bars represent proportionally larger numeric values. One simple way to display numeric data graphically is with a bar chart that shows each numeric value as a bar of asterisks (*).

Professors often like to examine the distribution of grades on an exam. A professor might graph the number of grades in each of several categories to visualize the grade distribution. Suppose the grades on an exam were 87, 68, 94, 100, 83, 78, 85, 91, 76 and 87. Note that there was one grade of 100, two grades in the 90s, four grades in the 80s, two grades in the 70s, one grade in the 60s and no grades below 60. Our next application (Fig. 7.6) stores this grade distribution data in an array of 11 elements, each corresponding to a category of grades. For example, `array[0]` indicates the number of grades in the

```

1 // Fig. 7.5: SumArray.java
2 // Computing the sum of the elements of an array.
3
4 public class SumArray
5 {
6     public static void main( String args[] )
7     {
8         int array[] = { 87, 68, 94, 100, 83, 78, 85, 91, 76, 87 };
9         int total = 0;
10
11        // add each element's value to total
12        for ( int counter = 0; counter < array.length; counter++ )
13            total += array[ counter ];
14
15        System.out.printf( "Total of array elements: %d\n", total );
16    } // end main
17 } // end class SumArray

```

Total of array elements: 849

Fig. 7.5 | Computing the sum of the elements of an array.

4 public class BarChart
5 {
6     public static void main( String args[] )
7     {
8         int array[] = { 0, 0, 0, 0, 0, 0, 1, 2, 4, 2, 1 };
9
10        System.out.println( "Grade distribution:" );
11
12        // for each array element, output a bar of the chart
13        for ( int counter = 0; counter < array.length; counter++ )
14        {
15            // output bar label ( "00-09: ", ..., "90-99: ", "100: " )
16            if ( counter == 10 )
17                System.out.printf( "%5d: ", 100 );
18            else
19                System.out.printf( "%02d-%02d: ",
20                    counter * 10, counter * 10 + 9 );
21
22            // print bar of asterisks
23            for ( int stars = 0; stars < array[ counter ]; stars++ )
24                System.out.print( "*" );
25
26            System.out.println(); // start a new line of output
27        } // end outer for
28    } // end main
29 } // end class BarChart

```

```

Grade distribution:
00-09:
10-19:
20-29:
30-39:

80-89: ****
90-99: **
100: *

```

Fig. 7.6 | Bar chart printing program.

range 0–9, `array[7]` indicates the number of grades in the range 70–79 and `array[10]` indicates the number of 100 grades. The two versions of class `GradeBook` later in the chapter (Fig. 7.14 and Fig. 7.18) contain code that calculates these grade frequencies based on a set of grades. For now, we manually create the array by looking at the set of grades.

The application reads the numbers from the array and graphs the information as a bar chart. The program displays each grade range followed by a bar of asterisks indicating the number of grades in that range. To label each bar, lines 16–20 output a grade range (e.g.,

7.4 Examples Using Arrays **305**

"70-79: ") based on the current value of counter. When counter is 10, line 17 outputs 100 with a field width of 5, followed by a colon and a space, to align the label "100: " with the other bar labels. The nested for statement (lines 23–24) outputs the bars. Note the loop-continuation condition at line 23 (stars < array[counter]). Each time the program reaches the inner for, the loop counts from 0 up to array[counter], thus using a value in array to determine the number of asterisks to display. In this example, array[0]–array[5] contain zeroes because no students received a grade below 60. Thus, the program displays no asterisks next to the first six grade ranges. Note that line 19 uses the format specifier %02d to output the numbers in a grade range. This specifier indicates that an int value should be formatted as a field of two digits. The 0 flag in the format specifier indicates that values with fewer digits than the field width (2) should begin with a leading 0.

Using the Elements of an Array as Counters

Sometimes, programs use counter variables to summarize data, such as the results of a survey. In Fig. 6.8, we used separate counters in our die-rolling program to track the number of occurrences of each side of a die as the program rolled the die 6000 times. An array version of the application in Fig. 6.8 is shown in Fig. 7.7.

```

1 // Fig. 7.7: RollDie.java
2 // Roll a six-sided die 6000 times.
3 import java.util.Random;
4
5 public class RollDie
6 {
7     public static void main( String args[] )
8     {
9         Random randomNumbers = new Random(); // random number generator
10        int frequency[] = new int[ 7 ]; // array of frequency counters
11
12        // roll die 6000 times; use die value as frequency index
13        for ( int roll = 1; roll <= 6000; roll++ )
14            ++frequency[ 1 + randomNumbers.nextInt( 6 ) ];
15
16        System.out.printf( "%s%10s\n", "Face", "Frequency" );
17
18        // output each array element's value
19        for ( int face = 1; face < frequency.length; face++ )
20            System.out.printf( "%4d%10d\n", face, frequency[ face ] );
21    } // end main
22 } // end class RollDie

```

Face	Frequency
1	988
2	963
3	1018
4	1041
5	978
6	1012

Fig. 7.7 | Die-rolling program using arrays instead of switch.

306 Chapter 7 Arrays

Fig. 7.7 uses the array `frequency` (line 10) to count the occurrences of each side of the die. *The single statement in line 14 of this program replaces lines 23–46 of Fig. 6.8.* Line 14 uses the random value to determine which `frequency` element to increment during each iteration of the loop. The calculation in line 14 produces random numbers from 1 to 6, so the array `frequency` must be large enough to store six counters. However, we use a seven-element array in which we ignore `frequency[0]`—it is more logical to have the face value 1 increment `frequency[1]` than `frequency[0]`. Thus, each face value is used as an index for array `frequency` to output the results (lines 19–20).

Using Arrays to Analyze Survey Results

Our next example uses arrays to summarize the results of data collected in a survey:

Forty students were asked to rate the quality of the food in the student cafeteria on a scale of 1 to 10 (where 1 means awful and 10 means excellent). Place the 40 responses in an integer array, and summarize the results of the poll.

This is a typical array-processing application (see Fig. 7.8). We wish to summarize the number of responses of each type (i.e., 1 through 10). The array `responses` (lines 9–11) is a 40-element integer array of the students' responses to the survey. We use an 11-element array `frequency` (line 12) to count the number of occurrences of each response. Each element of the array is used as a counter for one of the survey responses and is initialized to zero by default. As in Fig. 7.7, we ignore `frequency[0]`.

```

1 // Fig. 7.8: StudentPoll.java
2 // Poll analysis program.
3
4 public class StudentPoll
5 {
6     public static void main( String args[] )
7     {
8         // array of survey responses
9         int responses[] = { 1, 2, 6, 4, 8, 5, 9, 7, 8, 10, 1, 6, 3, 8, 6,
10            10, 3, 8, 2, 7, 6, 5, 7, 6, 8, 6, 7, 5, 6, 6, 5, 6, 7, 5, 6,
11            4, 8, 6, 8, 10 };
12         int frequency[] = new int[ 11 ]; // array of frequency counters
13
14         // for each answer, select responses element and use that value
15         // as frequency index to determine element to increment
16         for ( int answer = 0; answer < responses.length; answer++ )
17             ++frequency[ responses[ answer ] ];
18
19         System.out.printf( "%s%10s", "Rating", "Frequency" );
20
21         // output each array element's value
22         for ( int rating = 1; rating < frequency.length; rating++ )
23             System.out.printf( "%d%10d", rating, frequency[ rating ] );
24     } // end main
25 } // end class StudentPoll

```

7	5
8	7
9	1
10	3

Fig. 7.8 | Poll analysis program. (Part 2 of 2.)

The `for` loop at lines 16–17 takes the responses one at a time from array `responses` and increments one of the 10 counters in the `frequency` array (`frequency[1]` to `frequency[10]`). The key statement in the loop is line 17, which increments the appropriate `frequency` counter, depending on the value of `responses[answer]`.

Let's consider several iterations of the `for` loop. When control variable `answer` is 0, the value of `responses[answer]` is the value of `responses[0]` (i.e., 1), so the program interprets `++frequency[responses[answer]]` as

```
++frequency[ 1 ]
```

which increments the value in array element 1. To evaluate the expression, start with the value in the innermost set of square brackets (`answer`). Once you know `answer`'s value (which is the value of the loop control variable in line 16), plug it into the expression and evaluate the next outer set of square brackets (i.e., `responses[answer]`, which is a value selected from the `responses` array in lines 9–11). Then use the resulting value as the index for the `frequency` array to specify which counter to increment.

When `answer` is 1, `responses[answer]` is the value of `responses[1]` (2), so the program interprets `++frequency[responses[answer]]` as

```
++frequency[ 2 ]
```

which increments array element 2.

When `answer` is 2, `responses[answer]` is the value of `responses[2]` (6), so the program interprets `++frequency[responses[answer]]` as

```
++frequency[ 6 ]
```

which increments array element 6, and so on. Regardless of the number of responses processed in the survey, the program requires only an 11-element array (ignoring element zero) to summarize the results, because all the response values are between 1 and 10 and the index values for an 11-element array are 0 through 10.

If the data in the `responses` array had contained invalid values, such as 13, the program would have attempted to add 1 to `frequency[13]`, which is outside the bounds of the array. Java disallows this. When a Java program executes, the JVM checks array indices to ensure that they are valid (i.e., they must be greater than or equal to 0 and less than the length of the array). If a program uses an invalid index, Java generates a so-called exception to indicate that an error occurred in the program at execution time. A control statement

308 Chapter 7 Arrays

can be used to prevent such an “out-of-bounds” error from occurring. For example, the condition in a control statement could determine whether an index is valid before allowing it to be used in an array-access expression.

**Error-Prevention Tip 7.1**

An exception indicates that an error has occurred in a program. A programmer often can write code to recover from an exception and continue program execution, rather than abnormally terminating the program. When a program attempts to access an element outside the array bounds, an `ArrayIndexOutOfBoundsException` occurs. Exception handling is discussed in Chapter 13.

**Error-Prevention Tip 7.2**

When writing code to loop through an array, ensure that the array index is always greater than or equal to 0 and less than the length of the array. The loop-continuation condition should prevent the accessing of elements outside this range.

7.5 Case Study: Card Shuffling and Dealing Simulation

The examples in the chapter thus far have used arrays containing elements of primitive types. Recall from Section 7.2 that the elements of an array can be either primitive types or reference types. This section uses random number generation and an array of reference-type elements, namely objects representing playing cards, to develop a class that simulates card shuffling and dealing. This class can then be used to implement applications that play specific card games. The exercises at the end of the chapter use the classes developed here to build a simple poker application.

We first develop class `Card` (Fig. 7.9), which represents a playing card that has a face (e.g., "Ace", "Deuce", "Three", ..., "Jack", "Queen", "King") and a suit (e.g., "Hearts", "Diamonds", "Clubs", "Spades"). Next, we develop the `DeckOfCards` class (Fig. 7.10), which creates a deck of 52 playing cards in which each element is a `Card` object. We then build a test application (Fig. 7.11) that demonstrates class `DeckOfCards`'s card shuffling and dealing capabilities.

Class Card

Class `Card` (Fig. 7.9) contains two `String` instance variables—`face` and `suit`—that are used to store references to the face name and suit name for a specific `Card`. The constructor for the class (lines 10–14) receives two `Strings` that it uses to initialize `face` and `suit`. Method `toString` (lines 17–20) creates a `String` consisting of the face of the card, the `String` " of " and the suit of the card. Recall from Chapter 6 that the `+` operator can be used to concatenate (i.e., combine) several `Strings` to form one larger `String`. `Card`'s `toString` method can be invoked explicitly to obtain a string representation of a `Card` object (e.g., "Ace of Spades"). The `toString` method of an object is called implicitly when the object is used where a `String` is expected (e.g., when `printf` outputs the object as a `String` using the `%s` format specifier or when the object is concatenated to a `String` using the `+` operator). For this behavior to occur, `toString` must be declared with the header shown in Fig. 7.9.

Class DeckOfCards

Class `DeckOfCards` (Fig. 7.10) declares an instance variable array named `deck` of `Card` objects (line 7). Like primitive-type array declarations, the declaration of an array of objects

7.5 Case Study: Card Shuffling and Dealing Simulation **309**

```

1 // Fig. 7.9: Card.java
2 // Card class represents a playing card.
3
4 public class Card
5 {
6     private String face; // face of card ("Ace", "Deuce", ...)
7     private String suit; // suit of card ("Hearts", "Diamonds", ...)
8
9     // two-argument constructor initializes card's face and suit
10    public Card( String cardFace, String cardSuit )
11    {
12        face = cardFace; // initialize face of card
13        suit = cardSuit; // initialize suit of card
14    } // end two-argument Card constructor
15
16    // return String representation of Card
17    public String toString()
18    {
19        return face + " of " + suit;
20    } // end method toString
21 } // end class Card

```

310 Chapter 7 Arrays

```

20     currentCard = 0; // set currentCard so first Card dealt is deck[ 0 ]
21     randomNumbers = new Random(); // create random number generator
22
23     // populate deck with Card objects
24     for ( int count = 0; count < deck.length; count++ )
25         deck[ count ] =
26             new Card( faces[ count % 13 ], suits[ count / 13 ] );
27 } // end DeckOfCards constructor
28
29 // shuffle deck of Cards with one-pass algorithm
30 public void shuffle()
31 {
32     // after shuffling, dealing should start at deck[ 0 ] again
33     currentCard = 0; // reinitialize currentCard
34
35     // for each Card, pick another random Card and swap them
36     for ( int first = 0; first < deck.length; first++ )
37     {
38         // select a random number between 0 and 51
39         int second = randomNumbers.nextInt( NUMBER_OF_CARDS );
40
41         // swap current Card with randomly selected Card
42         Card temp = deck[ first ];
43         deck[ first ] = deck[ second ];
44         deck[ second ] = temp;
45     } // end for
46 } // end method shuffle
47
48 // deal one Card
49 public Card dealCard()
50 {
51     // determine whether Cards remain to be dealt
52     if ( currentCard < deck.length )
53         return deck[ currentCard++ ]; // return current Card in array
54     else
55         return null; // return null to indicate that all Cards were dealt
56 } // end method dealCard
57 } // end class DeckOfCards

```

Fig. 7.10 | DeckOfCards class represents a deck of playing cards that can be shuffled and dealt one at a time. (Part 2 of 2.)

The class's constructor instantiates the `deck` array (line 19) to be of size `NUMBER_OF_CARDS`. When first created, the elements of the `deck` array are `null` by default, so the constructor uses a `for` statement (lines 24–26) to fill the `deck` array with `Cards`. The `for` statement initializes control variable `count` to 0 and loops while `count` is less than `deck.length`, causing `count` to take on each integer value from 0 to 51 (the indices of the `deck` array). Each `Card` is instantiated and initialized with two `Strings`—one from the `faces` array (which contains the `Strings` "Ace" through "King") and one from the `suits` array (which contains the `Strings` "Hearts", "Diamonds", "Clubs" and "Spades"). The calculation `count % 13` always results in a value from 0 to 12 (the 13 indices of the `faces` array in lines 15–16), and the calculation `count / 13` always results in a value from 0 to 3

7.5 Case Study: Card Shuffling and Dealing Simulation 311

(the four indices of the `suits` array in line 17). When the `deck` array is initialized, it contains the `Cards` with faces "Ace" through "King" in order for each suit ("Hearts" then "Diamonds" then "Clubs" then "Spades").

Method `shuffle` (lines 30–46) shuffles the `Cards` in the deck. The method loops through all 52 `Cards` (array indices 0 to 51). For each `Card`, a number between 0 and 51 is picked randomly to select another `Card`. Next, the current `Card` object and the randomly selected `Card` object are swapped in the array. This exchange is performed by the three assignments in lines 42–44. The extra variable `temp` temporarily stores one of the two `Card` objects being swapped. The swap cannot be performed with only the two statements

```
deck[ first ] = deck[ second ];
deck[ second ] = deck[ first ];
```

If `deck[first]` is the "Ace" of "Spades" and `deck[second]` is the "Queen" of "Hearts", after the first assignment, both array elements contain the "Queen" of "Hearts" and the "Ace" of "Spades" is lost—hence, the extra variable `temp` is needed. After the `for` loop terminates, the `Card` objects are randomly ordered. A total of only 52 swaps are made in a single pass of the entire array, and the array of `Card` objects is shuffled!

Method `dealCard` (lines 49–56) deals one `Card` in the array. Recall that `currentCard` indicates the index of the next `Card` to be dealt (i.e., the `Card` at the top of the deck). Thus, line 52 compares `currentCard` to the length of the `deck` array. If the deck is not empty (i.e., `currentCard` is less than 52), line 53 returns the "top" `Card` and postincrements `currentCard` to prepare for the next call to `dealCard`—otherwise, `null` is returned. Recall from Chapter 3 that `null` represents a "reference to nothing."

Shuffling and Dealing Cards

The application of Fig. 7.11 demonstrates the card dealing and shuffling capabilities of class `DeckOfCards` (Fig. 7.10). Line 9 creates a `DeckOfCards` object named `myDeckOfCards`. Recall that the `DeckOfCards` constructor creates the deck with the 52 `Card` objects in order by suit and face. Line 10 invokes `myDeckOfCards`'s `shuffle` method to rearrange the `Card` objects. The `for` statement in lines 13–19 deals all 52 `Cards` in the deck and prints them in four columns of 13 `Cards` each. Lines 16–18 deal and print four `Card` objects, each obtained by invoking `myDeckOfCards`'s `dealCard` method. When `printf` outputs a `Card` with the `%-20s` format specifier, the `Card`'s `toString` method (declared in lines 17–20 of Fig. 7.9) is implicitly invoked, and the result is output left justified in a field of width 20.

```

7.6 Enhanced for Statement

In previous examples, we demonstrated how to use counter-controlled `for` statements to iterate through the elements of an array. In this section, we introduce the **enhanced for statement**, which iterates through the elements of an array or a collection without using a counter (thus avoiding the possibility of “stepping outside” the array). This section discusses how to use the enhanced `for` statement to loop through an array. We show how to use the enhanced `for` statement with collections in Chapter 19, Collections. The syntax of an enhanced `for` statement is:

```
for ( parameter : arrayName )
    statement
```

where *parameter* has two parts—a type and an identifier (e.g., `int number`)—and *arrayName* is the array through which to iterate. The type of the parameter must be consistent with the type of the elements in the array. As the next example illustrates, the identifier represents successive values in the array on successive iterations of the enhanced `for` statement.

Figure 7.12 uses the enhanced `for` statement (lines 12–13) to sum the integers in an array of student grades. The type specified in the parameter to the enhanced `for` is `int`, because `array` contains `int` values—the loop selects one `int` value from the array during each iteration. The enhanced `for` statement iterates through successive values in the array one by one. The enhanced `for` header can be read as “for each iteration, assign the next element of `array` to `int` variable `number`, then execute the following statement.” Thus, for

7.7 Passing Arrays to Methods **313**

```

1 // Fig. 7.12: EnhancedForTest.java
2 // Using enhanced for statement to total integers in an array.
3
4 public class EnhancedForTest
5 {
6     public static void main( String args[] )
7     {
8         int array[] = { 87, 68, 94, 100, 83, 78, 85, 91, 76, 87 };
9         int total = 0;
10
11        // add each element's value to total
12        for ( int number : array )
13            total += number;
14
15        System.out.printf( "Total of array elements: %d\n", total );
16    } // end main
17 } // end class EnhancedForTest

```

Total of array elements: 849

Fig. 7.12 | Using the enhanced `for` statement to total integers in an array.

each iteration, identifier `number` represents an `int` value in `array`. Lines 12–13 are equivalent to the following counter-controlled repetition used in lines 12–13 of Fig. 7.5 to total the integers in `array`:

```

for ( int counter = 0; counter < array.length; counter++ )
    total += array[ counter ];

```

The enhanced `for` statement simplifies the code for iterating through an array. Note, however, that the enhanced `for` statement can be used only to obtain array elements—it cannot be used to modify elements. If your program needs to modify elements, use the traditional counter-controlled `for` statement.

The enhanced `for` statement can be used in place of the counter-controlled `for` statement whenever code looping through an array does not require access to the counter indicating the index of the current array element. For example, totaling the integers in an array requires access only to the element values—the index of each element is irrelevant. However, if a program must use a counter for some reason other than simply to loop through an array (e.g., to print an index number next to each array element value, as in the examples earlier in this chapter), use the counter-controlled `for` statement.

7.7 Passing Arrays to Methods

This section demonstrates how to pass arrays and individual array elements as arguments to methods. At the end of the section, we discuss how all types of arguments are passed to methods. To pass an array argument to a method, specify the name of the array without any brackets. For example, if array `hourlyTemperatures` is declared as

```
double hourlyTemperatures[] = new double[ 24 ];
```

314 Chapter 7 Arrays

then the method call

```
modifyArray( hourlyTemperatures );
```

passes the reference of array `hourlyTemperatures` to method `modifyArray`. Every array object “knows” its own length (via its `length` field). Thus, when we pass an array object’s reference into a method, we need not pass the array length as an additional argument.

For a method to receive an array reference through a method call, the method’s parameter list must specify an array parameter. For example, the method header for method `modifyArray` might be written as

```
void modifyArray( int b[] )
```

indicating that `modifyArray` receives the reference of an integer array in parameter `b`. The method call passes array `hourlyTemperature`’s reference, so when the called method uses the array variable `b`, it refers to the same array object as `hourlyTemperatures` in the caller.

When an argument to a method is an entire array or an individual array element of a reference type, the called method receives a copy of the reference. However, when an argument to a method is an individual array element of a primitive type, the called method receives a copy of the element’s value. Such primitive values are called **scalars** or **scalar quantities**. To pass an individual array element to a method, use the indexed name of the array element as an argument in the method call.

Figure 7.13 demonstrates the difference between passing an entire array and passing a primitive-type array element to a method. The enhanced `for` statement at lines 16–17 outputs the five elements of `array` (an array of `int` values). Line 19 invokes method `modifyArray`, passing `array` as an argument. Method `modifyArray` (lines 36–40) receives a copy of `array`’s reference and uses the reference to multiply each of `array`’s elements by 2. To prove that `array`’s elements were modified, the `for` statement at lines 23–24 outputs the five elements of `array` again. As the output shows, method `modifyArray` doubled the value of each element. Note that we could not use the enhanced `for` statement in lines 38–39 because we are modifying the array’s elements.

```

1 // Fig. 7.13: PassArray.java
2 // Passing arrays and individual array elements to methods.
3
4 public class PassArray
5 {
6     // main creates array and calls modifyArray and modifyElement
7     public static void main( String args[] )
8     {
9         int array[] = { 1, 2, 3, 4, 5 };
10
11        System.out.println(
12            "Effects of passing reference to entire array:\n" +
13            "The values of the original array are:" );
14
15        // output original array elements
16        for ( int value : array )
17            System.out.printf( "    %d", value );

```

Fig. 7.13 | Passing arrays and individual array elements to methods. (Part I of 2.)

7.7 Passing Arrays to Methods **315**

```

18     modifyArray( array ); // pass array reference
19     System.out.println( "\n\nThe values of the modified array are:" );
20
21     // output modified array elements
22     for ( int value : array )
23         System.out.printf( "    %d", value );
24
25     System.out.printf(
26         "\n\nEffects of passing array element value:\n" +
27         "array[3] before modifyElement: %d\n", array[ 3 ] );
28
29     modifyElement( array[ 3 ] ); // attempt to modify array[ 3 ]
30     System.out.printf(
31         "array[3] after modifyElement: %d\n", array[ 3 ] );
32 } // end main
33
34 // multiply each element of an array by 2
35 public static void modifyArray( int array2[] )
36 {
37     for ( int counter = 0; counter < array2.length; counter++ )
38         array2[ counter ] *= 2;
39 } // end method modifyArray
40
41 // multiply argument by 2
42 public static void modifyElement( int element )
43 {
44     element *= 2;
45     System.out.printf(
46         "Value of element in modifyElement: %d\n", element );
47 } // end method modifyElement
48 } // end class PassArray

```

Effects of passing reference to entire array:

The values of the original array are:

1 2 3 4 5

The values of the modified array are:

2 4 6 8 10

Effects of passing array element value:

array[3] before modifyElement: 8

Value of element in modifyElement: 16

array[3] after modifyElement: 8

Fig. 7.13 | Passing arrays and individual array elements to methods. (Part 2 of 2.)

Figure 7.13 next demonstrates that when a copy of an individual primitive-type array element is passed to a method, modifying the copy in the called method does not affect the original value of that element in the calling method’s array. Lines 26–28 output the value of `array[3]` (8) before invoking method `modifyElement`. Line 30 calls method `modifyElement` and passes `array[3]` as an argument. Remember that `array[3]` is actually one `int` value (8) in `array`. Therefore, the program passes a copy of the value of

316 Chapter 7 Arrays

`array[3]`. Method `modifyElement` (lines 43–48) multiplies the value received as an argument by 2, stores the result in its parameter `element`, then outputs the value of `element` (16). Since method parameters, like local variables, cease to exist when the method in which they are declared completes execution, the method parameter `element` is destroyed when method `modifyElement` terminates. Thus, when the program returns control to `main`, lines 31–32 output the unmodified value of `array[3]` (i.e., 8).

Notes on Passing Arguments to Methods

The preceding example demonstrated the different ways that arrays and primitive-type array elements are passed as arguments to methods. We now take a closer look at how arguments in general are passed to methods. Two ways to pass arguments in method calls in many programming languages are **pass-by-value** and **pass-by-reference** (also called **call-by-value** and **call-by-reference**). When an argument is passed by value, a copy of the argument's value is passed to the called method. The called method works exclusively with the copy. Changes to the called method's copy do not affect the original variable's value in the caller.

When an argument is passed by reference, the called method can access the argument's value in the caller directly and modify that data, if necessary. Pass-by-reference improves performance by eliminating the need to copy possibly large amounts of data.

Unlike some other languages, Java does not allow programmers to choose pass-by-value or pass-by-reference—all arguments are passed by value. A method call can pass two types of values to a method—copies of primitive values (e.g., values of type `int` and `double`) and copies of references to objects (including references to arrays). Objects themselves cannot be passed to methods. When a method modifies a primitive-type parameter, changes to the parameter have no effect on the original argument value in the calling method. For example, when line 30 in `main` of Fig. 7.13 passes `array[3]` to method `modifyElement`, the statement in line 45 that doubles the value of parameter `element` has no effect on the value of `array[3]` in `main`. This is also true for reference-type parameters. If you modify a reference-type parameter by assigning it the reference of another object, the parameter refers to the new object, but the reference stored in the caller's variable still refers to the original object.

Although an object's reference is passed by value, a method can still interact with the referenced object by calling its `public` methods using the copy of the object's reference. Since the reference stored in the parameter is a copy of the reference that was passed as an argument, the parameter in the called method and the argument in the calling method refer to the same object in memory. For example, in Fig. 7.13, both parameter `array2` in method `modifyArray` and variable `array` in `main` refer to the same array object in memory. Any changes made using the parameter `array2` are carried out on the same object that is referenced by the variable that was passed as an argument in the calling method. In Fig. 7.13, the changes made in `modifyArray` using `array2` affect the contents of the array object referenced by `array` in `main`. Thus, with a reference to an object, the called method can manipulate the caller's object directly.

**Performance Tip 7.1**

Passing arrays by reference makes sense for performance reasons. If arrays were passed by value, a copy of each element would be passed. For large, frequently passed arrays, this would waste time and consume considerable storage for the copies of the arrays.

7.8 Case Study: Class GradeBook Using an Array to Store Grades 317

7.8 Case Study: Class GradeBook Using an Array to Store Grades

This section further evolves class `GradeBook`, introduced in Chapter 3 and expanded in Chapters 4–5. Recall that this class represents a grade book used by a professor to store and analyze a set of student grades. Previous versions of the class process a set of grades entered by the user, but do not maintain the individual grade values in instance variables of the class. Thus, repeat calculations require the user to reenter the same grades. One way to solve this problem would be to store each grade entered in an individual instance of the class. For example, we could create instance variables `grade1`, `grade2`, ..., `grade10` in class `GradeBook` to store 10 student grades. However, the code to total the grades and determine the class average would be cumbersome, and the class would not be able to process any more than 10 grades at a time. In this section, we solve this problem by storing grades in an array.

Storing Student Grades in an Array in Class GradeBook

The version of class `GradeBook` (Fig. 7.14) presented here uses an array of integers to store the grades of several students on a single exam. This eliminates the need to repeatedly input the same set of grades. Array `grades` is declared as an instance variable in line 7—therefore, each `GradeBook` object maintains its own set of grades. The class's constructor (lines 10–14) has two parameters—the name of the course and an array of grades. When an application (e.g., class `GradeBookTest` in Fig. 7.15) creates a `GradeBook` object, the application passes an existing `int` array to the constructor, which assigns the array's reference to instance variable `grades` (line 13). The size of the array `grades` is determined by the class that passes the array to the constructor. Thus, a `GradeBook` object can process a variable number of grades. The grade values in the passed array could have been input from a user or read from a file on disk (as discussed in Chapter 14). In our test application, we simply initialize an array with a set of grade values (Fig. 7.15, line 10). Once the grades are stored in instance variable `grades` of class `GradeBook`, all the class's methods can access the elements of `grades` as often as needed to perform various calculations.

```

320 Chapter 7 Arrays

```

120      // print bar of asterisks
121      for ( int stars = 0; stars < frequency[ count ]; stars++ )
122          System.out.print( "*" );
123
124      System.out.println(); // start a new line of output
125  } // end outer for
126 } // end method outputBarChart
127
128 // output the contents of the grades array
129 public void outputGrades()
130 {
131     System.out.println( "The grades are:\n" );
132
133     // output each student's grade
134     for ( int student = 0; student < grades.length; student++ )
135         System.out.printf( "Student %2d: %3d\n",
136             student + 1, grades[ student ] );
137 } // end method outputGrades
138 } // end class GradeBook

```

Fig. 7.14 | GradeBook class using an array to store test grades. (Part 4 of 4.)

Method `processGrades` (lines 37–51) contains a series of method calls that output a report summarizing the grades. Line 40 calls method `outputGrades` to print the contents of the array `grades`. Lines 134–136 in method `outputGrades` use a `for` statement to output the students' grades. A counter-controlled `for` must be used in this case, because lines 135–136 use counter variable `student`'s value to output each grade next to a particular student number (see Fig. 7.15). Although array indices start at 0, a professor would typically number students starting at 1. Thus, lines 135–136 output `student + 1` as the student number to produce grade labels "Student 1:", "Student 2:", and so on.

Method `processGrades` next calls method `getAverage` (line 43) to obtain the average of the grades in the array. Method `getAverage` (lines 86–96) uses an enhanced `for` statement to total the values in array `grades` before calculating the average. The parameter in the enhanced `for`'s header (e.g., `int grade`) indicates that for each iteration, the `int` variable `grade` takes on a value in the array `grades`. Note that the averaging calculation in line 95 uses `grades.length` to determine the number of grades being averaged.

Lines 46–47 in method `processGrades` calls methods `getMinimum` and `getMaximum` to determine the lowest and highest grades of any student on the exam, respectively. Each of these methods uses an enhanced `for` statement to loop through array `grades`. Lines 59–64 in method `getMinimum` loop through the array. Lines 62–63 compare each grade to `lowGrade`; if a grade is less than `lowGrade`, `lowGrade` is set to that grade. When line 66 executes, `lowGrade` contains the lowest grade in the array. Method `getMaximum` (lines 70–83) works similarly to method `getMinimum`.

Finally, line 50 in method `processGrades` calls method `outputBarChart` to print a distribution chart of the grade data using a technique similar to that in Fig. 7.6. In that example, we manually calculated the number of grades in each category (i.e., 0–9, 10–19, ..., 90–99 and 100) by simply looking at a set of grades. In this example, lines 107–108 use a technique similar to that in Fig. 7.7 and Fig. 7.8 to calculate the frequency of grades in each category. Line 104 declares and creates array `frequency` of 11 `ints` to store the fre-

7.8 Case Study: Class GradeBook Using an Array to Store Grades 321

quency of grades in each grade category. For each grade in array `grades`, lines 107–108 increment the appropriate element of the `frequency` array. To determine which element to increment, line 108 divides the current grade by 10 using integer division. For example, if `grade` is 85, line 108 increments `frequency[8]` to update the count of grades in the range 80–89. Lines 111–125 next print the bar chart (see Fig. 7.15) based on the values in array `frequency`. Like lines 23–24 of Fig. 7.6, lines 121–122 of Fig. 7.14 use a value in array `frequency` to determine the number of asterisks to display in each bar.

Class GradeBookTest That Demonstrates Class GradeBook

The application of Fig. 7.15 creates an object of class `GradeBook` (Fig. 7.14) using the `int` array `gradesArray` (declared and initialized in line 10). Lines 12–13 pass a course name and `gradesArray` to the `GradeBook` constructor. Line 14 displays a welcome message, and

```

1 // Fig. 7.15: GradeBookTest.java
2 // Creates GradeBook object using an array of grades.
3
4 public class GradeBookTest
5 {
6     // main method begins program execution
7     public static void main( String args[] )
8     {
9         // array of student grades
10        int gradesArray[] = { 87, 68, 94, 100, 83, 78, 85, 91, 76, 87 };
11
12        GradeBook myGradeBook = new GradeBook(
13            "CS101 Introduction to Java Programming", gradesArray );
14        myGradeBook.displayMessage();
15        myGradeBook.processGrades();
16    } // end main
17 } // end class GradeBookTest

```

Welcome to the grade book for
CS101 Introduction to Java Programming!

The grades are:

Student 1: 87
Student 2: 68
Student 3: 94
Student 4: 100
Student 5: 83
Student 6: 78
Student 7: 85
Student 8: 91
Student 9: 76
Student 10: 87

(continued...)

Fig. 7.15 | GradeBookTest creates a GradeBook object using an array of grades, then invokes method `processGrades` to analyze them. (Part 1 of 2.)

322 Chapter 7 Arrays

```

Class average is 84.90
Lowest grade is 68
Highest grade is 100

Grade distribution:
00-09:
10-19:
20-29:
30-39:
40-49:
50-59:
60-69: *
70-79: **
80-89: ****
90-99: **
100: *

```

Fig. 7.15 | GradeBookTest creates a GradeBook object using an array of grades, then invokes method `processGrades` to analyze them. (Part 2 of 2.)

line 15 invokes the `GradeBook` object's `processGrades` method. The output summarizes the 10 grades in `myGradeBook`.

Software Engineering Observation 7.1

A test harness (or test application) is responsible for creating an object of the class being tested and providing it with data. This data could come from any of several sources. Test data can be placed directly into an array with an array initializer, it can come from the user at the keyboard, it can come from a file (as you will see in Chapter 14), or it can come from a network (as you will see in Chapter 24). After passing this data to the class's constructor to instantiate the object, the test harness should call upon the object to test its methods and manipulate its data. Gathering data in the test harness like this allows the class to manipulate data from several sources.

7.9 Multidimensional Arrays

Multidimensional arrays with two dimensions are often used to represent **tables of values** consisting of information arranged in **rows** and **columns**. To identify a particular table element, we must specify two indices. By convention, the first identifies the element's row and the second its column. Arrays that require two indices to identify a particular element are called **two-dimensional arrays**. (Multidimensional arrays can have more than two dimensions.) Java does not support multidimensional arrays directly, but it does allow the programmer to specify one-dimensional arrays whose elements are also one-dimensional arrays, thus achieving the same effect. Figure 7.16 illustrates a two-dimensional array `a` that contains three rows and four columns (i.e., a three-by-four array). In general, an array with m rows and n columns is called an **m -by- n array**.

Every element in array `a` is identified in Fig. 7.16 by an array-access expression of the form `a[row][column]`; `a` is the name of the array, and `row` and `column` are the indices that uniquely identify each element in array `a` by row and column number. Note that the names of the elements in row 0 all have a first index of 0, and the names of the elements in column 3 all have a second index of 3.

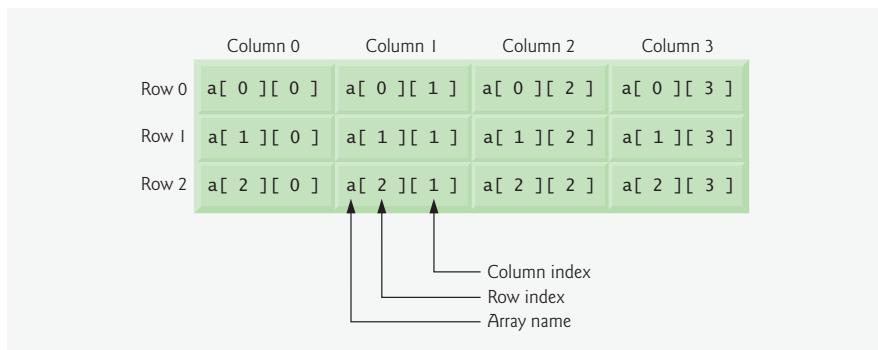

7.9 Multidimensional Arrays **323**

Fig. 7.16 | Two-dimensional array with three rows and four columns.

Arrays of One-Dimensional Arrays

Like one-dimensional arrays, multidimensional arrays can be initialized with array initializers in declarations. A two-dimensional array *b* with two rows and two columns could be declared and initialized with [nested array initializers](#) as follows:

```
int b[][] = { { 1, 2 }, { 3, 4 } };
```

The initializer values are grouped by row in braces. So 1 and 2 initialize *b*[0][0] and *b*[0][1], respectively, and 3 and 4 initialize *b*[1][0] and *b*[1][1], respectively. The compiler counts the number of nested array initializers (represented by sets of braces within the outer braces) in the array declaration to determine the number of rows in array *b*. The compiler counts the initializer values in the nested array initializer for a row to determine the number of columns in that row. As we will see momentarily, this means that rows can have different lengths.

Multidimensional arrays are maintained as arrays of one-dimensional arrays. Therefore array *b* in the preceding declaration is actually composed of two separate one-dimensional arrays—one containing the values in the first nested initializer list { 1, 2 } and one containing the values in the second nested initializer list { 3, 4 }. Thus, array *b* itself is an array of two elements, each a one-dimensional array of *int* values.

Two-Dimensional Arrays with Rows of Different Lengths

The manner in which multidimensional arrays are represented makes them quite flexible. In fact, the lengths of the rows in array *b* are not required to be the same. For example,

```
int b[][] = { { 1, 2 }, { 3, 4, 5 } };
```

creates integer array *b* with two elements (determined by the number of nested array initializers) that represent the rows of the two-dimensional array. Each element of *b* is a reference to a one-dimensional array of *int* variables. The *int* array for row 0 is a one-dimensional array with two elements (1 and 2), and the *int* array for row 1 is a one-dimensional array with three elements (3, 4 and 5).

324 Chapter 7 Arrays***Creating Two-Dimensional Arrays with Array-Creation Expressions***

A multidimensional array with the same number of columns in every row can be created with an array-creation expression. For example, the following lines declare array *b* and assign it a reference to a three-by-four array:

```
int b[][] = new int[ 3 ][ 4 ];
```

In this case, we use the literal values 3 and 4 to specify the number of rows and number of columns, respectively, but this is not required. Programs can also use variables to specify array dimensions, because `new` creates arrays at execution time—not at compile time. As with one-dimensional arrays, the elements of a multidimensional array are initialized when the array object is created.

A multidimensional array in which each row has a different number of columns can be created as follows:

```
int b[][] = new int[ 2 ][ ]; // create 2 rows
b[ 0 ] = new int[ 5 ]; // create 5 columns for row 0
b[ 1 ] = new int[ 3 ]; // create 3 columns for row 1
```

The preceding statements create a two-dimensional array with two rows. Row 0 has five columns, and row 1 has three columns.

Two-Dimensional Array Example: Displaying Element Values

Figure 7.17 demonstrates initializing two-dimensional arrays with array initializers and using nested `for` loops to `traverse` the arrays (i.e., manipulate every element of each array).

Class `InitArray`'s `main` declares two arrays. The declaration of `array1` (line 9) uses nested array initializers to initialize the first row of the array to the values 1, 2 and 3, and the second row to the values 4, 5 and 6. The declaration of `array2` (line 10) uses nested initializers of different lengths. In this case, the first row is initialized to have two elements with the values 1 and 2, respectively. The second row is initialized to have one element with the value 3. The third row is initialized to have three elements with the values 4, 5 and 6, respectively.

```

1 // Fig. 7.17: InitArray.java
2 // Initializing two-dimensional arrays.
3
4 public class InitArray
5 {
6     // create and output two-dimensional arrays
7     public static void main( String args[] )
8     {

Fig. 7.17 | Initializing two-dimensional arrays. (Part 2 of 2.)

Lines 13 and 16 call method `outputArray` (lines 20–31) to output the elements of `array1` and `array2`, respectively. Method `outputArray` specifies the array parameter as `int array[][]` to indicate that the method receives a two-dimensional array. The `for` statement (lines 23–30) outputs the rows of a two-dimensional array. In the loop-continuation condition of the outer `for` statement, the expression `array.length` determines the number of rows in the array. In the inner `for` statement, the expression `array[row].length` determines the number of columns in the current row of the array. This condition enables the loop to determine the exact number of columns in each row.

Common Multidimensional-Array Manipulations Performed with for Statements

Many common array manipulations use `for` statements. As an example, the following `for` statement sets all the elements in row 2 of array `a` in Fig. 7.16 to zero:

```

for ( int column = 0; column < a[ 2 ].length; column++ )
    a[ 2 ][ column ] = 0;

```

We specified row 2; therefore, we know that the first index is always 2 (0 is the first row, and 1 is the second row). This `for` loop varies only the second index (i.e., the column index). If row 2 of array `a` contains four elements, then the preceding `for` statement is equivalent to the assignment statements

```

a[ 2 ][ 0 ] = 0;
a[ 2 ][ 1 ] = 0;
a[ 2 ][ 2 ] = 0;
a[ 2 ][ 3 ] = 0;

```

326 Chapter 7 Arrays

The following nested `for` statement totals the values of all the elements in array `a`:

```
int total = 0;
for ( int row = 0; row < a.length; row++ )
{
    for ( int column = 0; column < a[ row ].length; column++ )
        total += a[ row ][ column ];
} // end outer for
```

This nested `for` statements total the array elements one row at a time. The outer `for` statement begins by setting the `row` index to 0 so that the first row's elements can be totaled by the inner `for` statement. The outer `for` then increments `row` to 1 so that the second row can be totaled. Then, the outer `for` increments `row` to 2 so that the third row can be totaled. The variable `total` can be displayed when the outer `for` statement terminates. In the next example, we show how to process a two-dimensional array in a similar manner using nested enhanced `for` statements.

7.10 Case Study: Class GradeBook Using a Two-Dimensional Array

In Section 7.8, we presented class `GradeBook` (Fig. 7.14), which used a one-dimensional array to store student grades on a single exam. In most semesters, students take several exams. Professors are likely to want to analyze grades across the entire semester, both for a single student and for the class as a whole.

Storing Student Grades in a Two-Dimensional Array in Class GradeBook

Figure 7.18 contains a version of class `GradeBook` that uses a two-dimensional array `grades` to store the grades of a number of students on multiple exams. Each row of the array represents a single student's grades for the entire course, and each column represents a grade on one of the exams the students took during the course. An application such as `GradeBookTest` (Fig. 7.19) passes the array as an argument to the `GradeBook` constructor. In this example, we use a ten-by-three array containing ten students' grades on three exams. Five methods perform array manipulations to process the grades. Each method is similar to its counterpart in the earlier one-dimensional array version of class `GradeBook` (Fig. 7.14). Method `getMinimum` (lines 52–70) determines the lowest grade of any student for the semester. Method `getMaximum` (lines 73–91) determines the highest grade of any student for the semester. Method `getAverage` (lines 94–104) determines a particular student's semester average. Method `outputBarChart` (lines 107–137) outputs a bar chart of the distribution of all student grades for the semester. Method `outputGrades` (lines 140–164) outputs the two-dimensional array in a tabular format, along with each student's semester average.

Methods `getMinimum`, `getMaximum`, `outputBarChart` and `outputGrades` each loop through array `grades` by using nested `for` statements—for example, the nested enhanced `for` statement from the declaration of method `getMinimum` (lines 58–67). The outer enhanced `for` statement iterates through the two-dimensional array `grades`, assigning successive rows to parameter `studentGrades` on successive iterations. The square brackets following the parameter name indicate that `studentGrades` refers to a one-dimensional `int` array—namely, a row in array `grades` containing one student's grades. To find the lowest overall grade, the inner `for` statement compares the elements of the current one-dimen-

330 Chapter 7 Arrays

```

158      // call method getAverage to calculate student's average grade;
159      // pass row of grades as the argument to getAverage
160      double average = getAverage( grades[ student ] );
161      System.out.printf( "%9.2f\n", average );
162  } // end outer for
163 } // end method outputGrades
164 } // end class GradeBook

```

Fig. 7.18 | GradeBook class using a two-dimensional array to store grades. (Part 4 of 4.)

sional array `studentGrades` to variable `lowGrade`. For example, on the first iteration of the outer `for`, row 0 of `grades` is assigned to parameter `studentGrades`. The inner enhanced `for` statement then loops through `studentGrades` and compares each grade value with `lowGrade`. If a grade is less than `lowGrade`, `lowGrade` is set to that grade. On the second iteration of the outer enhanced `for` statement, row 1 of `grades` is assigned to `studentGrades`, and the elements of this row are compared with variable `lowGrade`. This repeats until all rows of `grades` have been traversed. When execution of the nested statement is complete, `lowGrade` contains the lowest grade in the two-dimensional array. Method `getMaximum` works similarly to method `getMinimum`.

Method `outputBarChart` in Fig. 7.18 is nearly identical to the one in Fig. 7.14. However, to output the overall grade distribution for a whole semester, the method here uses a nested enhanced `for` statement (lines 115–119) to create the one-dimensional array `frequency` based on all the grades in the two-dimensional array. The rest of the code in each of the two `outputBarChart` methods that displays the chart is identical.

Method `outputGrades` (lines 140–164) also uses nested `for` statements to output values of the array `grades` and each student's semester average. The output in Fig. 7.19 shows the result, which resembles the tabular format of a professor's physical grade book. Lines 146–147 print the column headings for each test. We use a counter-controlled `for` statement here so that we can identify each test with a number. Similarly, the `for` statement in lines 152–163 first outputs a row label using a counter variable to identify each student (line 154). Although array indices start at 0, note that lines 147 and 154 output `test + 1` and `student + 1`, respectively, to produce test and student numbers starting at 1 (see Fig. 7.19). The inner `for` statement in lines 156–157 uses the outer `for` statement's counter variable `student` to loop through a specific row of array `grades` and output each student's test grade. Note that an enhanced `for` statement can be nested in a counter-controlled `for` statement, and vice versa. Finally, line 161 obtains each student's semester average by passing the current row of `grades` (i.e., `grades[student]`) to method `getAverage`.

Method `getAverage` (lines 94–104) takes one argument—a one-dimensional array of test results for a particular student. When line 161 calls `getAverage`, the argument is `grades[student]`, which specifies that a particular row of the two-dimensional array `grades` should be passed to `getAverage`. For example, based on the array created in Fig. 7.19, the argument `grades[1]` represents the three values (a one-dimensional array of grades) stored in row 1 of the two-dimensional array `grades`. Recall that a two-dimensional array is an array whose elements are one-dimensional arrays. Method `getAverage` calculates the sum of the array elements, divides the total by the number of test results and returns the floating-point result as a `double` value (line 103).

7.10 Case Study: Class GradeBook Using a Two-Dimensional Array

331

Class GradeBookTest That Demonstrates Class GradeBook

The application in Fig. 7.19 creates an object of class GradeBook (Fig. 7.18) using the two-dimensional array of ints named gradesArray (declared and initialized in lines 10–19). Lines 21–22 pass a course name and gradesArray to the GradeBook constructor. Lines 23–24 then invoke myGradeBook's displayMessage and processGrades methods to display a welcome message and obtain a report summarizing the students' grades for the semester, respectively.

```

1 // Fig. 7.19: GradeBookTest.java
2 // Creates GradeBook object using a two-dimensional array of grades.
3
4 public class GradeBookTest
5 {
6     // main method begins program execution
7     public static void main( String args[] )
8     {
9         // two-dimensional array of student grades
10        int gradesArray[][] = { { 87, 96, 70 },
11                                { 68, 87, 90 },
12                                { 94, 100, 90 },
13                                { 100, 81, 82 },
14                                { 83, 65, 85 },
15                                { 78, 87, 65 },
16                                { 85, 75, 83 },
17                                { 91, 94, 100 },
18                                { 76, 72, 84 },
19                                { 87, 93, 73 } };
20
21        GradeBook myGradeBook = new GradeBook(
22            "CS101 Introduction to Java Programming", gradesArray );
23        myGradeBook.displayMessage();
24        myGradeBook.processGrades();
25    } // end main
26 } // end class GradeBookTest

```

Welcome to the grade book for
CS101 Introduction to Java Programming!

The grades are:

	Test 1	Test 2	Test 3	Average
Student 1	87	96	70	84.33
Student 2	68	87	90	81.67
Student 3	94	100	90	94.67
Student 4	100	81	82	87.67
Student 5	83	65	85	77.67
Student 6	78	87	65	76.67
Student 7	85	75	83	81.00
Student 8	91	94	100	95.00
Student 9	76	72	84	77.33
Student 10	87	93	73	84.33

7.11 Variable-Length Argument Lists

With **variable-length argument lists**, you can create methods that receive an unspecified number of arguments. An argument type followed by an **ellipsis (...)** in a method's **parameter list** indicates that the method receives a variable number of arguments of that particular type. This use of the ellipsis can occur only once in a parameter list, and the ellipsis, together with its type, must be placed at the end of the parameter list. While programmers can use method overloading and array passing to accomplish much of what is accomplished with "varargs," or variable-length argument lists, using an ellipsis in a method's parameter list is more concise.

Figure 7.20 demonstrates method `average` (lines 7–16), which receives a variable-length sequence of `doubles`. Java treats the variable-length argument list as an array whose elements are all of the same type. Hence, the method body can manipulate the parameter `numbers` as an array of `doubles`. Lines 12–13 use the enhanced for loop to walk through the array and calculate the total of the `doubles` in the array. Line 15 accesses `numbers.length` to obtain the size of the `numbers` array for use in the averaging calculation. Lines 29, 31 and 33 in `main` call method `average` with two, three and four arguments, respectively. Method `average` has a variable-length argument list (line 7), so it can average as many `double` arguments as the caller passes. The output shows that each call to method `average` returns the correct value.

```

7.12 Using Command-Line Arguments **333**

```

9      double total = 0.0; // initialize total
10
11     // calculate total using the enhanced for statement
12     for ( double d : numbers )
13         total += d;
14
15     return total / numbers.length;
16 } // end method average
17
18 public static void main( String args[] )
19 {
20     double d1 = 10.0;
21     double d2 = 20.0;
22     double d3 = 30.0;
23     double d4 = 40.0;
24
25     System.out.printf( "d1 = %.1f\n" +
26                         "d2 = %.1f\n" +
27                         "d3 = %.1f\n" +
28                         "d4 = %.1f\n\n",
29                         d1, d2, d3, d4 );
30
31     System.out.printf( "Average of d1 and d2 is %.1f\n",
32                         average( d1, d2 ) );
33     System.out.printf( "Average of d1, d2 and d3 is %.1f\n",
34                         average( d1, d2, d3 ) );
35     System.out.printf( "Average of d1, d2, d3 and d4 is %.1f\n",
36                         average( d1, d2, d3, d4 ) );
37 } // end main
38 } // end class VarargsTest

```

```

d1 = 10.0
d2 = 20.0
d3 = 30.0
d4 = 40.0

Average of d1 and d2 is 15.0
Average of d1, d2 and d3 is 20.0
Average of d1, d2, d3 and d4 is 25.0

```

Fig. 7.20 | Using variable-length argument lists. (Part 2 of 2.)

**Common Programming Error 7.6**

Placing an ellipsis indicating a variable-length argument list in the middle of a method parameter list is a syntax error. An ellipsis may be placed only at the end of the parameter list.

7.12 Using Command-Line Arguments

On many systems it is possible to pass arguments from the command line (these are known as **command-line arguments**) to an application by including a parameter of type `String[]` (i.e., an array of `Strings`) in the parameter list of `main`, exactly as we have done in every application in the book. By convention, this parameter is named `args`. When an application is executed using the `java` command, Java passes the command-line arguments that appear after the class name in the `java` command to the application's `main` method as `Strings` in the array `args`. The number of arguments passed in from the command line is

334 Chapter 7 Arrays

obtained by accessing the array's `length` attribute. For example, the command "java MyClass a b" passes two command-line arguments, `a` and `b`, to application `MyClass`. Note that command-line arguments are separated by white space, not commas. When this command executes, `MyClass`'s `main` method receives the two-element array `args` (i.e., `args.length` is 2) in which `args[0]` contains the `String` "`a`" and `args[1]` contains the `String` "`b`". Common uses of command-line arguments include passing options and file names to applications.

Figure 7.21 uses three command-line arguments to initialize an array. When the program executes, if `args.length` is not 3, the program prints an error message and terminates (lines 9–12). Otherwise, lines 14–32 initialize and display the array based on the values of the command-line arguments.

The command-line arguments become available to `main` as `Strings` in `args`. Line 16 gets `args[0]`—a `String` that specifies the array size—and converts it to an `int` value that the program uses to create the array in line 17. The `static` method `parseInt` of class `Integer` converts its `String` argument to an `int`.

```

2 // Using command-line arguments to initialize an array.
3
4 public class InitArray
5 {
6     public static void main( String args[] )
7     {
8         // check number of command-line arguments
9         if ( args.length != 3 )
10             System.out.println(
11                 "Error: Please re-enter the entire command, including\n" +
12                 "an array size, initial value and increment." );
13     else
14     {
15         // get array size from first command-line argument
16         int arrayLength = Integer.parseInt( args[ 0 ] );
17         int array[] = new int[ arrayLength ]; // create array
18
19         // get initial value and increment from command-line arguments
20         int initialValue = Integer.parseInt( args[ 1 ] );
21         int increment = Integer.parseInt( args[ 2 ] );
22
23         // calculate value for each array element
24         for ( int counter = 0; counter < array.length; counter++ )
25             array[ counter ] = initialValue + increment * counter;
26
27         System.out.printf( "%s%8s\n", "Index", "Value" );
28
29         // display array index and value
30         for ( int counter = 0; counter < array.length; counter++ )
31             System.out.printf( "%5d%8d\n", counter, array[ counter ] );
32     } // end else
33 } // end main
34 } // end class InitArray

Fig. 7.21 | Initializing an array using command-line arguments. (Part 2 of 2.)

Lines 20–21 convert the `args[1]` and `args[2]` command-line arguments to `int` values and store them in `initialValue` and `increment`, respectively. Lines 24–25 calculate the value for each array element.

The output of the first execution shows that the application received an insufficient number of command-line arguments. The second execution uses command-line arguments 5, 0 and 4 to specify the size of the array (5), the value of the first element (0) and the increment of each value in the array (4), respectively. The corresponding output shows that these values create an array containing the integers 0, 4, 8, 12 and 16. The output from the third execution shows that the command-line arguments 10, 1 and 2 produce an array whose 10 elements are the nonnegative odd integers from 1 to 19.

7.13 (Optional) GUI and Graphics Case Study: Drawing Arcs

Using Java's graphics features, we can create complex drawings that would be more tedious to code line by line. In Fig. 7.22 and Fig. 7.23, we use arrays and repetition statements to draw a rainbow by using `Graphics` method `fillArc`. Drawing arcs in Java is similar to drawing ovals—an arc is simply a section of an oval.

Figure 7.22 begins with the usual `import` statements for creating drawings (lines 3–5). Lines 9–10 declare and create two new colors—`VIOLET` and `INDIGO`. As you may know, the colors of a rainbow are red, orange, yellow, green, blue, indigo and violet. Java has pre-

336 Chapter 7 Arrays

```

1 // Fig. 7.22: DrawRainbow.java
2 // Demonstrates using colors in an array.
3 import java.awt.Color;
4 import java.awt.Graphics;
5 import javax.swing.JPanel;
6
7 public class DrawRainbow extends JPanel
8 {
9     // Define indigo and violet
10    final Color VIOLET = new Color( 128, 0, 128 );
11    final Color INDIGO = new Color( 75, 0, 130 );
12
13    // colors to use in the rainbow, starting from the innermost
14    // The two white entries result in an empty arc in the center
15    private Color colors[] =
16        { Color.WHITE, Color.WHITE, VIOLET, INDIGO, Color.BLUE,
17          Color.GREEN, Color.YELLOW, Color.ORANGE, Color.RED };
18
19    // constructor
20    public DrawRainbow()
21    {
22        setBackground( Color.WHITE ); // set the background to white
23    } // end DrawRainbow constructor
24
25    // draws a rainbow using concentric circles
26    public void paintComponent( Graphics g )
27    {
28        super.paintComponent( g );
29
30        int radius = 20; // radius of an arc
31
32        // draw the rainbow near the bottom-center
33        int centerX = getWidth() / 2;
34        int centerY = getHeight() - 10;
35
36        // draws filled arcs starting with the outermost
37        for ( int counter = colors.length; counter > 0; counter-- )
38        {
39            // set the color for the current arc
40            g.setColor( colors[ counter - 1 ] );
41
42            // fill the arc from 0 to 180 degrees
43            g.fillArc( centerX - counter * radius,
44                       centerY - counter * radius,
45                       counter * radius * 2, counter * radius * 2, 0, 180 );
46        } // end for
47    } // end method paintComponent
48 } // end class DrawRainbow

```

Fig. 7.22 | Drawing a rainbow using arcs and an array of colors.

defined constants only for the first five colors. Lines 15–17 initialize an array with the colors of the rainbow, starting with the innermost arcs first. The array begins with two `Color.WHITE` elements, which, as you will soon see, are for drawing the empty arcs at the

7.13 (Optional) GUI and Graphics Case Study: Drawing Arcs **337**

center of the rainbow. Note that the instance variables can be initialized when they are declared, as shown in lines 10–17. The constructor (lines 20–23) contains a single statement that calls method `setBackground` (which is inherited from class `JPanel`) with the parameter `Color.WHITE`. Method `setBackground` takes a single `Color` argument and sets the background of the component to that color.

Line 30 in `paintComponent` declares local variable `radius`, which determines the radius of each arc. Local variables `centerX` and `centerY` (lines 33–34) determine the location of the midpoint on the base of the rainbow. The loop at lines 37–46 uses control variable `counter` to count backward from the end of the array, drawing the largest arcs first and placing each successive smaller arc on top of the previous one. Line 40 sets the color to draw the current arc from the array. The reason we have `Color.WHITE` entries at the beginning of the array is to create the empty arc in the center. Otherwise, the center of the rainbow would just be a solid violet semicircle. [Note: You can change the individual colors and the number of entries in the array to create new designs.]

The `fillArc` method call at lines 43–45 draws a filled semicircle. Method `fillArc` requires six parameters. The first four represent the bounding rectangle in which the arc will be drawn. The first two of these specify the coordinates for the upper-left corner of

```

1 // Fig. 7.23: DrawRainbowTest.java
2 // Test application to display a rainbow.
3 import javax.swing.JFrame;
4
5 public class DrawRainbowTest
6 {
7     public static void main( String args[] )
8     {
9         DrawRainbow panel = new DrawRainbow();
10        JFrame application = new JFrame();
11
12        application.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
13        application.add( panel );
14        application.setSize( 400, 250 );
15        application.setVisible( true );
16    } // end main
17 } // end class DrawRainbowTest

```

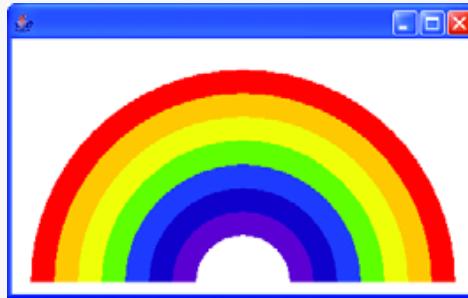

Fig. 7.23 | Creating `JFrame` to display a rainbow.

338 Chapter 7 Arrays

the bounding rectangle, and the next two specify its width and height. The fifth parameter is the starting angle on the oval, and the sixth specifies the **sweep**, or the amount of arc to cover. The starting angle and sweep are measured in degrees, with zero degrees pointing right. A positive sweep draws the arc counterclockwise, while a negative sweep draws the arc clockwise. A method similar to `fillArc` is `drawArc`—it requires the same parameters as `fillArc`, but draws the edge of the arc rather than filling it.

Class `DrawRainbowTest` (Fig. 7.23) creates and sets up a `JFrame` to display the rainbow. Once the program makes the `JFrame` visible, the system calls the `paintComponent` method in class `DrawRainbow` to draw the rainbow on the screen.

GUI and Graphics Case Study Exercise

7.1 (*Drawing Spirals*) In this exercise, you will draw spirals with methods `drawLine` and `drawArc`.

- Draw a square-shaped spiral (as in the left screen capture of Fig. 7.24), centered on the panel, using method `drawLine`. One technique is to use a loop that increases the line length after drawing every second line. The direction in which to draw the next line should follow a distinct pattern, such as down, left, up, right.
- Draw a circular spiral (as in the right screen capture of Fig. 7.24), using method `drawArc` to draw one semicircle at a time. Each successive semicircle should have a larger radius (as specified by the bounding rectangle's width) and should continue drawing where the previous semicircle finished.

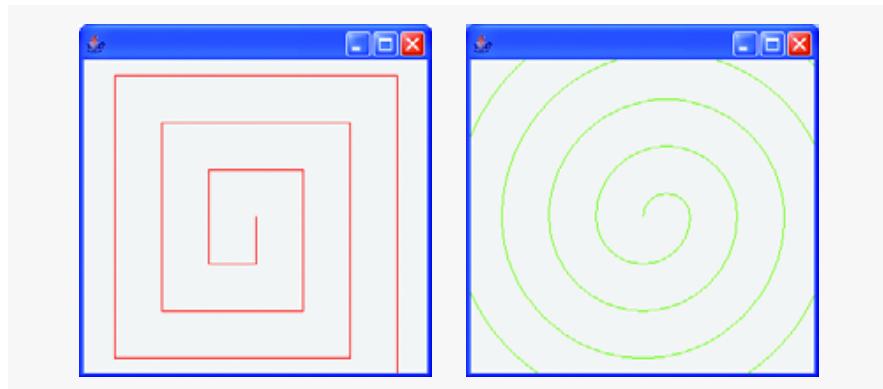

Fig. 7.24 | Drawing a spiral using `drawLine` (left) and `drawArc` (right).

7.14 (Optional) Software Engineering Case Study: Collaboration Among Objects

In this section, we concentrate on the collaborations (interactions) among objects. When two objects communicate with each other to accomplish a task, they are said to **collaborate**—objects do this by invoking one another's operations. A **collaboration** consists of an object of one class sending a **message** to an object of another class. Messages are sent in Java via method calls.

In Section 6.14, we determined many of the operations of the classes in our system. In this section, we concentrate on the messages that invoke these operations. To identify

7.14 Collaboration Among Objects **339**

the collaborations in the system, we return to the requirements document in Section 2.9. Recall that this document specifies the range of activities that occur during an ATM session (e.g., authenticating a user, performing transactions). The steps used to describe how the system must perform each of these tasks are our first indication of the collaborations in our system. As we proceed through this and the remaining Software Engineering Case Study sections, we may discover additional collaborations.

Identifying the Collaborations in a System

We identify the collaborations in the system by carefully reading the sections of the requirements document that specify what the ATM should do to authenticate a user and to perform each transaction type. For each action or step described in the requirements document, we decide which objects in our system must interact to achieve the desired result. We identify one object as the sending object and another as the receiving object. We then select one of the receiving object's operations (identified in Section 6.14) that must be invoked by the sending object to produce the proper behavior. For example, the ATM displays a welcome message when idle. We know that an object of class `Screen` displays a message to the user via its `displayMessage` operation. Thus, we decide that the system can display a welcome message by employing a collaboration between the ATM and the `Screen` in which the ATM sends a `displayMessage` message to the `Screen` by invoking the `displayMessage` operation of class `Screen`. [Note: To avoid repeating the phrase "an object of class...," we refer to an object by using its class name preceded by an article (e.g., "a," "an" or "the")—for example, "the ATM" refers to an object of class `ATM`.]

Figure 7.25 lists the collaborations that can be derived from the requirements document. For each sending object, we list the collaborations in the order in which they first occur during an ATM session (i.e., the order in which they are discussed in the require-

ments document). We list each collaboration involving a unique sender, message and recipient only once, even though the collaborations may occur at several different times throughout an ATM session. For example, the first row in Fig. 7.25 indicates that the ATM collaborates with the Screen whenever the ATM needs to display a message to the user.

Let's consider the collaborations in Fig. 7.25. Before allowing a user to perform any transactions, the ATM must prompt the user to enter an account number, then to enter a PIN. It accomplishes each of these tasks by sending a `displayMessage` message to the `Screen`. Both of these actions refer to the same collaboration between the ATM and the `Screen`, which is already listed in Fig. 7.25. The ATM obtains input in response to a prompt by sending a `getInput` message to the `Keypad`. Next, the ATM must determine whether the user-specified account number and PIN match those of an account in the database. It does so by sending an `authenticateUser` message to the `BankDatabase`. Recall that the `BankDatabase` cannot authenticate a user directly—only the user's `Account` (i.e., the `Account` that contains the account number specified by the user) can access the user's PIN on record to authenticate the user. Figure 7.25 therefore lists a collaboration in which the `BankDatabase` sends a `validatePIN` message to an `Account`.

After the user is authenticated, the ATM displays the main menu by sending a series of `displayMessage` messages to the `Screen` and obtains input containing a menu selection by sending a `getInput` message to the `Keypad`. We have already accounted for these collaborations, so we do not add anything to Fig. 7.25. After the user chooses a type of transaction to perform, the ATM executes the transaction by sending an `execute` message to an object of the appropriate transaction class (i.e., a `BalanceInquiry`, a `Withdrawal` or a `Deposit`). For example, if the user chooses to perform a balance inquiry, the ATM sends an `execute` message to a `BalanceInquiry`.

Further examination of the requirements document reveals the collaborations involved in executing each transaction type. A `BalanceInquiry` retrieves the amount of money available in the user's account by sending a `getAvailableBalance` message to the `BankDatabase`, which responds by sending a `getAvailableBalance` message to the user's `Account`. Similarly, the `BalanceInquiry` retrieves the amount of money on deposit by sending a `getTotalBalance` message to the `BankDatabase`, which sends the same message

7.14 Collaboration Among Objects **341**

to the user's Account. To display both measures of the user's balance at the same time, the BalanceInquiry sends a `displayMessage` message to the Screen.

A Withdrawal sends a series of `displayMessage` messages to the Screen to display a menu of standard withdrawal amounts (i.e., \$20, \$40, \$60, \$100, \$200). The Withdrawal sends a `getInput` message to the Keypad to obtain the user's menu selection. Next, the Withdrawal determines whether the requested withdrawal amount is less than or equal to the user's account balance. The Withdrawal can obtain the amount of money available in the user's account by sending a `getAvailableBalance` message to the BankDatabase. The Withdrawal then tests whether the cash dispenser contains enough cash by sending an `isSufficientCashAvailable` message to the CashDispenser. A Withdrawal sends a `debit` message to the BankDatabase to decrease the user's account balance. The BankDatabase in turn sends the same message to the appropriate Account. Recall that debiting funds from an Account decreases both the `totalBalance` and the `availableBalance`. To dispense the requested amount of cash, the Withdrawal sends a `dispenseCash` message to the CashDispenser. Finally, the Withdrawal sends a `displayMessage` message to the Screen, instructing the user to take the cash.

A Deposit responds to an `execute` message first by sending a `displayMessage` message to the Screen to prompt the user for a deposit amount. The Deposit sends a `getInput` message to the Keypad to obtain the user's input. The Deposit then sends a `displayMessage` message to the Screen to tell the user to insert a deposit envelope. To determine whether the deposit slot received an incoming deposit envelope, the Deposit sends an `isEnvelopeReceived` message to the DepositSlot. The Deposit updates the user's account by sending a `credit` message to the BankDatabase, which subsequently sends a `credit` message to the user's Account. Recall that crediting funds to an Account increases the `totalBalance` but not the `availableBalance`.

Interaction Diagrams

Now that we have identified a set of possible collaborations between the objects in our ATM system, let us graphically model these interactions using the UML. The UML provides several types of [interaction diagrams](#) that model the behavior of a system by modeling how objects interact. The [communication diagram](#) emphasizes *which objects* participate in collaborations. [Note: Communication diagrams were called [collaboration diagrams](#) in earlier versions of the UML.] Like the communication diagram, the [sequence diagram](#) shows collaborations among objects, but it emphasizes *when* messages are sent between objects *over time*.

Communication Diagrams

Figure 7.26 shows a communication diagram that models the ATM executing a `BalanceInquiry`. Objects are modeled in the UML as rectangles containing names in the form `objectName : ClassName`. In this example, which involves only one object of each type, we disregard the object name and list only a colon followed by the class name. [Note: Specifying the name of each object in a communication diagram is recommended when modeling multiple objects of the same type.] Communicating objects are connected with solid lines, and messages are passed between objects along these lines in the direction shown by arrows. The name of the message, which appears next to the arrow, is the name of an operation (i.e., a method in Java) belonging to the receiving object—think of the name as a “service” that the receiving object provides to sending objects (its “clients”).

342 Chapter 7 Arrays

Fig. 7.26 | Communication diagram of the ATM executing a balance inquiry.

The solid filled arrow in Fig. 7.26 represents a message—or **synchronous call**—in the UML and a method call in Java. This arrow indicates that the flow of control is from the sending object (the ATM) to the receiving object (a BalanceInquiry). Since this is a synchronous call, the sending object may not send another message, or do anything at all, until the receiving object processes the message and returns control to the sending object. The sender just waits. For example, in Fig. 7.26, the ATM calls method `execute` of a BalanceInquiry and may not send another message until `execute` has finished and returns control to the ATM. [Note: If this were an **asynchronous call**, represented by a stick arrowhead, the sending object would not have to wait for the receiving object to return control—it would continue sending additional messages immediately following the asynchronous call. Asynchronous calls are implemented in Java using a technique called multithreading, which is discussed in Chapter 23, Multithreading.]

Sequence of Messages in a Communication Diagram

Figure 7.27 shows a communication diagram that models the interactions among objects in the system when an object of class BalanceInquiry executes. We assume that the object's `accountNumber` attribute contains the account number of the current user. The collaborations in Fig. 7.27 begin after the ATM sends an `execute` message to a BalanceInquiry (i.e., the interaction modeled in Fig. 7.26). The number to the left of a message name indicates the order in which the message is passed. The **sequence of messages** in a communication diagram progresses in numerical order from least to greatest. In this diagram, the numbering starts with message 1 and ends with message 3. The BalanceInquiry first sends a `getAvailableBalance` message to the BankDatabase (message 1), then sends a `getTotalBalance` message to the BankDatabase (message 2). Within the parentheses following a message name, we can specify a comma-separated list of the names of the parameters sent with the message (i.e., arguments in a Java method call)—the BalanceInquiry passes attribute `accountNumber` with its messages to the BankDatabase to indicate which Account's balance information to retrieve. Recall from Fig. 6.22 that operations `getAvailableBalance` and `getTotalBalance` of class BankDatabase each require a parameter to identify an account. The BalanceInquiry next displays the availableBalance and the totalBalance to the user by passing a `displayMessage` message to the Screen (message 3) that includes a parameter indicating the message to be displayed.

Note that Fig. 7.27 models two additional messages passing from the BankDatabase to an Account (message 1.1 and message 2.1). To provide the ATM with the two balances of the user's Account (as requested by messages 1 and 2), the BankDatabase must pass a `getAvailableBalance` and a `getTotalBalance` message to the user's Account. Such messages passed within the handling of another message are called **nested messages**. The UML recommends using a decimal numbering scheme to indicate nested messages. For example, message 1.1 is the first message nested in message 1—the BankDatabase passes a `getAvailableBalance` message during BankDatabase's processing of a message by the same name. [Note: If the BankDatabase needed to pass a second nested message while pro-

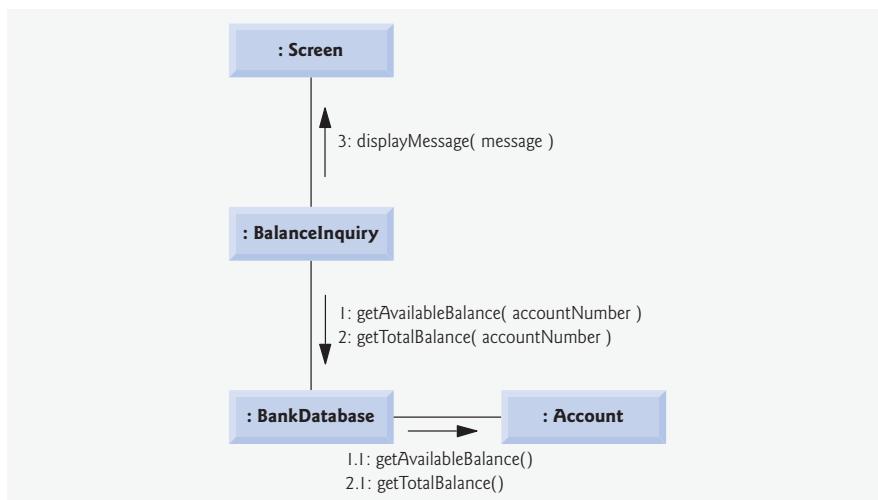

7.14 Collaboration Among Objects **343**

Fig. 7.27 | Communication diagram for executing a balance inquiry.

cessing message 1, the second message would be numbered 1.2.] A message may be passed only when all the nested messages from the previous message have been passed. For example, the `BalanceInquiry` passes message 3 only after messages 2 and 2.1 have been passed, in that order.

The nested numbering scheme used in communication diagrams helps clarify precisely when and in what context each message is passed. For example, if we numbered the messages in Fig. 7.27 using a flat numbering scheme (i.e., 1, 2, 3, 4, 5), someone looking at the diagram might not be able to determine that `BankDatabase` passes the `getAvailableBalance` message (message 1.1) to an `Account` during the `BankDatabase`'s processing of message 1, as opposed to *after* completing the processing of message 1. The nested decimal numbers make it clear that the second `getAvailableBalance` message (message 1.1) is passed to an `Account` within the handling of the first `getAvailableBalance` message (message 1) by the `BankDatabase`.

Sequence Diagrams

Communication diagrams emphasize the participants in collaborations, but model their timing a bit awkwardly. A sequence diagram helps model the timing of collaborations more clearly. Figure 7.28 shows a sequence diagram modeling the sequence of interactions that occur when a `Withdrawal` executes. The dotted line extending down from an object's rectangle is that object's **lifeline**, which represents the progression of time. Actions occur along an object's lifeline in chronological order from top to bottom—an action near the top happens before one near the bottom.

Message passing in sequence diagrams is similar to message passing in communication diagrams. A solid arrow with a filled arrowhead extending from the sending object to the receiving object represents a message between two objects. The arrowhead points to an activation on the receiving object's lifeline. An **activation**, shown as a thin vertical rectangle, indicates that an object is executing. When an object returns control, a return mes-

344 Chapter 7 Arrays

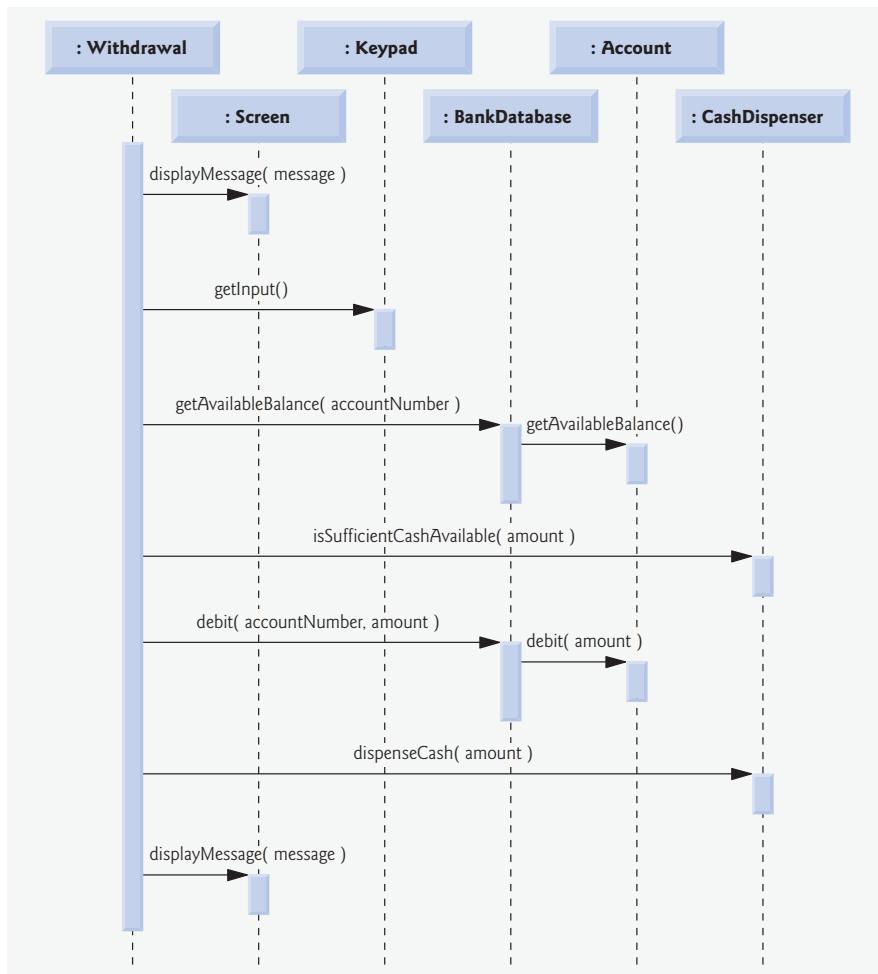

Fig. 7.28 | Sequence diagram that models a `Withdrawal` executing.

sage, represented as a dashed line with a stick arrowhead, extends from the activation of the object returning control to the activation of the object that initially sent the message. To eliminate clutter, we omit the return-message arrows—the UML allows this practice to make diagrams more readable. Like communication diagrams, sequence diagrams can indicate message parameters between the parentheses following a message name.

The sequence of messages in Fig. 7.28 begins when a `Withdrawal` prompts the user to choose a withdrawal amount by sending a `displayMessage` message to the `Screen`. The `Withdrawal` then sends a `getInput` message to the `Keypad`, which obtains input from the user. We have already modeled the control logic involved in a `Withdrawal` in the activity diagram of Fig. 5.31, so we do not show this logic in the sequence diagram of Fig. 7.28.

7.14 Collaboration Among Objects **345**

Instead, we model the best-case scenario in which the balance of the user's account is greater than or equal to the chosen withdrawal amount, and the cash dispenser contains a sufficient amount of cash to satisfy the request. For information on how to model control logic in a sequence diagram, please refer to the web resources and recommended readings listed at the end of Section 2.9.

After obtaining a withdrawal amount, the `Withdrawal` sends a `getAvailableBalance` message to the `BankDatabase`, which in turn sends a `getAvailableBalance` message to the user's `Account`. Assuming that the user's account has enough money available to permit the transaction, the `Withdrawal` next sends an `isSufficientCashAvailable` message to the `CashDispenser`. Assuming that there is enough cash available, the `Withdrawal` decreases the balance of the user's account (i.e., both the `totalBalance` and the `availableBalance`) by sending a `debit` message to the `BankDatabase`. The `BankDatabase` responds by sending a `debit` message to the user's `Account`. Finally, the `Withdrawal` sends a `dispenseCash` message to the `CashDispenser` and a `displayMessage` message to the `Screen`, telling the user to remove the cash from the machine.

We have identified the collaborations among objects in the ATM system and modeled some of these collaborations using UML interaction diagrams—both communication diagrams and sequence diagrams. In the next Software Engineering Case Study section (Section 8.19), we enhance the structure of our model to complete a preliminary object-oriented design, then we begin implementing the ATM system in Java.

Software Engineering Case Study Self-Review Exercises

- 7.1** A(n) _____ consists of an object of one class sending a message to an object of another class.
- association
 - aggregation
 - collaboration
 - composition

7.2 Which form of interaction diagram emphasizes *what* collaborations occur? Which form emphasizes *when* collaborations occur?

7.3 Create a sequence diagram that models the interactions among objects in the ATM system that occur when a `Deposit` executes successfully, and explain the sequence of messages modeled by the diagram.

Answers to Software Engineering Case Study Self-Review Exercises

7.1 c.

7.2 Communication diagrams emphasize *what* collaborations occur. Sequence diagrams emphasize *when* collaborations occur.

7.3 Figure 7.29 presents a sequence diagram that models the interactions between objects in the ATM system that occur when a `Deposit` executes successfully. Figure 7.29 indicates that a `Deposit` first sends a `displayMessage` message to the `Screen` to ask the user to enter a deposit amount. Next the `Deposit` sends a `getInput` message to the `Keypad` to receive input from the user. The `Deposit` then instructs the user to enter a deposit envelope by sending a `displayMessage` message to the `Screen`. The `Deposit` next sends an `isEnvelopeReceived` message to the `DepositSlot` to confirm that the deposit envelope has been received by the ATM. Finally, the `Deposit` increases the `totalBalance` attribute (but not the `availableBalance` attribute) of the user's `Account` by sending a `credit` message to the `BankDatabase`. The `BankDatabase` responds by sending the same message to the user's `Account`.

346 Chapter 7 Arrays

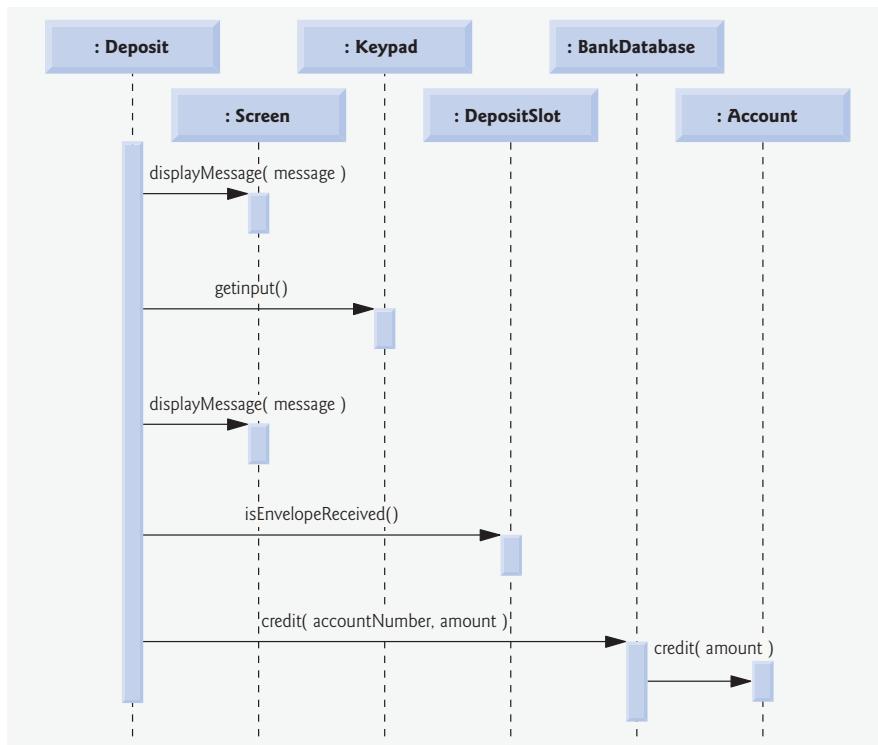

Fig. 7.29 | Sequence diagram that models a Deposit executing.

7.15 Wrap-Up

This chapter began our introduction to data structures, exploring the use of arrays to store data in and retrieve data from lists and tables of values. The chapter examples demonstrated how to declare an array, initialize an array and refer to individual elements of an array. The chapter introduced the enhanced `for` statement to iterate through arrays. We also illustrated how to pass arrays to methods and how to declare and manipulate multidimensional arrays. Finally, the chapter showed how to write methods that use variable-length argument lists and how to read arguments passed to a program from the command line.

We continue our coverage of data structures in Chapter 17, Data Structures, which introduces dynamic data structures, such as lists, queues, stacks and trees, that can grow and shrink as programs execute. Chapter 18, Generics, presents the topic of generics, which provide the means to create general models of methods and classes that can be declared once, but used with many different data types. Chapter 19, Collections, introduces the Java Collections Framework, which uses generics to allow programmers to specify the exact types of objects that a particular data structure will store. Chapter 19 also introduces Java's predefined data structures, which programmers can use instead of building their own. Chapter 19 discusses many data structures classes, including `Vector`

7.15 Wrap-Up **347**

and `ArrayList`, which are array-like data structures that can grow and shrink in response to a program's changing storage requirements. The Collections API also provides class `Arrays`, which contains utility methods for array manipulation. Chapter 19 uses several `static` methods of class `Arrays` to perform such manipulations as sorting and searching the data in an array. You will be able to use some of the `Arrays` methods discussed in Chapter 19 after reading the current chapter, but some of the `Arrays` methods require knowledge of concepts presented later in the book.

We have now introduced the basic concepts of classes, objects, control statements, methods and arrays. In Chapter 8, we take a deeper look at classes and objects.

Summary

Section 7.1, Introduction

- Arrays are data structures consisting of related data items of the same type. Arrays are fixed-length entities—they remain the same length once they are created, although an array variable may be reassigned the reference of a new array of a different length.

Section 7.2, Arrays

- An array is a group of variables (called elements or components) containing values that all have the same type. Arrays are objects, so they are considered reference types. The elements of an array can be either primitive types or reference types (including arrays).
- To refer to a particular element in an array, we specify the name of the reference to the array and the index (subscript) of the element in the array.
- A program refers to any one of an array's elements with an array-access expression that includes the name of the array followed by the index of the particular element in square brackets (`[]`).
- The first element in every array has index zero and is sometimes called the zeroth element.
- An index must be a nonnegative integer. A program can use an expression as an index.
- Every array object knows its own length and maintains this information in a `length` field. The expression `array.length` accesses `array`'s `length` field to determine the length of the array.

Section 7.3, Declaring and Creating Arrays

- To create an array object, the programmer specifies the type of the array elements and the number of elements as part of an array-creation expression that uses keyword `new`. The following array-creation expression creates an array of 100 `int` values:

```
int b[] = new int[ 100 ];
```

- When an array is created, each element of the array receives a default value—zero for numeric primitive-type elements, `false` for boolean elements and `null` for references (any nonprimitive type).
- When an array is declared, the type of the array and the square brackets can be combined at the beginning of the declaration to indicate that all the identifiers in the declaration are array variables, as in

```
double[] array1, array2;
```

- A program can declare arrays of any type. Every element of a primitive-type array contains a variable of the array's declared type. Similarly, in an array of a reference type, every element is a reference to an object of the array's declared type.

348 [Chapter 7 Arrays](#)**Section 7.4, Examples Using Arrays**

- A program can create an array and initialize its elements with an array initializer (i.e., an initializer list enclosed in braces).
- Constant variables (also called named constants or read-only variables) must be initialized before they are used and cannot be modified thereafter.
- When a Java program executes, the JVM checks array indices to ensure that they are valid (i.e., they must be greater than or equal to 0 and less than the length of the array). If a program uses an invalid index, Java generates a so-called exception to indicate that an error occurred in the program at execution time.

Section 7.6, Enhanced for Statement

- The enhanced `for` statement allows programmers to iterate through the elements of an array or a collection without using a counter. The syntax of an enhanced `for` statement is:

```
for ( parameter : arrayName )
    statement
```

where `parameter` has two parts—a type and an identifier (e.g., `int number`), and `arrayName` is the array through which to iterate.

- The enhanced `for` statement cannot be used to modify elements in an array. If a program needs to modify elements, use the traditional counter-controlled `for` statement.

Section 7.7, Passing Arrays to Methods

- When an argument is passed by value, a copy of the argument's value is made and passed to the called method. The called method works exclusively with the copy.
- When an argument is passed by reference, the called method can access the argument's value in the caller directly and possibly modify it.
- Java does not allow programmers to choose between pass-by-value and pass-by-reference—all arguments are passed by value. A method call can pass two types of values to a method—copies of primitive values (e.g., values of type `int` and `double`) and copies of references to objects. Although an object's reference is passed by value, a method can still interact with the referenced object by calling its `public` methods using the copy of the object's reference.
- To pass an object reference to a method, simply specify in the method call the name of the variable that refers to the object.
- When an argument to a method is an entire array or an individual array element of a reference type, the called method receives a copy of the array or element's reference. When an argument to a method is an individual array element of a primitive type, the called method receives a copy of the element's value.
- To pass an individual array element to a method, use the indexed name of the array as an argument in the method call.

Section 7.9, Multidimensional Arrays

- Multidimensional arrays with two dimensions are often used to represent tables of values consisting of information arranged in rows and columns.
- Arrays that require two indices to identify a particular element are called two-dimensional arrays. An array with m rows and n columns is called an m -by- n array. A two-dimensional array can be initialized with an array initializer of the form

```
arrayType arrayName[][] = { { row1 initializer }, { row2 initializer }, ... };
```

Terminology 349

- Multidimensional arrays are maintained as arrays of separate one-dimensional arrays. As a result, the lengths of the rows in a two-dimensional array are not required to be the same.
- A multidimensional array with the same number of columns in every row can be created with an array-creation expression of the form

```
arrayType arrayName[][] = new arrayType[ numRows ][ numColumns ];
```

- An argument type followed by an ellipsis (...) in a method's parameter list indicates that the method receives a variable number of arguments of that particular type. The ellipsis can occur only once in a method's parameter list, and it must be at the end of the parameter list.

Section 7.11, Variable-Length Argument Lists

- A variable-length argument list is treated as an array within the method body. The number of arguments in the array can be obtained using the array's `length` field.

Section 7.12, Using Command-Line Arguments

- Passing arguments to `main` in a Java application from the command line is achieved by including a parameter of type `String[]` in the parameter list of `main`. By convention, `main`'s parameter is named `args`.
- Java passes the command-line arguments that appear after the class name in the `java` command to the application's `main` method as `Strings` in the array `args`. The number of arguments passed in from the command line is obtained by accessing the array's `length` attribute.

Terminology

0 flag (in a format specifier)	<code>length</code> field of an array
<code>a[i]</code>	<i>m</i> -by- <i>n</i> array
<code>a[i][j]</code>	multidimensional array
array	name of an array
array-access expression	named constant
array-creation expression	nested array initializers
array initializer	off-by-one error
bounds checking	one-dimensional array
call-by-reference	<code>parseInt</code> method of class <code>Integer</code>
call-by-value	pass-by-reference
column index	pass-by-value
column of a two-dimensional array	passing arrays to methods
command-line arguments	position number
component of an array	read-only variable
constant variable	row index
data structure	row of a two-dimensional array
declare a constant variable	scalar
declare an array	scalar quantity
element of an array	square brackets, []
ellipsis (...) in a method's parameter list	subscript
enhanced <code>for</code> statement	table of values
<code>final</code> keyword	tabular format
index	traverse an array
index zero	two-dimensional array
initialize an array	value of an element
initializer list	variable-length argument list

350 Chapter 7 Arrays**Self-Review Exercises**

- 7.1** Fill in the blank(s) in each of the following statements:
- Lists and tables of values can be stored in _____.
 - An array is a group of _____ (called elements or components) containing values that all have the same _____.
 - The _____ allows programmers to iterate through the elements in an array without using a counter.
 - The number used to refer to a particular element of an array is called the element's _____.
 - An array that uses two indices is referred to as a(n) _____ array.
 - Use the enhanced for statement _____ to walk through double array numbers.
 - Command-line arguments are stored in _____.
 - Use the expression _____ to receive the total number of arguments in a command line. Assume that command-line arguments are stored in String args[].
 - Given the command java MyClass test, the first command-line argument is _____.
 - A(n) _____ in the parameter list of a method indicates that the method can receive a variable number of arguments.
- 7.2** Determine whether each of the following is *true* or *false*. If *false*, explain why.
- An array can store many different types of values.
 - An array index should normally be of type float.
 - An individual array element that is passed to a method and modified in that method will contain the modified value when the called method completes execution.
 - Command-line arguments are separated by commas.
- 7.3** Perform the following tasks for an array called fractions:
- Declare a constant ARRAY_SIZE that is initialized to 10.
 - Declare an array with ARRAY_SIZE elements of type double, and initialize the elements to 0.
 - Refer to array element 4.
 - Assign the value 1.667 to array element 9.
 - Assign the value 3.333 to array element 6.
 - Sum all the elements of the array, using a for statement. Declare the integer variable x as a control variable for the loop.
- 7.4** Perform the following tasks for an array called table:
- Declare and create the array as an integer array that has three rows and three columns. Assume that the constant ARRAY_SIZE has been declared to be 3.
 - How many elements does the array contain?
 - Use a for statement to initialize each element of the array to the sum of its indices. Assume that the integer variables x and y are declared as control variables.
- 7.5** Find and correct the error in each of the following program segments:
- `final int ARRAY_SIZE = 5;`
`ARRAY_SIZE = 10;`
 - Assume `int b[] = new int[10];`
`for (int i = 0; i <= b.length; i++)`
`b[i] = 1;`
 - Assume `int a[][] = { { 1, 2 }, { 3, 4 } };`
`a[1, 1] = 5;`

Answers to Self-Review Exercises **351****Answers to Self-Review Exercises**

- 7.1** a) arrays. b) variables, type. c) enhanced for statement. d) index (or subscript or position number). e) two-dimensional. f) `for (double d : numbers)`. g) an array of Strings, called args by convention. h) `args.length`. i) `test`. j) ellipsis (...).
- 7.2** a) False. An array can store only values of the same type.
 b) False. An array index must be an integer or an integer expression.
 c) For individual primitive-type elements of an array: False. A called method receives and manipulates a copy of the value of such an element, so modifications do not affect the original value. If the reference of an array is passed to a method, however, modifications to the array elements made in the called method are indeed reflected in the original. For individual elements of a nonprimitive type: True. A called method receives a copy of the reference of such an element, and changes to the referenced object will be reflected in the original array element.
 d) False. Command-line arguments are separated by white space.
- 7.3** a) `final int ARRAY_SIZE = 10;`
 b) `double fractions[] = new double[ARRAY_SIZE];`
 c) `fractions[4]`
 d) `fractions[9] = 1.667;`
 e) `fractions[6] = 3.333;`
 f) `double total = 0.0;`
`for (int x = 0; x < fractions.length; x++)`
 `total += fractions[x];`
- 7.4** a) `int table[][] = new int[ARRAY_SIZE][ARRAY_SIZE];`
 b) Nine.
 c) `for (int x = 0; x < table.length; x++)`
 `for (int y = 0; y < table[x].length; y++)`
 `table[x][y] = x + y;`
- 7.5** a) Error: Assigning a value to a constant after it has been initialized.
 Correction: Assign the correct value to the constant in a `final int ARRAY_SIZE` declaration or declare another variable.
 b) Error: Referencing an array element outside the bounds of the array (`b[10]`).
 Correction: Change the `<=` operator to `<`.
 c) Error: Array indexing is performed incorrectly.
 Correction: Change the statement to `a[1][1] = 5;`.

Exercises

- 7.6** Fill in the blanks in each of the following statements:
- One-dimensional array `p` contains four elements. The names of those elements are _____, _____, _____ and _____.
 - Naming an array, stating its type and specifying the number of dimensions in the array is called _____ the array.
 - In a two-dimensional array, the first index identifies the _____ of an element and the second index identifies the _____ of an element.
 - An m -by- n array contains _____ rows, _____ columns and _____ elements.
 - The name of the element in row 3 and column 5 of array `d` is _____.

352 Chapter 7 Arrays

7.7 Determine whether each of the following is *true* or *false*. If *false*, explain why.

- a) To refer to a particular location or element within an array, we specify the name of the array and the value of the particular element.
- b) An array declaration reserves space for the array.
- c) To indicate that 100 locations should be reserved for integer array *p*, the programmer writes the declaration

$$\text{p[100]};$$
- d) An application that initializes the elements of a 15-element array to zero must contain at least one *for* statement.
- e) An application that totals the elements of a two-dimensional array must contain nested *for* statements.

7.8 Write Java statements to accomplish each of the following tasks:

- a) Display the value of element 6 of array *f*.
- b) Initialize each of the five elements of one-dimensional integer array *g* to 8.
- c) Total the 100 elements of floating-point array *c*.
- d) Copy 11-element array *a* into the first portion of array *b*, which contains 34 elements.
- e) Determine and display the smallest and largest values contained in 99-element floating-point array *w*.

7.9 Consider a two-by-three integer array *t*.

- a) Write a statement that declares and creates *t*.
- b) How many rows does *t* have?
- c) How many columns does *t* have?
- d) How many elements does *t* have?
- e) Write access expressions for all the elements in row 1 of *t*.
- f) Write access expressions for all the elements in column 2 of *t*.
- g) Write a single statement that sets the element of *t* in row 0 and column 1 to zero.
- h) Write a series of statements that initializes each element of *t* to zero. Do not use a repetition statement.
- i) Write a nested *for* statement that initializes each element of *t* to zero.
- j) Write a nested *for* statement that inputs the values for the elements of *t* from the user.
- k) Write a series of statements that determines and displays the smallest value in *t*.
- l) Write a *printf* statement that displays the elements of the first row of *t*. Do not use repetition.
- m) Write a statement that totals the elements of the third column of *t*. Do not use repetition.
- n) Write a series of statements that displays the contents of *t* in tabular format. List the column indices as headings across the top, and list the row indices at the left of each row.

7.10 (*Sales Commissions*) Use a one-dimensional array to solve the following problem: A company pays its salespeople on a commission basis. The salespeople receive \$200 per week plus 9% of their gross sales for that week. For example, a salesperson who grosses \$5000 in sales in a week receives \$200 plus 9% of \$5000, or a total of \$650. Write an application (using an array of counters) that determines how many of the salespeople earned salaries in each of the following ranges (assume that each salesperson's salary is truncated to an integer amount):

- a) \$200–299
- b) \$300–399
- c) \$400–499
- d) \$500–599
- e) \$600–699
- f) \$700–799

[Exercises](#) **353**

- g) \$800–899
- h) \$900–999
- i) \$1000 and over

Summarize the results in tabular format.

7.11 Write statements that perform the following one-dimensional-array operations:

- a) Set the 10 elements of integer array `counts` to zero.
- b) Add one to each of the 15 elements of integer array `bonus`.
- c) Display the five values of integer array `bestScores` in column format.

7.12 (*Duplicate Elimination*) Use a one-dimensional array to solve the following problem: Write an application that inputs five numbers, each between 10 and 100, inclusive. As each number is read, display it only if it is not a duplicate of a number already read. Provide for the “worst case,” in which all five numbers are different. Use the smallest possible array to solve this problem. Display the complete set of unique values input after the user enters each new value.

7.13 Label the elements of three-by-five two-dimensional array `sales` to indicate the order in which they are set to zero by the following program segment:

```
for ( int row = 0; row < sales.length; row++ )
{
    for ( int col = 0; col < sales[ row ].length; col++ )
    {
        sales[ row ][ col ] = 0;
    }
}
```

7.14 Write an application that calculates the product of a series of integers that are passed to method `product` using a variable-length argument list. Test your method with several calls, each with a different number of arguments.

7.15 Rewrite Fig. 7.2 so that the size of the array is specified by the first command-line argument. If no command-line argument is supplied, use 10 as the default size of the array.

7.16 Write an application that uses an enhanced `for` statement to sum the `double` values passed by the command-line arguments. [Hint: Use the `static` method `parseDouble` of class `Double` to convert a `String` to a `double` value.]

7.17 (*Dice Rolling*) Write an application to simulate the rolling of two dice. The application should use an object of class `Random` once to roll the first die and again to roll the second die. The sum of the two values should then be calculated. Each die can show an integer value from 1 to 6, so the sum of the values will vary from 2 to 12, with 7 being the most frequent sum, and 2 and 12 the least frequent. Figure 7.30 shows the 36 possible combinations of the two dice. Your application should roll the dice 36,000 times. Use a one-dimensional array to tally the number of times each possible sum appears. Display the results in tabular format. Determine whether the totals are reasonable (e.g., there are six ways to roll a 7, so approximately one-sixth of the rolls should be 7).

7.18 (*Game of Craps*) Write an application that runs 1000 games of craps (Fig. 6.9) and answers the following questions:

- a) How many games are won on the first roll, second roll, ..., twentieth roll and after the twentieth roll?
- b) How many games are lost on the first roll, second roll, ..., twentieth roll and after the twentieth roll?
- c) What are the chances of winning at craps? [Note: You should discover that craps is one of the fairest casino games. What do you suppose this means?]
- d) What is the average length of a game of craps?
- e) Do the chances of winning improve with the length of the game?

354 Chapter 7 Arrays

	1	2	3	4	5	6
1	2	3	4	5	6	7
2	3	4	5	6	7	8
3	4	5	6	7	8	9
4	5	6	7	8	9	10
5	6	7	8	9	10	11
6	7	8	9	10	11	12

Fig. 7.30 | The 36 possible sums of two dice.

7.19 (*Airline Reservations System*) A small airline has just purchased a computer for its new automated reservations system. You have been asked to develop the new system. You are to write an application to assign seats on each flight of the airline's only plane (capacity: 10 seats).

Your application should display the following alternatives: Please type 1 for First Class and Please type 2 for Economy. If the user types 1, your application should assign a seat in the first-class section (seats 1–5). If the user types 2, your application should assign a seat in the economy section (seats 6–10). Your application should then display a boarding pass indicating the person's seat number and whether it is in the first-class or economy section of the plane.

Use a one-dimensional array of primitive type `boolean` to represent the seating chart of the plane. Initialize all the elements of the array to `false` to indicate that all the seats are empty. As each seat is assigned, set the corresponding elements of the array to `true` to indicate that the seat is no longer available.

Your application should never assign a seat that has already been assigned. When the economy section is full, your application should ask the person if it is acceptable to be placed in the first-class section (and vice versa). If yes, make the appropriate seat assignment. If no, display the message "Next flight leaves in 3 hours."

7.20 (*Total Sales*) Use a two-dimensional array to solve the following problem: A company has four salespeople (1 to 4) who sell five different products (1 to 5). Once a day, each salesperson passes in a slip for each type of product sold. Each slip contains the following:

- a) The salesperson number
- b) The product number
- c) The total dollar value of that product sold that day

Thus, each salesperson passes in between 0 and 5 sales slips per day. Assume that the information from all the slips for last month is available. Write an application that will read all this information for last month's sales and summarize the total sales by salesperson and by product. All totals should be stored in the two-dimensional array `sales`. After processing all the information for last month, display the results in tabular format, with each column representing a particular salesperson and each row representing a particular product. Cross-total each row to get the total sales of each product for last month. Cross-total each column to get the total sales by salesperson for last month. Your tabular output should include these cross-totals to the right of the totaled rows and to the bottom of the totaled columns.

7.21 (*Turtle Graphics*) The Logo language made the concept of *turtle graphics* famous. Imagine a mechanical turtle that walks around the room under the control of a Java application. The turtle holds a pen in one of two positions, up or down. While the pen is down, the turtle traces out shapes as it moves, and while the pen is up, the turtle moves about freely without writing anything. In this problem, you will simulate the operation of the turtle and create a computerized sketchpad.

Exercises **355**

Use a 20-by-20 array `floor` that is initialized to zeros. Read commands from an array that contains them. Keep track of the current position of the turtle at all times and whether the pen is currently up or down. Assume that the turtle always starts at position (0, 0) of the floor with its pen up. The set of turtle commands your application must process are shown in Fig. 7.31.

Suppose that the turtle is somewhere near the center of the floor. The following “program” would draw and display a 12-by-12 square, leaving the pen in the up position:

```
2
5,12
3
5,12
3
5,12
3
5,12
1
6
9
```

As the turtle moves with the pen down, set the appropriate elements of array `floor` to 1s. When the 6 command (display the array) is given, wherever there is a 1 in the array, display an asterisk or any character you choose. Wherever there is a 0, display a blank.

Write an application to implement the turtle graphics capabilities discussed here. Write several turtle graphics programs to draw interesting shapes. Add other commands to increase the power of your turtle graphics language.

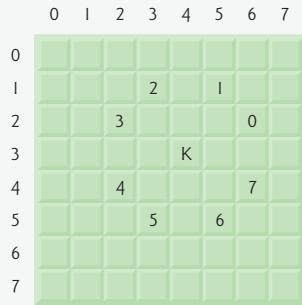

7.22 (*Knight’s Tour*) One of the more interesting puzzlers for chess buffs is the Knight’s Tour problem, originally proposed by the mathematician Euler. Can the chess piece called the knight move around an empty chessboard and touch each of the 64 squares once and only once? We study this intriguing problem in depth here.

The knight makes only L-shaped moves (two spaces in one direction and one space in a perpendicular direction). Thus, as shown in Fig. 7.32, from a square near the middle of an empty chessboard, the knight (labeled K) can make eight different moves (numbered 0 through 7).

- Draw an eight-by-eight chessboard on a sheet of paper, and attempt a Knight’s Tour by hand. Put a 1 in the starting square, a 2 in the second square, a 3 in the third, and so on. Before starting the tour, estimate how far you think you will get, remembering that a full tour consists of 64 moves. How far did you get? Was this close to your estimate?

Command	Meaning
1	Pen up
2	Pen down
3	Turn right
4	Turn left
5, 10	Move forward 10 spaces (replace 10 for a different number of spaces)
6	Display the 20-by-20 array
9	End of data (sentinel)

Fig. 7.31 | Turtle graphics commands.

356 Chapter 7 Arrays**Fig. 7.32** | The eight possible moves of the knight.

- b) Now let us develop an application that will move the knight around a chessboard. The board is represented by an eight-by-eight two-dimensional array board. Each square is initialized to zero. We describe each of the eight possible moves in terms of its horizontal and vertical components. For example, a move of type 0, as shown in Fig. 7.32, consists of moving two squares horizontally to the right and one square vertically upward. A move of type 2 consists of moving one square horizontally to the left and two squares vertically upward. Horizontal moves to the left and vertical moves upward are indicated with negative numbers. The eight moves may be described by two one-dimensional arrays, `horizontal` and `vertical`, as follows:

```
horizontal[ 0 ] = 2      vertical[ 0 ] = -1
horizontal[ 1 ] = 1      vertical[ 1 ] = -2
horizontal[ 2 ] = -1     vertical[ 2 ] = -2
horizontal[ 3 ] = -2     vertical[ 3 ] = -1
horizontal[ 4 ] = -2     vertical[ 4 ] = 1
horizontal[ 5 ] = -1     vertical[ 5 ] = 2
horizontal[ 6 ] = 1      vertical[ 6 ] = 2
horizontal[ 7 ] = 2      vertical[ 7 ] = 1
```

Let the variables `currentRow` and `currentColumn` indicate the row and column, respectively, of the knight's current position. To make a move of type `moveNumber`, where `moveNumber` is between 0 and 7, your application should use the statements

```
currentRow += vertical[ moveNumber ];
currentColumn += horizontal[ moveNumber ];
```

Write an application to move the knight around the chessboard. Keep a counter that varies from 1 to 64. Record the latest count in each square the knight moves to. Test each potential move to see if the knight has already visited that square. Test every potential move to ensure that the knight does not land off the chessboard. Run the application. How many moves did the knight make?

- c) After attempting to write and run a Knight's Tour application, you have probably developed some valuable insights. We will use these insights to develop a *heuristic* (or "rule of thumb") for moving the knight. Heuristics do not guarantee success, but a carefully developed heuristic greatly improves the chance of success. You may have observed that the outer squares are more troublesome than the squares nearer the center of the board. In fact, the most troublesome or inaccessible squares are the four corners.

[Exercises](#) **357**

Intuition may suggest that you should attempt to move the knight to the most troublesome squares first and leave open those that are easiest to get to, so that when the board gets congested near the end of the tour, there will be a greater chance of success.

We could develop an “accessibility heuristic” by classifying each of the squares according to how accessible it is and always moving the knight (using the knight’s L-shaped moves) to the most inaccessible square. We label a two-dimensional array accessibility with numbers indicating from how many squares each particular square is accessible. On a blank chessboard, each of the 16 squares nearest the center is rated as 8, each corner square is rated as 2, and the other squares have accessibility numbers of 3, 4 or 6 as follows:

2	3	4	4	4	4	3	2
3	4	6	6	6	6	4	3
4	6	8	8	8	6	4	
4	6	8	8	8	6	4	
4	6	8	8	8	8	6	4
4	6	8	8	8	8	6	4
3	4	6	6	6	6	4	3
2	3	4	4	4	4	3	2

Write a new version of the Knight’s Tour, using the accessibility heuristic. The knight should always move to the square with the lowest accessibility number. In case of a tie, the knight may move to any of the tied squares. Therefore, the tour may begin in any of the four corners. [Note: As the knight moves around the chessboard, your application should reduce the accessibility numbers as more squares become occupied. In this way, at any given time during the tour, each available square’s accessibility number will remain equal to precisely the number of squares from which that square may be reached.] Run this version of your application. Did you get a full tour? Modify the application to run 64 tours, one starting from each square of the chessboard. How many full tours did you get?

- d) Write a version of the Knight’s Tour application that, when encountering a tie between two or more squares, decides what square to choose by looking ahead to those squares reachable from the “tied” squares. Your application should move to the tied square for which the next move would arrive at a square with the lowest accessibility number.

7.23 (*Knight’s Tour: Brute-Force Approaches*) In part (c) of Exercise 7.22, we developed a solution to the Knight’s Tour problem. The approach used, called the “accessibility heuristic,” generates many solutions and executes efficiently.

As computers continue to increase in power, we will be able to solve more problems with sheer computer power and relatively unsophisticated algorithms. Let us call this approach “brute-force” problem solving.

- a) Use random-number generation to enable the knight to walk around the chessboard (in its legitimate L-shaped moves) at random. Your application should run one tour and display the final chessboard. How far did the knight get?
- b) Most likely, the application in part (a) produced a relatively short tour. Now modify your application to attempt 1000 tours. Use a one-dimensional array to keep track of the number of tours of each length. When your application finishes attempting the 1000 tours, it should display this information in neat tabular format. What was the best result?
- c) Most likely, the application in part (b) gave you some “respectable” tours, but no full tours. Now let your application run until it produces a full tour. [Caution: This version of the application could run for hours on a powerful computer.] Once again, keep a ta-

358 Chapter 7 Arrays

ble of the number of tours of each length, and display this table when the first full tour is found. How many tours did your application attempt before producing a full tour? How much time did it take?

- d) Compare the brute-force version of the Knight's Tour with the accessibility-heuristic version. Which required a more careful study of the problem? Which algorithm was more difficult to develop? Which required more computer power? Could we be certain (in advance) of obtaining a full tour with the accessibility-heuristic approach? Could we be certain (in advance) of obtaining a full tour with the brute-force approach? Argue the pros and cons of brute-force problem solving in general.

7.24 (*Eight Queens*) Another puzzler for chess buffs is the Eight Queens problem, which asks the following: Is it possible to place eight queens on an empty chessboard so that no queen is “attacking” any other (i.e., no two queens are in the same row, in the same column or along the same diagonal)? Use the thinking developed in Exercise 7.22 to formulate a heuristic for solving the Eight Queens problem. Run your application. [Hint: It is possible to assign a value to each square of the chessboard to indicate how many squares of an empty chessboard are “eliminated” if a queen is placed in that square. Each of the corners would be assigned the value 22, as demonstrated by Fig. 7.33. Once these “elimination numbers” are placed in all 64 squares, an appropriate heuristic might be as follows: Place the next queen in the square with the smallest elimination number. Why is this strategy intuitively appealing?]

7.25 (*Eight Queens: Brute-Force Approaches*) In this exercise, you will develop several brute-force approaches to solving the Eight Queens problem introduced in Exercise 7.24.

- a) Use the random brute-force technique developed in Exercise 7.23 to solve the Eight Queens problem.
- b) Use an exhaustive technique (i.e., try all possible combinations of eight queens on the chessboard) to solve the Eight Queens problem.
- c) Why might the exhaustive brute-force approach not be appropriate for solving the Knight's Tour problem?
- d) Compare and contrast the random brute-force and exhaustive brute-force approaches.

7.26 (*Knight's Tour: Closed-Tour Test*) In the Knight's Tour (Exercise 7.22), a full tour occurs when the knight makes 64 moves, touching each square of the chessboard once and only once. A closed tour occurs when the 64th move is one move away from the square in which the knight started the tour. Modify the application you wrote in Exercise 7.22 to test for a closed tour if a full tour has occurred.

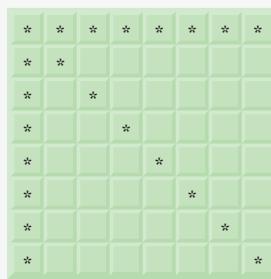

Fig. 7.33 | The 22 squares eliminated by placing a queen in the upper left corner.

[Exercises](#) **359**

7.27 (*Sieve of Eratosthenes*) A prime number is any integer greater than 1 that is evenly divisible only by itself and 1. The Sieve of Eratosthenes is a method of finding prime numbers. It operates as follows:

- Create a primitive type `boolean` array with all elements initialized to `true`. Array elements with prime indices will remain `true`. All other array elements will eventually be set to `false`.
- Starting with array index 2, determine whether a given element is `true`. If so, loop through the remainder of the array and set to `false` every element whose index is a multiple of the index for the element with value `true`. Then continue the process with the next element with value `true`. For array index 2, all elements beyond element 2 in the array that have indices which are multiples of 2 (indices 4, 6, 8, 10, etc.) will be set to `false`; for array index 3, all elements beyond element 3 in the array that have indices which are multiples of 3 (indices 6, 9, 12, 15, etc.) will be set to `false`; and so on.

When this process completes, the array elements that are still `true` indicate that the index is a prime number. These indices can be displayed. Write an application that uses an array of 1000 elements to determine and display the prime numbers between 2 and 999. Ignore array elements 0 and 1.

7.28 (*Simulation: The Tortoise and the Hare*) In this problem, you will re-create the classic race of the tortoise and the hare. You will use random-number generation to develop a simulation of this memorable event.

Our contenders begin the race at square 1 of 70 squares. Each square represents a possible position along the race course. The finish line is at square 70. The first contender to reach or pass square 70 is rewarded with a pail of fresh carrots and lettuce. The course weaves its way up the side of a slippery mountain, so occasionally the contenders lose ground.

A clock ticks once per second. With each tick of the clock, your application should adjust the position of the animals according to the rules in Fig. 7.34. Use variables to keep track of the positions of the animals (i.e., position numbers are 1–70). Start each animal at position 1 (the “starting gate”). If an animal slips left before square 1, move it back to square 1.

Generate the percentages in Fig. 7.34 by producing a random integer i in the range $1 \leq i \leq 10$. For the tortoise, perform a “fast plod” when $1 \leq i \leq 5$, a “slip” when $6 \leq i \leq 7$ or a “slow plod” when $8 \leq i \leq 10$. Use a similar technique to move the hare.

Animal	Move type	Percentage of the time	Actual move
Tortoise	Fast plod	50%	3 squares to the right
	Slip	20%	6 squares to the left
	Slow plod	30%	1 square to the right
Hare	Sleep	20%	No move at all
	Big hop	20%	9 squares to the right
	Big slip	10%	12 squares to the left
	Small hop	30%	1 square to the right
	Small slip	20%	2 squares to the left

Fig. 7.34 | Rules for adjusting the positions of the tortoise and the hare.

360 Chapter 7 Arrays

Begin the race by displaying

BANG !!!!!
AND THEY'RE OFF !!!!!

Then, for each tick of the clock (i.e., each repetition of a loop), display a 70-position line showing the letter T in the position of the tortoise and the letter H in the position of the hare. Occasionally, the contenders will land on the same square. In this case, the tortoise bites the hare, and your application should display OUCH!!! beginning at that position. All output positions other than the T, the H or the OUCH!!! (in case of a tie) should be blank.

After each line is displayed, test for whether either animal has reached or passed square 70. If so, display the winner and terminate the simulation. If the tortoise wins, display TORTOISE WINS!!! YAY!!! If the hare wins, display Hare wins. Yuch. If both animals win on the same tick of the clock, you may want to favor the tortoise (the “underdog”), or you may want to display It's a tie. If neither animal wins, perform the loop again to simulate the next tick of the clock. When you are ready to run your application, assemble a group of fans to watch the race. You'll be amazed at how involved your audience gets!

Later in the book, we introduce a number of Java capabilities, such as graphics, images, animation, sound and multithreading. As you study those features, you might enjoy enhancing your tortoise-and-hare contest simulation.

7.29 (*Fibonacci Series*) The Fibonacci series

0, 1, 1, 2, 3, 5, 8, 13, 21, ...

begins with the terms 0 and 1 and has the property that each succeeding term is the sum of the two preceding terms.

- a) Write a method `fibonacci(n)` that calculates the *n*th Fibonacci number. Incorporate this method into an application that enables the user to enter the value of *n*.
- b) Determine the largest Fibonacci number that can be displayed on your system.
- c) Modify the application you wrote in part (a) to use `double` instead of `int` to calculate and return Fibonacci numbers, and use this modified application to repeat part (b).

Exercises 7.30—7.33 are reasonably challenging. Once you have done these problems, you ought to be able to implement most popular card games easily.

7.30 (*Card Shuffling and Dealing*) Modify the application of Fig. 7.11 to deal a five-card poker hand. Then modify class `DeckOfCards` of Fig. 7.10 to include methods that determine whether a hand contains

- a) a pair
- b) two pairs
- c) three of a kind (e.g., three jacks)
- d) four of a kind (e.g., four aces)
- e) a flush (i.e., all five cards of the same suit)
- f) a straight (i.e., five cards of consecutive face values)
- g) a full house (i.e., two cards of one face value and three cards of another face value)

[Hint: Add methods `getFace` and `getSuit` to class `Card` of Fig. 7.9.]

7.31 (*Card Shuffling and Dealing*) Use the methods developed in Exercise 7.30 to write an application that deals two five-card poker hands, evaluates each hand and determines which is better.

7.32 (*Card Shuffling and Dealing*) Modify the application developed in Exercise 7.31 so that it can simulate the dealer. The dealer's five-card hand is dealt “face down,” so the player cannot see it. The application should then evaluate the dealer's hand, and, based on the quality of the hand, the

Special Section: Building Your Own Computer **361**

dealer should draw one, two or three more cards to replace the corresponding number of unneeded cards in the original hand. The application should then reevaluate the dealer's hand. [Caution: This is a difficult problem!]

7.33 (*Card Shuffling and Dealing*) Modify the application developed in Exercise 7.32 so that it can handle the dealer's hand automatically, but the player is allowed to decide which cards of the player's hand to replace. The application should then evaluate both hands and determine who wins. Now use this new application to play 20 games against the computer. Who wins more games, you or the computer? Have a friend play 20 games against the computer. Who wins more games? Based on the results of these games, refine your poker-playing application. (This, too, is a difficult problem.) Play 20 more games. Does your modified application play a better game?

Special Section: Building Your Own Computer

In the next several problems, we take a temporary diversion from the world of high-level language programming to "peel open" a computer and look at its internal structure. We introduce machine-language programming and write several machine-language programs. To make this an especially valuable experience, we then build a computer (through the technique of software-based *simulation*) on which you can execute your machine-language programs.

7.34 (*Machine-Language Programming*) Let us create a computer called the Simpletron. As its name implies, it is a simple, but powerful, machine. The Simpletron runs programs written in the only language it directly understands: Simpletron Machine Language (SML).

The Simpletron contains an *accumulator*—a special register in which information is put before the Simpletron uses that information in calculations or examines it in various ways. All the information in the Simpletron is handled in terms of *words*. A word is a signed four-digit decimal number, such as +3364, -1293, +0007 and -0001. The Simpletron is equipped with a 100-word memory, and these words are referenced by their location numbers 00, 01, ..., 99.

Before running an SML program, we must *load*, or place, the program into memory. The first instruction (or statement) of every SML program is always placed in location 00. The simulator will start executing at this location.

Each instruction written in SML occupies one word of the Simpletron's memory (and hence instructions are signed four-digit decimal numbers). We shall assume that the sign of an SML instruction is always plus, but the sign of a data word may be either plus or minus. Each location in the Simpletron's memory may contain an instruction, a data value used by a program or an unused (and hence undefined) area of memory. The first two digits of each SML instruction are the *operation code* specifying the operation to be performed. SML operation codes are summarized in Fig. 7.35.

Operation code	Meaning
<i>Input/output operations:</i>	
<code>final int READ = 10;</code>	Read a word from the keyboard into a specific location in memory.
<code>final int WRITE = 11;</code>	Write a word from a specific location in memory to the screen.

Fig. 7.35 | Simpletron Machine Language (SML) operation codes. (Part 1 of 2.)

362 Chapter 7 Arrays

Operation code	Meaning
<i>Load/store operations:</i>	
<code>final int LOAD = 20;</code>	Load a word from a specific location in memory into the accumulator.
<code>final int STORE = 21;</code>	Store a word from the accumulator into a specific location in memory.
<i>Arithmetic operations:</i>	
<code>final int ADD = 30;</code>	Add a word from a specific location in memory to the word in the accumulator (leave the result in the accumulator).
<code>final int SUBTRACT = 31;</code>	Subtract a word from a specific location in memory from the word in the accumulator (leave the result in the accumulator).
<code>final int DIVIDE = 32;</code>	Divide a word from a specific location in memory into the word in the accumulator (leave result in the accumulator).
<code>final int MULTIPLY = 33;</code>	Multiply a word from a specific location in memory by the word in the accumulator (leave the result in the accumulator).
<i>Transfer-of-control operations:</i>	
<code>final int BRANCH = 40;</code>	Branch to a specific location in memory.
<code>final int BRANCHNEG = 41;</code>	Branch to a specific location in memory if the accumulator is negative.
<code>final int BRANCHZERO = 42;</code>	Branch to a specific location in memory if the accumulator is zero.
<code>final int HALT = 43;</code>	Halt. The program has completed its task.

Fig. 7.35 | Simpletron Machine Language (SML) operation codes. (Part 2 of 2.)

The last two digits of an SML instruction are the *operand*—the address of the memory location containing the word to which the operation applies. Let's consider several simple SML programs.

The first SML program (Fig. 7.36) reads two numbers from the keyboard and computes and displays their sum. The instruction +1007 reads the first number from the keyboard and places it into location 07 (which has been initialized to 0). Then instruction +1008 reads the next number into location 08. The *load* instruction, +2007, puts the first number into the accumulator, and the *add* instruction, +3008, adds the second number to the number in the accumulator. *All SML arithmetic instructions leave their results in the accumulator.* The *store* instruction, +2109, places the result back into memory location 09, from which the *write* instruction, +1109, takes the number and displays it (as a signed four-digit decimal number). The *halt* instruction, +4300, terminates execution.

Special Section: Building Your Own Computer

363

Location	Number	Instruction
00	+1007	(Read A)
01	+1008	(Read B)
02	+2007	(Load A)
03	+3008	(Add B)
04	+2109	(Store C)
05	+1109	(Write C)
06	+4300	(Halt)
07	+0000	(Variable A)
08	+0000	(Variable B)
09	+0000	(Result C)

Fig. 7.36 | SML program that reads two integers and computes their sum.

The second SML program (Fig. 7.37) reads two numbers from the keyboard and determines and displays the larger value. Note the use of the instruction +4107 as a conditional transfer of control, much the same as Java's `if` statement.

Location	Number	Instruction
00	+1009	(Read A)
01	+1010	(Read B)
02	+2009	(Load A)
03	+3110	(Subtract B)
04	+4107	(Branch negative to 07)
05	+1109	(Write A)
06	+4300	(Halt)
07	+1110	(Write B)
08	+4300	(Halt)
09	+0000	(Variable A)
10	+0000	(Variable B)

Fig. 7.37 | SML program that reads two integers and determines the larger.

364 Chapter 7 Arrays

Now write SML programs to accomplish each of the following tasks:

- Use a sentinel-controlled loop to read 10 positive numbers. Compute and display their sum.
- Use a counter-controlled loop to read seven numbers, some positive and some negative, and compute and display their average.
- Read a series of numbers, and determine and display the largest number. The first number read indicates how many numbers should be processed.

7.35 (*Computer Simulator*) In this problem, you are going to build your own computer. No, you will not be soldering components together. Rather, you will use the powerful technique of *software-based simulation* to create an object-oriented *software model* of the Simpletron of Exercise 7.34. Your Simpletron simulator will turn the computer you are using into a Simpletron, and you will actually be able to run, test and debug the SML programs you wrote in Exercise 7.34.

When you run your Simpletron simulator, it should begin by displaying:

```
*** Welcome to Simpletron! ***
*** Please enter your program one instruction ***
*** (or data word) at a time into the input ***
*** text field. I will display the location ***
*** number and a question mark (?). You then ***
*** type the word for that location. Press the ***
*** Done button to stop entering your program. ***
```

Your application should simulate the memory of the Simpletron with a one-dimensional array `memory` that has 100 elements. Now assume that the simulator is running, and let us examine the dialog as we enter the program of Fig. 7.37 (Exercise 7.34):

```
00 ? +1009
01 ? +1010
02 ? +2009
03 ? +3110
04 ? +4107
05 ? +1109
06 ? +4300
07 ? +1110
08 ? +4300
09 ? +0000
10 ? +0000
11 ? -9999
```

Your program should display the memory location followed by a question mark. Each value to the right of a question mark is input by the user. When the sentinel value `-99999` is input, the program should display the following:

```
*** Program loading completed ***
*** Program execution begins ***
```

The SML program has now been placed (or loaded) in array `memory`. Now the Simpletron executes the SML program. Execution begins with the instruction in location 00 and, as in Java, continues sequentially, unless directed to some other part of the program by a transfer of control.

Use the variable `accumulator` to represent the accumulator register. Use the variable `instructionCounter` to keep track of the location in memory that contains the instruction being performed. Use the variable `operationCode` to indicate the operation currently being performed (i.e., the left two digits of the instruction word). Use the variable `operand` to indicate the memory location on which the current instruction operates. Thus, `operand` is the rightmost two digits of the instruction currently being performed. Do not execute instructions directly from memory. Rather,

Special Section: Building Your Own Computer **365**

transfer the next instruction to be performed from memory to a variable called `instructionRegister`. Then “pick off” the left two digits and place them in `operationCode`, and “pick off” the right two digits and place them in `operand`. When the Simpletron begins execution, the special registers are all initialized to zero.

Now, let us “walk through” execution of the first SML instruction, +1009 in memory location 00. This procedure is called an *instruction execution cycle*.

The `instructionCounter` tells us the location of the next instruction to be performed. We *fetch* the contents of that location from `memory` by using the Java statement

```
instructionRegister = memory[ instructionCounter ];
```

The operation code and the operand are extracted from the instruction register by the statements

```
operationCode = instructionRegister / 100;
operand = instructionRegister % 100;
```

Now the Simpletron must determine that the operation code is actually a *read* (versus a *write*, a *load*, and so on). A `switch` differentiates among the 12 operations of SML. In the `switch` statement, the behavior of various SML instructions is simulated as shown in Fig. 7.38. We discuss branch instructions shortly and leave the others to you.

When the SML program completes execution, the name and contents of each register as well as the complete contents of `memory` should be displayed. Such a printout is often called a computer dump (no, a computer dump is not a place where old computers go). To help you program your dump method, a sample dump format is shown in Fig. 7.39. Note that a dump after executing a Simpletron program would show the actual values of instructions and data values at the moment execution terminated.

Let us proceed with the execution of our program’s first instruction—namely, the +1009 in location 00. As we have indicated, the `switch` statement simulates this task by prompting the user to enter a value, reading the value and storing it in memory location `memory[operand]`. The value is then read into location 09.

At this point, simulation of the first instruction is completed. All that remains is to prepare the Simpletron to execute the next instruction. Since the instruction just performed was not a transfer of control, we need merely increment the instruction-counter register as follows:

```
instructionCounter++;
```

This action completes the simulated execution of the first instruction. The entire process (i.e., the instruction execution cycle) begins anew with the fetch of the next instruction to execute.

Instruction	Description
<code>read:</code>	Display the prompt "Enter an integer", then input the integer and store it in location <code>memory[operand]</code> .
<code>load:</code>	<code>accumulator = memory[operand];</code>
<code>add:</code>	<code>accumulator += memory[operand];</code>
<code>halt:</code>	This instruction displays the message *** Simpletron execution terminated ***

Fig. 7.38 | Behavior of several SML instructions in the Simpletron.

366 Chapter 7 Arrays

```

REGISTERS:
accumulator      +0000
instructionCounter 00
instructionRegister +0000
operationCode      00
operand            00

MEMORY:
 0   1   2   3   4   5   6   7   8   9
0 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
10 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
20 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
30 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
40 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
50 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
60 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
70 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
80 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000
90 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000 +0000

```

Fig. 7.39 | A sample dump.

Now let us consider how the branching instructions—the transfers of control—are simulated. All we need to do is adjust the value in the instruction counter appropriately. Therefore, the unconditional branch instruction (40) is simulated within the `switch` as

```
instructionCounter = operand;
```

The conditional “branch if accumulator is zero” instruction is simulated as

```
if ( accumulator == 0 )
    instructionCounter = operand;
```

At this point, you should implement your Simpletron simulator and run each of the SML programs you wrote in Exercise 7.34. If you desire, you may embellish SML with additional features and provide for these features in your simulator.

Your simulator should check for various types of errors. During the program-loading phase, for example, each number the user types into the Simpletron’s memory must be in the range -9999 to +9999. Your simulator should test that each number entered is in this range and, if not, keep prompting the user to reenter the number until the user enters a correct number.

During the execution phase, your simulator should check for various serious errors, such as attempts to divide by zero, attempts to execute invalid operation codes, and accumulator overflows (i.e., arithmetic operations resulting in values larger than +9999 or smaller than -9999). Such serious errors are called *fatal errors*. When a fatal error is detected, your simulator should display an error message, such as

```
*** Attempt to divide by zero ***
*** Simpletron execution abnormally terminated ***
```

and should display a full computer dump in the format we discussed previously. This treatment will help the user locate the error in the program.

7.36 (*Simpletron Simulator Modifications*) In Exercise 7.35, you wrote a software simulation of a computer that executes programs written in Simpletron Machine Language (SML). In this exercise,

Special Section: Building Your Own Computer **367**

we propose several modifications and enhancements to the Simpletron Simulator. In Exercises 17.26–17.27, we propose building a compiler that converts programs written in a high-level programming language (a variation of Basic) to Simpletron Machine Language. Some of the following modifications and enhancements may be required to execute the programs produced by the compiler:

- a) Extend the Simpletron Simulator's memory to contain 1000 memory locations to enable the Simpletron to handle larger programs.
- b) Allow the simulator to perform remainder calculations. This modification requires an additional SML instruction.
- c) Allow the simulator to perform exponentiation calculations. This modification requires an additional SML instruction.
- d) Modify the simulator to use hexadecimal values rather than integer values to represent SML instructions.
- e) Modify the simulator to allow output of a newline. This modification requires an additional SML instruction.
- f) Modify the simulator to process floating-point values in addition to integer values.
- g) Modify the simulator to handle string input. [*Hint:* Each Simpletron word can be divided into two groups, each holding a two-digit integer. Each two-digit integer represents the ASCII (see Appendix B) decimal equivalent of a character. Add a machine-language instruction that will input a string and store the string, beginning at a specific Simpletron memory location. The first half of the word at that location will be a count of the number of characters in the string (i.e., the length of the string). Each succeeding half-word contains one ASCII character expressed as two decimal digits. The machine-language instruction converts each character into its ASCII equivalent and assigns it to a half-word.]
- h) Modify the simulator to handle output of strings stored in the format of part (g). [*Hint:* Add a machine-language instruction that will display a string, beginning at a certain Simpletron memory location. The first half of the word at that location is a count of the number of characters in the string (i.e., the length of the string). Each succeeding half-word contains one ASCII character expressed as two decimal digits. The machine-language instruction checks the length and displays the string by translating each two-digit number into its equivalent character.]

8

Classes and Objects: A Deeper Look

OBJECTIVES

In this chapter you will learn:

- Encapsulation and data hiding.
- The notions of data abstraction and abstract data types (ADTs).
- To use keyword `this`.
- To use `static` variables and methods.
- To import `static` members of a class.
- To use the `enum` type to create sets of constants with unique identifiers.
- To declare `enum` constants with parameters.
- To organize classes in packages to promote reuse.

Instead of this absurd division into sexes, they ought to class people as static and dynamic.

—Evelyn Waugh

Is it a world to hide virtues in?

—William Shakespeare

*But what, to serve our private ends,
Forbids the cheating of our friends?*

—Charles Churchill

This above all: to thine own self be true.

—William Shakespeare

*Don't be "consistent,"
but be simply true.*

—Oliver Wendell Holmes, Jr.

[Summary](#) | [Terminology](#) | [Self-Review Exercise](#) | [Answers to Self-Review Exercise](#) | [Exercises](#)

8.1 Introduction

In our discussions of object-oriented programs in the preceding chapters, we introduced many basic concepts and terminology that relate to Java object-oriented programming (OOP). We also discussed our program development methodology: We selected appropriate variables and methods for each program and specified the manner in which an object of our class collaborated with objects of Java API classes to accomplish the program's overall goals.

In this chapter, we take a deeper look at building classes, controlling access to members of a class and creating constructors. We discuss composition—a capability that allows a class to have references to objects of other classes as members. We reexamine the use of *set* and *get* methods and further explore the class type `enum` (introduced in Section 6.10) that enables programmers to declare and manipulate sets of unique identifiers that represent constant values. In Section 6.10, we introduced the basic `enum` type, which appeared within another class and simply declared a set of constants. In this chapter, we discuss the relationship between `enum` types and classes, demonstrating that an `enum`, like a class, can be declared in its own file with constructors, methods and fields. The chapter also discusses `static` class members and `final` instance variables in detail. We investigate issues such as software reusability, data abstraction and encapsulation. Finally, we explain how to orga-

370 Chapter 8 Classes and Objects: A Deeper Look

nize classes in packages to help manage large applications and promote reuse, then show a special relationship between classes in the same package.

Chapter 9, Object-Oriented Programming: Inheritance, and Chapter 10, Object-Oriented Programming: Polymorphism, introduce two additional key object-oriented programming technologies.

8.2 Time Class Case Study

Time1 Class Declaration

Our first example consists of two classes—`Time1` (Fig. 8.1) and `Time1Test` (Fig. 8.2). Class `Time1` represents the time of day. Class `Time1Test` is an application class in which the `main` method creates one object of class `Time1` and invokes its methods. These classes must be declared in separate files because they are both `public` classes. The output of this program appears in Fig. 8.2.

Class `Time1` contains three `private` instance variables of type `int` (Fig. 8.1, lines 6–8)—`hour`, `minute` and `second`—that represent the time in universal-time format (24-hour clock format in which hours are in the range 0–23). Class `Time1` contains `public` methods `setTime` (lines 12–17), `toUniversalString` (lines 20–23) and `toString` (lines 26–31). These methods are also called the `public services` or the `public interface` that the class provides to its clients.

In this example, class `Time1` does not declare a constructor, so the class has a default constructor that is supplied by the compiler. Each instance variable implicitly receives the default value 0 for an `int`. Note that instance variables also can be initialized when they are declared in the class body using the same initialization syntax as with a local variable.

```

1 // Fig. 8.1: Time1.java
2 // Time1 class declaration maintains the time in 24-hour format.
3
4 public class Time1
5 {
6     private int hour;    // 0 - 23
7     private int minute; // 0 - 59
8     private int second; // 0 - 59
9
10    // set a new time value using universal time; ensure that
11    // the data remains consistent by setting invalid values to zero
12    public void setTime( int h, int m, int s )
13    {
14        hour = ( ( h >= 0 && h < 24 ) ? h : 0 );    // validate hour
15        minute = ( ( m >= 0 && m < 60 ) ? m : 0 ); // validate minute
16        second = ( ( s >= 0 && s < 60 ) ? s : 0 ); // validate second
17    } // end method setTime
18
19    // convert to String in universal-time format (HH:MM:SS)
20    public String toUniversalString()
21    {
22        return String.format( "%02d:%02d:%02d", hour, minute, second );
23    } // end method toUniversalString

```

Fig. 8.1 | `Time1` class declaration maintains the time in 24-hour format. (Part I of 2.)

8.2 Time Class Case Study **371**

```

24
25      // convert to String in standard-time format (H:MM:SS AM or PM)
26      public String toString()
27      {
28          return String.format( "%d:%02d:%02d %s",
29                  ( ( hour == 0 || hour == 12 ) ? 12 : hour % 12 ),
30                  minute, second, ( hour < 12 ? "AM" : "PM" ) );
31      } // end method toString
32  } // end class Time1

```

Fig. 8.1 | Time1 class declaration maintains the time in 24-hour format. (Part 2 of 2.)

Method `setTime` (lines 12–17) is a `public` method that declares three `int` parameters and uses them to set the time. A conditional expression tests each argument to determine whether the value is in a specified range. For example, the `hour` value (line 14) must be greater than or equal to 0 and less than 24, because universal-time format represents hours as integers from 0 to 23 (e.g., 1 PM is hour 13 and 11 PM is hour 23; midnight is hour 0 and noon is hour 12). Similarly, both `minute` and `second` values (lines 15 and 16) must be greater than or equal to 0 and less than 60. Any values outside these ranges are set to zero to ensure that a `Time1` object always contains *consistent data*—that is, the object's data values are always kept in range, even if the values provided as arguments to method `setTime` were *incorrect*. In this example, zero is a consistent value for `hour`, `minute` and `second`.

A value passed to `setTime` is a correct value if it is in the allowed range for the member it is initializing. So, any number in the range 0–23 would be a correct value for the `hour`. A correct value is always a consistent value. However, a consistent value is not necessarily a correct value. If `setTime` sets `hour` to 0 because the argument received was out of range, then `setTime` is taking an incorrect value and making it consistent, so the object remains in a consistent state at all times. The *correct* time of day could actually be 11 AM, but because the person may have accidentally entered an out-of-range (*incorrect*) time, we choose to set the `hour` to the consistent value of zero. In this case, you might want to indicate that the object is *incorrect*. In Chapter 13, Exception Handling, you will learn elegant techniques that enable your classes to indicate when *incorrect* values are received.

**Software Engineering Observation 8.1**

Methods that modify the values of private variables should verify that the intended new values are proper. If they are not, the set methods should place the private variables into an appropriate consistent state.

Method `toUniversalString` (lines 20–23) takes no arguments and returns a `String` in universal-time format, consisting of six digits—two for the hour, two for the minute and two for the second. For example, if the time were 1:30:07 PM, method `toUniversalString` would return 13:30:07. The `return` statement (line 22) uses `static` method `format` of class `String` to return a `String` containing the formatted hour, minute and second values, each with two digits and possibly a leading 0 (specified with the 0 flag). Method `format` is similar to method `System.out.printf` except that `format` returns a formatted `String` rather than displaying it in a command window. The formatted `String` is returned by method `toUniversalString`.

372 Chapter 8 Classes and Objects: A Deeper Look

Method `toString` (lines 26–31) takes no arguments and returns a `String` in standard-time format, consisting of the hour, minute and second values separated by colons and followed by an AM or PM indicator (e.g., 1:27:06 PM). Like method `toUniversalString`, method `toString` uses `static String` method `format` to format the minute and second as two-digit values with leading zeros if necessary. Line 29 uses a conditional operator (`?:`) to determine the value for hour in the string—if the hour is 0 or 12 (AM or PM), it appears as 12—otherwise, the hour appears as a value from 1 to 11. The conditional operator in line 30 determines whether AM or PM will be returned as part of the `String`.

Recall from Section 6.4 that all objects in Java have a `toString` method that returns a `String` representation of the object. We chose to return a `String` containing the time in standard-time format. Method `toString` can be called implicitly whenever a `Time1` object appears in the code where a `String` is needed, such as the value to output with a `%s` format specifier in a call to `System.out.printf`.

Using Class Time1

As you learned in Chapter 3, each class you declare represents a new type in Java. Therefore, after declaring class `Time1`, we can use it as a type in declarations such as

```
Time1 sunset; // sunset can hold a reference to a Time1 object
```

The `Time1Test` application class (Fig. 8.2) uses class `Time1`. Line 9 declares and creates a `Time1` object and assigns it to local variable `time`. Note that `new` implicitly invokes class `Time1`'s default constructor, since `Time1` does not declare any constructors. Lines 12–16 output the time first in universal-time format (by invoking `time`'s `toUniversalString` method in line 13), then in standard-time format (by explicitly invoking `time`'s `toString` method in line 15) to confirm that the `Time1` object was initialized properly.

```

1 // Fig. 8.2: Time1Test.java
2 // Time1 object used in an application.
3
4 public class Time1Test
5 {
6     public static void main( String args[] )
7     {
8         // create and initialize a Time1 object
9         Time1 time = new Time1(); // invokes Time1 constructor
10
11        // output string representations of the time
12        System.out.print( "The initial universal time is: " );
13        System.out.println( time.toUniversalString() );
14        System.out.print( "The initial standard time is: " );
15        System.out.println( time.toString() );
16        System.out.println(); // output a blank line
17
18        // change time and output updated time
19        time.setTime( 13, 27, 6 );
20        System.out.print( "Universal time after setTime is: " );
21        System.out.println( time.toUniversalString() );
22        System.out.print( "Standard time after setTime is: " );

```

Fig. 8.2 | `Time1` object used in an application. (Part I of 2.)

8.2 Time Class Case Study **373**

```

23     System.out.println( time.toString() );
24     System.out.println(); // output a blank line
25
26     // set time with invalid values; output updated time
27     time.setTime( 99, 99, 99 );
28     System.out.println( "After attempting invalid settings:" );
29     System.out.print( "Universal time: " );
30     System.out.println( time.toUniversalString() );
31     System.out.print( "Standard time: " );
32     System.out.println( time.toString() );
33 } // end main
34 } // end class Time1Test

```

The initial universal time is: 00:00:00
The initial standard time is: 12:00:00 AM

Universal time after setTime is: 13:27:06
Standard time after setTime is: 1:27:06 PM

After attempting invalid settings:
Universal time: 00:00:00
Standard time: 12:00:00 AM

Fig. 8.2 | Time1 object used in an application. (Part 2 of 2.)

Line 19 invokes method `setTime` of the `time` object to change the time. Then lines 20–24 output the time again in both formats to confirm that the time was set correctly.

To illustrate that method `setTime` maintains the object in a consistent state, line 27 calls method `setTime` with arguments of 99 for the hour, minute and second. Lines 28–32 output the time again in both formats to confirm that `setTime` maintained the object's consistent state, then the program terminates. The last two lines of the application's output show that the time is reset to midnight—the initial value of a `Time1` object—after an attempt to set the time with three out-of-range values.

Notes on the Time1 Class Declaration

Consider several issues of class design with respect to class `Time1`. The instance variables `hour`, `minute` and `second` are each declared `private`. The actual data representation used within the class is of no concern to the class's clients. For example, it would be perfectly reasonable for `Time1` to represent the time internally as the number of seconds since midnight or the number of minutes and seconds since midnight. Clients could use the same `public` methods and get the same results without being aware of this. (Exercise 8.5 asks you to represent the time in class `Time1` as the number of seconds since midnight and show that there is indeed no change visible to the clients of the class.)

Software Engineering Observation 8.2

Classes simplify programming, because the client can use only the public methods exposed by the class. Such methods are usually client oriented rather than implementation oriented. Clients are neither aware of, nor involved in, a class's implementation. Clients generally care about what the class does but not how the class does it.

**Software Engineering Observation 8.3**

Interfaces change less frequently than implementations. When an implementation changes, implementation-dependent code must change accordingly. Hiding the implementation reduces the possibility that other program parts will become dependent on class implementation details.

8.3 Controlling Access to Members

The access modifiers `public` and `private` control access to a class's variables and methods. (In Chapter 9, we will introduce the additional access modifier `protected`.) As we stated in Section 8.2, the primary purpose of `public` methods is to present to the class's clients a view of the services the class provides (the class's public interface). Clients of the class need not be concerned with how the class accomplishes its tasks. For this reason, the `private` variables and `private` methods of a class (i.e., the class's implementation details) are not directly accessible to the class's clients.

Figure 8.3 demonstrates that `private` class members are not directly accessible outside the class. Lines 9–11 attempt to access directly the `private` instance variables `hour`, `minute` and `second` of the `Time1` object `time`. When this program is compiled, the compiler generates error messages stating that these `private` members are not accessible. [Note: This program assumes that the `Time1` class from Fig. 8.1 is used.]

**Common Programming Error 8.1**

An attempt by a method that is not a member of a class to access a private member of that class is a compilation error.

```

1 // Fig. 8.3: MemberAccessTest.java
2 // Private members of class Time1 are not accessible.
3 public class MemberAccessTest
4 {
5     public static void main( String args[] )
6     {
7         Time1 time = new Time1(); // create and initialize Time1 object
8
9         time.hour = 7; // error: hour has private access in Time1
10        time.minute = 15; // error: minute has private access in Time1
11        time.second = 30; // error: second has private access in Time1
12    } // end main
13 } // end class MemberAccessTest

```

```

MemberAccessTest.java:9: hour has private access in Time1
    time.hour = 7; // error: hour has private access in Time1
                  ^
MemberAccessTest.java:10: minute has private access in Time1
    time.minute = 15; // error: minute has private access in Time1
                      ^
MemberAccessTest.java:11: second has private access in Time1
    time.second = 30; // error: second has private access in Time1
                      ^
3 errors

```

Fig. 8.3 | Private members of class `Time1` are not accessible.

8.4 Referring to the Current Object's Members with the `this` Reference 375

8.4 Referring to the Current Object's Members with the `this` Reference

Every object can access a reference to itself with keyword `this` (sometimes called the **this reference**). When a non-static method is called for a particular object, the method's body implicitly uses keyword `this` to refer to the object's instance variables and other methods. As you will see in Fig. 8.4, you can also use keyword `this` explicitly in a non-static method's body. Section 8.5 shows another interesting use of keyword `this`. Section 8.11 explains why keyword `this` cannot be used in a static method.

We now demonstrate implicit and explicit use of the `this` reference to enable class `ThisTest`'s `main` method to display the private data of a class `SimpleTime` object (Fig. 8.4). Note that this example is the first in which we declare two classes in one file—class `ThisTest` is declared in lines 4–11, and class `SimpleTime` is declared in lines 14–47. We did this to demonstrate that when you compile a `.java` file that contains more than one class, the compiler produces a separate class file with the `.class` extension for every compiled class. In this case two separate files are produced—`SimpleTime.class` and `ThisTest.class`. When one source-code (`.java`) file contains multiple class declarations, the class files for those classes are both placed in the same directory by the compiler. Also, note that only class `ThisTest` is declared `public` in Fig. 8.4. A source-code file can contain only one `public` class—otherwise, a compilation error occurs.

```

1 // Fig. 8.4: ThisTest.java
2 // this used implicitly and explicitly to refer to members of an object.
3
4 public class ThisTest
5 {
6     public static void main( String args[] )
7     {
8         SimpleTime time = new SimpleTime( 15, 30, 19 );
9         System.out.println( time.buildString() );
10    } // end main
11 } // end class ThisTest
12
13 // class SimpleTime demonstrates the "this" reference
14 class SimpleTime
15 {
16     private int hour;    // 0-23
17     private int minute; // 0-59
18     private int second; // 0-59
19
20     // if the constructor uses parameter names identical to
21     // instance variable names the "this" reference is
22     // required to distinguish between names
23     public SimpleTime( int hour, int minute, int second )
24     {
25         this.hour = hour;      // set "this" object's hour
26         this.minute = minute; // set "this" object's minute
27         this.second = second; // set "this" object's second
28     } // end SimpleTime constructor

```

Fig. 8.4 | `this` used implicitly and explicitly to refer to members of an object. (Part I of 2.)

376 Chapter 8 Classes and Objects: A Deeper Look

```

29      // use explicit and implicit "this" to call toUniversalString
30  public String buildString()
31  {
32      return String.format( "%24s: %s\n%24s: %s",
33          "this.toUniversalString()", this.toUniversalString(),
34          "toUniversalString()", toUniversalString() );
35  } // end method buildString
36
37
38  // convert to String in universal-time format (HH:MM:SS)
39  public String toUniversalString()
40  {
41      // "this" is not required here to access instance variables,
42      // because method does not have local variables with same
43      // names as instance variables
44      return String.format( "%02d:%02d:%02d",
45          this.hour, this.minute, this.second );
46  } // end method toUniversalString
47 } // end class SimpleTime

```

```

this.toUniversalString(): 15:30:19
toUniversalString(): 15:30:19

```

Fig. 8.4 | this used implicitly and explicitly to refer to members of an object. (Part 2 of 2.)

Class `SimpleTime` (lines 14–47) declares three `private` instance variables—`hour`, `minute` and `second` (lines 16–18). The constructor (lines 23–28) receives three `int` arguments to initialize a `SimpleTime` object. Note that we used parameter names for the constructor (line 23) that are identical to the class's instance variable names (lines 16–18). We don't recommend this practice, but we did it here to shadow (hide) the corresponding instance variables so that we could illustrate explicit use of the `this` reference. If a method contains a local variable with the same name as a field, that method will refer to the local variable rather than the field. In this case, the local variable shadows the field in the method's scope. However, the method can use the `this` reference to refer to the shadowed field explicitly, as shown in lines 25–27 for `SimpleTime`'s shadowed instance variables.

Method `buildString` (lines 31–36) returns a `String` created by a statement that uses the `this` reference explicitly and implicitly. Line 34 uses the `this` reference explicitly to call method `toUniversalString`. Line 35 uses the `this` reference implicitly to call the same method. Note that both lines perform the same task. Programmers typically do not use `this` explicitly to reference other methods within the current object. Also, note that line 45 in method `toUniversalString` explicitly uses the `this` reference to access each instance variable. This is not necessary here, because the method does not have any local variables that shadow the instance variables of the class.

**Common Programming Error 8.2**

It is often a logic error when a method contains a parameter or local variable that has the same name as a field of the class. In this case, use reference `this` if you wish to access the field of the class—otherwise, the method parameter or local variable will be referenced.

8.5 Time Class Case Study: Overloaded Constructors **377****Error-Prevention Tip 8.1**

Avoid method parameter names or local variable names that conflict with field names. This helps prevent subtle, hard-to-locate bugs.

Application class `ThisTest` (lines 4–11) demonstrates class `SimpleTime`. Line 8 creates an instance of class `SimpleTime` and invokes its constructor. Line 9 invokes the object's `buildString` method, then displays the results.

**Performance Tip 8.1**

Java conserves storage by maintaining only one copy of each method per class—this method is invoked by every object of the class. Each object, on the other hand, has its own copy of the class's instance variables (i.e., non-static fields). Each method of the class implicitly uses `this` to determine the specific object of the class to manipulate.

8.5 Time Class Case Study: Overloaded Constructors

As you know, you can declare your own constructor to specify how objects of a class should be initialized. Next, we demonstrate a class with several **overloaded constructors** that enable objects of that class to be initialized in different ways. To overload constructors, simply provide multiple constructor declarations with different signatures. Recall from Section 6.12 that the compiler differentiates signatures by the number of parameters, the types of the parameters and the order of the parameter types in each signature.

Class `Time2` with Overloaded Constructors

The default constructor for class `Time1` (Fig. 8.1) initialized `hour`, `minute` and `second` to their default 0 values (which is midnight in universal time). The default constructor does not enable the class's clients to initialize the time with specific nonzero values. Class `Time2` (Fig. 8.5) contains five overloaded constructors that provide convenient ways to initialize objects of the new class `Time2`. Each constructor initializes the object to begin in a consistent state. In this program, four of the constructors invoke a fifth, which in turn calls method `setTime` to ensure that the value supplied for `hour` is in the range 0 to 23, and the values for `minute` and `second` are each in the range 0 to 59. If a value is out of range, it is set to zero by `setTime` (once again ensuring that each instance variable remains in a consistent state). The compiler invokes the appropriate constructor by matching the number, types and order of the types of the arguments specified in the constructor call with the number, types and order of the types of the parameters specified in each constructor declaration. Note that class `Time2` also provides `set` and `get` methods for each instance variable.

```

1 // Fig. 8.5: Time2.java
2 // Time2 class declaration with overloaded constructors.
3
4 public class Time2
5 {
6     private int hour;    // 0 - 23
7     private int minute; // 0 - 59
8     private int second; // 0 - 59
9

```

378 Chapter 8 Classes and Objects: A Deeper Look

```

10  // Time2 no-argument constructor: initializes each instance variable
11 // to zero; ensures that Time2 objects start in a consistent state
12 public Time2()
13 {
14     this( 0, 0, 0 ); // invoke Time2 constructor with three arguments
15 } // end Time2 no-argument constructor
16
17 // Time2 constructor: hour supplied, minute and second defaulted to 0
18 public Time2( int h )
19 {
20     this( h, 0, 0 ); // invoke Time2 constructor with three arguments
21 } // end Time2 one-argument constructor
22
23 // Time2 constructor: hour and minute supplied, second defaulted to 0
24 public Time2( int h, int m )
25 {
26     this( h, m, 0 ); // invoke Time2 constructor with three arguments
27 } // end Time2 two-argument constructor
28
29 // Time2 constructor: hour, minute and second supplied
30 public Time2( int h, int m, int s )
31 {
32     setTime( h, m, s ); // invoke setTime to validate time
33 } // end Time2 three-argument constructor
34
35 // Time2 constructor: another Time2 object supplied
36 public Time2( Time2 time )
37 {
38     // invoke Time2 three-argument constructor
39     this( time.getHour(), time.getMinute(), time.getSecond() );
40 } // end Time2 constructor with a Time2 object argument
41
42 // Set Methods
43 // set a new time value using universal time; ensure that
44 // the data remains consistent by setting invalid values to zero
45 public void setTime( int h, int m, int s )
46 {
47     setHour( h ); // set the hour
48     setMinute( m ); // set the minute
49     setSecond( s ); // set the second
50 } // end method setTime
51
52 // validate and set hour
53 public void setHour( int h )
54 {
55     hour = ( ( h >= 0 && h < 24 ) ? h : 0 );
56 } // end method setHour
57
58 // validate and set minute
59 public void setMinute( int m )
60 {
61     minute = ( ( m >= 0 && m < 60 ) ? m : 0 );
62 } // end method setMinute

```

8.5 Time Class Case Study: Overloaded Constructors **379**

```

63      // validate and set second
64      public void setSecond( int s )
65      {
66          second = ( ( s >= 0 && s < 60 ) ? s : 0 );
67      } // end method setSecond
68
69
70      // Get Methods
71      // get hour value
72      public int getHour()
73      {
74          return hour;
75      } // end method getHour
76
77      // get minute value
78      public int getMinute()
79      {
80          return minute;
81      } // end method getMinute
82
83      // get second value
84      public int getSecond()
85      {
86          return second;
87      } // end method getSecond
88
89      // convert to String in universal-time format (HH:MM:SS)
90      public String toUniversalString()
91      {
92          return String.format(
93              "%02d:%02d:%02d", getHour(), getMinute(), getSecond() );
94      } // end method toUniversalString
95
96      // convert to String in standard-time format (H:MM:SS AM or PM)
97      public String toString()
98      {
99          return String.format( "%d:%02d:%02d %s",
100              ( getHour() == 0 || getHour() == 12 ) ? 12 : getHour() % 12 ,
101              getMinute(), getSecond(), ( getHour() < 12 ? "AM" : "PM" ) );
102      } // end method toString
103  } // end class Time2

```

Fig. 8.5 | Time2 class with overloaded constructors. (Part 3 of 3.)*Class Time2's Constructors*

Lines 12–15 declare a so-called **no-argument constructor**—that is, a constructor invoked without arguments. Such a constructor simply initializes the object as specified in the constructor's body. In the body, we introduce a use of the `this` reference that is allowed only as the first statement in a constructor's body. Line 14 uses `this` in method-call syntax to invoke the `Time2` constructor that takes three arguments (lines 30–33). The no-argument constructor passes values of 0 for the `hour`, `minute` and `second` to the constructor with three parameters. Using the `this` reference as shown here is a popular way to reuse initialization code provided by another of the class's constructors rather than defining similar

380 Chapter 8 Classes and Objects: A Deeper Look

code in the no-argument constructor's body. We use this syntax in four of the five `Time2` constructors to make the class easier to maintain and modify. If we need to change how objects of class `Time2` are initialized, only the constructor that the class's other constructors call will need to be modified. In fact, even that constructor might not need modification in this example. That constructor simply calls the `setTime` method to perform the actual initialization, so it is possible that the changes the class might require would be localized to the `set` methods.

**Common Programming Error 8.3**

It is a syntax error when `this` is used in a constructor's body to call another constructor of the same class if that call is not the first statement in the constructor. It is also a syntax error when a method attempts to invoke a constructor directly via `this`.

Lines 18–21 declare a `Time2` constructor with a single `int` parameter representing the `hour`, which is passed with 0 for the `minute` and `second` to the constructor at lines 30–33. Lines 24–27 declare a `Time2` constructor that receives two `int` parameters representing the `hour` and `minute`, which are passed with 0 for the `second` to the constructor at lines 30–33. Like the no-argument constructor, each of these constructors invokes the constructor at lines 30–33 to minimize code duplication. Lines 30–33 declare the `Time2` constructor that receives three `int` parameters representing the `hour`, `minute` and `second`. This constructor calls `setTime` to initialize the instance variables to consistent values.

**Common Programming Error 8.4**

A constructor can call methods of the class. Be aware that the instance variables might not yet be in a consistent state, because the constructor is in the process of initializing the object. Using instance variables before they have been initialized properly is a logic error.

Lines 36–40 declare a `Time2` constructor that receives a `Time2` reference to another `Time2` object. In this case, the values from the `Time2` argument are passed to the three-argument constructor at lines 30–33 to initialize the `hour`, `minute` and `second`. Note that line 39 could have directly accessed the `hour`, `minute` and `second` values of the constructor's argument `time` with the expressions `time.hour`, `time.minute` and `time.second`—even though `hour`, `minute` and `second` are declared as `private` variables of class `Time2`. This is due to a special relationship between objects of the same class. We'll see in a moment why it's preferable to use the `get` methods.

**Software Engineering Observation 8.4**

When one object of a class has a reference to another object of the same class, the first object can access all the second object's data and methods (including those that are private).

Notes Regarding Class `Time2`'s Set and Get Methods and Constructors

Note that `Time2`'s `set` and `get` methods are called throughout the body of the class. In particular, method `setTime` calls methods `setHour`, `setMinute` and `setSecond` in lines 47–49, and methods `toUniversalString` and `toString` call methods `getHour`, `getMinute` and `getSecond` in line 93 and lines 100–101, respectively. In each case, these methods could have accessed the class's private data directly without calling the `set` and `get` methods. However, consider changing the representation of the time from three `int` values (requiring 12 bytes of memory) to a single `int` value representing the total number of seconds that have

8.5 Time Class Case Study: Overloaded Constructors 381

elapsed since midnight (requiring only 4 bytes of memory). If we made such a change, only the bodies of the methods that access the `private` data directly would need to change—in particular, the individual `set` and `get` methods for the `hour`, `minute` and `second`. There would be no need to modify the bodies of methods `setTime`, `toUniversalString` or `toString` because they do not access the data directly. Designing the class in this manner reduces the likelihood of programming errors when altering the class's implementation.

Similarly, each `Time2` constructor could be written to include a copy of the appropriate statements from methods `setHour`, `setMinute` and `setSecond`. Doing so may be slightly more efficient, because the extra constructor call and call to `setTime` are eliminated. However, duplicating statements in multiple methods or constructors makes changing the class's internal data representation more difficult. Having the `Time2` constructors call the constructor with three arguments (or even call `setTime` directly) requires any changes to the implementation of `setTime` to be made only once.

Software Engineering Observation 8.5

When implementing a method of a class, use the class's set and get methods to access the class's private data. This simplifies code maintenance and reduces the likelihood of errors.

Using Class `Time2`'s Overloaded Constructors

Class `Time2Test` (Fig. 8.6) creates six `Time2` objects (lines 8–13) to invoke the overloaded `Time2` constructors. Line 8 shows that the no-argument constructor (lines 12–15 of Fig. 8.5) is invoked by placing an empty set of parentheses after the class name when allocating a `Time2` object with `new`. Lines 9–13 of the program demonstrate passing arguments to the other `Time2` constructors. Line 9 invokes the constructor at lines 18–21 of Fig. 8.5. Line 10 invokes the constructor at lines 24–27 of Fig. 8.5. Lines 11–12 invoke the constructor at lines 30–33 of Fig. 8.5. Line 13 invokes the constructor at lines 36–40 of Fig. 8.5. The application displays the `String` representation of each initialized `Time2` object to confirm that it was initialized properly.

```

1 // Fig. 8.6: Time2Test.java
2 // Overloaded constructors used to initialize Time2 objects.
3
4 public class Time2Test
5 {
6     public static void main( String args[] )
7     {
8         Time2 t1 = new Time2();           // 00:00:00
9         Time2 t2 = new Time2( 2 );       // 02:00:00
10        Time2 t3 = new Time2( 21, 34 ); // 21:34:00
11        Time2 t4 = new Time2( 12, 25, 42 ); // 12:25:42
12        Time2 t5 = new Time2( 27, 74, 99 ); // 00:00:00
13        Time2 t6 = new Time2( t4 );      // 12:25:42
14
15        System.out.println( "Constructed with:" );
16        System.out.println( "t1: all arguments defaulted" );
17        System.out.printf( "%s\n", t1.toUniversalString() );
18        System.out.printf( "%s\n", t1.toString() );

```

12:00:00 AM
t6: Time2 object t4 specified
12:25:42
12:25:42 PM

```

Fig. 8.6 | Overloaded constructors used to initialize `Time2` objects. (Part 2 of 2.)

8.6 Default and No-Argument Constructors

Every class must have at least one constructor. Recall from Section 3.7, that if you do not provide any constructors in a class's declaration, the compiler creates a default constructor that takes no arguments when it is invoked. The default constructor initializes the instance variables to the initial values specified in their declarations or to their default values (zero for primitive numeric types, `false` for `boolean` values and `null` for references). In Section 9.4.1, you'll learn that the default constructor performs another task in addition to initializing each instance variable to its default value.

8.7 Notes on Set and Get Methods **383**

If your class declares constructors, the compiler will not create a default constructor. In this case, to specify the default initialization for objects of your class, you must declare a no-argument constructor—as in lines 12–15 of Fig. 8.5. Like a default constructor, a no-argument constructor is invoked with empty parentheses. Note that the `Time2` no-argument constructor explicitly initializes a `Time2` object by passing to the three-argument constructor 0 for each parameter. Since 0 is the default value for `int` instance variables, the no-argument constructor in this example could actually be declared with an empty body. In this case, each instance variable would receive its default value when the no-argument constructor was called. If we omit the no-argument constructor, clients of this class would not be able to create a `Time2` object with the expression `new Time2()`.

**Common Programming Error 8.5**

If a class has constructors, but none of the public constructors are no-argument constructors, and a program attempts to call a no-argument constructor to initialize an object of the class, a compilation error occurs. A constructor can be called with no arguments only if the class does not have any constructors (in which case the default constructor is called) or if the class has a public no-argument constructor.

**Software Engineering Observation 8.6**

Java allows other methods of the class besides its constructors to have the same name as the class and to specify return types. Such methods are not constructors and will not be called when an object of the class is instantiated. Java determines which methods are constructors by locating the methods that have the same name as the class and do not specify a return type.

8.7 Notes on Set and Get Methods

As you know, a class's private fields can be manipulated only by methods of that class. A typical manipulation might be the adjustment of a customer's bank balance (e.g., a private instance variable of a class `BankAccount`) by a method `computeInterest`. Classes often provide `public` methods to allow clients of the class to *set* (i.e., assign values to) or *get* (i.e., obtain the values of) private instance variables.

As a naming example, a method that sets instance variable `interestRate` would typically be named `setInterestRate` and a method that gets the `interestRate` would typically be called `getInterestRate`. *Set* methods are also commonly called **mutator methods**, because they typically change a value. *Get* methods are also commonly called **accessor methods** or **query methods**.

Set and Get Methods vs. `public` Data

It would seem that providing *set* and *get* capabilities is essentially the same as making the instance variables `public`. This is a subtlety of Java that makes the language so desirable for software engineering. A `public` instance variable can be read or written by any method that has a reference to an object that contains the instance variable. If an instance variable is declared `private`, a `public` *get* method certainly allows other methods to access the variable, but the *get* method can control how the client can access the variable. For example, a *get* method might control the format of the data it returns and thus shield the client code from the actual data representation. A `public` *set* method can—and should—carefully scrutinize attempts to modify the variable's value to ensure that the new value is appropriate for that data item. For example, an attempt to *set* the day of the month to 37 would be

384 Chapter 8 Classes and Objects: A Deeper Look

rejected, an attempt to *set* a person's weight to a negative value would be rejected, and so on. Thus, although *set* and *get* methods provide access to *private* data, the access is restricted by the programmer's implementation of the methods. This helps promote good software engineering.

Validity Checking in Set Methods

The benefits of data integrity are not automatic simply because instance variables are declared *private*—the programmer must provide validity checking. Java enables programmers to design better programs in a convenient manner. A class's *set* methods can return values indicating that attempts were made to assign invalid data to objects of the class. A client of the class can test the return value of a *set* method to determine whether the client's attempt to modify the object was successful and to take appropriate action.

**Software Engineering Observation 8.7**

When necessary, provide public methods to change and retrieve the values of private instance variables. This architecture helps hide the implementation of a class from its clients, which improves program modifiability.

**Software Engineering Observation 8.8**

Class designers need not provide set or get methods for each private field. These capabilities should be provided only when it makes sense.

Predicate Methods

Another common use for accessor methods is to test whether a condition is true or false—such methods are often called **predicate methods**. An example would be an *isEmpty* method for a *container class*—a class capable of holding many objects, such as a linked list, a stack or a queue. (These data structures are discussed in depth in Chapters 17 and 19.) A program might test *isEmpty* before attempting to read another item from a container object. A program might test *isFull* before attempting to insert another item into a container object.

Using Set and Get Methods to Create a Class That Is Easier to Debug and Maintain
If only one method performs a particular task, such as setting the hour in a *Time2* object, it is easier to debug and maintain the class. If the hour is not being set properly, the code that actually modifies instance variable *hour* is localized to one method's body—*setHour*. Thus, your debugging efforts can be focused on method *setHour*.

8.8 Composition

A class can have references to objects of other classes as members. Such a capability is called **composition** and is sometimes referred to as a *has-a relationship*. For example, an object of class *AlarmClock* needs to know the current time and the time when it is supposed to sound its alarm, so it is reasonable to include two references to *Time* objects as members of the *AlarmClock* object.

**Software Engineering Observation 8.9**

One form of software reuse is composition, in which a class has as members references to objects of other classes.

8.8 Composition **385**

Our example of composition contains three classes—`Date` (Fig. 8.7), `Employee` (Fig. 8.8) and `EmployeeTest` (Fig. 8.9). Class `Date` (Fig. 8.7) declares instance variables `month`, `day` and `year` (lines 6–8) to represent a date. The constructor receives three `int` parameters. Line 14 invokes utility method `checkMonth` (lines 23–33) to validate the month—an out-of-range value is set to 1 to maintain a consistent state. Line 15 assumes that the value for `year` is correct and does not validate it. Line 16 invokes utility method `checkDay` (lines 36–52) to validate the value for `day` based on the current `month` and `year`. Lines 42–43 determine whether the `day` is correct based on the number of days in the particular `month`. If the `day` is not correct, lines 46–47 determine whether the `month` is February, the `day` is 29 and the `year` is a leap year. If lines 42–48 do not return a correct value for `day`, line 51 returns 1 to maintain the `Date` in a consistent state. Note that lines 18–19 in the constructor output the `this` reference as a `String`. Since `this` is a reference to the current `Date` object, the object's `toString` method (lines 55–58) is called implicitly to obtain the object's `String` representation.

```

1 // Fig. 8.7: Date.java
2 // Date class declaration.
3
4 public class Date
5 {
6     private int month; // 1-12
7     private int day; // 1-31 based on month
8     private int year; // any year
9
10    // constructor: call checkMonth to confirm proper value for month;
11    // call checkDay to confirm proper value for day
12    public Date( int theMonth, int theDay, int theYear )
13    {
14        month = checkMonth( theMonth ); // validate month
15        year = theYear; // could validate year
16        day = checkDay( theDay ); // validate day
17
18        System.out.printf(
19            "Date object constructor for date %s\n", this );
20    } // end Date constructor
21
22    // utility method to confirm proper month value
23    private int checkMonth( int testMonth )
24    {
25        if ( testMonth > 0 && testMonth <= 12 ) // validate month
26            return testMonth;
27        else // month is invalid
28        {
29            System.out.printf(
30                "Invalid month (%d) set to 1.", testMonth );
31            return 1; // maintain object in consistent state
32        } // end else
33    } // end method checkMonth
34

```

Fig. 8.7 | Date class declaration. (Part I of 2.)

386 Chapter 8 Classes and Objects: A Deeper Look

```

35  // utility method to confirm proper day value based on month and year
36  private int checkDay( int testDay )
37  {
38      int daysPerMonth[] =
39          { 0, 31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31 };
40
41      // check if day in range for month
42      if ( testDay > 0 && testDay <= daysPerMonth[ month ] )
43          return testDay;
44
45      // check for leap year
46      if ( month == 2 && testDay == 29 && ( year % 400 == 0 ||
47          ( year % 4 == 0 && year % 100 != 0 ) ) )
48          return testDay;
49
50      System.out.printf( "Invalid day (%d) set to 1.", testDay );
51      return 1; // maintain object in consistent state
52 } // end method checkDay
53
54 // return a String of the form month/day/year
55 public String toString()
56 {
57     return String.format( "%d/%d/%d", month, day, year );
58 } // end method toString
59 } // end class Date

```

Fig. 8.7 | Date class declaration. (Part 2 of 2.)

Class `Employee` (Fig. 8.8) has instance variables `firstName`, `lastName`, `birthDate` and `hireDate`. Members `birthDate` and `hireDate` (lines 8–9) are references to `Date` objects. This demonstrates that a class can have as instance variables references to objects of other classes. The `Employee` constructor (lines 12–19) takes four parameters—`first`, `last`, `dateOfBirth` and `dateOfHire`. The objects referenced by the parameters `dateOfBirth` and `dateOfHire` are assigned to the `Employee` object's `birthDate` and `hireDate` instance variables. Note that when class `Employee`'s `toString` method is called, it returns a `String` containing the `String` representations of the two `Date` objects. Each of these `Strings` is obtained with an implicit call to the `Date` class's `toString` method.

```

1 // Fig. 8.8: Employee.java
2 // Employee class with references to other objects.
3
4 public class Employee
5 {
6     private String firstName;
7     private String lastName;
8     private Date birthDate;
9     private Date hireDate;
10

```

Fig. 8.8 | Employee class with references to other objects. (Part I of 2.)

8.9 Enumerations **387**

```

11  // constructor to initialize name, birth date and hire date
12  public Employee( String first, String last, Date dateOfBirth,
13      Date dateOfHire )
14  {
15      firstName = first;
16      lastName = last;
17      birthDate = dateOfBirth;
18      hireDate = dateOfHire;
19  } // end Employee constructor
20
21  // convert Employee to String format
22  public String toString()
23  {
24      return String.format( "%s, %s Hired: %s Birthday: %s",
25          lastName, firstName, hireDate, birthDate );
26  } // end method toString
27 } // end class Employee

```

Fig. 8.8 | Employee class with references to other objects. (Part 2 of 2.)

Class `EmployeeTest` (Fig. 8.9) creates two `Date` objects (lines 8–9) to represent an `Employee`'s birthday and hire date, respectively. Line 10 creates an `Employee` and initializes its instance variables by passing to the constructor two `Strings` (representing the `Employee`'s first and last names) and two `Date` objects (representing the birthday and hire date). Line 12 implicitly invokes the `Employee`'s `toString` method to display the values of its instance variables and demonstrate that the object was initialized properly.

```

8.9 Enumerations

In Fig. 6.9 (`Craps.java`), we introduced the basic `enum` type which defines a set of constants that are represented as unique identifiers. In that program, the `enum` constants rep-

388 Chapter 8 Classes and Objects: A Deeper Look

resented the game's status. In this section, we discuss the relationship between `enum` types and classes. Like classes, all `enum` types are reference types. An `enum` type is declared with an `enum declaration`, which is a comma-separated list of `enum` constants—the declaration may optionally include other components of traditional classes, such as constructors, fields and methods. Each `enum` declaration declares an `enum` class with the following restrictions:

1. `enum` types are implicitly `final`, because they declare constants that should not be modified.
2. `enum` constants are implicitly `static`.
3. Any attempt to create an object of an `enum` type with operator `new` results in a compilation error.

The `enum` constants can be used anywhere constants can be used, such as in the `case` labels of `switch` statements and to control enhanced `for` statements.

Figure 8.10 illustrates how to declare instance variables, a constructor and methods in an `enum` type. The `enum` declaration (lines 5–37) contains two parts—the `enum` constants and the other members of the `enum` type. The first part (lines 8–13) declares six `enum` constants. Each `enum` constant is optionally followed by arguments which are passed to the `enum constructor` (lines 20–24). Like the constructors you have seen in classes, an `enum` constructor can specify any number of parameters and can be overloaded. In this example, the `enum` constructor has two `String` parameters, hence each `enum` constant is followed by parentheses containing two `String` arguments. The second part (lines 16–36) declares the other members of the `enum` type—two instance variables (lines 16–17), a constructor (lines 20–24) and two methods (lines 27–30 and 33–36).

```

1 // Fig. 8.10: Book.java
2 // Declaring an enum type with constructor and explicit instance fields
3 // and accessors for these fields
4
5 public enum Book
6 {
7     // declare constants of enum type
8     JHTP6( "Java How to Program 6e", "2005" ),
9     CHTP4( "C How to Program 4e", "2004" ),
10    IW3HTP3( "Internet & World Wide Web How to Program 3e", "2004" ),
11    CPPHTP4( "C++ How to Program 4e", "2003" ),
12    VBHTP2( "Visual Basic .NET How to Program 2e", "2002" ),
13    CSHARPHTP( "C# How to Program", "2002" );
14
15    // instance fields
16    private final String title; // book title
17    private final String copyrightYear; // copyright year
18
19    // enum constructor
20    Book( String bookTitle, String year )
21    {
22        title = bookTitle;
23        copyrightYear = year;
24    } // end enum Book constructor

```

Fig. 8.10 | Declaring `enum` type with instance fields, constructor and methods. (Part I of 2.)

```

25 // accessor for field title
26 public String getTitle()
27 {
28     return title;
29 } // end method getTitle
30
31 // accessor for field copyrightYear
32 public String getCopyrightYear()
33 {
34     return copyrightYear;
35 } // end method getCopyrightYear
36
37 } // end enum Book

```

Fig. 8.10 | Declaring enum type with instance fields, constructor and methods. (Part 2 of 2.)

Lines 16–17 declare the instance variables `title` and `copyrightYear`. Each `enum` constant in `Book` is actually an object of type `Book` that has its own copy of instance variables `title` and `copyrightYear`. The constructor (lines 20–24) takes two `String` parameters, one that specifies the book title and one that specifies the copyright year of the book. Lines 22–23 assign these parameters to the instance variables. Lines 27–36 declare two methods, which return the book title and copyright year, respectively.

Figure 8.11 tests the `enum` type declared in Fig. 8.10 and illustrates how to iterate through a range of `enum` constants. For every `enum`, the compiler generates the `static` method `values` (called in line 12) that returns an array of the `enum`'s constants in the order they were declared. Recall from Section 7.6 that the enhanced `for` statement can be used

```

CPPHTP4	C++ How to Program 4e	2003

Fig. 8.11 | Testing an enum type. (Part 2 of 2.)

to iterate through an array. Lines 12–14 use the enhanced `for` statement to display all the constants declared in the enum `Book`. Line 14 invokes the `enum` `Book`'s `getTitle` and `getCopyrightYear` methods to get the title and copyright year associated with the constant. Note that when an `enum` constant is converted to a `String` (e.g., `book` in line 13), the constant's identifier is used as the `String` representation (e.g., `JHTP6` for the first `enum` constant).

Lines 19–21 use the `static` method `range` of class `EnumSet` (declared in package `java.util`) to display a range of the enum `Book`'s constants. Method `range` takes two parameters—the first and the last enum constants in the range—and returns an `EnumSet` that contains all the constants between these two constants, inclusive. For example, the expression `EnumSet.range(Book.JHTP6, Book.CPPHTP4)` returns an `EnumSet` containing `Book.JHTP6`, `Book.CHTP4`, `Book.IW3HTP3` and `Book.CPPHTP4`. The enhanced `for` statement can be used with an `EnumSet` just as it can with an array, so lines 19–21 use the enhanced `for` statement to display the title and copyright year of every book in the `EnumSet`. Class `EnumSet` provides several other `static` methods for creating sets of `enum` constants from the same `enum` type. For more details of class `EnumSet`, visit java.sun.com/javase/6/docs/api/java/util/EnumSet.html.

Common Programming Error 8.6

In an `enum` declaration, it is a syntax error to declare `enum` constants after the `enum` type's constructors, fields and methods in the `enum` declaration.

8.10 Garbage Collection and Method `finalize`

Every class in Java has the methods of class `Object` (package `java.lang`), one of which is the `finalize` method. This method is rarely used. In fact, we searched over 6500 source-code files for the Java API classes and found fewer than 50 declarations of the `finalize` method. Nevertheless, because `finalize` is part of every class, we discuss it here to help you understand its intended purpose in case you encounter it in your studies or in industry. The complete details of the `finalize` method are beyond the scope of this book, and most programmers should not use it—you'll soon see why. You will learn more about class `Object` in Chapter 9, Object-Oriented Programming: Inheritance.

8.11 static Class Members **391**

Every object you create uses various system resources, such as memory. To avoid “resource leaks,” we need a disciplined way to give resources back to the system when they are no longer needed. The Java Virtual Machine (JVM) performs automatic [garbage collection](#) to reclaim the memory occupied by objects that are no longer in use. When there are no more references to an object, the object is [marked for garbage collection](#) by the JVM. The memory for such an object can be reclaimed when the JVM executes its [garbage collector](#), which is responsible for retrieving the memory of objects that are no longer used so it can be used for other objects. Therefore, memory leaks that are common in other languages like C and C++ (because memory is not automatically reclaimed in those languages) are less likely in Java (but some can still happen in subtle ways). Other types of resource leaks can occur. For example, an application could open a file on disk to modify the file’s contents. If the application does not close the file, no other application can use it until the application that opened the file completes.

The `finalize` method is called by the garbage collector to perform [termination housekeeping](#) on an object just before the garbage collector reclaims the object’s memory. Method `finalize` does not take parameters and has return type `void`. A problem with method `finalize` is that the garbage collector is not guaranteed to execute at a specified time. In fact, the garbage collector may never execute before a program terminates. Thus, it is unclear if, or when, method `finalize` will be called. For this reason, most programmers should avoid method `finalize`. In Section 8.11, we demonstrate a situation in which method `finalize` is called by the garbage collector.

**Software Engineering Observation 8.10**

A class that uses system resources, such as files on disk, should provide a method to eventually release the resources. Many Java API classes provide `close` or `dispose` methods for this purpose.

For example, class `Scanner` (java.sun.com/javase/6/docs/api/java/util/Scanner.html) has a `close` method.

8.11 static Class Members

Every object has its own copy of all the instance variables of the class. In certain cases, only one copy of a particular variable should be shared by all objects of a class. A [static field](#)—called a [class variable](#)—is used in such cases. A [static variable](#) represents [classwide information](#)—all objects of the class share the same piece of data. The declaration of a [static variable](#) begins with the keyword `static`.

Let’s motivate [static](#) data with an example. Suppose that we have a video game with Martians and other space creatures. Each Martian tends to be brave and willing to attack other space creatures when the Martian is aware that at least four other Martians are present. If fewer than five Martians are present, each of them becomes cowardly. Thus each Martian needs to know the `martianCount`. We could endow class `Martian` with `martianCount` as an instance variable. If we do this, then every `Martian` will have a separate copy of the instance variable, and every time we create a new `Martian`, we’ll have to update the instance variable `martianCount` in every `Martian`. This wastes space with the redundant copies, wastes time in updating the separate copies and is error prone. Instead, we declare `martianCount` to be `static`, making `martianCount` classwide data. Every `Martian` can see the `martianCount` as if it were an instance variable of class `Martian`, but only one copy of the `static martianCount` is maintained. This saves space. We save time by having

392 Chapter 8 Classes and Objects: A Deeper Look

the Martian constructor increment the static `martianCount`—there is only one copy, so we do not have to increment separate copies of `martianCount` for each `Martian` object.

**Software Engineering Observation 8.11**

Use a static variable when all objects of a class must use the same copy of the variable.

Static variables have class scope. A class's `public static` members can be accessed through a reference to any object of the class, or by qualifying the member name with the class name and a dot (.), as in `Math.random()`. A class's `private static` class members can be accessed only through methods of the class. Actually, `static` class members exist even when no objects of the class exist—they are available as soon as the class is loaded into memory at execution time. To access a `public static` member when no objects of the class exist (and even when they do), prefix the class name and a dot (.) to the `static` member, as in `Math.PI`. To access a `private static` member when no objects of the class exist, a `public static` method must be provided and the method must be called by qualifying its name with the class name and a dot.

**Software Engineering Observation 8.12**

Static class variables and methods exist, and can be used, even if no objects of that class have been instantiated.

Our next program declares two classes—`Employee` (Fig. 8.12) and `EmployeeTest` (Fig. 8.13). Class `Employee` declares `private static` variable `count` (Fig. 8.12, line 9), and `public static` method `getCount` (lines 46–49). The static variable `count` is initialized to zero in line 9. If a static variable is not initialized, the compiler assigns a default value to the variable—in this case 0, the default value for type `int`. Variable `count` maintains a count of the number of objects of class `Employee` that currently reside in memory. This includes objects that have already been marked for garbage collection by the JVM but have not yet been reclaimed by the garbage collector.

```

1 // Fig. 8.12: Employee.java
2 // Static variable used to maintain a count of the number of
3 // Employee objects in memory.
4
5 public class Employee
6 {
7     private String firstName;
8     private String lastName;
9     private static int count = 0; // number of objects in memory
10
11    // initialize employee, add 1 to static count and
12    // output String indicating that constructor was called
13    public Employee( String first, String last )
14    {
15        firstName = first;
16        lastName = last;

```

Fig. 8.12 | static variable used to maintain a count of the number of `Employee` objects in memory. (Part I of 2.)

```

17     count++; // increment static count of employees
18     System.out.printf( "Employee constructor: %s %s; count = %d\n",
19                         firstName, lastName, count );
20 } // end Employee constructor
21
22 // subtract 1 from static count when garbage
23 // collector calls finalize to clean up object;
24 // confirm that finalize was called
25 protected void finalize()
26 {
27     count--; // decrement static count of employees
28     System.out.printf( "Employee finalizer: %s %s; count = %d\n",
29                         firstName, lastName, count );
30 } // end method finalize
31
32
33 // get first name
34 public String getFirstName()
35 {
36     return firstName;
37 } // end method getFirstName
38
39 // get last name
40 public String getLastNames()
41 {
42     return lastName;
43 } // end method getLastNames
44
45 // static method to get static count value
46 public static int getCount()
47 {
48     return count;
49 } // end method getCount
50 } // end class Employee

```

Fig. 8.12 | static variable used to maintain a count of the number of Employee objects in memory. (Part 2 of 2.)

When Employee objects exist, member `count` can be used in any method of an Employee object—this example increments `count` in the constructor (line 18) and decrements it in the `finalize` method (line 28). When no objects of class Employee exist, member `count` can still be referenced, but only through a call to `public static` method `getCount` (lines 46–49), as in `Employee.getCount()`, which returns the number of Employee objects currently in memory. When objects exist, method `getCount` can also be called through any reference to an Employee object, as in the call `e1.getCount()`.

Good Programming Practice 8.1

Invoke every static method by using the class name and a dot (.) to emphasize that the method being called is a static method.

Note that the Employee class has a `finalize` method (lines 26–31). This method is included only to show when the garbage collector executes in this program. Method

394 Chapter 8 Classes and Objects: A Deeper Look

`finalize` is normally declared `protected`, so it is not part of the `public` services of a class. We will discuss the `protected` member access modifier in detail in Chapter 9.

`EmployeeTest` method `main` (Fig. 8.13) instantiates two `Employee` objects (lines 13–14). When each `Employee` object's constructor is invoked, lines 15–16 of Fig. 8.12 assign the `Employee`'s first name and last name to instance variables `firstName` and `lastName`. Note that these two statements do not make copies of the original `String` arguments. Actually, `String` objects in Java are immutable—they cannot be modified after they are created. Therefore, it is safe to have many references to one `String` object. This is not normally the case for objects of most other classes in Java. If `String` objects are immutable, you might wonder why we are able to use operators `+` and `+=` to concatenate `String` objects. String concatenation operations actually result in a new `String` object containing the concatenated values. The original `String` objects are not modified.

When `main` has finished using the two `Employee` objects, the references `e1` and `e2` are set to `null` at lines 31–32. At this point, references `e1` and `e2` no longer refer to the objects that were instantiated in lines 13–14. This “marks the objects for garbage collection” because there are no more references to the objects in the program.

```

1 // Fig. 8.13: EmployeeTest.java
2 // Static member demonstration.
3
4 public class EmployeeTest
5 {
6     public static void main( String args[] )
7     {
8         // show that count is 0 before creating Employees
9         System.out.printf( "Employees before instantiation: %d\n",
10                           Employee.getCount() );
11
12         // create two Employees; count should be 2
13         Employee e1 = new Employee( "Susan", "Baker" );
14         Employee e2 = new Employee( "Bob", "Blue" );
15
16         // show that count is 2 after creating two Employees
17         System.out.println( "\nEmployees after instantiation: " );
18         System.out.printf( "via e1.getCount(): %d\n", e1.getCount() );
19         System.out.printf( "via e2.getCount(): %d\n", e2.getCount() );
20         System.out.printf( "via Employee.getCount(): %d\n",
21                           Employee.getCount() );
22
23         // get names of Employees
24         System.out.printf( "\nEmployee 1: %s %s\nEmployee 2: %s %s\n\n",
25                           e1.getFirstName(), e1.getLastName(),
26                           e2.getFirstName(), e2.getLastName() );
27
28         // in this example, there is only one reference to each Employee,
29         // so the following two statements cause the JVM to mark each
30         // Employee object for garbage collection
31         e1 = null;
32         e2 = null;
```

Fig. 8.13 | static member demonstration. (Part I of 2.)

8.11 static Class Members **395**

```

33
34     System.gc(); // ask for garbage collection to occur now
35
36     // show Employee count after calling garbage collector; count
37     // displayed may be 0, 1 or 2 based on whether garbage collector
38     // executes immediately and number of Employee objects collected
39     System.out.printf( "\nEmployees after System.gc(): %d\n",
40                         Employee.getCount() );
41 } // end main
42 } // end class EmployeeTest

```

```

Employees before instantiation: 0
Employee constructor: Susan Baker; count = 1
Employee constructor: Bob Blue; count = 2

Employees after instantiation:
via e1.getCount(): 2
via e2.getCount(): 2
via Employee.getCount(): 2

Employee 1: Susan Baker
Employee 2: Bob Blue

Employee finalizer: Bob Blue; count = 1
Employee finalizer: Susan Baker; count = 0

Employees after System.gc(): 0

```

Fig. 8.13 | static member demonstration. (Part 2 of 2.)

Eventually, the garbage collector might reclaim the memory for these objects (or the operating system surely will reclaim the memory when the program terminates). The JVM does not guarantee when the garbage collector will execute (or even whether it will execute), so this program explicitly calls the garbage collector in line 34 (Fig. 8.13) using `static` method `gc` of class `System` (package `java.lang`) to indicate that the garbage collector should make a best-effort attempt to reclaim objects that are eligible for garbage collection. This is just a best effort—it is possible that no objects or only a subset of the eligible objects will be collected. In Fig. 8.13's sample output, the garbage collector did execute before lines 39–40 displayed current `Employee` count. The last output line indicates that the number of `Employee` objects in memory is 0 after the call to `System.gc()`. The third- and second-to-last lines of the output show that the `Employee` object for Bob Blue was finalized before the `Employee` object for Susan Baker. The output on your system may differ, because the garbage collector is not guaranteed to execute when `System.gc()` is called, nor is it guaranteed to collect objects in a specific order.

[*Note:* A method declared `static` cannot access non-`static` class members, because a `static` method can be called even when no objects of the class have been instantiated. For the same reason, the `this` reference cannot be used in a `static` method—it must refer to a specific object of the class, and when a `static` method is called, there might not be any objects of its class in memory. The `this` reference is required to allow a method of a class to access other non-`static` members of the same class.]

396 Chapter 8 Classes and Objects: A Deeper Look**Common Programming Error 8.7**

A compilation error occurs if a static method calls an instance (non-static) method in the same class by using only the method name. Similarly, a compilation error occurs if a static method attempts to access an instance variable in the same class by using only the variable name.

**Common Programming Error 8.8**

Referring to this in a static method is a syntax error.

8.12 static Import

In Section 6.3, you learned about the static fields and methods of class Math. We invoked class Math's static fields and methods by preceding each with the class name Math and a dot (.). A static import declaration enables you to refer to imported static members as if they were declared in the class that uses them—the class name and a dot (.) are not required to use an imported static member.

A static import declaration has two forms—one that imports a particular static member (which is known as single static import) and one that imports all static members of a class (which is known as static import on demand). The following syntax imports a particular static member:

```
import static packageName.ClassName.staticMemberName;
```

where *packageName* is the package of the class (e.g., java.lang), *ClassName* is the name of the class (e.g., Math) and *staticMemberName* is the name of the static field or method (e.g., PI or abs). The following syntax imports all static members of a class:

```
import static packageName.ClassName.*;
```

where *packageName* is the package of the class (e.g., java.lang) and *ClassName* is the name of the class (e.g., Math). The asterisk (*) indicates that *all* static members of the specified class should be available for use in the class(es) declared in the file. Note that static import declarations import only static class members. Regular import statements should be used to specify the classes used in a program.

Figure 8.14 demonstrates a static import. Line 3 is a static import declaration, which imports all static fields and methods of class Math from package java.lang. Lines 9–12 access the Math class's static field E (line 11) and the static methods sqrt (line 9),

```

1 // Fig. 8.14: StaticImportTest.java
2 // Using static import to import static methods of class Math.
3 import static java.lang.Math.*;
4
5 public class StaticImportTest
6 {
7     public static void main( String args[] )
8     {
9         System.out.printf( "sqrt( 900.0 ) = %.1f\n", sqrt( 900.0 ) );
10        System.out.printf( "ceil( -9.8 ) = %.1f\n", ceil( -9.8 ) );
11    }
12 }
```

Fig. 8.14 | Static import Math methods. (Part I of 2.)

8.13 final Instance Variables **397**

```

11     System.out.printf( "log( E ) = %.1f\n", log( E ) );
12     System.out.printf( "cos( 0.0 ) = %.1f\n", cos( 0.0 ) );
13 } // end main
14 } // end class StaticImportTest

```

```

sqrt( 900.0 ) = 30.0
ceil( -9.8 ) = -9.0
log( E ) = 1.0
cos( 0.0 ) = 1.0

```

Fig. 8.14 | Static import Math methods. (Part 2 of 2.)

`ceil` (line 10), `log` (line 11) and `cos` (line 12) without preceding the field name or method names with class name `Math` and a dot.

Common Programming Error 8.9

A compilation error occurs if a program attempts to import static methods that have the same signature or static fields that have the same name from two or more classes.

8.13 final Instance Variables

The [principle of least privilege](#) is fundamental to good software engineering. In the context of an application, the principle states that code should be granted only the amount of privilege and access that it needs to accomplish its designated task, but no more. Let us see how this principle applies to instance variables.

Some instance variables need to be modifiable and some do not. You can use the keyword `final` to specify that a variable is not modifiable (i.e., it is a constant) and that any attempt to modify it is an error. For example,

```
private final int INCREMENT;
```

declares a `final` (constant) instance variable `INCREMENT` of type `int`. Although constants can be initialized when they are declared, this is not required. Constants can be initialized by each of the class's constructors.

Software Engineering Observation 8.13

Declaring an instance variable as `final` helps enforce the principle of least privilege. If an instance variable should not be modified, declare it to be `final` to prevent modification.

Our next example contains two classes—class `Increment` (Fig. 8.15) and class `IncrementTest` (Fig. 8.16). Class `Increment` contains a `final` instance variable of type `int` named `INCREMENT` (Fig. 8.15, line 7). Note that the `final` variable is not initialized in its declaration, so it must be initialized by the class's constructor (lines 9–13). If the class provided multiple constructors, every constructor would be required to initialize the `final` variable. The constructor receives `int` parameter `incrementValue` and assigns its value to `INCREMENT` (line 12). A `final` variable cannot be modified by assignment after it is initialized. Application class `IncrementTest` creates an object of class `Increment` (Fig. 8.16, line 8) and provides as the argument to the constructor the value 5 to be assigned to the constant `INCREMENT`.

398 Chapter 8 Classes and Objects: A Deeper Look

```

1 // Fig. 8.15: Increment.java
2 // final instance variable in a class.
3
4 public class Increment
5 {
6     private int total = 0; // total of all increments
7     private final int INCREMENT; // constant variable (uninitialized)
8
9     // constructor initializes final instance variable INCREMENT
10    public Increment( int incrementValue )
11    {
12        INCREMENT = incrementValue; // initialize constant variable (once)
13    } // end Increment constructor
14
15    // add INCREMENT to total
16    public void addIncrementToTotal()
17    {
18        total += INCREMENT;
19    } // end method addIncrementToTotal
20
21    // return String representation of an Increment object's data
22    public String toString()
23    {
24        return String.format( "total = %d", total );
25    } // end method toIncrementString
26 } // end class Increment

```

Fig. 8.15 | final instance variable in a class.

```

1 // Fig. 8.16: IncrementTest.java
2 // final variable initialized with a constructor argument.
3
4 public class IncrementTest
5 {
6     public static void main( String args[] )
7     {
8         Increment value = new Increment( 5 );
9
10        System.out.printf( "Before incrementing: %s\n\n", value );
11
12        for ( int i = 1; i <= 3; i++ )
13        {
14            value.addIncrementToTotal();
15            System.out.printf( "After increment %d: %s\n", i, value );
16        } // end for
17    } // end main
18 } // end class IncrementTest

```

```

Before incrementing: total = 0
After increment 1: total = 5
After increment 2: total = 10
After increment 3: total = 15

```

Fig. 8.16 | final variable initialized with a constructor argument.

**Common Programming Error 8.10**

Attempting to modify a `final` instance variable after it is initialized is a compilation error.

**Error-Prevention Tip 8.2**

Attempts to modify a `final` instance variable are caught at compilation time rather than causing execution-time errors. It is always preferable to get bugs out at compilation time, if possible, rather than allow them to slip through to execution time (where studies have found that repair is often many times more expensive).

**Software Engineering Observation 8.14**

A `final` field should also be declared `static` if it is initialized in its declaration. Once a `final` field is initialized in its declaration, its value can never change. Therefore, it is not necessary to have a separate copy of the field for every object of the class. Making the field `static` enables all objects of the class to share the `final` field.

If a `final` variable is not initialized, a compilation error occurs. To demonstrate this, we placed line 12 of Fig. 8.15 in a comment and recompiled the class. Figure 8.17 shows the error message produced by the compiler.

**Common Programming Error 8.11**

Not initializing a `final` instance variable in its declaration or in every constructor of the class yields a compilation error indicating that the variable might not have been initialized. The same error occurs if the class initializes the variable in some, but not all, of the class's constructors.

```
Increment.java:13: variable INCREMENT might not have been initialized
    } // end Increment constructor
    ^
1 error
```

Fig. 8.17 | `final` variable `INCREMENT` must be initialized.

8.14 Software Reusability

Java programmers concentrate on crafting new classes and reusing existing classes. Many class libraries exist, and others are being developed worldwide. Software is then constructed from existing, well-defined, carefully tested, well-documented, portable, widely available components. This kind of software reusability speeds the development of powerful, high-quality software. **Rapid application development (RAD)** is of great interest today.

There are thousands of classes in the Java API from which to choose to help you implement Java programs. Indeed, Java is not just a programming language. It is a framework in which Java developers can work to achieve true reusability and rapid application development. Java programmers can focus on the task at hand when developing their programs and leave the lower-level details to the classes of the Java API. For example, to write a program that draws graphics, a Java programmer does not require knowledge of graphics on every computer platform where the program will execute. Instead, the programmer can concentrate on learning Java's graphics capabilities (which are quite substantial and growing) and write a Java program that draws the graphics, using Java's API classes, such

400 Chapter 8 Classes and Objects: A Deeper Look

as `Graphics`. When the program executes on a given computer, it is the job of the JVM to translate Java commands into commands that the local computer can understand.

The Java API classes enable Java programmers to bring new applications to market faster by using preexisting, tested components. Not only does this reduce development time, it also improves the programmer's ability to debug and maintain applications. To take advantage of Java's many capabilities, it is essential that you familiarize yourself with the variety of packages and classes in the Java API. There are many Web-based resources at java.sun.com to help you with this task. The primary resource for learning about the Java API is the Java API documentation, which can be found at

java.sun.com/javase/6/docs/api/

We overview how to use the documentation in Appendix G, Using the Java API Documentation. You can download the API documentation from

java.sun.com/javase/downloads/ea.jsp

In addition, java.sun.com provides many other resources, including tutorials, articles and sites specific to individual Java topics.

Good Programming Practice 8.2

Avoid reinventing the wheel. Study the capabilities of the Java API. If the API contains a class that meets your program's requirements, use that class rather than create your own.

To realize the full potential of software reusability, we need to improve cataloging schemes, licensing schemes, protection mechanisms which ensure that master copies of classes are not corrupted, description schemes that system designers use to determine whether existing objects meet their needs, browsing mechanisms that determine what classes are available and how closely they meet software developer requirements, and the like. Many interesting research and development problems have been solved and many more need to be solved. These problems will likely be solved because the potential value of increased software reuse is enormous.

8.15 Data Abstraction and Encapsulation

Classes normally hide the details of their implementation from their clients. This is called **information hiding**. As an example, let us consider the `stack` data structure introduced in Section 6.6. Recall that a stack is a **last-in, first-out (LIFO)** data structure—the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.

Stacks can be implemented with arrays and with other data structures, such as linked lists. (We discuss stacks and linked lists in Chapter 17, Data Structures, and in Chapter 19, Collections.) A client of a stack class need not be concerned with the stack's implementation. The client knows only that when data items are placed in the stack, they will be recalled in last-in, first-out order. The client cares about what functionality a stack offers, not about how that functionality is implemented. This concept is referred to as **data abstraction**. Although programmers might know the details of a class's implementation, they should not write code that depends on these details. This enables a particular class (such as one that implements a stack and its operations, `push` and `pop`) to be replaced with another version without affecting the rest of the system. As long as the `public` services of

8.15 Data Abstraction and Encapsulation **401**

the class do not change (i.e., every original method still has the same name, return type and parameter list in the new class declaration), the rest of the system is not affected.

Most programming languages emphasize actions. In these languages, data exists to support the actions that programs must take. Data is “less interesting” than actions. Data is “crude.” Only a few primitive types exist, and it is difficult for programmers to create their own types. Java and the object-oriented style of programming elevate the importance of data. The primary activities of object-oriented programming in Java are the creation of types (e.g., classes) and the expression of the interactions among objects of those types. To create languages that emphasize data, the programming-languages community needed to formalize some notions about data. The formalization we consider here is the notion of **abstract data types (ADTs)**, which improve the program-development process.

Consider primitive type `int`, which most people would associate with an integer in mathematics. Rather, an `int` is an abstract representation of an integer. Unlike mathematical integers, computer `ints` are fixed in size. For example, type `int` in Java is limited to the range $-2,147,483,648$ to $+2,147,483,647$. If the result of a calculation falls outside this range, an error occurs, and the computer responds in some machine-dependent manner. It might, for example, “quietly” produce an incorrect result, such as a value too large to fit in an `int` variable (commonly called **arithmetic overflow**). Mathematical integers do not have this problem. Therefore, the notion of a computer `int` is only an approximation of the notion of a real-world integer. The same is true of `float` and other built-in types.

We have taken the notion of `int` for granted until this point, but we now consider it from a new perspective. Types like `int`, `float`, and `char` are all examples of abstract data types. They are representations of real-world notions to some satisfactory level of precision within a computer system.

An ADT actually captures two notions: a **data representation** and the **operations** that can be performed on that data. For example, in Java, an `int` contains an integer value (data) and provides addition, subtraction, multiplication, division and remainder operations—division by zero is undefined. Java programmers use classes to implement abstract data types.

**Software Engineering Observation 8.15**

Programmers create types through the class mechanism. New types can be designed to be convenient to use as the built-in types. This marks Java as an extensible language. Although the language is easy to extend via new types, you cannot alter the base language itself.

Another abstract data type we discuss is a **queue**, which is similar to a “waiting line.” Computer systems use many queues internally. A queue offers well-understood behavior to its clients: Clients place items in a queue one at a time via an `enqueue` operation, then get them back one at a time via a `dequeue` operation. A queue returns items in **first-in, first-out (FIFO)** order, which means that the first item inserted in a queue is the first item removed from the queue. Conceptually, a queue can become infinitely long, but real queues are finite.

The queue hides an internal data representation that keeps track of the items currently waiting in line, and it offers operations to its clients (`enqueue` and `dequeue`). The clients are not concerned about the implementation of the queue—they simply depend on the queue to operate “as advertised.” When a client enqueues an item, the queue should accept that item and place it in some kind of internal FIFO data structure. Similarly, when the client

402 Chapter 8 Classes and Objects: A Deeper Look

wants the next item from the front of the queue, the queue should remove the item from its internal representation and deliver it in FIFO order (i.e., the item that has been in the queue the longest should be the next one returned by the next dequeue operation).

The queue ADT guarantees the integrity of its internal data structure. Clients cannot manipulate this data structure directly—only the queue ADT has access to its internal data. Clients are able to perform only allowable operations on the data representation—the ADT rejects operations that its public interface does not provide.

8.16 Time Class Case Study: Creating Packages

We have seen in almost every example in the text that classes from preexisting libraries, such as the Java API, can be imported into a Java program. Each class in the Java API belongs to a package that contains a group of related classes. As applications become more complex, packages help programmers manage the complexity of application components. Packages also facilitate software reuse by enabling programs to import classes from other packages (as we have done in most examples). Another benefit of packages is that they provide a convention for unique class names, which helps prevent class-name conflicts (discussed later in this section). This section introduces how to create your own packages.

Steps for Declaring a Reusable Class

Before a class can be imported into multiple applications, it must be placed in a package to make it reusable. Figure 8.18 shows how to specify the package in which a class should be placed. Figure 8.19 shows how to import our packaged class so that it can be used in an application. The steps for creating a reusable class are:

1. Declare a **public** class. If the class is not **public**, it can be used only by other classes in the same package.
2. Choose a unique package name and add a **package declaration** to the source-code file for the reusable class declaration. There can be only one package declaration in each Java source-code file, and it must precede all other declarations and statements in the file. Note that comments are not statements, so comments can be placed before a **package** statement in a file.
3. Compile the class so that it is placed in the appropriate package directory structure.
4. Import the reusable class into a program and use the class.

*Steps 1 and 2: Creating a **public** Class and Adding the **package** Statement*

For Step 1, we modify the **public** class **Time1** declared in Fig. 8.1. The new version is shown in Fig. 8.18. No modifications have been made to the implementation of the class, so we will not discuss its implementation details again here.

```

1 // Fig. 8.18: Time1.java
2 // Time1 class declaration maintains the time in 24-hour format.
3 package com.deitel.jhtp7.ch08;
4

```

Fig. 8.18 | Packaging class **Time1** for reuse. (Part 1 of 2.)

8.16 Time Class Case Study: Creating Packages **403**

```

5  public class Time1
6  {
7      private int hour; // 0 - 23
8      private int minute; // 0 - 59
9      private int second; // 0 - 59
10
11     // set a new time value using universal time; perform
12     // validity checks on the data; set invalid values to zero
13     public void setTime( int h, int m, int s )
14     {
15         hour = ( ( h >= 0 && h < 24 ) ? h : 0 ); // validate hour
16         minute = ( ( m >= 0 && m < 60 ) ? m : 0 ); // validate minute
17         second = ( ( s >= 0 && s < 60 ) ? s : 0 ); // validate second
18     } // end method setTime
19
20     // convert to String in universal-time format (HH:MM:SS)
21     public String toUniversalString()
22     {
23         return String.format( "%02d:%02d:%02d", hour, minute, second );
24     } // end method toUniversalString
25
26     // convert to String in standard-time format (H:MM:SS AM or PM)
27     public String toString()
28     {
29         return String.format( "%d:%02d:%02d %s",
30             ( ( hour == 0 || hour == 12 ) ? 12 : hour % 12 ),
31             minute, second, ( hour < 12 ? "AM" : "PM" ) );
32     } // end method toString
33 } // end class Time1

```

Fig. 8.18 | Packaging class `Time1` for reuse. (Part 2 of 2.)

For *Step 2*, we add a package declaration (line 3) that declares a package named `com.deitel.jhttp7.ch08`. Placing a package declaration at the beginning of a Java source file indicates that the class declared in the file is part of the specified package. Only package declarations, import declarations and comments can appear outside the braces of a class declaration. A Java source-code file must have the following order:

1. a package declaration (if any),
2. import declarations (if any), then
3. class declarations.

Only one of the class declarations in a particular file can be `public`. Other classes in the file are placed in the package and can be used only by the other classes in the package. Non-public classes are in a package to support the reusable classes in the package.

In an effort to provide unique names for every package, Sun Microsystems specifies a convention for package naming that all Java programmers should follow. Every package name should start with your Internet domain name in reverse order. For example, our domain name is `deitel.com`, so our package names begin with `com.deitel`. For the domain name `yourcollege.edu`, the package name should begin with `edu.yourcollege`. After the domain name is reversed, you can choose any other names you want for your package.

8.16 Time Class Case Study: Creating Packages

405

```

1 // Fig. 8.19: Time1PackageTest.java
2 // Time1 object used in an application.
3 import com.deitel.jhttp7.ch08.Time1; // import class Time1
4
5 public class Time1PackageTest
6 {
7     public static void main( String args[] )
8     {
9         // create and initialize a Time1 object
10        Time1 time = new Time1(); // calls Time1 constructor
11
12        // output string representations of the time
13        System.out.print( "The initial universal time is: " );
14        System.out.println( time.toUniversalString() );
15        System.out.print( "The initial standard time is: " );
16        System.out.println( time.toString() );
17        System.out.println(); // output a blank line
18
19        // change time and output updated time
20        time.setTime( 13, 27, 6 );
21        System.out.print( "Universal time after setTime is: " );
22        System.out.println( time.toUniversalString() );
23        System.out.print( "Standard time after setTime is: " );
24        System.out.println( time.toString() );
25        System.out.println(); // output a blank line
26
27        // set time with invalid values; output updated time
28        time.setTime( 99, 99, 99 );
29        System.out.println( "After attempting invalid settings:" );
30        System.out.print( "Universal time: " );
31        System.out.println( time.toUniversalString() );
32        System.out.print( "Standard time: " );
33        System.out.println( time.toString() );
34    } // end main
35 } // end class Time1PackageTest

```

```

The initial universal time is: 00:00:00
The initial standard time is: 12:00:00 AM

Universal time after setTime is: 13:27:06
Standard time after setTime is: 1:27:06 PM

After attempting invalid settings:
Universal time: 00:00:00
Standard time: 12:00:00 AM

```

Fig. 8.19 | Time1 object used in an application.

Line 3 is known as a **single-type-import declaration**—that is, the `import` declaration specifies one class to import. When your program uses multiple classes from the same package, you can import those classes with a single `import` declaration. For example, the `import` declaration

```
import java.util.*; // import classes from package java.util
```

404 Chapter 8 Classes and Objects: A Deeper Look

If you are part of a company with many divisions or a university with many schools, you may want to use the name of your division or school as the next name in the package. We chose to use `jhtp7` as the next name in our package name to indicate that this class is from *Java How to Program, Seventh Edition*. The last name in our package name specifies that this package is for Chapter 8 (`ch08`).

Step 3: Compiling the Packaged Class

Step 3 is to compile the class so that it is stored in the appropriate package. When a Java file containing a package declaration is compiled, the resulting class file is placed in the directory specified by the package declaration. The package declaration in Fig. 8.18 indicates that class `Time1` should be placed in the directory

```
com
  deitel
    jhtp7
      ch08
```

The directory names in the package declaration specify the exact location of the classes in the package.

When compiling a class in a package, the `javac` command-line option `-d` causes the `javac` compiler to create appropriate directories based on the class's package declaration. The option also specifies where the directories should be stored. For example, in a command window, we used the compilation command

```
javac -d . Time1.java
```

to specify that the first directory in our package name should be placed in the current directory. The period (.) after `-d` in the preceding command represents the current directory on the Windows, UNIX and Linux operating systems (and several others as well). After executing the compilation command, the current directory contains a directory called `com`, `com` contains a directory called `deitel`, `deitel` contains a directory called `jhtp7` and `jhtp7` contains a directory called `ch08`. In the `ch08` directory, you can find the file `Time1.class`. [Note: If you do not use the `-d` option, then you must copy or move the class file to the appropriate package directory after compiling it.]

The package name is part of the fully qualified class name, so the name of class `Time1` is actually `com.deitel.jhtp7.ch08.Time1`. You can use this fully qualified name in your programs, or you can `import` the class and use its **simple name** (the class name by itself—`Time1`) in the program. If another package also contains a `Time1` class, the fully qualified class names can be used to distinguish between the classes in the program and prevent a **name conflict** (also called a **name collision**).

Step 4: Importing the Reusable Class

Once the class is compiled and stored in its package, the class can be imported into programs (*Step 4*). In the `Time1PackageTest` application of Fig. 8.19, line 3 specifies that class `Time1` should be imported for use in class `Time1PackageTest`. Class `Time1PackageTest` is in the default package because the class's `.java` file does not contain a package declaration. Since the two classes are in different packages, the `import` at line 3 is required so that class `Time1PackageTest` can use class `Time1`.

406 Chapter 8 Classes and Objects: A Deeper Look

uses an asterisk (*) at the end of the `import` declaration to inform the compiler that all classes from the `java.util` package are available for use in the program. This is known as a **type-import-on-demand declaration**. Only the classes from package `java.util` that are used in the program are loaded by the JVM. The preceding `import` allows you to use the simple name of any class from the `java.util` package in the program. Throughout this book, we use single-type-import declarations for clarity.

Common Programming Error 8.12

Using the import declaration `import java.;` causes a compilation error. You must specify the exact name of the package from which you want to import classes.*

Specifying the Classpath During Compilation

When compiling `Time1PackageTest`, `javac` must locate the `.class` file for `Time1` to ensure that class `Time1PackageTest` uses class `Time1` correctly. The compiler uses a special object called a **class loader** to locate the classes it needs. The class loader begins by searching the standard Java classes that are bundled with the JDK. Then it searches for **optional packages**. Java provides an **extension mechanism** that enables new (optional) packages to be added to Java for development and execution purposes. [Note: The extension mechanism is beyond the scope of this book. For more information, visit java.sun.com/javase/6/docs/technotes/guides/extensions/.] If the class is not found in the standard Java classes or in the extension classes, the class loader searches the **classpath**, which contains a list of locations in which classes are stored. The classpath consists of a list of directories or **archive files**, each separated by a **directory separator**—a semicolon (;) on Windows or a colon (:) on UNIX/Linux/Mac OS X. Archive files are individual files that contain directories of other files, typically in a compressed format. For example, the standard classes used by your programs are contained in the archive file `rt.jar`, which is installed with the JDK. Archive files normally end with the `.jar` or `.zip` file-name extensions. The directories and archive files specified in the classpath contain the classes you wish to make available to the Java compiler and the JVM.

By default, the classpath consists only of the current directory. However, the classpath can be modified by

1. providing the `-classpath` option to the `javac` compiler or
2. setting the `CLASSPATH` environment variable (a special variable that you define and the operating system maintains so that applications can search for classes in the specified locations).

For more information on the classpath, visit java.sun.com/javase/6/docs/technotes/tools/index.html. The section entitled “General Information” contains information on setting the classpath for UNIX/Linux and Windows.

Common Programming Error 8.13

Specifying an explicit classpath eliminates the current directory from the classpath. This prevents classes in the current directory (including packages in the current directory) from loading properly. If classes must be loaded from the current directory, include a dot (.) in the classpath to specify the current directory.

Software Engineering Observation 8.16

In general, it is a better practice to use the `-classpath` option of the compiler, rather than the `CLASSPATH` environment variable, to specify the classpath for a program. This enables each application to have its own classpath.

Error-Prevention Tip 8.3

Specifying the classpath with the `CLASSPATH` environment variable can cause subtle and difficult-to-locate errors in programs that use different versions of the same package.

For the example of Fig. 8.18 and Fig. 8.19, we did not specify an explicit classpath. Thus, to locate the classes in the `com.deitel.jhttp7.ch08` package from this example, the class loader looks in the current directory for the first name in the package—`com`. Next, the class loader navigates the directory structure. Directory `com` contains the subdirectory `deitel`. Directory `deitel` contains the subdirectory `jhttp7`. Finally, directory `jhttp7` contains subdirectory `ch08`. In the `ch08` directory is the file `Time1.class`, which is loaded by the class loader to ensure that the class is used properly in our program.

Specifying the Classpath When Executing an Application

When you execute an application, the JVM must be able to locate the classes used in that application. Like the compiler, the `java` command uses a class loader that searches the standard classes and extension classes first, then searches the classpath (the current directory by default). The classpath for the JVM can be specified explicitly by using either of the techniques discussed for the compiler. As with the compiler, it is better to specify an individual program's classpath via command-line options to the JVM. You can specify the classpath in the `java` command via the `-classpath` or `-cp` command-line options, followed by a list of directories or archive files separated by semicolons (`;`) on Microsoft Windows or by colons (`:`) on UNIX/Linux/Mac OS X. Again, if classes must be loaded from the current directory, be sure to include a dot (`.`) in the classpath to specify the current directory.

8.17 Package Access

If no access modifier (`public`, `protected` or `private`—`protected` is discussed in Chapter 9) is specified for a method or variable when it is declared in a class, the method or variable is considered to have **package access**. In a program that consists of one class declaration, this has no specific effect. However, if a program uses multiple classes from the same package (i.e., a group of related classes), these classes can access each other's package-access members directly through references to objects of the appropriate classes.

The application in Fig. 8.20 demonstrates package access. The application contains two classes in one source-code file—the `PackageDataTest` application class (lines 5–21) and the `PackageData` class (lines 24–41). When you compile this program, the compiler produces two separate .class files—`PackageDataTest.class` and `PackageData.class`. The compiler places the two .class files in the same directory, so the classes are considered to be part of the same package. Since they are part of the same package, class `PackageDataTest` is allowed to modify the package-access data of `PackageData` objects.

In the `PackageData` class declaration, lines 26–27 declare the instance variables `number` and `string` with no access modifiers—therefore, these are package-access instance variables. The `PackageDataTest` application's `main` method creates an instance of the `PackageData` class (line 9) to demonstrate the ability to modify the `PackageData` instance

408 Chapter 8 Classes and Objects: A Deeper Look

variables directly (as shown in lines 15–16). The results of the modification can be seen in the output window.

```

1 // Fig. 8.20: PackageDataTest.java
2 // Package-access members of a class are accessible by other classes
3 // in the same package.
4
5 public class PackageDataTest
6 {
7     public static void main( String args[] )
8     {
9         PackageData packageData = new PackageData();
10
11        // output String representation of packageData
12        System.out.printf( "After instantiation:\n%s\n", packageData );
13
14        // change package access data in packageData object
15        packageData.number = 77;
16        packageData.string = "Goodbye";
17
18        // output String representation of packageData
19        System.out.printf( "\nAfter changing values:\n%s\n", packageData );
20    } // end main
21 } // end class PackageDataTest
22
23 // class with package access instance variables
24 class PackageData
25 {
26     int number; // package-access instance variable
27     String string; // package-access instance variable
28
29     // constructor
30     public PackageData()
31     {
32         number = 0;
33         string = "Hello";
34     } // end PackageData constructor
35
36     // return PackageData object String representation
37     public String toString()
38     {
39         return String.format( "number: %d; string: %s", number, string );
40     } // end method toString
41 } // end class PackageData

```

After instantiation:
number: 0; string: Hello

After changing values:
number: 77; string: Goodbye

Fig. 8.20 | Package-access members of a class are accessible by other classes in the same package.

8.18 (Optional) GUI and Graphics Case Study: Using Objects with Graphics **409**

8.18 (Optional) GUI and Graphics Case Study: Using Objects with Graphics

Most of the graphics you have seen to this point did not vary each time you executed the program. However, Exercise 6.2 asked you to create a program that generated shapes and colors at random. In that exercise, the drawing changed every time the system called `paintComponent` to redraw the panel. To create a more consistent drawing that remains the same each time it is drawn, we must store information about the displayed shapes so that we can reproduce them exactly each time the system calls `paintComponent`.

To do this, we will create a set of shape classes that store information about each shape. We will make these classes “smart” by allowing objects of these classes to draw themselves if provided with a `Graphics` object. Figure 8.21 declares class `MyLine`, which has all these capabilities.

Class `MyLine` imports `Color` and `Graphics` (lines 3–4). Lines 8–11 declare instance variables for the coordinates needed to draw a line, and line 12 declares the instance variable that stores the color of the line. The constructor at lines 15–22 takes five parameters, one for each instance variable that it initializes. Method `draw` at lines 25–29 requires a `Graphics` object and uses it to draw the line in the proper color and at the proper coordinates.

```

1 // Fig. 8.21: MyLine.java
2 // Declaration of class MyLine.
3 import java.awt.Color;
4 import java.awt.Graphics;
5
6 public class MyLine
7 {
8     private int x1; // x-coordinate of first endpoint
9     private int y1; // y-coordinate of first endpoint
10    private int x2; // x-coordinate of second endpoint
11    private int y2; // y-coordinate of second endpoint
12    private Color myColor; // color of this shape
13
14    // constructor with input values
15    public MyLine( int x1, int y1, int x2, int y2, Color color )
16    {
17        this.x1 = x1; // set x-coordinate of first endpoint
18        this.y1 = y1; // set y-coordinate of first endpoint
19        this.x2 = x2; // set x-coordinate of second endpoint
20        this.y2 = y2; // set y-coordinate of second endpoint
21        myColor = color; // set the color
22    } // end MyLine constructor
23
24    // Draw the line in the specified color
25    public void draw( Graphics g )
26    {
27        g.setColor( myColor );
28        g.drawLine( x1, y1, x2, y2 );
29    } // end method draw
30 } // end class MyLine

```

Fig. 8.21 | `MyLine` class represents a line.

410 Chapter 8 Classes and Objects: A Deeper Look

In Fig. 8.22, we declare class `DrawPanel`, which will generate random objects of class `MyLine`. Line 12 declares a `MyLine` array to store the lines to draw. Inside the constructor (lines 15–37), line 17 sets the background color to `Color.WHITE`. Line 19 creates the array with a random length between 5 and 9. The loop at lines 22–36 creates a new `MyLine` for every element in the array. Lines 25–28 generate random coordinates for each line's endpoints, and lines 31–32 generate a random color for the line. Line 35 creates a new `MyLine` object with the randomly generated values and stores it in the array.

```

1 // Fig. 8.22: DrawPanel.java
2 // Program that uses class MyLine
3 // to draw random lines.
4 import java.awt.Color;
5 import java.awt.Graphics;
6 import java.util.Random;
7 import javax.swing.JPanel;
8
9 public class DrawPanel extends JPanel
10 {
11     private Random randomNumbers = new Random();
12     private MyLine lines[]; // array of lines
13
14     // constructor, creates a panel with random shapes
15     public DrawPanel()
16     {
17         setBackground( Color.WHITE );
18
19         lines = new MyLine[ 5 + randomNumbers.nextInt( 5 ) ];
20
21         // create lines
22         for ( int count = 0; count < lines.length; count++ )
23         {
24             // generate random coordinates
25             int x1 = randomNumbers.nextInt( 300 );
26             int y1 = randomNumbers.nextInt( 300 );
27             int x2 = randomNumbers.nextInt( 300 );
28             int y2 = randomNumbers.nextInt( 300 );
29
30             // generate a random color
31             Color color = new Color( randomNumbers.nextInt( 256 ),
32                                     randomNumbers.nextInt( 256 ), randomNumbers.nextInt( 256 ) );
33
34             // add the line to the list of lines to be displayed
35             lines[ count ] = new MyLine( x1, y1, x2, y2, color );
36         } // end for
37     } // end DrawPanel constructor
38
39     // for each shape array, draw the individual shapes
40     public void paintComponent( Graphics g )
41     {
42         super.paintComponent( g );
43

```

Fig. 8.22 | Creating random `MyLine` objects. (Part I of 2.)

8.18 (Optional) GUI and Graphics Case Study: Using Objects with Graphics

411

```

44     // draw the lines
45     for ( MyLine line : lines )
46         line.draw( g );
47     } // end method paintComponent
48 } // end class DrawPanel

```

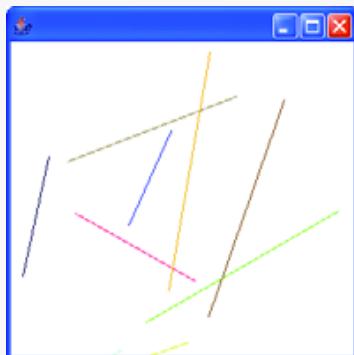

Fig. 8.22 | Creating random `MyLine` objects. (Part 2 of 2.)

Method `paintComponent` iterates through the `MyLine` objects in array `lines` using an enhanced for statement (lines 45–46). Each iteration calls the `draw` method of the current `MyLine` object and passes it the `Graphics` object for drawing on the panel. Class `TestDraw` in Fig. 8.23 sets up a new window to display our drawing. Since we are setting the coordinates for the lines only once in the constructor, the drawing does not change if `paintComponent` is called to refresh the drawing on the screen.

```

1 // Fig. 8.23: TestDraw.java
2 // Test application to display a DrawPanel.
3 import javax.swing.JFrame;
4
5 public class TestDraw
6 {
7     public static void main( String args[] )
8     {
9         DrawPanel panel = new DrawPanel();
10        JFrame application = new JFrame();
11
12        application.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
13        application.add( panel );
14        application.setSize( 300, 300 );
15        application.setVisible( true );
16    } // end main
17 } // end class TestDraw

```

**Fig. 8.23** | Creating `JFrame` to display `DrawPanel`.

412 Chapter 8 Classes and Objects: A Deeper Look

GUI and Graphics Case Study Exercise

8.1 Extend the program in Figs. 8.21–8.23 to randomly draw rectangles and ovals. Create classes `MyRectangle` and `MyOval`. Both of these classes should include `x1`, `y1`, `x2`, `y2` coordinates, a color and a boolean flag to determine whether the shape is a filled shape. Declare a constructor in each class with arguments for initializing all the instance variables. To help draw rectangles and ovals, each class should provide methods `getUpperLeftX`, `getUpperLeftY`, `getWidth` and `getHeight` that calculate the upper-left *x*-coordinate, upper-left *y*-coordinate, width and height, respectively. The upper-left *x*-coordinate is the smaller of the two *x*-coordinate values, the upper-left *y*-coordinate is the smaller of the two *y*-coordinate values, the width is the absolute value of the difference between the two *x*-coordinate values, and the height is the absolute value of the difference between the two *y*-coordinate values.

Class `DrawPanel1`, which extends `JPanel` and handles the creation of the shapes, should declare three arrays, one for each shape type. The length of each array should be a random number between 1 and 5. The constructor of class `DrawPanel1` will fill each of the arrays with shapes of random position, size, color and fill.

In addition, modify all three shape classes to include the following:

- a) A constructor with no arguments that sets all the coordinates of the shape to 0, the color of the shape to `Color.BLACK`, and the filled property to `false` (`MyRect` and `MyOval` only).
- b) *Set* methods for the instance variables in each class. The methods that set a coordinate value should verify that the argument is greater than or equal to zero before setting the coordinate—if it is not, they should set the coordinate to zero. The constructor should call the *set* methods rather than initialize the local variables directly.
- c) *Get* methods for the instance variables in each class. Method `draw` should reference the coordinates by the *get* methods rather than access them directly.

8.19 (Optional) Software Engineering Case Study: Starting to Program the Classes of the ATM System

In the Software Engineering Case Study sections in Chapters 1–7, we introduced the fundamentals of object orientation and developed an object-oriented design for our ATM system. Earlier in this chapter, we discussed many of the details of programming with classes. We now begin implementing our object-oriented design in Java. At the end of this section, we show how to convert class diagrams to Java code. In the final Software Engineering Case Study section (Section 10.9), we modify the code to incorporate the object-oriented concept of inheritance. We present the full Java code implementation in Appendix J.

Visibility

We now apply access modifiers to the members of our classes. In Chapter 3, we introduced access modifiers `public` and `private`. Access modifiers determine the **visibility** or accessibility of an object's attributes and methods to other objects. Before we can begin implementing our design, we must consider which attributes and methods of our classes should be `public` and which should be `private`.

In Chapter 3, we observed that attributes normally should be `private` and that methods invoked by clients of a given class should be `public`. Methods that are called only by other methods of the class as “utility methods,” however, normally should be `private`. The UML employs **visibility markers** for modeling the visibility of attributes and operations. Public visibility is indicated by placing a plus sign (+) before an operation or an attribute, whereas a minus sign (−) indicates private visibility. Figure 8.24 shows our

8.19 Starting to Program the Classes of the ATM System

413

updated class diagram with visibility markers included. [Note: We do not include any operation parameters in Fig. 8.24—this is perfectly normal. Adding visibility markers does not affect the parameters already modeled in the class diagrams of Figs. 6.22–6.25.]

Navigability

Before we begin implementing our design in Java, we introduce an additional UML notation. The class diagram in Fig. 8.25 further refines the relationships among classes in the ATM system by adding navigability arrows to the association lines. **Navigability arrows** (represented as arrows with stick arrowheads in the class diagram) indicate in which direction an association can be traversed. When implementing a system designed using the UML, programmers use navigability arrows to help determine which objects need references to other objects. For example, the navigability arrow pointing from class ATM to class BankDatabase indicates that we can navigate from the former to the latter, thereby enabling the ATM to invoke the BankDatabase's operations. However, since Fig. 8.25 does not contain a navigability arrow pointing from class BankDatabase to class ATM, the BankData-

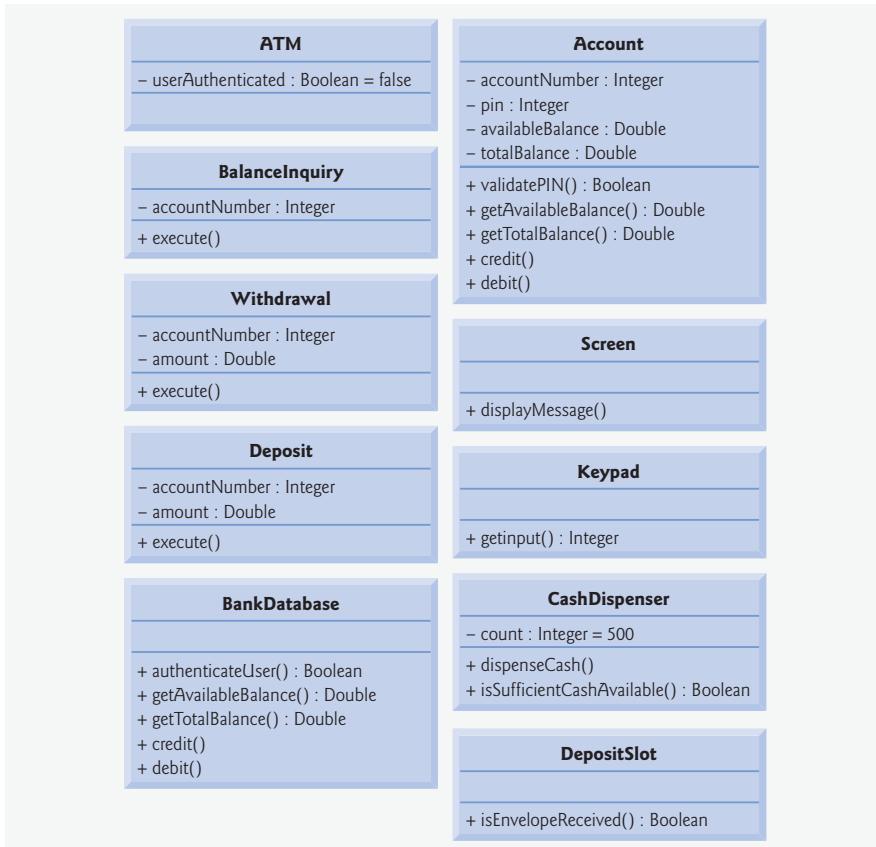

Fig. 8.24 | Class diagram with visibility markers.

414 Chapter 8 Classes and Objects: A Deeper Look

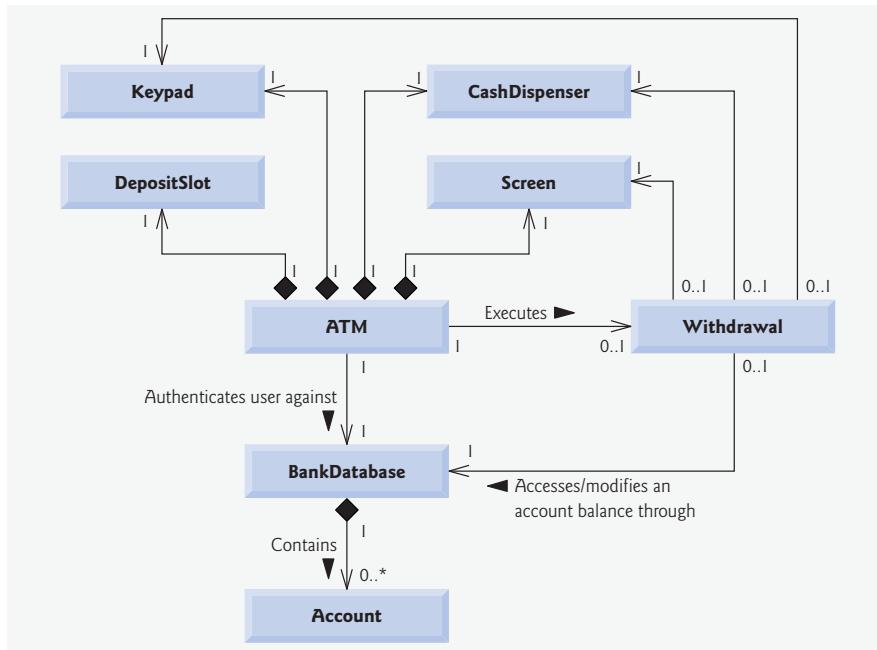

Fig. 8.25 | Class diagram with navigability arrows.

base cannot access the ATM's operations. Note that associations in a class diagram that have navigability arrows at both ends or do not have navigability arrows at all indicate **bidirectional navigability**—navigation can proceed in either direction across the association.

Like the class diagram of Fig. 3.24, the class diagram of Fig. 8.25 omits classes `BalanceInquiry` and `Deposit` to keep the diagram simple. The navigability of the associations in which these classes participate closely parallels the navigability of class `Withdrawal`. Recall from Section 3.10 that `BalanceInquiry` has an association with class `Screen`. We can navigate from class `BalanceInquiry` to class `Screen` along this association, but we cannot navigate from class `Screen` to class `BalanceInquiry`. Thus, if we were to model class `BalanceInquiry` in Fig. 8.25, we would place a navigability arrow at class `Screen`'s end of this association. Also recall that class `Deposit` associates with classes `Screen`, `Keypad` and `DepositSlot`. We can navigate from class `Deposit` to each of these classes, but not vice versa. We therefore would place navigability arrows at the `Screen`, `Keypad` and `DepositSlot` ends of these associations. [Note: We model these additional classes and associations in our final class diagram in Section 10.9, after we have simplified the structure of our system by incorporating the object-oriented concept of inheritance.]

Implementing the ATM System from Its UML Design

We are now ready to begin implementing the ATM system. We first convert the classes in the diagrams of Fig. 8.24 and Fig. 8.25 into Java code. The code will represent the “skeleton” of the system. In Chapter 10, we modify the code to incorporate the object-oriented

8.19 Starting to Program the Classes of the ATM System **415**

concept of inheritance. In Appendix J, ATM Case Study Code, we present the complete working Java code for our model.

As an example, we develop the code from our design of class `Withdrawal` in Fig. 8.24. We use this figure to determine the attributes and operations of the class. We use the UML model in Fig. 8.25 to determine the associations among classes. We follow the following four guidelines for each class:

1. Use the name located in the first compartment to declare the class as a `public` class with an empty no-argument constructor. We include this constructor simply as a placeholder to remind us that most classes will indeed need constructors. In Appendix J, when we complete a working version of this class, we add any necessary arguments and code the body of the constructor as needed. For example, class `Withdrawal` yields the code in Fig. 8.26. [Note: If we find that the class's instance variables require only default initialization, then we remove the empty no-argument constructor because it is unnecessary.]
2. Use the attributes located in the second compartment to declare the instance variables. For example, the `private` attributes `accountNumber` and `amount` of class `Withdrawal` yield the code in Fig. 8.27. [Note: The constructor of the complete working version of this class will assign values to these attributes.]
3. Use the associations described in the class diagram to declare the references to other objects. For example, according to Fig. 8.25, `Withdrawal` can access one object of class `Screen`, one object of class `Keypad`, one object of class `CashDispenser` and one object of class `BankDatabase`. This yields the code in Fig. 8.28.

```

1 // Class Withdrawal represents an ATM withdrawal transaction
2 public class Withdrawal
3 {
4     // no-argument constructor
5     public Withdrawal()
6     {
7     } // end no-argument Withdrawal constructor
8 } // end class Withdrawal

```

Fig. 8.26 | Java code for class `Withdrawal` based on Fig. 8.24 and Fig. 8.25.

```

1 // Class Withdrawal represents an ATM withdrawal transaction
2 public class Withdrawal
3 {
4     // attributes
5     private int accountNumber; // account to withdraw funds from
6     private double amount; // amount to withdraw
7
8     // no-argument constructor
9     public Withdrawal()
10    {
11    } // end no-argument Withdrawal constructor
12 } // end class Withdrawal

```

Fig. 8.27 | Java code for class `Withdrawal` based on Fig. 8.24 and Fig. 8.25.

416 Chapter 8 Classes and Objects: A Deeper Look

```

1 // Class Withdrawal represents an ATM withdrawal transaction
2 public class Withdrawal
3 {
4     // attributes
5     private int accountNumber; // account to withdraw funds from
6     private double amount; // amount to withdraw
7
8     // references to associated objects
9     private Screen screen; // ATM's screen
10    private Keypad keypad; // ATM's keypad
11    private CashDispenser cashDispenser; // ATM's cash dispenser
12    private BankDatabase bankDatabase; // account info database
13
14    // no-argument constructor
15    public Withdrawal()
16    {
17    } // end no-argument Withdrawal constructor
18 } // end class Withdrawal

```

Fig. 8.28 | Java code for class `Withdrawal` based on Fig. 8.24 and Fig. 8.25.

[*Note:* The constructor of the complete working version of this class will initialize these instance variables with references to actual objects.]

4. Use the operations located in the third compartment of Fig. 8.24 to declare the shells of the methods. If we have not yet specified a return type for an operation, we declare the method with return type `void`. Refer to the class diagrams of Figs. 6.22–6.25 to declare any necessary parameters. For example, adding the `public` operation `execute` in class `Withdrawal`, which has an empty parameter list, yields the code in Fig. 8.29. [*Note:* We code the bodies of methods when we implement the complete system in Appendix J.]

```

1 // Class Withdrawal represents an ATM withdrawal transaction
2 public class Withdrawal
3 {
4     // attributes
5     private int accountNumber; // account to withdraw funds from
6     private double amount; // amount to withdraw
7
8     // references to associated objects
9     private Screen screen; // ATM's screen
10    private Keypad keypad; // ATM's keypad
11    private CashDispenser cashDispenser; // ATM's cash dispenser
12    private BankDatabase bankDatabase; // account info database
13
14    // no-argument constructor
15    public Withdrawal()
16    {
17    } // end no-argument Withdrawal constructor
18

```

Fig. 8.29 | Java code for class `Withdrawal` based on Fig. 8.24 and Fig. 8.25. (Part I of 2.)

8.19 Starting to Program the Classes of the ATM System

417

```

19    // operations
20    public void execute()
21    {
22    } // end method execute
23 } // end class Withdrawal

```

Fig. 8.29 | Java code for class `Withdrawal` based on Fig. 8.24 and Fig. 8.25. (Part 2 of 2.)

This concludes our discussion of the basics of generating classes from UML diagrams.

Software Engineering Case Study Self-Review Exercises

8.1 State whether the following statement is *true* or *false*, and if *false*, explain why: If an attribute of a class is marked with a minus sign (-) in a class diagram, the attribute is not directly accessible outside of the class.

8.2 In Fig. 8.25, the association between the `ATM` and the `Screen` indicates that:

- a) we can navigate from the `Screen` to the `ATM`
- b) we can navigate from the `ATM` to the `Screen`
- c) Both (a) and (b); the association is bidirectional
- d) None of the above

8.3 Write Java code to begin implementing the design for class `Keypad`.

Answers to Software Engineering Case Study Self-Review Exercises

8.1 True. The minus sign (-) indicates private visibility.

8.2 b.

8.3 The design for class `Keypad` yields the code in Fig. 8.30. Recall that class `Keypad` has no attributes for the moment, but attributes may become apparent as we continue the implementation. Also note that if we were designing a real ATM, method `getInput` would need to interact with the ATM's keypad hardware. We will actually do input from the keyboard of a personal computer when we write the complete Java code in Appendix J.

```

1 // Class Keypad represents an ATM's keypad
2 public class Keypad
3 {
4     // no attributes have been specified yet
5
6     // no-argument constructor
7     public Keypad()
8     {
9         // end no-argument Keypad constructor
10
11    // operations
12    public int getInput()
13    {
14    } // end method getInput
15 } // end class Keypad

```

Fig. 8.30 | Java code for class `Keypad` based on Fig. 8.24 and Fig. 8.25.

418 Chapter 8 Classes and Objects: A Deeper Look

8.20 Wrap-Up

In this chapter, we presented additional class concepts. The `Time` class case study presented a complete class declaration consisting of `private` data, overloaded `public` constructors for initialization flexibility, `set` and `get` methods for manipulating the class's data, and methods that returned `String` representations of a `Time` object in two different formats. You also learned that every class can declare a `toString` method that returns a `String` representation of an object of the class and that method `toString` can be called implicitly whenever an object of a class appears in the code where a `String` is expected.

You learned that the `this` reference is used implicitly in a class's non-`static` methods to access the class's instance variables and other non-`static` methods. You also saw explicit uses of the `this` reference to access the class's members (including shadowed fields) and how to use keyword `this` in a constructor to call another constructor of the class.

We discussed the differences between default constructors provided by the compiler and no-argument constructors provided by the programmer. You learned that a class can have references to objects of other classes as members—a concept known as composition. You saw the `enum` class type and learned how it can be used to create a set of constants for use in a program. You learned about Java's garbage collection capability and how it reclaims the memory of objects that are no longer used. The chapter explained the motivation for `static` fields in a class and demonstrated how to declare and use `static` fields and methods in your own classes. You also learned how to declare and initialize `final` variables.

You learned how to package your own classes for reuse and how to import those classes into an application. Finally, you learned that fields declared without an access modifier are given package access by default. You saw the relationship between classes in the same package that allows each class in a package to access the package-access members of other classes in the package.

In the next chapter, you will learn about an important aspect of object-oriented programming in Java—inheritance. You will see that all classes in Java are related directly or indirectly to the class called `Object`. You will also begin to understand how the relationships between classes enable you to build more powerful applications.

Summary

Section 8.2 Time Class Case Study

- Every class you declare represents a new type in Java.
- The `public` methods of a class are also known as the class's `public` services or `public` interface. The primary purpose of `public` methods is to present to the class's clients a view of the services the class provides. Clients of the class need not be concerned with how the class accomplishes its tasks. For this reason, `private` class members are not directly accessible to the class's clients.
- An object that contains consistent data has data values that are always kept in range.
- A value passed to a method to modify an instance variable is a correct value if that value is in the instance variable's allowed range. A correct value is always a consistent value, but a consistent value is not correct if a method receives an out-of-range value and sets it to a consistent value to maintain the object in a consistent state.
- `String` class `static` method `format` is similar to method `System.out.printf` except that `format` returns a formatted `String` rather than displaying it in a command window.

- All objects in Java have a `toString` method that returns a `String` representation of the object. Method `toString` is called implicitly when an object appears in code where a `String` is needed.

Section 8.4 Referring to the Current Object's Members with the `this` Reference

- A non-static method of an object implicitly uses keyword `this` to refer to the object's instance variables and other methods. Keyword `this` can also be used explicitly.
- The compiler produces a separate file with the `.class` extension for every compiled class.
- If a method contains a local variable with the same name as one of its class's fields, the local variable shadows the field in the method's scope. The method can use the `this` reference to refer to the shadowed field explicitly.

Section 8.5 Time Class Case Study: Overloaded Constructors

- Overloaded constructors enable objects of a class to be initialized in different ways. The compiler differentiates overloaded constructors by their signatures.

Section 8.6 Default and No-Argument Constructors

- Every class must have at least one constructor. If none are provided, the compiler creates a default constructor that initializes the instance variables to the initial values specified in their declarations or to their default values.
- If a class declares constructors, the compiler will not create a default constructor. To specify the default initialization for objects of a class with multiple constructors, the programmer must declare a no-argument constructor.

Section 8.7 Notes on Set and Get Methods

- *Set* methods are commonly called mutator methods because they typically change a value. *Get* methods are commonly called accessor methods or query methods. A predicate method tests whether a condition is true or false.

Section 8.8 Composition

- A class can have references to objects of other classes as members. Such a capability is called composition and is sometimes referred to as a *has-a* relationship.

Section 8.9 Enumerations

- All `enum` types are reference types. An `enum` type is declared with an `enum` declaration, which is a comma-separated list of `enum` constants. The declaration may optionally include other components of traditional classes, such as constructors, fields and methods.
- `enum` types are implicitly `final`, because they declare constants that should not be modified.
- `enum` constants are implicitly `static`.
- Any attempt to create an object of an `enum` type with operator `new` results in a compilation error.
- `enum` constants can be used anywhere constants can be used, such as in the case labels of `switch` statements and to control enhanced `for` statements.
- Each `enum` constant in an `enum` declaration is optionally followed by arguments which are passed to the `enum` constructor.
- For every `enum`, the compiler generates a `static` method called `values` that returns an array of the `enum`'s constants in the order in which they were declared.
- `EnumSet static` method `range` takes two parameters—the first `enum` constant in a range and the last `enum` constant in a range—and returns an `EnumSet` that contains all the constants between these two constants, inclusive.

420 Chapter 8 Classes and Objects: A Deeper Look***Section 8.10 Garbage Collection and Method `finalize`***

- Every class in Java has the methods of class `Object`, one of which is the `finalize` method.
- The Java Virtual Machine (JVM) performs automatic garbage collection to reclaim the memory occupied by objects that are no longer in use. When there are no more references to an object, the object is marked for garbage collection by the JVM. The memory for such an object can be reclaimed when the JVM executes its garbage collector.
- The `finalize` method is called by the garbage collector just before it reclaims the object's memory. Method `finalize` does not take parameters and has return type `void`.
- The garbage collector may never execute before a program terminates. Thus, it is unclear whether, or when, method `finalize` will be called.

Section 8.11 static Class Members

- A `static` variable represents classwide information that is shared among all objects of the class.
- Static variables have class scope. A class's `public static` members can be accessed through a reference to any object of the class, or they can be accessed by qualifying the member name with the class name and a dot (.). A class's `private static` class members can be accessed only through methods of the class.
- `static` class members exist even when no objects of the class exist—they are available as soon as the class is loaded into memory at execution time. To access a `private static` member when no objects of the class exist, a `public static` method must be provided.
- `System` class `static` method `gc` indicates that the garbage collector should make a best-effort attempt to reclaim objects that are eligible for garbage collection.
- A method declared `static` cannot access non-`static` class members, because a `static` method can be called even when no objects of the class have been instantiated.
- The `this` reference cannot be used in a `static` method.

Section 8.12 static Import

- A `static` import declaration enables programmers to refer to imported `static` members without the class name and a dot (.). A single `static` import declaration imports one `static` member, and a `static` import on demand imports all `static` members of a class.

Section 8.13 final Instance Variables

- In the context of an application, the principle of least privilege states that code should be granted only the amount of privilege and access that the code needs to accomplish its designated task.
- Keyword `final` specifies that a variable is not modifiable—in other words, it is constant. Constants can be initialized when they are declared or by each of a class's constructors. If a `final` variable is not initialized, a compilation error occurs.

Section 8.14 Software Reusability

- Software is constructed from existing, well-defined, carefully tested, well-documented, portable, widely available components. Software reusability speeds the development of powerful, high-quality software. Rapid application development (RAD) is of great interest today.
- Java programmers now have thousands of classes in the Java API from which to choose to help them implement Java programs. The Java API classes enable Java programmers to bring new applications to market faster by using preexisting, tested components.

Section 8.15 Data Abstraction and Encapsulation

- The client of a class cares about the functionality the class offers, but not about how the functionality is implemented. This is referred to as data abstraction. Although programmers may know the

Terminology **421**

details of a class's implementation, they should not write code that depends on these details. This enables a class to be replaced with another version without affecting the rest of the system.

- An abstract data type (ADT) consists of a data representation and the operations that can be performed on that data.

Section 8.16 Time Class Case Study: Creating Packages

- Each class in the Java API belongs to a package that contains a group of related classes. Packages help manage the complexity of application components and facilitate software reuse.
- Packages provide a convention for unique class names that helps prevent class name conflicts.
- Before a class can be imported into multiple applications, the class must be placed in a package. There can be only one package declaration in each Java source-code file, and it must precede all other declarations and statements in the file.
- Every package name should start with your Internet domain name in reverse order. After the domain name is reversed, you can choose any other names you want for your package.
- When compiling a class in a package, the `javac` command-line option `-d` specifies where to store the package and causes the compiler to create the package's directories if they do not exist.
- The package name is part of the fully qualified class name. This helps prevent name conflicts.
- A single-type-import declaration specifies one class to import. A type-import-on-demand declaration imports only the classes that the program uses from a particular package.
- The compiler uses a class loader to locate the classes it needs in the classpath. The classpath consists of a list of directories or archive files, each separated by a directory separator.
- The classpath for the compiler and JVM can be specified by providing the `-classpath` option to the `javac` or `java` command, or by setting the `CLASSPATH` environment variable. The classpath for the JVM can also be specified via the `-cp` command-line option. If classes must be loaded from the current directory, include a dot (.) in the classpath.

Section 8.17 Package Access

- If no access modifier is specified for a method or variable when it is declared in a class, the method or variable is considered to have package access.

Terminology

abstract data type (ADT)	constant variable
access modifier	<code>-d</code> command-line argument to <code>javac</code>
accessor method	data abstraction
archive file	data representation
arithmetic overflow	default constructor
attribute	directory separator
behavior	<code>enum</code> keyword
class library	enum constant
class loader	<code>EnumSet</code> class
class scope	extensible language
class variable	extensions mechanism
classpath	<code>finalize</code> method
<code>-classpath</code> command-line argument to <code>javac</code>	first-in, first-out (FIFO)
<code>CLASSPATH</code> environment variable	<code>format</code> method of class <code>String</code>
classwide information	garbage collector
composition	<code>gc</code> method of class <code>System</code>
container class	<i>has-a</i> relationship

422 Chapter 8 Classes and Objects: A Deeper Look

last-in, first-out (LIFO)	query method
mark an object for garbage collection	range method of <code>EnumSet</code>
memory leak	rapid application development (RAD)
mutator method	resource leak
name collision	service of a class
name conflict	simple name of a class, field or method
no-argument constructor	single static import
optional package	single-type-import declaration
overloaded constructors	stack
package access	static field (class variable)
package declaration	static import
predicate method	static import on demand
principle of least privilege	termination housekeeping
private access modifier	this keyword
protected access modifier	type-import-on-demand declaration
public access modifier	validity checking
public interface	values method of an enum
public service	variable is not modifiable

Self-Review Exercise

8.1 Fill in the blanks in each of the following statements:

- a) When compiling a class in a package, the `javac` command-line option _____ specifies where to store the package and causes the compiler to create the package's directories if they do not exist.
- b) `String` class `static` method _____ is similar to method `System.out.printf`, but returns a formatted `String` rather than displaying a `String` in a command window.
- c) If a method contains a local variable with the same name as one of its class's fields, the local variable _____ the field in that method's scope.
- d) The _____ method is called by the garbage collector just before it reclaims an object's memory.
- e) A(n) _____ declaration specifies one class to import.
- f) If a class declares constructors, the compiler will not create a(n) _____.
- g) An object's _____ method is called implicitly when an object appears in code where a `String` is needed.
- h) *Get* methods are commonly called _____ or _____.
- i) A(n) _____ method tests whether a condition is true or false.
- j) For every `enum`, the compiler generates a `static` method called _____ that returns an array of the `enum`'s constants in the order in which they were declared.
- k) Composition is sometimes referred to as a(n) _____ relationship.
- l) A(n) _____ declaration contains a comma-separated list of constants.
- m) A(n) _____ variable represents classwide information that is shared by all the objects of the class.
- n) A(n) _____ declaration imports one `static` member.
- o) The _____ states that code should be granted only the amount of privilege and access that the code needs to accomplish its designated task.
- p) Keyword _____ specifies that a variable is not modifiable.
- q) A(n) _____ consists of a data representation and the operations that can be performed on the data.
- r) There can be only one _____ in a Java source-code file, and it must precede all other declarations and statements in the file.

Answers to Self-Review Exercise **423**

- s) A(n) _____ declaration imports only the classes that the program uses from a particular package.
- t) The compiler uses a(n) _____ to locate the classes it needs in the classpath.
- u) The classpath for the compiler and JVM can be specified with the _____ option to the `javac` or `java` command, or by setting the _____ environment variable.
- v) *Set* methods are commonly called _____ because they typically change a value.
- w) A(n) _____ imports all static members of a class.
- x) The public methods of a class are also known as the class's _____ or _____.
- y) System class static method _____ indicates that the garbage collector should make a best-effort attempt to reclaim objects that are eligible for garbage collection.
- z) An object that contains _____ has data values that are always kept in range.

Answers to Self-Review Exercise

- 8.1** a) -d. b) `format`. c) shadows. d) `finalize`. e) single-type-import. f) default constructor. g) `toString`. h) accessor methods, query methods. i) predicate. j) `values`. k) *has-a*. l) enum. m) static. n) single static import. o) principle of least privilege. p) `final`. q) abstract data type (ADT). r) package declaration. s) type-import-on-demand. t) class loader. u) `-classpath`, `CLASSPATH`. v) mutator methods. w) static import on demand. x) `public` services, `public` interface. y) `gc`. z) consistent data.

Exercises

- 8.2** Explain the notion of package access in Java. Explain the negative aspects of package access.
- 8.3** What happens when a return type, even `void`, is specified for a constructor?
- 8.4** (*Rectangle Class*) Create a class `Rectangle`. The class has attributes `length` and `width`, each of which defaults to 1. It has methods that calculate the perimeter and the area of the rectangle. It has *set* and *get* methods for both `length` and `width`. The *set* methods should verify that `length` and `width` are each floating-point numbers larger than 0.0 and less than 20.0. Write a program to test class `Rectangle`.
- 8.5** (*Modifying the Internal Data Representation of a Class*) It would be perfectly reasonable for the `Time2` class of Fig. 8.5 to represent the time internally as the number of seconds since midnight rather than the three integer values `hour`, `minute` and `second`. Clients could use the same `public` methods and get the same results. Modify the `Time2` class of Fig. 8.5 to implement the `Time2` as the number of seconds since midnight and show that no change is visible to the clients of the class.
- 8.6** (*Savings Account Class*) Create class `SavingsAccount`. Use a `static` variable `annualInterestRate` to store the annual interest rate for all account holders. Each object of the class contains a `private` instance variable `savingsBalance` indicating the amount the saver currently has on deposit. Provide method `calculateMonthlyInterest` to calculate the monthly interest by multiplying the `savingsBalance` by `annualInterestRate` divided by 12—this interest should be added to `savingsBalance`. Provide a `static` method `modifyInterestRate` that sets the `annualInterestRate` to a new value. Write a program to test class `SavingsAccount`. Instantiate two `savingsAccount` objects, `saver1` and `saver2`, with balances of \$2000.00 and \$3000.00, respectively. Set `annualInterestRate` to 4%, then calculate the monthly interest and print the new balances for both savers. Then set the `annualInterestRate` to 5%, calculate the next month's interest and print the new balances for both savers.
- 8.7** (*Enhancing Class Time2*) Modify class `Time2` of Fig. 8.5 to include a `tick` method that increments the time stored in a `Time2` object by one second. Provide method `incrementMinute` to increment the minute and method `incrementHour` to increment the hour. The `Time2` object should

424 Chapter 8 Classes and Objects: A Deeper Look

always remain in a consistent state. Write a program that tests the `tick` method, the `incrementMinute` method and the `incrementHour` method to ensure that they work correctly. Be sure to test the following cases:

- a) incrementing into the next minute,
- b) incrementing into the next hour and
- c) incrementing into the next day (i.e., 11:59:59 PM to 12:00:00 AM).

8.8 (*Enhancing Class Date*) Modify class `Date` of Fig. 8.7 to perform error checking on the initializer values for instance variables `month`, `day` and `year` (currently it validates only the month and day). Provide a method `nextDay` to increment the day by one. The `Date` object should always remain in a consistent state. Write a program that tests the `nextDay` method in a loop that prints the date during each iteration of the loop to illustrate that the `nextDay` method works correctly. Test the following cases:

- a) incrementing into the next month and
- b) incrementing into the next year.

8.9 (*Returning Error Indicators from Methods*) Modify the `set` methods in class `Time2` of Fig. 8.5 to return appropriate error values if an attempt is made to set one of the instance variables `hour`, `minute` or `second` of an object of class `Time` to an invalid value. [Hint: Use `boolean` return types on each method.] Write a program that tests these new `set` methods and outputs error messages when incorrect values are supplied.

8.10 Rewrite Fig. 8.14 to use a separate `import` declaration for each `static` member of class `Math` that is used in the example.

8.11 Write an `enum` type `TrafficLight`, whose constants (`RED`, `GREEN`, `YELLOW`) take one parameter—the duration of the light. Write a program to test the `TrafficLight` `enum` so that it displays the `enum` constants and their durations.

8.12 (*Complex Numbers*) Create a class called `Complex` for performing arithmetic with complex numbers. Complex numbers have the form

$$\text{realPart} + \text{imaginaryPart} * i$$

where i is

$$\sqrt{-1}$$

Write a program to test your class. Use floating-point variables to represent the `private` data of the class. Provide a constructor that enables an object of this class to be initialized when it is declared. Provide a no-argument constructor with default values in case no initializers are provided. Provide `public` methods that perform the following operations:

- a) Add two `Complex` numbers: The real parts are added together and the imaginary parts are added together.
- b) Subtract two `Complex` numbers: The real part of the right operand is subtracted from the real part of the left operand, and the imaginary part of the right operand is subtracted from the imaginary part of the left operand.
- c) Print `Complex` numbers in the form (a, b) , where a is the real part and b is the imaginary part.

8.13 (*Date and Time Class*) Create class `DateAndTime` that combines the modified `Time2` class of Exercise 8.7 and the modified `Date` class of Exercise 8.8. Modify method `incrementHour` to call method `nextDay` if the time is incremented into the next day. Modify methods `toStandardString` and `toUniversalString` to output the date in addition to the time. Write a program to test the new class `DateAndTime`. Specifically, test incrementing the time to the next day.

Exercises **425**

8.14 (*Enhanced Rectangle Class*) Create a more sophisticated `Rectangle` class than the one you created in Exercise 8.4. This class stores only the Cartesian coordinates of the four corners of the rectangle. The constructor calls a `set` method that accepts four sets of coordinates and verifies that each of these is in the first quadrant with no single *x*- or *y*-coordinate larger than 20.0. The `set` method also verifies that the supplied coordinates specify a rectangle. Provide methods to calculate the `length`, `width`, `perimeter` and `area`. The length is the larger of the two dimensions. Include a predicate method `isSquare` which determines whether the rectangle is a square. Write a program to test class `Rectangle`.

8.15 (*Set of Integers*) Create class `IntegerSet`. Each `IntegerSet` object can hold integers in the range 0–100. The set is represented by an array of `booleans`. Array element `a[i]` is `true` if integer *i* is in the set. Array element `a[j]` is `false` if integer *j* is not in the set. The no-argument constructor initializes the Java array to the “empty set” (i.e., a set whose array representation contains all `false` values).

Provide the following methods: Method `union` creates a third set that is the set-theoretic union of two existing sets (i.e., an element of the third set’s array is set to `true` if that element is true in either or both of the existing sets—otherwise, the element of the third set is set to `false`). Method `intersection` creates a third set which is the set-theoretic intersection of two existing sets (i.e., an element of the third set’s array is set to `false` if that element is `false` in either or both of the existing sets—otherwise, the element of the third set is set to `true`). Method `insertElement` inserts a new integer *k* into a set (by setting `a[k]` to `true`). Method `deleteElement` deletes integer *m* (by setting `a[m]` to `false`). Method `toSetString` returns a string containing a set as a list of numbers separated by spaces. Include only those elements that are present in the set. Use `---` to represent an empty set. Method `isEqualTo` determines whether two sets are equal. Write a program to test class `IntegerSet`. Instantiate several `IntegerSet` objects. Test that all your methods work properly.

8.16 (*Date Class*) Create class `Date` with the following capabilities:

- Output the date in multiple formats, such as

```
MM/DD/YYYY
June 14, 1992
DDD YYYY
```

- Use overloaded constructors to create `Date` objects initialized with dates of the formats in part (a). In the first case the constructor should receive three integer values. In the second case it should receive a `String` and two integer values. In the third case it should receive two integer values, the first of which represents the day number in the year. [Hint: To convert the string representation of the month to a numeric value, compare strings using the `equals` method. For example, if `s1` and `s2` are strings, the method call `s1.equals(s2)` returns `true` if the strings are identical and otherwise returns `false`.]

8.17 (*Rational Numbers*) Create a class called `Rational` for performing arithmetic with fractions. Write a program to test your class. Use integer variables to represent the `private` instance variables of the class—the numerator and the denominator. Provide a constructor that enables an object of this class to be initialized when it is declared. The constructor should store the fraction in reduced form. The fraction

2/4

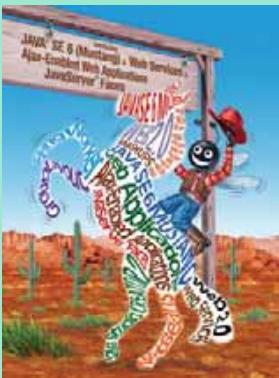

is equivalent to 1/2 and would be stored in the object as 1 in the `numerator` and 2 in the `denominator`. Provide a no-argument constructor with default values in case no initializers are provided. Provide `public` methods that perform each of the following operations:

426 Chapter 8 Classes and Objects: A Deeper Look

- a) Add two Rational numbers: The result of the addition should be stored in reduced form.
- b) Subtract two Rational numbers: The result of the subtraction should be stored in reduced form.
- c) Multiply two Rational numbers: The result of the multiplication should be stored in reduced form.
- d) Divide two Rational numbers: The result of the division should be stored in reduced form.
- e) Print Rational numbers in the form a/b , where a is the numerator and b is the denominator.
- f) Print Rational numbers in floating-point format. (Consider providing formatting capabilities that enable the user of the class to specify the number of digits of precision to the right of the decimal point.)

8.18 (*Huge Integer Class*) Create a class HugeInteger which uses a 40-element array of digits to store integers as large as 40 digits each. Provide methods `input`, `output`, `add` and `subtract`. For comparing HugeInteger objects, provide the following methods: `isEqualToString`, `isNotEqualToString`, `isGreater Than`, `isLessThan`, `isGreaterThanOrEqual` and `isLessThanOrEqual`. Each of these is a predicate method that returns true if the relationship holds between the two HugeInteger objects and returns false if the relationship does not hold. Provide a predicate method `isZero`. If you feel ambitious, also provide methods `multiply`, `divide` and `remainder`. [Note: Primitive boolean values can be output as the word “true” or the word “false” with format specifier `%b`.]

8.19 (*Tic-Tac-Toe*) Create a class TicTacToe that will enable you to write a complete program to play the game of Tic-Tac-Toe. The class contains a private 3-by-3 two-dimensional array of integers. The constructor should initialize the empty board to all zeros. Allow two human players. Wherever the first player moves, place a 1 in the specified square, and place a 2 wherever the second player moves. Each move must be to an empty square. After each move, determine whether the game has been won and whether it is a draw. If you feel ambitious, modify your program so that the computer makes the moves for one of the players. Also, allow the player to specify whether he or she wants to go first or second. If you feel exceptionally ambitious, develop a program that will play three-dimensional Tic-Tac-Toe on a 4-by-4-by-4 board [Note: This is a challenging project that could take many weeks of effort!].

9

Object-Oriented Programming: Inheritance

OBJECTIVES

In this chapter you will learn:

- How inheritance promotes software reusability.
 - The notions of superclasses and subclasses.
 - To use keyword **extends** to create a class that inherits attributes and behaviors from another class.
 - To use access modifier **protected** to give subclass methods access to superclass members.
 - To access superclass members with **super**.
 - How constructors are used in inheritance hierarchies.
 - The methods of class **Object**, the direct or indirect superclass of all classes in Java.

428 Chapter 9 Object-Oriented Programming: Inheritance**Outline**

- 9.1** Introduction
- 9.2** Superclasses and Subclasses
- 9.3** `protected` Members
- 9.4** Relationship between Superclasses and Subclasses
 - 9.4.1** Creating and Using a `CommissionEmployee` Class
 - 9.4.2** Creating a `BasePlusCommissionEmployee` Class without Using Inheritance
 - 9.4.3** Creating a `CommissionEmployee`-`BasePlusCommissionEmployee` Inheritance Hierarchy
 - 9.4.4** `CommissionEmployee`-`BasePlusCommissionEmployee` Inheritance Hierarchy Using `protected` Instance Variables
 - 9.4.5** `CommissionEmployee`-`BasePlusCommissionEmployee` Inheritance Hierarchy Using `private` Instance Variables
- 9.5** Constructors in Subclasses

- 9.8** (Optional) GUI and Graphics Case Study: Displaying Text and Images Using Labels
- 9.9** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

9.1 Introduction

This chapter continues our discussion of object-oriented programming (OOP) by introducing one of its primary features—**inheritance**, which is a form of software reuse in which a new class is created by absorbing an existing class’s members and embellishing them with new or modified capabilities. With inheritance, programmers save time during program development by reusing proven and debugged high-quality software. This also increases the likelihood that a system will be implemented effectively.

When creating a class, rather than declaring completely new members, you can designate that the new class should inherit the members of an existing class. The existing class is called the **superclass**, and the new class is the **subclass**. (The C++ programming language refers to the superclass as the **base class** and the subclass as the **derived class**.) Each subclass can become the superclass for future subclasses.

A subclass normally adds its own fields and methods. Therefore, a subclass is more specific than its superclass and represents a more specialized group of objects. Typically, the subclass exhibits the behaviors of its superclass and additional behaviors that are specific to the subclass.

The **direct superclass** is the superclass from which the subclass explicitly inherits. An **indirect superclass** is any class above the direct superclass in the **class hierarchy**, which defines the inheritance relationships between classes. In Java, the class hierarchy begins with class `Object` (in package `java.lang`), which *every* class in Java directly or indirectly `extends` (or “inherits from”). Section 9.7 lists the methods of class `Object`, which every other class inherits. In the case of **single inheritance**, a class is derived from one direct superclass. Java, unlike C++, does not support multiple inheritance (which occurs when a class is derived

9.2 Superclasses and Subclasses **429**

from more than one direct superclass). In Chapter 10, Object-Oriented Programming: Polymorphism, we explain how Java programmers can use interfaces to realize many of the benefits of multiple inheritance while avoiding the associated problems.

Experience in building software systems indicates that significant amounts of code deal with closely related special cases. When you are preoccupied with special cases, the details can obscure the big picture. With object-oriented programming, you focus on the commonalities among objects in the system rather than on the special cases.

We distinguish between the *is-a relationship* and the *has-a relationship*. *Is-a* represents inheritance. In an *is-a* relationship, an object of a subclass can also be treated as an object of its superclass. For example, a car *is a* vehicle. By contrast, *has-a* represents composition (see Chapter 8). In a *has-a* relationship, an object contains as members references to other objects. For example, a car *has a* steering wheel (and a car object has a reference to a steering wheel object).

New classes can inherit from classes in *class libraries*. Organizations develop their own class libraries and can take advantage of others available worldwide. Some day, most new software likely will be constructed from *standardized reusable components*, just as automobiles and most computer hardware are constructed today. This will facilitate the development of more powerful, abundant and economical software.

9.2 Superclasses and Subclasses

Often, an object of one class *is an* object of another class as well. For example, in geometry, a rectangle *is a* quadrilateral (as are squares, parallelograms and trapezoids). Thus, in Java, class Rectangle can be said to inherit from class Quadrilateral. In this context, class Quadrilateral is a superclass and class Rectangle is a subclass. A rectangle *is a* specific type of quadrilateral, but it is incorrect to claim that every quadrilateral *is a* rectangle—the quadrilateral could be a parallelogram or some other shape. Figure 9.1 lists several simple examples of superclasses and subclasses—note that superclasses tend to be “more general” and subclasses “more specific.”

Because every subclass object *is an* object of its superclass, and one superclass can have many subclasses, the set of objects represented by a superclass is typically larger than the set of objects represented by any of its subclasses. For example, the superclass Vehicle represents all vehicles, including cars, trucks, boats, bicycles and so on. By contrast, subclass Car represents a smaller, more specific subset of vehicles.

Superclass	Subclasses
Student	GraduateStudent, UndergraduateStudent
Shape	Circle, Triangle, Rectangle
Loan	CarLoan, HomeImprovementLoan, MortgageLoan
Employee	Faculty, Staff
BankAccount	CheckingAccount, SavingsAccount

Fig. 9.1 | Inheritance examples.

430 Chapter 9 Object-Oriented Programming: Inheritance

Inheritance relationships form tree-like hierarchical structures. A superclass exists in a hierarchical relationship with its subclasses. When classes participate in inheritance relationships, they become “affiliated” with other classes. A class becomes either a superclass, supplying members to other classes, or a subclass, inheriting its members from other classes. In some cases, a class is both a superclass and a subclass.

Let’s develop a sample class hierarchy (Fig. 9.2), also called an [inheritance hierarchy](#). A university community has thousands of members, including employees, students and alumni. Employees are either faculty or staff members. Faculty members are either administrators (e.g., deans and department chairpersons) or teachers. Note that the hierarchy could contain many other classes. For example, students can be graduate or undergraduate students. Undergraduate students can be freshmen, sophomores, juniors or seniors.

Each arrow in the hierarchy represents an *is a* relationship. As we follow the arrows in this class hierarchy, we can state, for instance, that “an Employee *is a* CommunityMember” and “a Teacher *is a* Faculty member.” `CommunityMember` is the direct superclass of `Employee`, `Student` and `Alumnus`, and is an indirect superclass of all the other classes in the diagram. Starting from the bottom of the diagram, the reader can follow the arrows and apply the *is a* relationship up to the topmost superclass. For example, an `Administrator` *is a* Faculty member, *is an* Employee and *is a* CommunityMember.

Now consider the Shape inheritance hierarchy in Fig. 9.3. This hierarchy begins with superclass `Shape`, which is extended by subclasses `TwoDimensionalShape` and `ThreeDimensionalShape`—Shapes are either `TwoDimensionalShapes` or `ThreeDimensionalShapes`. The third level of this hierarchy contains some more specific types of `TwoDimensionalShapes` and `ThreeDimensionalShapes`. As in Fig. 9.2, we can follow the arrows from the bottom of the diagram to the topmost superclass in this class hierarchy to identify several *is a* relationships. For instance, a `Triangle` *is a* `TwoDimensionalShape` and *is a* `Shape`, while a `Sphere` *is a* `ThreeDimensionalShape` and *is a* `Shape`. Note that this hierarchy could contain many other classes. For example, ellipses and trapezoids are `TwoDimensionalShapes`.

Not every class relationship is an inheritance relationship. In Chapter 8, we discussed the *has-a* relationship, in which classes have members that are references to objects of other classes. Such relationships create classes by composition of existing classes. For example,

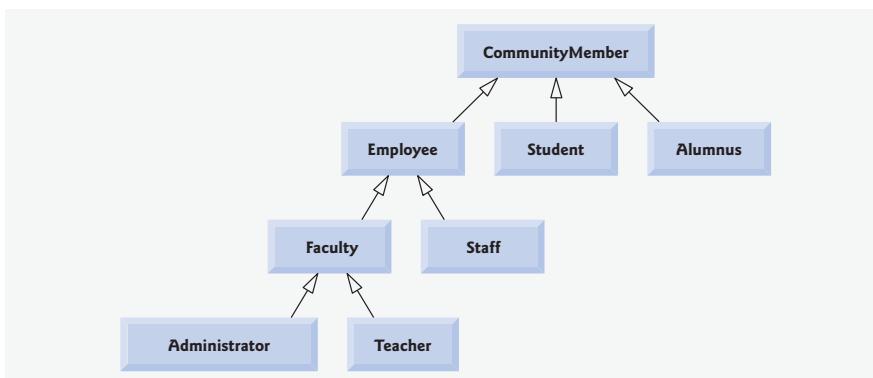

Fig. 9.2 | Inheritance hierarchy for university `CommunityMember`s.

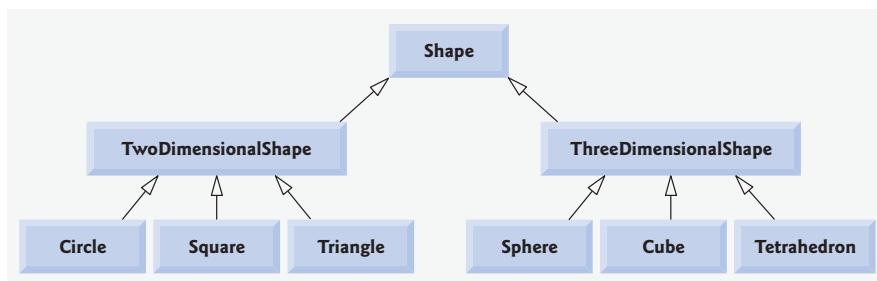

9.3 protected Members **431**

Fig. 9.3 | Inheritance hierarchy for Shapes.

given the classes `Employee`, `BirthDate` and `TelephoneNumber`, it is improper to say that an `Employee` *is a* `BirthDate` or that an `Employee` *is a* `TelephoneNumber`. However, an `Employee` *has a* `BirthDate`, and an `Employee` *has a* `TelephoneNumber`.

It is possible to treat superclass objects and subclass objects similarly—their commonalities are expressed in the members of the superclass. Objects of all classes that extend a common superclass can be treated as objects of that superclass (i.e., such objects have an *is a* relationship with the superclass). However, superclass objects cannot be treated as objects of their subclasses. For example, all cars are vehicles, but not all vehicles are cars (the other vehicles could be trucks, planes or bicycles, for example). Later in this chapter and in Chapter 10, Object-Oriented Programming: Polymorphism, we consider many examples that take advantage of the *is a* relationship.

One problem with inheritance is that a subclass can inherit methods that it does not need or should not have. Even when a superclass method is appropriate for a subclass, that subclass often needs a customized version of the method. In such cases, the subclass can **override** (redefine) the superclass method with an appropriate implementation, as we will see often in the chapter's code examples.

9.3 protected Members

Chapter 8 discussed access modifiers `public` and `private`. A class's `public` members are accessible wherever the program has a reference to an object of that class or one of its subclasses. A class's `private` members are accessible only from within the class itself. A superclass's `private` members are not inherited by its subclasses. In this section, we introduce access modifier `protected`. Using `protected` access offers an intermediate level of access between `public` and `private`. A superclass's `protected` members can be accessed by members of that superclass, by members of its subclasses and by members of other classes in the same package (i.e., `protected` members also have package access).

All `public` and `protected` superclass members retain their original access modifier when they become members of the subclass (i.e., `public` members of the superclass become `public` members of the subclass, and `protected` members of the superclass become `protected` members of the subclass).

Subclass methods can refer to `public` and `protected` members inherited from the superclass simply by using the member names. When a subclass method overrides a superclass method, the superclass method can be accessed from the subclass by preceding the

432 Chapter 9 Object-Oriented Programming: Inheritance

superclass method name with keyword `super` and a dot (.) separator. We discuss accessing overridden members of the superclass in Section 9.4.

Software Engineering Observation 9.1

Methods of a subclass cannot directly access private members of their superclass. A subclass can change the state of private superclass instance variables only through non-private methods provided in the superclass and inherited by the subclass.

Software Engineering Observation 9.2

Declaring private instance variables helps programmers test, debug and correctly modify systems. If a subclass could access its superclass's private instance variables, classes that inherit from that subclass could access the instance variables as well. This would propagate access to what should be private instance variables, and the benefits of information hiding would be lost.

9.4 Relationship between Superclasses and Subclasses

In this section, we use an inheritance hierarchy containing types of employees in a company's payroll application to discuss the relationship between a superclass and its subclass. In this company, commission employees (who will be represented as objects of a superclass) are paid a percentage of their sales, while base-salaried commission employees (who will be represented as objects of a subclass) receive a base salary plus a percentage of their sales.

We divide our discussion of the relationship between commission employees and base-salaried commission employees into five examples. The first example declares class `CommissionEmployee`, which directly inherits from class `Object` and declares as `private` instance variables a first name, last name, social security number, commission rate and gross (i.e., total) sales amount.

The second example declares class `BasePlusCommissionEmployee`, which also directly inherits from class `Object` and declares as `private` instance variables a first name, last name, social security number, commission rate, gross sales amount and base salary. We create the latter class by writing every line of code the class requires—we will soon see that it is much more efficient to create this class by inheriting from class `CommissionEmployee`.

The third example declares a separate `BasePlusCommissionEmployee2` class that extends class `CommissionEmployee` (i.e., a `BasePlusCommissionEmployee2` is a `CommissionEmployee` who also has a base salary) and attempts to access class `CommissionEmployee`'s `private` members—this results in compilation errors, because the subclass cannot access the superclass's `private` instance variables.

The fourth example shows that if `CommissionEmployee`'s instance variables are declared as `protected`, a `BasePlusCommissionEmployee3` class that extends class `CommissionEmployee2` can access that data directly. For this purpose, we declare class `CommissionEmployee2` with `protected` instance variables. Both of the `BasePlusCommissionEmployee` classes contain identical functionality, but we show how the class `BasePlusCommissionEmployee3` is easier to create and manage.

After we discuss the convenience of using `protected` instance variables, we create the fifth example, which sets the `CommissionEmployee` instance variables back to `private` in class `CommissionEmployee3` to enforce good software engineering. Then we show how a separate `BasePlusCommissionEmployee4` class, which extends class `CommissionEmployee3`, can use `CommissionEmployee3`'s `public` methods to manipulate `CommissionEmployee3`'s `private` instance variables.

9.4.1 Creating and Using a CommissionEmployee Class

We begin by declaring class `CommissionEmployee` (Fig. 9.4). Line 4 begins the class declaration and indicates that class `CommissionEmployee` `extends` (i.e., inherits from) class `Object` (from package `java.lang`). Java programmers use inheritance to create classes from existing classes. In fact, every class in Java (except `Object`) extends an existing class. Because class `CommissionEmployee` extends class `Object`, class `CommissionEmployee` inherits the methods of class `Object`—class `Object` does not have any fields. In fact, every Java class directly or indirectly inherits `Object`'s methods. If a class does not specify that it extends another class, the new class implicitly extends `Object`. For this reason, programmers typically do not include “`extends Object`” in their code—we do so in this example only for demonstration purposes.

Software Engineering Observation 9.3

The Java compiler sets the superclass of a class to Object when the class declaration does not explicitly extend a superclass.

```

1 // Fig. 9.4: CommissionEmployee.java
2 // CommissionEmployee class represents a commission employee.
3
4 public class CommissionEmployee extends Object
5 {
6     private String firstName;
7     private String lastName;
8     private String socialSecurityNumber;
9     private double grossSales; // gross weekly sales
10    private double commissionRate; // commission percentage
11
12    // five-argument constructor
13    public CommissionEmployee( String first, String last, String ssn,
14        double sales, double rate )
15    {
16        // implicit call to Object constructor occurs here
17        firstName = first;
18        lastName = last;
19        socialSecurityNumber = ssn;
20        setGrossSales( sales ); // validate and store gross sales
21        setCommissionRate( rate ); // validate and store commission rate
22    } // end five-argument CommissionEmployee constructor
23
24    // set first name
25    public void setFirstName( String first )
26    {
27        firstName = first;
28    } // end method setFirstName
29
30    // return first name
31    public String getFirstName()
32    {

```

Fig. 9.4 | `CommissionEmployee` class represents an employee paid a percentage of gross sales.
(Part I of 3.)

434 Chapter 9 Object-Oriented Programming: Inheritance

```

33     return firstName;
34 } // end method getFirstName
35
36 // set last name
37 public void setLastName( String last )
38 {
39     lastName = last;
40 } // end method setLastName
41
42 // return last name
43 public String getLastname()
44 {
45     return lastName;
46 } // end method getLastname
47
48 // set social security number
49 public void setSocialSecurityNumber( String ssn )
50 {
51     socialSecurityNumber = ssn; // should validate
52 } // end method setSocialSecurityNumber
53
54 // return social security number
55 public String getSocialSecurityNumber()
56 {
57     return socialSecurityNumber;
58 } // end method getSocialSecurityNumber
59
60 // set gross sales amount
61 public void setGrossSales( double sales )
62 {
63     grossSales = ( sales < 0.0 ) ? 0.0 : sales;
64 } // end method setGrossSales
65
66 // return gross sales amount
67 public double getGrossSales()
68 {
69     return grossSales;
70 } // end method getGrossSales
71
72 // set commission rate
73 public void setCommissionRate( double rate )
74 {
75     commissionRate = ( rate > 0.0 && rate < 1.0 ) ? rate : 0.0;
76 } // end method setCommissionRate
77
78 // return commission rate
79 public double getCommissionRate()
80 {
81     return commissionRate;
82 } // end method getCommissionRate
83

```

Fig. 9.4 | CommissionEmployee class represents an employee paid a percentage of gross sales.
(Part 2 of 3.)

9.4 Relationship between Superclasses and Subclasses

435

```

84     // calculate earnings
85     public double earnings()
86     {
87         return commissionRate * grossSales;
88     } // end method earnings
89
90    // return String representation of CommissionEmployee object
91    public String toString()
92    {
93        return String.format( "%s: %s %s\n%s: %s\n%s: %.2f\n%s: %.2f",
94            "commission employee", firstName, lastName,
95            "social security number", socialSecurityNumber,
96            "gross sales", grossSales,
97            "commission rate", commissionRate );
98    } // end method toString
99 } // end class CommissionEmployee

```

Fig. 9.4 | CommissionEmployee class represents an employee paid a percentage of gross sales.
(Part 3 of 3.)

The public services of class `CommissionEmployee` include a constructor (lines 13–22) and methods `earnings` (lines 85–88) and `toString` (lines 91–98). Lines 25–82 declare `public get` and `set` methods for manipulating the class's instance variables (declared in lines 6–10) `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate`. Class `CommissionEmployee` declares each of its instance variables as `private`, so objects of other classes cannot directly access these variables. Declaring instance variables as `private` and providing `get` and `set` methods to manipulate and validate the instance variables helps enforce good software engineering. Methods `setGrossSales` and `setCommissionRate`, for example, validate their arguments before assigning the values to instance variables `grossSales` and `commissionRate`, respectively.

Constructors are not inherited, so class `CommissionEmployee` does not inherit class `Object`'s constructor. However, class `CommissionEmployee`'s constructor calls class `Object`'s constructor implicitly. In fact, the first task of any subclass constructor is to call its direct superclass's constructor, either explicitly or implicitly (if no constructor call is specified), to ensure that the instance variables inherited from the superclass are initialized properly. The syntax for calling a superclass constructor explicitly is discussed in Section 9.4.3. If the code does not include an explicit call to the superclass constructor, Java implicitly calls the superclass's default or no-argument constructor. The comment in line 16 of Fig. 9.4 indicates where the implicit call to the superclass `Object`'s default constructor is made (the programmer does not write the code for this call). `Object`'s default (empty) constructor does nothing. Note that even if a class does not have constructors, the default constructor that the compiler implicitly declares for the class will call the superclass's default or no-argument constructor.

After the implicit call to `Object`'s constructor occurs, lines 17–21 of `CommissionEmployee`'s constructor assign values to the class's instance variables. Note that we do not validate the values of arguments `first`, `last` and `ssn` before assigning them to the corresponding instance variables. We could validate the `first` and `last` names—perhaps by ensuring that they are of a reasonable length. Similarly, a social security number could be

436 Chapter 9 Object-Oriented Programming: Inheritance

validated to ensure that it contains nine digits, with or without dashes (e.g., 123-45-6789 or 123456789).

Method `earnings` (lines 85–88) calculates a `CommissionEmployee`'s earnings. Line 87 multiplies the `commissionRate` by the `grossSales` and returns the result.

Method `toString` (lines 91–98) is special—it is one of the methods that every class inherits directly or indirectly from class `Object`, which is the root of the Java class hierarchy. Section 9.7 summarizes class `Object`'s methods. Method `toString` returns a `String` representing an object. This method is called implicitly by a program whenever an object must be converted to a string representation, such as when an object is output by `printf` or `String` method `format` using the `%s` format specifier. Class `Object`'s `toString` method returns a `String` that includes the name of the object's class. It is primarily a placeholder that can be overridden by a subclass to specify an appropriate string representation of the data in a subclass object. Method `toString` of class `CommissionEmployee` overrides (redefines) class `Object`'s `toString` method. When invoked, `CommissionEmployee`'s `toString` method uses `String` method `format` to return a `String` containing information about the `CommissionEmployee`. To override a superclass method, a subclass must declare a method with the same signature (method name, number of parameters, parameter types and order of parameter types) as the superclass method—`Object`'s `toString` method takes no parameters, so `CommissionEmployee` declares `toString` with no parameters.

Common Programming Error 9.1

It is a syntax error to override a method with a more restricted access modifier—a public method of the superclass cannot become a protected or private method in the subclass; a protected method of the superclass cannot become a private method in the subclass. Doing so would break the is-a relationship in which it is required that all subclass objects be able to respond to method calls that are made to public methods declared in the superclass. If a public method could be overridden as a protected or private method, the subclass objects would not be able to respond to the same method calls as superclass objects. Once a method is declared public in a superclass, the method remains public for all that class's direct and indirect subclasses.

Figure 9.5 tests class `CommissionEmployee`. Lines 9–10 instantiate a `CommissionEmployee` object and invoke `CommissionEmployee`'s constructor (lines 13–22 of Fig. 9.4) to initialize it with "Sue" as the first name, "Jones" as the last name, "222-22-2222" as the social security number, 10000 as the gross sales amount and .06 as the commission rate. Lines 15–24 use `CommissionEmployee`'s `get` methods to retrieve the object's instance vari-

```

1 // Fig. 9.5: CommissionEmployeeTest.java
2 // Testing class CommissionEmployee.
3
4 public class CommissionEmployeeTest
5 {
6     public static void main( String args[] )
7     {
8         // instantiate CommissionEmployee object
9         CommissionEmployee employee = new CommissionEmployee(
10             "Sue", "Jones", "222-22-2222", 10000, .06 );
11

```

Fig. 9.5 | `CommissionEmployee` class test program. (Part I of 2.)

9.4 Relationship between Superclasses and Subclasses

437

```

12     // get commission employee data
13     System.out.println(
14         "Employee information obtained by get methods: \n");
15     System.out.printf( "%s %s\n", "First name is",
16         employee.getFirstName() );
17     System.out.printf( "%s %s\n", "Last name is",
18         employee.getLastName() );
19     System.out.printf( "%s %s\n", "Social security number is",
20         employee.getSocialSecurityNumber() );
21     System.out.printf( "%s %.2f\n", "Gross sales is",
22         employee.getGrossSales() );
23     System.out.printf( "%s %.2f\n", "Commission rate is",
24         employee.getCommissionRate() );
25
26     employee.setGrossSales( 500 ); // set gross sales
27     employee.setCommissionRate( .1 ); // set commission rate
28
29     System.out.printf( "\n%s:\n%s\n", 
30         "Updated employee information obtained by toString", employee );
31 } // end main
32 } // end class CommissionEmployeeTest

```

Employee information obtained by get methods:

```

First name is Sue
Last name is Jones
Social security number is 222-22-2222
Gross sales is 10000.00
Commission rate is 0.06

```

Updated employee information obtained by toString:

```

commission employee: Sue Jones
social security number: 222-22-2222
gross sales: 500.00
commission rate: 0.10

```

Fig. 9.5 | CommissionEmployee class test program. (Part 2 of 2.)

able values for output. Lines 26–27 invoke the object's methods `setGrossSales` and `setCommissionRate` to change the values of instance variables `grossSales` and `commissionRate`. Lines 29–30 output the string representation of the updated `CommissionEmployee`. Note that when an object is output using the `%s` format specifier, the object's `toString` method is invoked implicitly to obtain the object's string representation.

9.4.2 Creating a BasePlusCommissionEmployee Class without Using Inheritance

We now discuss the second part of our introduction to inheritance by declaring and testing (a completely new and independent) class `BasePlusCommissionEmployee` (Fig. 9.6), which contains a first name, last name, social security number, gross sales amount, commission rate and base salary. Class `BasePlusCommissionEmployee`'s public services include a `BasePlusCommissionEmployee` constructor (lines 15–25) and methods `earnings`

438 Chapter 9 Object-Oriented Programming: Inheritance

```

1 // Fig. 9.6: BasePlusCommissionEmployee.java
2 // BasePlusCommissionEmployee class represents an employee that receives
3 // a base salary in addition to commission.
4
5 public class BasePlusCommissionEmployee
6 {
7     private String firstName;
8     private String lastName;
9     private String socialSecurityNumber;
10    private double grossSales; // gross weekly sales
11    private double commissionRate; // commission percentage
12    private double baseSalary; // base salary per week
13
14    // six-argument constructor
15    public BasePlusCommissionEmployee( String first, String last,
16        String ssn, double sales, double rate, double salary )
17    {
18        // implicit call to Object constructor occurs here
19        firstName = first;
20        lastName = last;
21        socialSecurityNumber = ssn;
22        setGrossSales( sales ); // validate and store gross sales
23        setCommissionRate( rate ); // validate and store commission rate
24        setBaseSalary( salary ); // validate and store base salary
25    } // end six-argument BasePlusCommissionEmployee constructor
26
27    // set first name
28    public void setFirstName( String first )
29    {
30        firstName = first;
31    } // end method setFirstName
32
33    // return first name
34    public String getFirstName()
35    {
36        return firstName;
37    } // end method getFirstName
38
39    // set last name
40    public void setLastName( String last )
41    {
42        lastName = last;
43    } // end method setLastName
44
45    // return last name
46    public String getLastNames()
47    {
48        return lastName;
49    } // end method getLastNames
50

```

9.4 Relationship between Superclasses and Subclasses

439

```

51  // set social security number
52  public void setSocialSecurityNumber( String ssn )
53  {
54      socialSecurityNumber = ssn; // should validate
55  } // end method setSocialSecurityNumber
56
57  // return social security number
58  public String getSocialSecurityNumber()
59  {
60      return socialSecurityNumber;
61  } // end method getSocialSecurityNumber
62
63  // set gross sales amount
64  public void setGrossSales( double sales )
65  {
66      grossSales = ( sales < 0.0 ) ? 0.0 : sales;
67  } // end method setGrossSales
68
69  // return gross sales amount
70  public double getGrossSales()
71  {
72      return grossSales;
73  } // end method getGrossSales
74
75  // set commission rate
76  public void setCommissionRate( double rate )
77  {
78      commissionRate = ( rate > 0.0 && rate < 1.0 ) ? rate : 0.0;
79  } // end method setCommissionRate
80
81  // return commission rate
82  public double getCommissionRate()
83  {
84      return commissionRate;
85  } // end method getCommissionRate
86
87  // set base salary
88  public void setBaseSalary( double salary )
89  {
90      baseSalary = ( salary < 0.0 ) ? 0.0 : salary;
91  } // end method setBaseSalary
92
93  // return base salary
94  public double getBaseSalary()
95  {
96      return baseSalary;
97  } // end method getBaseSalary
98
99  // calculate earnings
100 public double earnings()
101 {

```

Fig. 9.6 | BasePlusCommissionEmployee class represents an employee who receives a base salary in addition to a commission. (Part 2 of 3.)

440 Chapter 9 Object-Oriented Programming: Inheritance

```

102     return baseSalary + ( commissionRate * grossSales );
103 } // end method earnings
104
105 // return String representation of BasePlusCommissionEmployee
106 public String toString()
107 {
108     return String.format(
109         "%s: %s %s\n%s: %.2f\n%s: %.2f\n%s: %.2f",
110         "base-salaried commission employee", firstName, lastName,
111         "social security number", socialSecurityNumber,
112         "gross sales", grossSales, "commission rate", commissionRate,
113         "base salary", baseSalary );
114 } // end method toString
115 } // end class BasePlusCommissionEmployee

```

Fig. 9.6 | `BasePlusCommissionEmployee` class represents an employee who receives a base salary in addition to a commission. (Part 3 of 3.)

(lines 100–103) and `toString` (lines 106–114). Lines 28–97 declare `public get` and `set` methods for the class's `private` instance variables (declared in lines 7–12) `firstName`, `lastName`, `socialSecurityNumber`, `grossSales`, `commissionRate` and `baseSalary`. These variables and methods encapsulate all the necessary features of a base-salaried commission employee. Note the similarity between this class and class `CommissionEmployee` (Fig. 9.4)—in this example, we will not yet exploit that similarity.

Note that class `BasePlusCommissionEmployee` does not specify “`extends Object`” in line 5, so the class implicitly extends `Object`. Also note that, like class `CommissionEmployee`'s constructor (lines 13–22 of Fig. 9.4), class `BasePlusCommissionEmployee`'s constructor invokes class `Object`'s default constructor implicitly, as noted in the comment in line 18.

Class `BasePlusCommissionEmployee`'s `earnings` method (lines 100–103) computes the earnings of a base-salaried commission employee. Line 102 returns the result of adding the employee's base salary to the product of the commission rate and the employee's gross sales.

Class `BasePlusCommissionEmployee` overrides `Object` method `toString` to return a `String` containing the `BasePlusCommissionEmployee`'s information. Once again, we use format specifier `%.2f` to format the gross sales, commission rate and base salary with two digits of precision to the right of the decimal point (line 109).

Figure 9.7 tests class `BasePlusCommissionEmployee`. Lines 9–11 instantiate a `BasePlusCommissionEmployee` object and pass "Bob", "Lewis", "333-33-3333", 5000, .04 and 300 to the constructor as the first name, last name, social security number, gross sales, commission rate and base salary, respectively. Lines 16–27 use `BasePlusCommissionEmployee`'s `get` methods to retrieve the values of the object's instance variables for output. Line 29 invokes the object's `setBaseSalary` method to change the base salary. Method `setBaseSalary` (Fig. 9.6, lines 88–91) ensures that instance variable `baseSalary` is not assigned a negative value, because an employee's base salary cannot be negative. Lines 31–33 of Fig. 9.7 invoke the object's `toString` method explicitly to get the object's string representation.

9.4 Relationship between Superclasses and Subclasses

441

```

1 // Fig. 9.7: BasePlusCommissionEmployeeTest.java
2 // Testing class BasePlusCommissionEmployee.
3
4 public class BasePlusCommissionEmployeeTest
5 {
6     public static void main( String args[] )
7     {
8         // instantiate BasePlusCommissionEmployee object
9         BasePlusCommissionEmployee employee =
10            new BasePlusCommissionEmployee(
11                "Bob", "Lewis", "333-33-3333", 5000, .04, 300 );
12
13     // get base-salaried commission employee data
14     System.out.println(
15         "Employee information obtained by get methods: \n" );
16     System.out.printf( "%s %s\n", "First name is",
17         employee.getFirstName() );
18     System.out.printf( "%s %s\n", "Last name is",
19         employee.getLastName() );
20     System.out.printf( "%s %s\n", "Social security number is",
21         employee.getSocialSecurityNumber() );
22     System.out.printf( "%s %.2f\n", "Gross sales is",
23         employee.getGrossSales() );
24     System.out.printf( "%s %.2f\n", "Commission rate is",
25         employee.getCommissionRate() );
26     System.out.printf( "%s %.2f\n", "Base salary is",
27         employee.getBaseSalary() );
28
29     employee.setBaseSalary( 1000 ); // set base salary
30
31     System.out.printf( "\n%s:\n%s\n",
32         "Updated employee information obtained by toString",
33         employee.toString() );
34 } // end main
35 } // end class BasePlusCommissionEmployeeTest

```

Employee information obtained by get methods:

First name is Bob
 Last name is Lewis
 Social security number is 333-33-3333
 Gross sales is 5000.00
 Commission rate is 0.04
 Base salary is 300.00

Updated employee information obtained by toString:

base-salaried commission employee: Bob Lewis
 social security number: 333-33-3333
 gross sales: 5000.00
 commission rate: 0.04
 base salary: 1000.00

Fig. 9.7 | BasePlusCommissionEmployee test program.

442 Chapter 9 Object-Oriented Programming: Inheritance

Much of class `BasePlusCommissionEmployee`'s code (Fig. 9.6) is similar, if not identical, to that of class `CommissionEmployee` (Fig. 9.4). For example, in class `BasePlusCommissionEmployee`, private instance variables `firstName` and `lastName` and methods `setFirstName`, `getFirstName`, `setLastName` and `getLastName` are identical to those of class `CommissionEmployee`. Classes `CommissionEmployee` and `BasePlusCommissionEmployee` also both contain private instance variables `socialSecurityNumber`, `commissionRate` and `grossSales`, as well as `get` and `set` methods to manipulate these variables. In addition, the `BasePlusCommissionEmployee` constructor is almost identical to that of class `CommissionEmployee`, except that `BasePlusCommissionEmployee`'s constructor also sets the `baseSalary`. The other additions to class `BasePlusCommissionEmployee` are private instance variable `baseSalary` and methods `setBaseSalary` and `getBaseSalary`. Class `BasePlusCommissionEmployee`'s `toString` method is nearly identical to that of class `CommissionEmployee` except that `BasePlusCommissionEmployee`'s `toString` also outputs instance variable `baseSalary` with two digits of precision to the right of the decimal point.

We literally copied code from class `CommissionEmployee` and pasted it into class `BasePlusCommissionEmployee`, then modified class `BasePlusCommissionEmployee` to include a base salary and methods that manipulate the base salary. This “copy-and-paste” approach is often error prone and time consuming. Worse yet, it can spread many physical copies of the same code throughout a system, creating a code-maintenance nightmare. Is there a way to “absorb” the instance variables and methods of one class in a way that makes them part of other classes without duplicating code? In the next several examples, we answer this question, using a more elegant approach to building classes that emphasizes the benefits of inheritance.

Software Engineering Observation 9.4

Copying and pasting code from one class to another can spread errors across multiple source-code files. To avoid duplicating code (and possibly errors), use inheritance, rather than the “copy-and-paste” approach, in situations where you want one class to “absorb” the instance variables and methods of another class.

Software Engineering Observation 9.5

With inheritance, the common instance variables and methods of all the classes in the hierarchy are declared in a superclass. When changes are required for these common features, software developers need only to make the changes in the superclass—subclasses then inherit the changes. Without inheritance, changes would need to be made to all the source-code files that contain a copy of the code in question.

9.4.3 Creating a `CommissionEmployee`- `BasePlusCommissionEmployee` Inheritance Hierarchy

Now we declare class `BasePlusCommissionEmployee2` (Fig. 9.8), which extends class `CommissionEmployee` (Fig. 9.4). A `BasePlusCommissionEmployee2` object is a `CommissionEmployee` (because inheritance passes on the capabilities of class `CommissionEmployee`), but class `BasePlusCommissionEmployee2` also has instance variable `baseSalary` (Fig. 9.8, line 6). Keyword `extends` in line 4 of the class declaration indicates inheritance. As a subclass, `BasePlusCommissionEmployee2` inherits the `public` and `protected` instance variables and methods of class `CommissionEmployee`. The constructor of class `CommissionEmployee` is not inherited. Thus, the `public` services of `BasePlusCommissionEmployee2` include its con-

9.4 Relationship between Superclasses and Subclasses **443**

structor (lines 9–16), public methods inherited from class `CommissionEmployee`, method `setBaseSalary` (lines 19–22), method `getBaseSalary` (lines 25–28), method `earnings` (lines 31–35) and method `toString` (lines 38–47).

```

1 // Fig. 9.8: BasePlusCommissionEmployee2.java
2 // BasePlusCommissionEmployee2 inherits from class CommissionEmployee.
3
4 public class BasePlusCommissionEmployee2 extends CommissionEmployee
5 {
6     private double baseSalary; // base salary per week
7
8     // six-argument constructor
9     public BasePlusCommissionEmployee2( String first, String last,
10         String ssn, double sales, double rate, double salary )
11    {
12        // explicit call to superclass CommissionEmployee constructor
13        super( first, last, ssn, sales, rate );
14
15        setBaseSalary( salary ); // validate and store base salary
16    } // end six-argument BasePlusCommissionEmployee2 constructor
17
18    // set base salary
19    public void setBaseSalary( double salary )
20    {
21        baseSalary = ( salary < 0.0 ) ? 0.0 : salary;
22    } // end method setBaseSalary
23
24    // return base salary
25    public double getBaseSalary()
26    {
27        return baseSalary;
28    } // end method getBaseSalary
29
30    // calculate earnings
31    public double earnings()
32    {
33        // not allowed: commissionRate and grossSales private in superclass
34        return baseSalary + ( commissionRate * grossSales );
35    } // end method earnings
36
37    // return String representation of BasePlusCommissionEmployee2
38    public String toString()
39    {
40        // not allowed: attempts to access private superclass members
41        return String.format(
42            "%s: %s %s\n%s: %.2f\n%s: %.2f\n%s: %.2f",
43            "base-salaried commission employee", firstName, lastName,
44            "social security number", socialSecurityNumber,
45            "gross sales", grossSales, "commission rate", commissionRate,
46            "base salary", baseSalary );
47    } // end method toString
48 } // end class BasePlusCommissionEmployee2

```

7 errors

```

Fig. 9.8 | private superclass members cannot be accessed in a subclass. (Part 2 of 2.)

Each subclass constructor must implicitly or explicitly call its superclass constructor to ensure that the instance variables inherited from the superclass are initialized properly. `BasePlusCommissionEmployee2`'s six-argument constructor (lines 9–16) explicitly calls class `CommissionEmployee`'s five-argument constructor to initialize the superclass portion of a `BasePlusCommissionEmployee2` object (i.e., variables `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate`). Line 13 in `BasePlusCommissionEmployee2`'s six-argument constructor invokes the `CommissionEmployee`'s five-argument constructor (declared at lines 13–22 of Fig. 9.4) by using the **superclass constructor call syntax**—keyword `super`, followed by a set of parentheses containing the superclass constructor arguments. The arguments `first`, `last`, `ssn`, `sales` and `rate` are used to initialize superclass members `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate`, respectively. If `BasePlusCommissionEmployee2`'s constructor did not invoke `CommissionEmployee`'s constructor explicitly, Java would attempt to invoke class `CommissionEmployee`'s no-argument or default constructor—but the class does not have such a constructor, so the compiler would issue an error. The explicit superclass constructor call in line 13 of Fig. 9.8 must be the first statement in the subclass constructor's body. Also, when a superclass contains a no-argument constructor, you can use `super()` to call that constructor explicitly, but this is rarely done.

9.4 Relationship between Superclasses and Subclasses **445****Common Programming Error 9.2**

A compilation error occurs if a subclass constructor calls one of its superclass constructors with arguments that do not match exactly the number and types of parameters specified in one of the superclass constructor declarations.

The compiler generates errors for line 34 of Fig. 9.8 because superclass `CommissionEmployee`'s instance variables `commissionRate` and `grossSales` are `private`—subclass `BasePlusCommissionEmployee2`'s methods are not allowed to access superclass `CommissionEmployee`'s `private` instance variables. Note that we used red text in Fig. 9.8 to indicate erroneous code. The compiler issues additional errors at lines 43–45 of `BasePlusCommissionEmployee2`'s `toString` method for the same reason. The errors in `BasePlusCommissionEmployee2` could have been prevented by using the `get` methods inherited from class `CommissionEmployee`. For example, line 34 could have used `getCommissionRate` and `getGrossSales` to access `CommissionEmployee`'s `private` instance variables `commissionRate` and `grossSales`, respectively. Lines 43–45 also could have used appropriate `get` methods to retrieve the values of the superclass's instance variables.

9.4.4 CommissionEmployee–BasePlusCommissionEmployee Inheritance Hierarchy Using protected Instance Variables

To enable class `BasePlusCommissionEmployee` to directly access superclass instance variables `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate`, we can declare those members as `protected` in the superclass. As we discussed in Section 9.3, a superclass's `protected` members are inherited by all subclasses of that superclass. Class `CommissionEmployee2` (Fig. 9.9) is a modification of class `CommissionEmployee` (Fig. 9.4) that declares instance variables `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate` as `protected` (Fig. 9.9, lines 6–10) rather than `private`. Other than the change in the class name (and thus the change in the constructor name) to `CommissionEmployee2`, the rest of the class declaration in Fig. 9.9 is identical to that of Fig. 9.4.

```

1 // Fig. 9.9: CommissionEmployee2.java
2 // CommissionEmployee2 class represents a commission employee.
3
4 public class CommissionEmployee2
5 {
6     protected String firstName;
7     protected String lastName;
8     protected String socialSecurityNumber;
9     protected double grossSales; // gross weekly sales
10    protected double commissionRate; // commission percentage
11
12    // five-argument constructor
13    public CommissionEmployee2( String first, String last, String ssn,
14        double sales, double rate )
15    {
16        // implicit call to Object constructor occurs here
17        firstName = first;

```

Fig. 9.9 | `CommissionEmployee2` with `protected` instance variables. (Part I of 3.)

446 Chapter 9 Object-Oriented Programming: Inheritance

```

18     lastName = last;
19     socialSecurityNumber = ssn;
20     setGrossSales( sales ); // validate and store gross sales
21     setCommissionRate( rate ); // validate and store commission rate
22 } // end five-argument CommissionEmployee2 constructor
23
24 // set first name
25 public void setFirstName( String first )
26 {
27     firstName = first;
28 } // end method setFirstName
29
30 // return first name
31 public String getFirstName()
32 {
33     return firstName;
34 } // end method getFirstName
35
36 // set last name
37 public void setLastName( String last )
38 {
39     lastName = last;
40 } // end method setLastName
41
42 // return last name
43 public String getLastname()
44 {
45     return lastName;
46 } // end method getLastname
47
48 // set social security number
49 public void setSocialSecurityNumber( String ssn )
50 {
51     socialSecurityNumber = ssn; // should validate
52 } // end method setSocialSecurityNumber
53
54 // return social security number
55 public String getSocialSecurityNumber()
56 {
57     return socialSecurityNumber;
58 } // end method getSocialSecurityNumber
59
60 // set gross sales amount
61 public void setGrossSales( double sales )
62 {
63     grossSales = ( sales < 0.0 ) ? 0.0 : sales;
64 } // end method setGrossSales
65
66 // return gross sales amount
67 public double getGrossSales()
68 {
69     return grossSales;
70 } // end method getGrossSales

```

Fig. 9.9 | CommissionEmployee2 with protected instance variables. (Part 2 of 3.)

9.4 Relationship between Superclasses and Subclasses **447**

```

71
72     // set commission rate
73     public void setCommissionRate( double rate )
74     {
75         commissionRate = ( rate > 0.0 && rate < 1.0 ) ? rate : 0.0;
76     } // end method setCommissionRate
77
78     // return commission rate
79     public double getCommissionRate()
80     {
81         return commissionRate;
82     } // end method getCommissionRate
83
84     // calculate earnings
85     public double earnings()
86     {
87         return commissionRate * grossSales;
88     } // end method earnings
89
90     // return String representation of CommissionEmployee2 object
91     public String toString()
92     {
93         return String.format( "%s: %s %s\n%s: %s\n%s: %.2f\n%s: %.2f",
94             "commission employee", firstName, lastName,
95             "social security number", socialSecurityNumber,
96             "gross sales", grossSales,
97             "commission rate", commissionRate );
98     } // end method toString
99 } // end class CommissionEmployee2

```

Fig. 9.9 | CommissionEmployee2 with protected instance variables. (Part 3 of 3.)

We could have declared the superclass `CommissionEmployee2`'s instance variables `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate` as `public` to enable subclass `BasePlusCommissionEmployee2` to access the superclass instance variables. However, declaring `public` instance variables is poor software engineering because it allows unrestricted access to the instance variables, greatly increasing the chance of errors. With `protected` instance variables, the subclass gets access to the instance variables, but classes that are not subclasses and classes that are not in the same package cannot access these variables directly—recall that `protected` class members are also visible to other classes in the same package.

Class `BasePlusCommissionEmployee3` (Fig. 9.10) is a modification of class `BasePlusCommissionEmployee2` (Fig. 9.8) that extends `CommissionEmployee2` (line 5) rather than class `CommissionEmployee`. Objects of class `BasePlusCommissionEmployee3` inherit `CommissionEmployee2`'s `protected` instance variables `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate`—all these variables are now `protected` members of `BasePlusCommissionEmployee3`. As a result, the compiler does not generate errors when compiling line 32 of method `earnings` and lines 40–42 of method `toString`. If another class extends `BasePlusCommissionEmployee3`, the new subclass also inherits the `protected` members.

448 Chapter 9 Object-Oriented Programming: Inheritance

```

1 // Fig. 9.10: BasePlusCommissionEmployee3.java
2 // BasePlusCommissionEmployee3 inherits from CommissionEmployee2 and has
3 // access to CommissionEmployee2's protected members.
4
5 public class BasePlusCommissionEmployee3 extends CommissionEmployee2
6 {
7     private double baseSalary; // base salary per week
8
9     // six-argument constructor
10    public BasePlusCommissionEmployee3( String first, String last,
11        String ssn, double sales, double rate, double salary )
12    {
13        super( first, last, ssn, sales, rate );
14        setBaseSalary( salary ); // validate and store base salary
15    } // end six-argument BasePlusCommissionEmployee3 constructor
16
17    // set base salary
18    public void setBaseSalary( double salary )
19    {
20        baseSalary = ( salary < 0.0 ) ? 0.0 : salary;
21    } // end method setBaseSalary
22
23    // return base salary
24    public double getBaseSalary()
25    {
26        return baseSalary;
27    } // end method getBaseSalary
28
29    // calculate earnings
30    public double earnings()
31    {
32        return baseSalary + ( commissionRate * grossSales );
33    } // end method earnings
34
35    // return String representation of BasePlusCommissionEmployee3
36    public String toString()
37    {
38        return String.format(
39            "%s: %s %s\n%s: %.2f\n%s: %.2f\n%s: %.2f",
40            "base-salaried commission employee", firstName, lastName,
41            "social security number", socialSecurityNumber,
42            "gross sales", grossSales, "commission rate", commissionRate,
43            "base salary", baseSalary );
44    } // end method toString
45 } // end class BasePlusCommissionEmployee3

```

Fig. 9.10 | BasePlusCommissionEmployee3 inherits protected instance variables from CommissionEmployee2.

Class `BasePlusCommissionEmployee3` does not inherit class `CommissionEmployee2`'s constructor. However, class `BasePlusCommissionEmployee3`'s six-argument constructor (lines 10–15) calls class `CommissionEmployee2`'s five-argument constructor explicitly. `BasePlusCommissionEmployee3`'s six-argument constructor must explicitly call the five-

9.4 Relationship between Superclasses and Subclasses **449**

argument constructor of class `CommissionEmployee2`, because `CommissionEmployee2` does not provide a no-argument constructor that could be invoked implicitly.

Figure 9.11 uses a `BasePlusCommissionEmployee3` object to perform the same tasks that Fig. 9.7 performed on a `BasePlusCommissionEmployee` object (Fig. 9.6). Note that the outputs of the two programs are identical. Although we declared class `BasePlusCommissionEmployee` without using inheritance and declared class `BasePlusCommissionEmployee3` using inheritance, both classes provide the same functionality. The source code for class `BasePlusCommissionEmployee3`, which is 45 lines, is considerably shorter than that for class `BasePlusCommissionEmployee`, which is 115 lines, because class `BasePlusCommissionEmployee3` inherits most of its functionality from `CommissionEmployee2`, whereas class `BasePlusCommissionEmployee` inherits only class `Object`'s functionality. Also, there is now only one copy of the commission employee functionality

```

1 // Fig. 9.11: BasePlusCommissionEmployeeTest3.java
2 // Testing class BasePlusCommissionEmployee3.
3
4 public class BasePlusCommissionEmployeeTest3
5 {
6     public static void main( String args[] )
7     {
8         // instantiate BasePlusCommissionEmployee3 object
9         BasePlusCommissionEmployee3 employee =
10            new BasePlusCommissionEmployee3(
11                "Bob", "Lewis", "333-33-3333", 5000, .04, 300 );
12
13        // get base-salaried commission employee data
14        System.out.println(
15            "Employee information obtained by get methods: \n" );
16        System.out.printf( "%s %s\n", "First name is",
17            employee.getFirstName() );
18        System.out.printf( "%s %s\n", "Last name is",
19            employee.getLastName() );
20        System.out.printf( "%s %s\n", "Social security number is",
21            employee.getSocialSecurityNumber() );
22        System.out.printf( "%s %.2f\n", "Gross sales is",
23            employee.getGrossSales() );
24        System.out.printf( "%s %.2f\n", "Commission rate is",
25            employee.getCommissionRate() );
26        System.out.printf( "%s %.2f\n", "Base salary is",
27            employee.getBaseSalary() );
28
29        employee.setBaseSalary( 1000 ); // set base salary
30
31        System.out.printf( "\n%s:\n\n%s\n",
32            "Updated employee information obtained by toString",
33            employee.toString() );
34    } // end main
35 } // end class BasePlusCommissionEmployeeTest3

```

Fig. 9.11 | protected superclass members inherited into subclass `BasePlusCommissionEmployee3`. (Part I of 2.)

450 Chapter 9 Object-Oriented Programming: Inheritance

```
Employee information obtained by get methods:
```

```
First name is Bob
Last name is Lewis
Social security number is 333-33-3333
Gross sales is 5000.00
Commission rate is 0.04
Base salary is 300.00
```

```
Updated employee information obtained by toString:
```

```
base-salaried commission employee: Bob Lewis
social security number: 333-33-3333
gross sales: 5000.00
commission rate: 0.04
base salary: 1000.00
```

Fig. 9.11 | protected superclass members inherited into subclass `BasePlusCommissionEmployee3`. (Part 2 of 2.)

declared in class `CommissionEmployee2`. This makes the code easier to maintain, modify and debug, because the code related to a commission employee exists only in class `CommissionEmployee2`.

In this example, we declared superclass instance variables as `protected` so that subclasses could inherit them. Inheriting `protected` instance variables slightly increases performance, because we can directly access the variables in the subclass without incurring the overhead of a `set` or `get` method call. In most cases, however, it is better to use `private` instance variables to encourage proper software engineering, and leave code optimization issues to the compiler. Your code will be easier to maintain, modify and debug.

Using `protected` instance variables creates several potential problems. First, the subclass object can set an inherited variable's value directly without using a `set` method. Therefore, a subclass object can assign an invalid value to the variable, thus leaving the object in an inconsistent state. For example, if we were to declare `CommissionEmployee3`'s instance variable `grossSales` as `protected`, a subclass object (e.g., `BasePlusCommissionEmployee`) could then assign a negative value to `grossSales`. The second problem with using `protected` instance variables is that subclass methods are more likely to be written so that they depend on the superclass's data implementation. In practice, subclasses should depend only on the superclass services (i.e., non-`private` methods) and not on the superclass data implementation. With `protected` instance variables in the superclass, we may need to modify all the subclasses of the superclass if the superclass implementation changes. For example, if for some reason we were to change the names of instance variables `firstName` and `lastName` to `first` and `last`, then we would have to do so for all occurrences in which a subclass directly references superclass instance variables `firstName` and `lastName`. In such a case, the software is said to be `fragile` or `brittle`, because a small change in the superclass can "break" subclass implementation. The programmer should be able to change the superclass implementation while still providing the same services to the subclasses. (Of course, if the superclass services change, we must reimplement our subclasses.) A third problem is that a class's `protected` members are visible to all classes in the same package as the class containing the `protected` members—this is not always desirable.

9.4 Relationship between Superclasses and Subclasses

451

**Software Engineering Observation 9.6**

Use the `protected` access modifier when a superclass should provide a method only to its subclasses and other classes in the same package, but not to other clients.

**Software Engineering Observation 9.7**

Declaring superclass instance variables `private` (as opposed to `protected`) enables the superclass implementation of these instance variables to change without affecting subclass implementations.

**Error-Prevention Tip 9.1**

When possible, do not include `protected` instance variables in a superclass. Instead, include non-private methods that access `private` instance variables. This will ensure that objects of the class maintain consistent states.

9.4.5 CommissionEmployee–BasePlusCommissionEmployee Inheritance Hierarchy Using private Instance Variables

We now reexamine our hierarchy once more, this time using the best software engineering practices. Class `CommissionEmployee3` (Fig. 9.12) declares instance variables `firstName`, `lastName`, `socialSecurityNumber`, `grossSales` and `commissionRate` as `private` (lines 6–10) and provides public methods `setFirstName`, `getFirstName`, `setLastName`, `getLastName`, `setSocialSecurityNumber`, `getSocialSecurityNumber`, `setGrossSales`, `getGrossSales`, `setCommissionRate`, `getCommissionRate`, `earnings` and `toString` for manipulating these values. Note that methods `earnings` (lines 85–88) and `toString` (lines 91–98) use the class's `get` methods to obtain the values of its instance variables. If we decide to change the instance variable names, the `earnings` and `toString` declarations will not require modification—only the bodies of the `get` and `set` methods that directly manipulate the instance variables will need to change. Note that these changes occur solely within the

```

1 // Fig. 9.12: CommissionEmployee3.java
2 // CommissionEmployee3 class represents a commission employee.
3
4 public class CommissionEmployee3
5 {
6     private String firstName;
7     private String lastName;
8     private String socialSecurityNumber;
9     private double grossSales; // gross weekly sales
10    private double commissionRate; // commission percentage
11
12    // five-argument constructor
13    public CommissionEmployee3( String first, String last, String ssn,
14        double sales, double rate )
15    {
16        // implicit call to Object constructor occurs here
17        firstName = first;
18        lastName = last;
19        socialSecurityNumber = ssn;

```

452 Chapter 9 Object-Oriented Programming: Inheritance

```

20      setGrossSales( sales ); // validate and store gross sales
21      setCommissionRate( rate ); // validate and store commission rate
22  } // end five-argument CommissionEmployee3 constructor
23
24  // set first name
25  public void setFirstName( String first )
26  {
27      firstName = first;
28  } // end method setFirstName
29
30  // return first name
31  public String getFirstName()
32  {
33      return firstName;
34  } // end method getFirstName
35
36  // set last name
37  public void setLastName( String last )
38  {
39      lastName = last;
40  } // end method setLastName
41
42  // return last name
43  public String getLastname()
44  {
45      return lastName;
46  } // end method getLastname
47
48  // set social security number
49  public void setSocialSecurityNumber( String ssn )
50  {
51      socialSecurityNumber = ssn; // should validate
52  } // end method setSocialSecurityNumber
53
54  // return social security number
55  public String getSocialSecurityNumber()
56  {
57      return socialSecurityNumber;
58  } // end method getSocialSecurityNumber
59
60  // set gross sales amount
61  public void setGrossSales( double sales )
62  {
63      grossSales = ( sales < 0.0 ) ? 0.0 : sales;
64  } // end method setGrossSales
65
66  // return gross sales amount
67  public double getGrossSales()
68  {
69      return grossSales;
70  } // end method getGrossSales

```

Fig. 9.12 | CommissionEmployee3 class uses methods to manipulate its `private` instance variables. (Part 2 of 3.)

9.4 Relationship between Superclasses and Subclasses **453**

```

71      // set commission rate
72      public void setCommissionRate( double rate )
73      {
74          commissionRate = ( rate > 0.0 && rate < 1.0 ) ? rate : 0.0;
75      } // end method setCommissionRate
76
77      // return commission rate
78      public double getCommissionRate()
79      {
80          return commissionRate;
81      } // end method getCommissionRate
82
83      // calculate earnings
84      public double earnings()
85      {
86          return getCommissionRate() * getGrossSales();
87      } // end method earnings
88
89      // return String representation of CommissionEmployee3 object
90      public String toString()
91      {
92          return String.format( "%s: %s %s\n%s: %s\n%s: %.2f\n%s: %.2f",
93              "commission employee", getFirstName(), getLastName(),
94              "social security number", getSocialSecurityNumber(),
95              "gross sales", getGrossSales(),
96              "commission rate", getCommissionRate() );
97      } // end method toString
98  } // end class CommissionEmployee3

```

Fig. 9.12 | CommissionEmployee3 class uses methods to manipulate its private instance variables. (Part 3 of 3.)

superclass—no changes to the subclass are needed. Localizing the effects of changes like this is a good software engineering practice. Subclass `BasePlusCommissionEmployee4` (Fig. 9.13) inherits `CommissionEmployee3`'s non-private methods and can access the private superclass members via those methods.

Class `BasePlusCommissionEmployee4` (Fig. 9.13) has several changes to its method implementations that distinguish it from class `BasePlusCommissionEmployee3` (Fig. 9.10). Methods `earnings` (Fig. 9.13, lines 31–34) and `toString` (lines 37–41) each invoke method `getBaseSalary` to obtain the base salary value, rather than accessing `baseSalary` directly. If we decide to rename instance variable `baseSalary`, only the bodies of method `setBaseSalary` and `getBaseSalary` will need to change.

Class `BasePlusCommissionEmployee4`'s `earnings` method (Fig. 9.13, lines 31–34) overrides class `CommissionEmployee3`'s `earnings` method (Fig. 9.12, lines 85–88) to calculate the earnings of a base-salaried commission employee. The new version obtains the portion of the employee's earnings based on commission alone by calling `CommissionEmployee3`'s `earnings` method with the expression `super.earnings()` (Fig. 9.13, line 33). `BasePlusCommissionEmployee4`'s `earnings` method then adds the base salary to this value to calculate the total earnings of the employee. Note the syntax used to invoke an overridden superclass method from a subclass—place the keyword

454 Chapter 9 Object-Oriented Programming: Inheritance

```

1 // Fig. 9.13: BasePlusCommissionEmployee4.java
2 // BasePlusCommissionEmployee4 class inherits from CommissionEmployee3 and
3 // accesses CommissionEmployee3's private data via CommissionEmployee3's
4 // public methods.
5
6 public class BasePlusCommissionEmployee4 extends CommissionEmployee3
7 {
8     private double baseSalary; // base salary per week
9
10    // six-argument constructor
11    public BasePlusCommissionEmployee4( String first, String last,
12        String ssn, double sales, double rate, double salary )
13    {
14        super( first, last, ssn, sales, rate );
15        setBaseSalary( salary ); // validate and store base salary
16    } // end six-argument BasePlusCommissionEmployee4 constructor
17
18    // set base salary
19    public void setBaseSalary( double salary )
20    {
21        baseSalary = ( salary < 0.0 ) ? 0.0 : salary;
22    } // end method setBaseSalary
23
24    // return base salary
25    public double getBaseSalary()
26    {
27        return baseSalary;
28    } // end method getBaseSalary
29
30    // calculate earnings
31    public double earnings()
32    {
33        return getBaseSalary() + super.earnings();
34    } // end method earnings
35
36    // return String representation of BasePlusCommissionEmployee4
37    public String toString()
38    {
39        return String.format( "%s %s\n%: %.2f", "base-salaried",
40            super.toString(), "base salary", getBaseSalary() );
41    } // end method toString
42 } // end class BasePlusCommissionEmployee4

```

Fig. 9.13 | BasePlusCommissionEmployee4 class extends CommissionEmployee3, which provides only private instance variables.

super and a dot (.) separator before the superclass method name. This method invocation is a good software engineering practice: Recall from *Software Engineering Observation 8.5* that if a method performs all or some of the actions needed by another method, call that method rather than duplicate its code. By having BasePlusCommissionEmployee4's earnings method invoke CommissionEmployee3's earnings method to calculate part of a BasePlusCommissionEmployee4 object's earnings, we avoid duplicating the code and reduce code-maintenance problems.

Common Programming Error 9.3

When a superclass method is overridden in a subclass, the subclass version often calls the superclass version to do a portion of the work. Failure to prefix the superclass method name with the keyword super and a dot (.) separator when referencing the superclass's method causes the subclass method to call itself, creating an error called infinite recursion. Recursion, used correctly, is a powerful capability discussed in Chapter 15, Recursion.

Similarly, `BasePlusCommissionEmployee4`'s `toString` method (Fig. 9.13, lines 37–41) overrides class `CommissionEmployee3`'s `toString` method (Fig. 9.12, lines 91–98) to return a string representation that is appropriate for a base-salaried commission employee. The new version creates part of a `BasePlusCommissionEmployee4` object's string representation (i.e., the string "commission employee" and the values of class `CommissionEmployee3`'s private instance variables) by calling `CommissionEmployee3`'s `toString` method with the expression `super.toString()` (Fig. 9.13, line 40). `BasePlusCommissionEmployee4`'s `toString` method then outputs the remainder of a `BasePlusCommissionEmployee4` object's string representation (i.e., the value of class `BasePlusCommissionEmployee4`'s base salary).

Figure 9.14 performs the same manipulations on a `BasePlusCommissionEmployee4` object as did Fig. 9.7 and Fig. 9.11 on objects of classes `BasePlusCommissionEmployee` and `BasePlusCommissionEmployee3`, respectively. Although each "base-salaried commission employee" class behaves identically, class `BasePlusCommissionEmployee4` is the best engineered. By using inheritance and by calling methods that hide the data and ensure consistency, we have efficiently and effectively constructed a well-engineered class.

```

1 // Fig. 9.14: BasePlusCommissionEmployeeTest4.java
2 // Testing class BasePlusCommissionEmployee4.
3
4 public class BasePlusCommissionEmployeeTest4
5 {
6     public static void main( String args[] )
7     {
8         // instantiate BasePlusCommissionEmployee4 object
9         BasePlusCommissionEmployee4 employee =
10            new BasePlusCommissionEmployee4(
11                "Bob", "Lewis", "333-33-3333", 5000, .04, 300 );
12
13        // get base-salaried commission employee data
14        System.out.println(
15            "Employee information obtained by get methods: \n");
16        System.out.printf( "%s %s\n", "First name is",
17            employee.getFirstName() );
18        System.out.printf( "%s %s\n", "Last name is",
19            employee.getLastName() );
20        System.out.printf( "%s %s\n", "Social security number is",
21            employee.getSocialSecurityNumber() );
22        System.out.printf( "%s %.2f\n", "Gross sales is",
23            employee.getGrossSales() );

```

Fig. 9.14 | Superclass private instance variables are accessible to a subclass via `public` or `protected` methods inherited by the subclass. (Part I of 2.)

456 Chapter 9 Object-Oriented Programming: Inheritance

```

24     System.out.printf( "%s %.2f\n", "Commission rate is",
25         employee.getCommissionRate() );
26     System.out.printf( "%s %.2f\n", "Base salary is",
27         employee.getBaseSalary() );
28
29     employee.setBaseSalary( 1000 ); // set base salary
30
31     System.out.printf( "\n%s:\n%s\n",
32         "Updated employee information obtained by toString",
33         employee.toString() );
34 } // end main
35 } // end class BasePlusCommissionEmployeeTest4

```

Employee information obtained by get methods:

```

First name is Bob
Last name is Lewis
Social security number is 333-33-3333
Gross sales is 5000.00
Commission rate is 0.04
Base salary is 300.00

```

Updated employee information obtained by toString:

```

base-salaried commission employee: Bob Lewis
social security number: 333-33-3333
gross sales: 5000.00
commission rate: 0.04
base salary: 1000.00

```

Fig. 9.14 | Superclass private instance variables are accessible to a subclass via public or protected methods inherited by the subclass. (Part 2 of 2.)

In this section, you saw an evolutionary set of examples that was designed to teach key capabilities for good software engineering with inheritance. You learned how to use the keyword `extends` to create a subclass using inheritance, how to use `protected` superclass members to enable a subclass to access inherited superclass instance variables and how to override superclass methods to provide versions that are more appropriate for subclass objects. In addition, you learned how to apply software engineering techniques from Chapter 8 and this chapter to create classes that are easy to maintain, modify and debug.

9.5 Constructors in Subclasses

As we explained in the preceding section, instantiating a subclass object begins a chain of constructor calls in which the subclass constructor, before performing its own tasks, invokes its direct superclass's constructor either explicitly (via the `super` reference) or implicitly (calling the superclass's default constructor or no-argument constructor). Similarly, if the superclass is derived from another class (as is, of course, every class except `Object`), the superclass constructor invokes the constructor of the next class up in the hierarchy, and so on. The last constructor called in the chain is always the constructor for class `Object`. The original subclass constructor's body finishes executing last. Each superclass's constructor manipulates the superclass instance variables that the subclass object inherits. For example, consider again the

9.5 Constructors in Subclasses **457**

`CommissionEmployee3`–`BasePlusCommissionEmployee4` hierarchy from Fig. 9.12 and Fig. 9.13. When a program creates a `BasePlusCommissionEmployee4` object, the `BasePlusCommissionEmployee4` constructor is called. That constructor calls `CommissionEmployee3`'s constructor, which in turn calls `Object`'s constructor. Class `Object`'s constructor has an empty body, so it immediately returns control to `CommissionEmployee3`'s constructor, which then initializes the private instance variables of `CommissionEmployee3` that are part of the `BasePlusCommissionEmployee4` object. When `CommissionEmployee3`'s constructor completes execution, it returns control to `BasePlusCommissionEmployee4`'s constructor, which initializes the `BasePlusCommissionEmployee4` object's `baseSalary`.

**Software Engineering Observation 9.8**

When a program creates a subclass object, the subclass constructor immediately calls the superclass constructor (explicitly, via super, or implicitly). The superclass constructor's body executes to initialize the superclass's instance variables that are part of the subclass object, then the subclass constructor's body executes to initialize the subclass-only instance variables. Java ensures that even if a constructor does not assign a value to an instance variable, the variable is still initialized to its default value (e.g., 0 for primitive numeric types, false for booleans, null for references).

Our next example revisits the commission employee hierarchy by declaring a `CommissionEmployee4` class (Fig. 9.15) and a `BasePlusCommissionEmployee5` class (Fig. 9.16). Each class's constructor prints a message when invoked, enabling us to observe the order in which the constructors in the hierarchy execute.

```

1 // Fig. 9.15: CommissionEmployee4.java
2 // CommissionEmployee4 class represents a commission employee.
3
4 public class CommissionEmployee4
5 {
6     private String firstName;
7     private String lastName;
8     private String socialSecurityNumber;
9     private double grossSales; // gross weekly sales
10    private double commissionRate; // commission percentage
11
12    // five-argument constructor
13    public CommissionEmployee4( String first, String last, String ssn,
14        double sales, double rate )
15    {
16        // implicit call to Object constructor occurs here
17        firstName = first;
18        lastName = last;
19        socialSecurityNumber = ssn;
20        setGrossSales( sales ); // validate and store gross sales
21        setCommissionRate( rate ); // validate and store commission rate
22
23        System.out.printf(
24            "\nCommissionEmployee4 constructor:\n%<\n", this );
25    } // end five-argument CommissionEmployee4 constructor
26

```

55  } // end method setSocialSecurityNumber
56
57  // return social security number
58  public String getSocialSecurityNumber()
59  {
60      return socialSecurityNumber;
61  } // end method getSocialSecurityNumber
62
63  // set gross sales amount
64  public void setGrossSales( double sales )
65  {
66      grossSales = ( sales < 0.0 ) ? 0.0 : sales;
67  } // end method setGrossSales
68
69  // return gross sales amount
70  public double getGrossSales()
71  {
72      return grossSales;
73  } // end method getGrossSales
74
75  // set commission rate
76  public void setCommissionRate( double rate )
77  {
78      commissionRate = ( rate > 0.0 && rate < 1.0 ) ? rate : 0.0;
79  } // end method setCommissionRate

```

Fig. 9.15 | CommissionEmployee4's constructor outputs text. (Part 2 of 3.)

9.5 Constructors in Subclasses **459**

```

80
81     // return commission rate
82     public double getCommissionRate()
83     {
84         return commissionRate;
85     } // end method getCommissionRate
86
87     // calculate earnings
88     public double earnings()
89     {
90         return getCommissionRate() * getGrossSales();
91     } // end method earnings
92
93     // return String representation of CommissionEmployee4 object
94     public String toString()
95     {
96         return String.format( "%s: %s %s\n%s: %s\n%s: %.2f\n%s: %.2f",
97             "commission employee", getFirstName(), getLastName(),
98             "social security number", getSocialSecurityNumber(),
99             "gross sales", getGrossSales(),
100            "commission rate", getCommissionRate() );
101    } // end method toString
102 } // end class CommissionEmployee4

```

Fig. 9.15 | CommissionEmployee4's constructor outputs text. (Part 3 of 3.)

Class `CommissionEmployee4` (Fig. 9.15) contains the same features as the version of the class shown in Fig. 9.4. We modified the constructor (lines 13–25) to output text upon its invocation. Note that outputting `this` with the `%s` format specifier (lines 23–24) implicitly invokes the `toString` method of the object being constructed to obtain the object's string representation.

Class `BasePlusCommissionEmployee5` (Fig. 9.16) is almost identical to `BasePlusCommissionEmployee4` (Fig. 9.13), except that `BasePlusCommissionEmployee5`'s constructor also outputs text when invoked. As in `CommissionEmployee4` (Fig. 9.15), we output `this` using the `%s` format specifier (line 16) to get the object's string representation.

```

BasePlusCommissionEmployee5 constructor:
 base-salaried commission employee: Lisa Jones
 social security number: 555-55-5555
 gross sales: 2000.00
 commission rate: 0.06
 base salary: 800.00

CommissionEmployee4 constructor:
 base-salaried commission employee: Mark Sands
 social security number: 888-88-8888
 gross sales: 8000.00
 commission rate: 0.15
 base salary: 0.00

BasePlusCommissionEmployee5 constructor:
 base-salaried commission employee: Mark Sands
 social security number: 888-88-8888
 gross sales: 8000.00
 commission rate: 0.15
 base salary: 2000.00

Fig. 9.17 | Constructor call order. (Part 2 of 2.)

BasePlusCommissionEmployee5 object `employee2`. This invokes the `CommissionEmployee4` constructor, which prints output with the values passed from the `BasePlusCommissionEmployee5` constructor, then performs the output specified in the `BasePlusCommissionEmployee5` constructor. Lines 17–19 then instantiate `BasePlusCommissionEmployee5` object `employee3`. Again, the `CommissionEmployee4` and `BasePlusCommissionEmployee5` constructors are both called. In each case, the body of the `CommissionEmployee4` constructor executes before the body of the `BasePlusCommissionEmployee5` constructor executes. Note that `employee2` is constructed completely before construction of `employee3` begins.

462 Chapter 9 Object-Oriented Programming: Inheritance

9.6 Software Engineering with Inheritance

This section discusses customizing existing software with inheritance. When a new class extends an existing class, the new class inherits the non-private members of the existing class. We can customize the new class to meet our needs by including additional members and by overriding superclass members. Doing this does not require the subclass programmer to change the superclass's source code. Java simply requires access to the superclass's `.class` file so it can compile and execute any program that uses or extends the superclass. This powerful capability is attractive to independent software vendors (ISVs), who can develop proprietary classes for sale or license and make them available to users in bytecode format. Users then can derive new classes from these library classes rapidly and without accessing the ISVs' proprietary source code.

Software Engineering Observation 9.9

Although inheriting from a class does not require access to the class's source code, developers often insist on seeing the source code to understand how the class is implemented. Developers in industry want to ensure that they are extending a solid class—for example, a class that performs well and is implemented securely.

Sometimes, students have difficulty appreciating the scope of the problems faced by designers who work on large-scale software projects in industry. People experienced with such projects say that effective software reuse improves the software-development process. Object-oriented programming facilitates software reuse, potentially shortening development time.

The availability of substantial and useful class libraries delivers the maximum benefits of software reuse through inheritance. Application designers build their applications with these libraries, and library designers are rewarded by having their libraries included with the applications. The standard Java class libraries that are shipped with Java SE 6 tend to be rather general purpose. Many special-purpose class libraries exist and more are being created.

Software Engineering Observation 9.10

At the design stage in an object-oriented system, the designer often finds that certain classes are closely related. The designer should "factor out" common instance variables and methods and place them in a superclass. Then the designer should use inheritance to develop subclasses, specializing them with capabilities beyond those inherited from the superclass.

Software Engineering Observation 9.11

Declaring a subclass does not affect its superclass's source code. Inheritance preserves the integrity of the superclass.

Software Engineering Observation 9.12

Just as designers of non-object-oriented systems should avoid method proliferation, designers of object-oriented systems should avoid class proliferation. Such proliferation creates management problems and can hinder software reusability, because in a huge class library it becomes difficult for a client to locate the most appropriate classes. The alternative is to create fewer classes that provide more substantial functionality, but such classes might prove cumbersome.

**Performance Tip 9.1**

If subclasses are larger than they need to be (i.e., contain too much functionality), memory and processing resources might be wasted. Extend the superclass that contains the functionality that is closest to what is needed.

Reading subclass declarations can be confusing, because inherited members are not declared explicitly in the subclasses, but are nevertheless present in them. A similar problem exists in documenting subclass members.

9.7 Object Class

As we discussed earlier in this chapter, all classes in Java inherit directly or indirectly from the `Object` class (package `java.lang`), so its 11 methods are inherited by all other classes. Figure 9.18 summarizes `Object`'s methods.

Method	Description
<code>clone</code>	This protected method, which takes no arguments and returns an <code>Object</code> reference, makes a copy of the object on which it is called. When cloning is required for objects of a class, the class should override method <code>clone</code> as a public method and should implement interface <code>Cloneable</code> (package <code>java.lang</code>). The default implementation of this method performs a so-called shallow copy —instance variable values in one object are copied into another object of the same type. For reference types, only the references are copied. A typical overridden <code>clone</code> method's implementation would perform a deep copy that creates a new object for each reference-type instance variable. There are many subtleties to overriding method <code>clone</code> . You can learn more about cloning in the following article: java.sun.com/developer/JDCTechTips/2001/tt0306.html
<code>equals</code>	This method compares two objects for equality and returns <code>true</code> if they are equal and <code>false</code> otherwise. The method takes any <code>Object</code> as an argument. When objects of a particular class must be compared for equality, the class should override method <code>equals</code> to compare the contents of the two objects. The method's implementation should meet the following requirements: <ul style="list-style-type: none"> • It should return <code>false</code> if the argument is <code>null</code>. • It should return <code>true</code> if an object is compared to itself, as in <code>object1.equals(object1)</code>. • It should return <code>true</code> only if both <code>object1.equals(object2)</code> and <code>object2.equals(object1)</code> would return <code>true</code>. • For three objects, if <code>object1.equals(object2)</code> returns <code>true</code> and <code>object2.equals(object3)</code> returns <code>true</code>, then <code>object1.equals(object3)</code> should also return <code>true</code>. • If <code>equals</code> is called multiple times with the two objects and the objects do not change, the method should consistently return <code>true</code> if the objects are equal and <code>false</code> otherwise.

Fig. 9.18 | `Object` methods that are inherited directly or indirectly by all classes. (Part I of 2.)

464 Chapter 9 Object-Oriented Programming: Inheritance

Method	Description
equals (continued)	A class that overrides <code>equals</code> should also override <code>hashCode</code> to ensure that equal objects have identical hashcodes. The default <code>equals</code> implementation uses operator <code>==</code> to determine whether two references refer to the same object in memory. Section 30.3.3 demonstrates class <code>String</code> 's <code>equals</code> method and differentiates between comparing <code>String</code> objects with <code>==</code> and with <code>equals</code> .
finalize	This protected method (introduced in Section 8.10 and Section 8.11) is called by the garbage collector to perform termination housekeeping on an object just before the garbage collector reclaims the object's memory. It is not guaranteed that the garbage collector will reclaim an object, so it cannot be guaranteed that the object's <code>finalize</code> method will execute. The method must specify an empty parameter list and must return <code>void</code> . The default implementation of this method serves as a placeholder that does nothing.
getClass	Every object in Java knows its own type at execution time. Method <code>getClass</code> (used in Section 10.5 and Section 21.3) returns an object of class <code>Class</code> (package <code>java.lang</code>) that contains information about the object's type, such as its class name (returned by <code>Class</code> method <code>getName</code>). You can learn more about class <code>Class</code> in the online API documentation at java.sun.com/javase/6/docs/api/java/lang/Class.html .
hashCode	A hashtable is a data structure (discussed in Section 19.10) that relates one object, called the key, to another object, called the value. When initially inserting a value into a hashtable, the key's <code>hashCode</code> method is called. The <code>hashcode</code> value returned is used by the hashtable to determine the location at which to insert the corresponding value. The key's <code>hashcode</code> is also used by the hashtable to locate the key's corresponding value.
notify , notifyAll , wait	Methods <code>notify</code> , <code>notifyAll</code> and the three overloaded versions of <code>wait</code> are related to multithreading, which is discussed in Chapter 23. In recent versions of Java, the multithreading model has changed substantially, but these features continue to be supported.
toString	This method (introduced in Section 9.4.1) returns a <code>String</code> representation of an object. The default implementation of this method returns the package name and class name of the object's class followed by a hexadecimal representation of the value returned by the object's <code>hashCode</code> method.

Fig. 9.18 | Object methods that are inherited directly or indirectly by all classes. (Part 2 of 2.)

We discuss several of `Object` methods throughout this book (as indicated in Fig. 9.18). You can learn more about `Object`'s methods in `Object`'s online API documentation and in *The Java Tutorial* at the following sites:

java.sun.com/javase/6/docs/api/java/lang/Object.html
java.sun.com/docs/books/tutorial/java/IandI/objectclass.html

Recall from Chapter 7 that arrays are objects. As a result, like all other objects, an array inherits the members of class `Object`. Note that every array has an overridden `clone`

9.8 Displaying Text and Images Using Labels 465

method that copies the array. However, if the array stores references to objects, the objects are not copied. For more information about the relationship between arrays and class `Object`, please see *Java Language Specification, Chapter 10*, at

java.sun.com/docs/books/jls/second_edition/html/arrays.doc.html

9.8 (Optional) GUI and Graphics Case Study: Displaying Text and Images Using Labels

Programs often use labels when they need to display information or instructions to the user in a graphical user interface. `Labels` are a convenient way of identifying GUI components on the screen and keeping the user informed about the current state of the program. In Java, an object of class `JLabel` (from package `javax.swing`) can display a single line of text, an image or both. The example in Fig. 9.19 demonstrates several `JLabel` features.

```

1 // Fig. 9.19: LabelDemo.java
2 // Demonstrates the use of labels.
3 import java.awt.BorderLayout;
4 import javax.swing.ImageIcon;
5 import javax.swing.JLabel;
6 import javax.swing.JFrame;
7
8 public class LabelDemo
9 {
10     public static void main( String args[] )
11     {
12         // Create a label with plain text
13         JLabel northLabel = new JLabel( "North" );
14
15         // create an icon from an image so we can put it on a JLabel
16         ImageIcon labelIcon = new ImageIcon( "GUITip.gif" );
17
18         // create a label with an Icon instead of text
19         JLabel centerLabel = new JLabel( labelIcon );
20
21         // create another label with an Icon
22         JLabel southLabel = new JLabel( labelIcon );
23
24         // set the label to display text (as well as an icon)
25         southLabel.setText( "South" );
26
27         // create a frame to hold the labels
28         JFrame application = new JFrame();
29
30         application.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
31
32         // add the labels to the frame; the second argument specifies
33         // where on the frame to add the label
34         application.add( northLabel, BorderLayout.NORTH );
35         application.add( centerLabel, BorderLayout.CENTER );
36         application.add( southLabel, BorderLayout.SOUTH );

```

Fig. 9.19 | `JLabel` with text and with images. (Part I of 2.)

466 Chapter 9 Object-Oriented Programming: Inheritance

```

37
38     application.setSize( 300, 300 ); // set the size of the frame
39     application.setVisible( true ); // show the frame
40 } // end main
41 } // end class LabelDemo

```

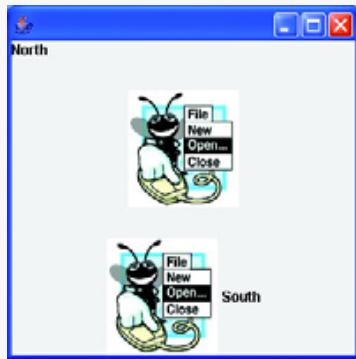

Fig. 9.19 | JLabel with text and with images. (Part 2 of 2.)

Lines 3–6 import the classes we need to display JLabels. BorderLayout from package java.awt contains constants that specify where we can place GUI components in the JFrame. Class ImageIcon represents an image that can be displayed on a JLabel, and class JFrame represents the window that will contain all the labels.

Line 13 creates a JLabel that displays its constructor argument—the string "North". Line 16 declares local variable labelIcon and assigns it a new ImageIcon. The constructor for ImageIcon receives a String that specifies the path to the image. Since we specify only a file name, Java assumes that it is in the same directory as class LabelDemo. ImageIcon can load images in GIF, JPEG and PNG image formats. Line 19 declares and initializes local variable centerLabel with a JLabel that displays the labelIcon. Line 22 declares and initializes local variable southLabel with a JLabel similar to the one in line 19. However, line 25 calls method setText to change the text the label displays. Method setText can be called on any JLabel to change its text. This JLabel displays both the icon and the text.

Line 28 creates the JFrame that displays the JLabels, and line 30 indicates that the program should terminate when the JFrame is closed. We attach the labels to the JFrame in lines 34–36 by calling an overloaded version of method add that takes two parameters. The first parameter is the component we want to attach, and the second is the region in which it should be placed. Each JFrame has an associated layout that helps the JFrame position the GUI components that are attached to it. The default layout for a JFrame is known as a BorderLayout and has five regions—NORTH (top), SOUTH (bottom), EAST (right side), WEST (left side) and CENTER. Each of these is declared as a constant in class BorderLayout. When calling method add with one argument, the JFrame places the component in the CENTER automatically. If a position already contains a component, then the new component takes its place. Lines 38 and 39 set the size of the JFrame and make it visible on screen.

GUI and Graphics Case Study Exercise

9.1 Modify Exercise 8.1 to include a `JLabel` as a status bar that displays counts representing the number of each shape displayed. Class `DrawPanel` should declare a method that returns a `String` containing the status text. In `main`, first create the `DrawPanel`, then create the `JLabel` with the status text as an argument to the `JLabel`'s constructor. Attach the `JLabel` to the `SOUTH` region of the `JFrame`, as shown in Fig. 9.20.

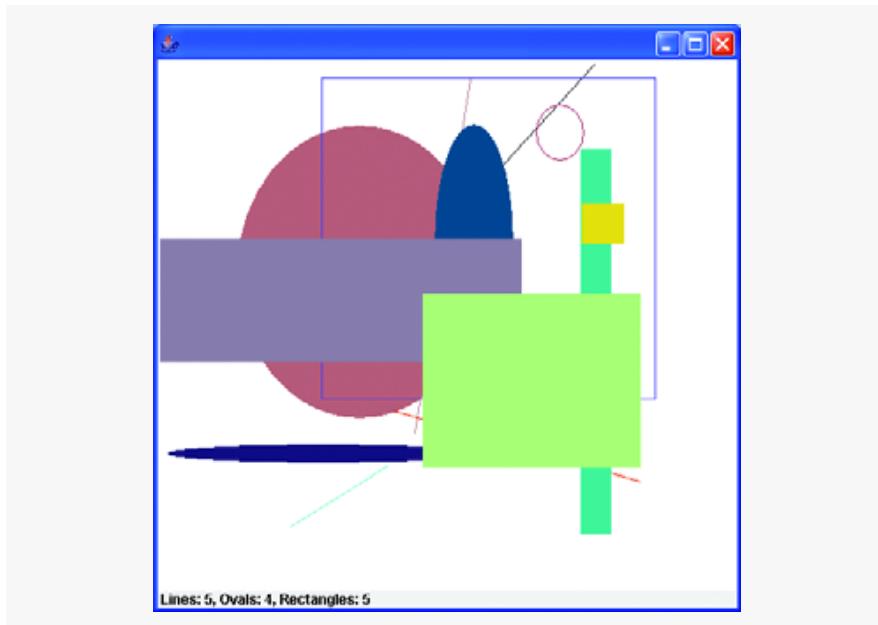

Fig. 9.20 | `JLabel` displaying shape statistics.

9.9 Wrap-Up

This chapter introduced inheritance—the ability to create classes by absorbing an existing class's members and embellishing them with new capabilities. You learned the notions of superclasses and subclasses and used keyword `extends` to create a subclass that inherits members from a superclass. The chapter introduced the access modifier `protected`; subclass methods can access `protected` superclass members. You learned how to access superclass members with `super`. You also saw how constructors are used in inheritance hierarchies. Finally, you learned about the methods of class `Object`, the direct or indirect superclass of all classes in Java.

In Chapter 10, Object-Oriented Programming: Polymorphism, we build on our discussion of inheritance by introducing polymorphism—an object-oriented concept that enables us to write programs that conveniently handle, in a more general manner, objects of a wide variety of classes related by inheritance. After studying Chapter 10, you will be familiar with classes, objects, encapsulation, inheritance and polymorphism—the key technologies of object-oriented programming.

468 Chapter 9 Object-Oriented Programming: Inheritance

Summary

Section 9.1 Introduction

- Software reuse reduces program-development time.
- The direct superclass of a subclass (specified by the keyword `extends` in the first line of a class declaration) is the superclass from which the subclass inherits. An indirect superclass of a subclass is two or more levels up the class hierarchy from that subclass.
- In single inheritance, a class is derived from one direct superclass. In multiple inheritance, a class is derived from more than one direct superclass. Java does not support multiple inheritance.
- A subclass is more specific than its superclass and represents a smaller group of objects.
- Every object of a subclass is also an object of that class's superclass. However, a superclass object is not an object of its class's subclasses.
- An *is-a* relationship represents inheritance. In an *is-a* relationship, an object of a subclass also can be treated as an object of its superclass.
- A *has-a* relationship represents composition. In a *has-a* relationship, a class object contains references to objects of other classes.

Section 9.2 Superclasses and Subclasses

- Single-inheritance relationships form tree-like hierarchical structures—a superclass exists in a hierarchical relationship with its subclasses.

Section 9.3 `protected` Members

- A superclass's `public` members are accessible wherever the program has a reference to an object of that superclass or one of its subclasses.
- A superclass's `private` members are accessible only within the declaration of that superclass.
- A superclass's `protected` members have an intermediate level of protection between `public` and `private` access. They can be accessed by members of the superclass, by members of its subclasses and by members of other classes in the same package.
- When a subclass method overrides a superclass method, the superclass method can be accessed from the subclass if the superclass method name is preceded by the keyword `super` and a dot (.) separator.

Section 9.4 Relationship between Superclasses and Subclasses

- A subclass cannot access or inherit the `private` members of its superclass—allowing this would violate the encapsulation of the superclass. A subclass can, however, inherit the `non-private` members of its superclass.
- A superclass method can be overridden in a subclass to declare an appropriate implementation for the subclass.
- Method `toString` takes no arguments and returns a `String`. The `Object` class's `toString` method is normally overridden by a subclass.
- When an object is output using the `%s` format specifier, the object's `toString` method is called implicitly to obtain its string representation.

Section 9.5 Constructors in Subclasses

- The first task of any subclass constructor is to call its direct superclass's constructor, either explicitly or implicitly, to ensure that the instance variables inherited from the superclass are initialized properly.

- A subclass can explicitly invoke a constructor of its superclass by using the superclass constructor call syntax—keyword `super`, followed by a set of parentheses containing the superclass constructor arguments.

Section 9.6 Software Engineering with Inheritance

- Declaring instance variables `private`, while providing non-`private` methods to manipulate and perform validation, helps enforce good software engineering.

Terminology

base class	invoke a superclass method
brittle software	<i>is a</i> relationship
class hierarchy	<code>Object</code> class
class library	object of a subclass
<code>clone</code> method of class <code>Object</code>	object of a superclass
composition	override (redefine) a superclass method
derived class	private superclass member
direct superclass	<code>protected</code> keyword
<code>equals</code> method of class <code>Object</code>	<code>protected</code> superclass member
<code>extends</code> keyword	<code>public</code> superclass member
fragile software	single inheritance
<code>getClass</code> method of class <code>Object</code>	software reusability
<i>has-a</i> relationship	standardized reusable components
<code>hashCode</code> method of class <code>Object</code>	subclass
hierarchical relationship	subclass constructor
hierarchy diagram	<code>super</code> keyword
indirect superclass	superclass
inheritance	superclass constructor
inheritance hierarchy	superclass constructor call syntax
inherited member	superclass no-argument constructor
inherited method	<code>toString</code> method of class <code>Object</code>
invoke a superclass constructor	

Self-Review Exercises

- 9.1** Fill in the blanks in each of the following statements:
- _____ is a form of software reusability in which new classes acquire the members of existing classes and embellish those classes with new capabilities.
 - A superclass's _____ members can be accessed in the superclass declaration and in subclass declarations.
 - In a(n) _____ relationship, an object of a subclass can also be treated as an object of its superclass.
 - In a(n) _____ relationship, a class object has references to objects of other classes as members.
 - In single inheritance, a class exists in a(n) _____ relationship with its subclasses.
 - A superclass's _____ members are accessible anywhere that the program has a reference to an object of that superclass or to an object of one of its subclasses.
 - When an object of a subclass is instantiated, a superclass _____ is called implicitly or explicitly.
 - Subclass constructors can call superclass constructors via the _____ keyword.

470 Chapter 9 Object-Oriented Programming: Inheritance

- 9.2** State whether each of the following is *true* or *false*. If a statement is *false*, explain why.
- Superclass constructors are not inherited by subclasses.
 - A *has-a* relationship is implemented via inheritance.
 - A Car class has an *is a* relationship with the SteeringWheel and Brakes classes.
 - Inheritance encourages the reuse of proven high-quality software.
 - When a subclass redefines a superclass method by using the same signature, the subclass is said to overload that superclass method.

Answers to Self-Review Exercises

9.1 a) Inheritance. b) public and protected. c) *is a* or inheritance. d) *has-a* or composition. e) hierarchical. f) public. g) constructor. h) super.

9.2 a) True. b) False. A *has-a* relationship is implemented via composition. An *is a* relationship is implemented via inheritance. c) False. This is an example of a *has-a* relationship. Class Car has an *is a* relationship with class Vehicle. d) True. e) False. This is known as overriding, not overloading—an overloaded method has the same name, but a different signature.

Exercises

9.3 Many programs written with inheritance could be written with composition instead, and vice versa. Rewrite class BasePlusCommissionEmployee4 (Fig. 9.13) of the CommissionEmployee3–BasePlusCommissionEmployee4 hierarchy to use composition rather than inheritance. After you do this, assess the relative merits of the two approaches for the CommissionEmployee3 and BasePlusCommissionEmployee4 problems, as well as for object-oriented programs in general. Which approach is more natural? Why?

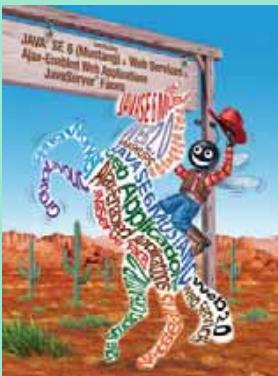

9.4 Discuss the ways in which inheritance promotes software reuse, saves time during program development and helps prevent errors.

9.5 Draw an inheritance hierarchy for students at a university similar to the hierarchy shown in Fig. 9.2. Use Student as the superclass of the hierarchy, then extend Student with classes UndergraduateStudent and GraduateStudent. Continue to extend the hierarchy as deep (i.e., as many levels) as possible. For example, Freshman, Sophomore, Junior and Senior might extend UndergraduateStudent, and DoctoralStudent and MastersStudent might be subclasses of GraduateStudent. After drawing the hierarchy, discuss the relationships that exist between the classes. [Note: You do not need to write any code for this exercise.]

9.6 The world of shapes is much richer than the shapes included in the inheritance hierarchy of Fig. 9.3. Write down all the shapes you can think of—both two-dimensional and three-dimensional—and form them into a more complete Shape hierarchy with as many levels as possible. Your hierarchy should have class Shape at the top. Class TwoDimensionalShape and class ThreeDimensionalShape should extend Shape. Add additional subclasses, such as Quadrilateral and Sphere, at their correct locations in the hierarchy as necessary.

9.7 Some programmers prefer not to use protected access, because they believe it breaks the encapsulation of the superclass. Discuss the relative merits of using protected access vs. using private access in superclasses.

9.8 Write an inheritance hierarchy for classes Quadrilateral, Trapezoid, Parallelogram, Rectangle and Square. Use Quadrilateral as the superclass of the hierarchy. Make the hierarchy as deep (i.e., as many levels) as possible. Specify the instance variables and methods for each class. The private instance variables of Quadrilateral should be the *x-y* coordinate pairs for the four endpoints of the Quadrilateral. Write a program that instantiates objects of your classes and outputs each object's area (except Quadrilateral).

*One Ring to rule them all,
One Ring to find them,
One Ring to bring them all
and in the darkness bind
them.*

—John Ronald Reuel Tolkien

*General propositions do not
decide concrete cases.*

—Oliver Wendell Holmes

*A philosopher of imposing
stature doesn't think in a
vacuum. Even his most
abstract ideas are, to some
extent, conditioned by
what is or is not known
in the time when he lives.*

Object- Oriented Programming: Polymorphism

OBJECTIVES

In this chapter you will learn:

- The concept of polymorphism.
- To use overridden methods to effect polymorphism.
- To distinguish between abstract and concrete classes.
- To declare abstract methods to create abstract classes.
- How polymorphism makes systems extensible and maintainable.
- To determine an object's type at execution time.
- To declare and implement interfaces.

472 Chapter 10 Object-Oriented Programming: Polymorphism**Outline**

- 10.1** Introduction
- 10.2** Polymorphism Examples
- 10.3** Demonstrating Polymorphic Behavior
- 10.4** Abstract Classes and Methods
- 10.5** Case Study: Payroll System Using Polymorphism
 - 10.5.1** Creating Abstract Superclass `Employee`
 - 10.5.2** Creating Concrete Subclass `SalariedEmployee`
 - 10.5.3** Creating Concrete Subclass `HourlyEmployee`
 - 10.5.4** Creating Concrete Subclass `CommissionEmployee`
 - 10.5.5** Creating Indirect Concrete Subclass `BasePlusCommissionEmployee`
 - 10.5.6** Demonstrating Polymorphic Processing. Operator `instanceof` and Downcasting
 - 10.5.7** Summary of the Allowed Assignments Between Superclass and Subclass Variables
- 10.6** `final` Methods and Classes
- 10.7** Case Study: Creating and Using Interfaces
 - 10.7.1** Developing a `Payable` Hierarchy
 - 10.7.2** Declaring Interface `Payable`
 - 10.7.3** Creating Class `Invoice`
 - 10.7.4** Modifying Class `Employee` to Implement Interface `Payable`
 - 10.7.5** Modifying Class `SalariedEmployee` for Use in the `Payable` Hierarchy
 - 10.7.6** Using Interface `Payable` to Process `Invoices` and `Employees` Polymorphically
 - 10.7.7** Declaring Constants with Interfaces
 - 10.7.8** Common Interfaces of the Java API
- 10.8** (Optional) GUI and Graphics Case Study: Drawing with Polymorphism
- 10.9** (Optional) Software Engineering Case Study: Incorporating Inheritance into the ATM System
- 10.10** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

10.1 Introduction

We now continue our study of object-oriented programming by explaining and demonstrating **polymorphism** with inheritance hierarchies. Polymorphism enables us to “program in the general” rather than “program in the specific.” In particular, polymorphism enables us to write programs that process objects that share the same superclass in a class hierarchy as if they are all objects of the superclass; this can simplify programming.

Consider the following example of polymorphism. Suppose we create a program that simulates the movement of several types of animals for a biological study. Classes `Fish`, `Frog` and `Bird` represent the three types of animals under investigation. Imagine that each of these classes extends superclass `Animal`, which contains a method `move` and maintains

10.1 Introduction **473**

an animal's current location as *x-y* coordinates. Each subclass implements method `move`. Our program maintains an array of references to objects of the various `Animal` subclasses. To simulate the animals' movements, the program sends each object the same message once per second—namely, `move`. However, each specific type of `Animal` responds to a `move` message in a unique way—a `Fish` might swim three feet, a `Frog` might jump five feet and a `Bird` might fly ten feet. The program issues the same message (i.e., `move`) to each animal object generically, but each object knows how to modify its *x-y* coordinates appropriately for its specific type of movement. Relying on each object to know how to “do the right thing” (i.e., do what is appropriate for that type of object) in response to the same method call is the key concept of polymorphism. The same message (in this case, `move`) sent to a variety of objects has “many forms” of results—hence the term polymorphism.

With polymorphism, we can design and implement systems that are easily extensible—new classes can be added with little or no modification to the general portions of the program, as long as the new classes are part of the inheritance hierarchy that the program processes generically. The only parts of a program that must be altered to accommodate new classes are those that require direct knowledge of the new classes that the programmer adds to the hierarchy. For example, if we extend class `Animal` to create class `Tortoise` (which might respond to a `move` message by crawling one inch), we need to write only the `Tortoise` class and the part of the simulation that instantiates a `Tortoise` object. The portions of the simulation that process each `Animal` generically can remain the same.

This chapter has several parts. First, we discuss common examples of polymorphism. We then provide an example demonstrating polymorphic behavior. We'll use superclass references to manipulate both superclass objects and subclass objects polymorphically.

We then present a case study that revisits the employee hierarchy of Section 9.4.5. We develop a simple payroll application that polymorphically calculates the weekly pay of several different types of employees using each employee's `earnings` method. Though the earnings of each type of employee are calculated in a specific way, polymorphism allows us to process the employees “in the general.” In the case study, we enlarge the hierarchy to include two new classes—`SalariedEmployee` (for people paid a fixed weekly salary) and `HourlyEmployee` (for people paid an hourly salary and so-called time-and-a-half for overtime). We declare a common set of functionality for all the classes in the updated hierarchy in a so-called abstract class, `Employee`, from which classes `SalariedEmployee`, `HourlyEmployee` and `CommissionEmployee` inherit directly and class `BasePlusCommissionEmployee4` inherits indirectly. As you'll soon see, when we invoke each employee's `earnings` method off a superclass `Employee` reference, the correct earnings calculation is performed due to Java's polymorphic capabilities.

Occasionally, when performing polymorphic processing, we need to program “in the specific.” Our `Employee` case study demonstrates that a program can determine the type of an object at execution time and act on that object accordingly. In the case study, we use these capabilities to determine whether a particular employee object is a `BasePlusCommissionEmployee`. If so, we increase that employee's base salary by 10%.

The chapter continues with an introduction to Java interfaces. An interface describes a set of methods that can be called on an object, but does not provide concrete implementations for the methods. Programmers can declare classes that `implement` (i.e., provide concrete implementations for the methods of) one or more interfaces. Each interface method must be declared in all the classes that implement the interface. Once a class

474 Chapter 10 Object-Oriented Programming: Polymorphism

implements an interface, all objects of that class have an *is-a* relationship with the interface type, and all objects of the class are guaranteed to provide the functionality described by the interface. This is true of all subclasses of that class as well.

Interfaces are particularly useful for assigning common functionality to possibly unrelated classes. This allows objects of unrelated classes to be processed polymorphically—objects of classes that implement the same interface can respond to the same method calls. To demonstrate creating and using interfaces, we modify our payroll application to create a general accounts payable application that can calculate payments due for company employees and invoice amounts to be billed for purchased goods. As you'll see, interfaces enable polymorphic capabilities similar to those possible with inheritance.

10.2 Polymorphism Examples

We now consider several additional examples of polymorphism. If class `Rectangle` is derived from class `Quadrilateral`, then a `Rectangle` object is a more specific version of a `Quadrilateral` object. Any operation (e.g., calculating the perimeter or the area) that can be performed on a `Quadrilateral` object can also be performed on a `Rectangle` object. These operations can also be performed on other `Quadrilaterals`, such as `Squares`, `Parallelograms` and `Trapezoids`. The polymorphism occurs when a program invokes a method through a superclass variable—at execution time, the correct subclass version of the method is called, based on the type of the reference stored in the superclass variable. You will see a simple code example that illustrates this process in Section 10.3.

As another example, suppose we design a video game that manipulates objects of classes `Martian`, `Venusian`, `Plutonian`, `SpaceShip` and `LaserBeam`. Imagine that each class inherits from the common superclass called `SpaceObject`, which contains method `draw`. Each subclass implements this method. A screen-manager program maintains a collection (e.g., a `SpaceObject` array) of references to objects of the various classes. To refresh the screen, the screen manager periodically sends each object the same message—namely, `draw`. However, each object responds in a unique way. For example, a `Martian` object might draw itself in red with green eyes and the appropriate number of antennae. A `SpaceShip` object might draw itself as a bright silver flying saucer. A `LaserBeam` object might draw itself as a bright red beam across the screen. Again, the same message (in this case, `draw`) sent to a variety of objects has “many forms” of results.

A polymorphic screen manager might use polymorphism to facilitate adding new classes to a system with minimal modifications to the system's code. Suppose that we want to add `Mercurian` objects to our video game. To do so, we must build a class `Mercurian` that extends `SpaceObject` and provides its own `draw` method implementation. When objects of class `Mercurian` appear in the `SpaceObject` collection, the screen manager code invokes method `draw`, exactly as it does for every other object in the collection, regardless of its type. So the new `Mercurian` objects simply “plug right in” without any modification of the screen manager code by the programmer. Thus, without modifying the system (other than to build new classes and modify the code that creates new objects), programmers can use polymorphism to conveniently include additional types that were not envisioned when the system was created.

With polymorphism, the same method name and signature can be used to cause different actions to occur, depending on the type of object on which the method is invoked. This gives the programmer tremendous expressive capability.

Software Engineering Observation 10.1

Polymorphism enables programmers to deal in generalities and let the execution-time environment handle the specifics. Programmers can command objects to behave in manners appropriate to those objects, without knowing the types of the objects (as long as the objects belong to the same inheritance hierarchy).

Software Engineering Observation 10.2

Polymorphism promotes extensibility: Software that invokes polymorphic behavior is independent of the object types to which messages are sent. New object types that can respond to existing method calls can be incorporated into a system without requiring modification of the base system. Only client code that instantiates new objects must be modified to accommodate new types.

10.3 Demonstrating Polymorphic Behavior

Section 9.4 created a commission employee class hierarchy, in which class `BasePlusCommissionEmployee` inherited from class `CommissionEmployee`. The examples in that section manipulated `CommissionEmployee` and `BasePlusCommissionEmployee` objects by using references to them to invoke their methods—we aimed superclass references at superclass objects and subclass references at subclass objects. These assignments are natural and straightforward—superclass references are intended to refer to superclass objects, and subclass references are intended to refer to subclass objects. However, as you will soon see, other assignments are possible.

In the next example, we aim a superclass reference at a subclass object. We then show how invoking a method on a subclass object via a superclass reference invokes the subclass functionality—the type of the *actual referenced object*, not the type of the *reference*, determines which method is called. This example demonstrates the key concept that an object of a subclass can be treated as an object of its superclass. This enables various interesting manipulations. A program can create an array of superclass references that refer to objects of many subclass types. This is allowed because each subclass object is an object of its superclass. For instance, we can assign the reference of a `BasePlusCommissionEmployee` object to a superclass `CommissionEmployee` variable because a `BasePlusCommissionEmployee` is a `CommissionEmployee`—we can treat a `BasePlusCommissionEmployee` as a `CommissionEmployee`.

As you'll learn later in the chapter, we cannot treat a superclass object as a subclass object because a superclass object is not an object of any of its subclasses. For example, we cannot assign the reference of a `CommissionEmployee` object to a subclass `BasePlusCommissionEmployee` variable because a `CommissionEmployee` is not a `BasePlusCommissionEmployee`—a `CommissionEmployee` does not have a `baseSalary` instance variable and does not have methods `setBaseSalary` and `getBaseSalary`. The *is-a* relationship applies only from a subclass to its direct (and indirect) superclasses, and not vice versa.

The Java compiler does allow the assignment of a superclass reference to a subclass variable if we explicitly cast the superclass reference to the subclass type—a technique we discuss in detail in Section 10.5. Why would we ever want to perform such an assignment? A superclass reference can be used to invoke only the methods declared in the superclass—attempting to invoke subclass-only methods through a superclass reference results in com-

476 Chapter 10 Object-Oriented Programming: Polymorphism

pilation errors. If a program needs to perform a subclass-specific operation on a subclass object referenced by a superclass variable, the program must first cast the superclass reference to a subclass reference through a technique known as [downcasting](#). This enables the program to invoke subclass methods that are not in the superclass. We show a concrete example of downcasting in Section 10.5.

The example in Fig. 10.1 demonstrates three ways to use superclass and subclass variables to store references to superclass and subclass objects. The first two are straightforward—as in Section 9.4, we assign a superclass reference to a superclass variable, and we assign a subclass reference to a subclass variable. Then we demonstrate the relationship between subclasses and superclasses (i.e., the *is-a* relationship) by assigning a subclass reference to a superclass variable. [Note: This program uses classes `CommissionEmployee3` and `BasePlusCommissionEmployee4` from Fig. 9.12 and Fig. 9.13, respectively.]

```

1 // Fig. 10.1: PolymorphismTest.java
2 // Assigning superclass and subclass references to superclass and
3 // subclass variables.
4
5 public class PolymorphismTest
6 {
7     public static void main( String args[] )
8     {
9         // assign superclass reference to superclass variable
10        CommissionEmployee3 commissionEmployee = new CommissionEmployee3(
11            "Sue", "Jones", "222-22-2222", 10000, .06 );
12
13        // assign subclass reference to subclass variable
14        BasePlusCommissionEmployee4 basePlusCommissionEmployee =
15            new BasePlusCommissionEmployee4(
16                "Bob", "Lewis", "333-33-3333", 5000, .04, 300 );
17
18        // invoke toString on superclass object using superclass variable
19        System.out.printf( "%s %s:\n%n%s\n%n",
20            "Call CommissionEmployee3's toString with superclass reference ",
21            "to superclass object", commissionEmployee.toString() );
22
23        // invoke toString on subclass object using subclass variable
24        System.out.printf( "%s %s:\n%n%s\n%n",
25            "Call BasePlusCommissionEmployee4's toString with subclass",
26            "reference to subclass object",
27            basePlusCommissionEmployee.toString() );
28
29        // invoke toString on subclass object using superclass variable
30        CommissionEmployee3 commissionEmployee2 =
31            basePlusCommissionEmployee;
32        System.out.printf( "%s %s:\n%n%s\n%n",
33            "Call BasePlusCommissionEmployee4's toString with superclass",
34            "reference to subclass object", commissionEmployee2.toString() );
35    } // end main
36 } // end class PolymorphismTest

```

Fig. 10.1 | Assigning superclass and subclass references to superclass and subclass variables.
(Part 1 of 2.)

10.3 Demonstrating Polymorphic Behavior

477

Call `CommissionEmployee3`'s `toString` with superclass reference to superclass object:

```
commission employee: Sue Jones
social security number: 222-22-2222
gross sales: 10000.00
commission rate: 0.06
```

Call `BasePlusCommissionEmployee4`'s `toString` with subclass reference to subclass object:

```
base-salaried commission employee: Bob Lewis
social security number: 333-33-3333
gross sales: 5000.00
commission rate: 0.04
base salary: 300.00
```

Call `BasePlusCommissionEmployee4`'s `toString` with superclass reference to subclass object:

```
base-salaried commission employee: Bob Lewis
social security number: 333-33-3333
gross sales: 5000.00
commission rate: 0.04
base salary: 300.00
```

Fig. 10.1 | Assigning superclass and subclass references to superclass and subclass variables.
(Part 2 of 2.)

In Fig. 10.1, lines 10–11 create a `CommissionEmployee3` object and assign its reference to a `CommissionEmployee3` variable. Lines 14–16 create a `BasePlusCommissionEmployee4` object and assign its reference to a `BasePlusCommissionEmployee4` variable. These assignments are natural—for example, a `CommissionEmployee3` variable's primary purpose is to hold a reference to a `CommissionEmployee3` object. Lines 19–21 use reference `commissionEmployee` to invoke `toString` explicitly. Because `commissionEmployee` refers to a `CommissionEmployee3` object, superclass `CommissionEmployee3`'s version of `toString` is called. Similarly, lines 24–27 use `basePlusCommissionEmployee` to invoke `toString` explicitly on the `BasePlusCommissionEmployee4` object. This invokes subclass `BasePlusCommissionEmployee4`'s version of `toString`.

Lines 30–31 then assign the reference to subclass object `basePlusCommissionEmployee` to a superclass `CommissionEmployee3` variable, which lines 32–34 use to invoke method `toString`. When a superclass variable contains a reference to a subclass object, and that reference is used to call a method, the subclass version of the method is called. Hence, `commissionEmployee2.toString()` in line 34 actually calls class `BasePlusCommissionEmployee4`'s `toString` method. The Java compiler allows this “crossover” because an object of a subclass *is an* object of its superclass (but not vice versa). When the compiler encounters a method call made through a variable, the compiler determines if the method can be called by checking the variable's class type. If that class contains the proper method declaration (or inherits one), the call is compiled. At execution time, the type of the object to which the variable refers determines the actual method to use.

478 Chapter 10 Object-Oriented Programming: Polymorphism

10.4 Abstract Classes and Methods

When we think of a class type, we assume that programs will create objects of that type. In some cases, however, it is useful to declare classes for which the programmer never intends to instantiate objects. Such classes are called **abstract classes**. Because they are used only as superclasses in inheritance hierarchies, we refer to them as **abstract superclasses**. These classes cannot be used to instantiate objects, because, as we will soon see, abstract classes are incomplete. Subclasses must declare the “missing pieces.” We demonstrate abstract classes in Section 10.5.

An abstract class’s purpose is to provide an appropriate superclass from which other classes can inherit and thus share a common design. In the Shape hierarchy of Fig. 9.3, for example, subclasses inherit the notion of what it means to be a Shape—common attributes such as `location`, `color` and `borderThickness`, and behaviors such as `draw`, `move`, `resize` and `changeColor`. Classes that can be used to instantiate objects are called **concrete classes**. Such classes provide implementations of every method they declare (some of the implementations can be inherited). For example, we could derive concrete classes `Circle`, `Square` and `Triangle` from abstract superclass `TwoDimensionalShape`. Similarly, we could derive concrete classes `Sphere`, `Cube` and `Tetrahedron` from abstract superclass `ThreeDimensionalShape`. Abstract superclasses are too general to create real objects—they specify only what is common among subclasses. We need to be more specific before we can create objects. For example, if you send the `draw` message to abstract class `TwoDimensionalShape`, it knows that two-dimensional shapes should be drawable, but it does not know what specific shape to draw, so it cannot implement a real `draw` method. Concrete classes provide the specifics that make it reasonable to instantiate objects.

Not all inheritance hierarchies contain abstract classes. However, programmers often write client code that uses only abstract superclass types to reduce client code’s dependencies on a range of specific subclass types. For example, a programmer can write a method with a parameter of an abstract superclass type. When called, such a method can be passed an object of any concrete class that directly or indirectly extends the superclass specified as the parameter’s type.

Abstract classes sometimes constitute several levels of the hierarchy. For example, the Shape hierarchy of Fig. 9.3 begins with abstract class `Shape`. On the next level of the hierarchy are two more abstract classes, `TwoDimensionalShape` and `ThreeDimensionalShape`. The next level of the hierarchy declares concrete classes for `TwoDimensionalShapes` (`Circle`, `Square` and `Triangle`) and for `ThreeDimensionalShapes` (`Sphere`, `Cube` and `Tetrahedron`).

You make a class abstract by declaring it with keyword **abstract**. An abstract class normally contains one or more **abstract methods**. An abstract method is one with keyword **abstract** in its declaration, as in

```
public abstract void draw(); // abstract method
```

Abstract methods do not provide implementations. A class that contains any abstract methods must be declared as an abstract class even if that class contains some concrete (nonabstract) methods. Each concrete subclass of an abstract superclass also must provide concrete implementations of each of the superclass’s abstract methods. Constructors and **static** methods cannot be declared **abstract**. Constructors are not inherited, so an **abstract** constructor could never be implemented. Though **static** methods are inher-

10.4 Abstract Classes and Methods **479**

ited, they are not associated with particular objects of the classes that declare the `static` methods. Since `abstract` methods are meant to be overridden so they can process objects based on their types, it would not make sense to declare a `static` method as `abstract`.

**Software Engineering Observation 10.3**

An abstract class declares common attributes and behaviors of the various classes in a class hierarchy. An abstract class typically contains one or more abstract methods that subclasses must override if the subclasses are to be concrete. The instance variables and concrete methods of an abstract class are subject to the normal rules of inheritance.

**Common Programming Error 10.1**

Attempting to instantiate an object of an abstract class is a compilation error.

**Common Programming Error 10.2**

Failure to implement a superclass's abstract methods in a subclass is a compilation error unless the subclass is also declared abstract.

Although we cannot instantiate objects of abstract superclasses, you will soon see that we *can* use abstract superclasses to declare variables that can hold references to objects of any concrete class derived from those abstract superclasses. Programs typically use such variables to manipulate subclass objects polymorphically. We also can use abstract superclass names to invoke `static` methods declared in those abstract superclasses.

Consider another application of polymorphism. A drawing program needs to display many shapes, including new shape types that the programmer will add to the system after writing the drawing program. The drawing program might need to display shapes, such as `Circles`, `Triangles`, `Rectangles` or others, that derive from abstract superclass `Shape`. The drawing program uses `Shape` variables to manage the objects that are displayed. To draw any object in this inheritance hierarchy, the drawing program uses a superclass `Shape` variable containing a reference to the subclass object to invoke the object's `draw` method. This method is declared `abstract` in superclass `Shape`, so each concrete subclass *must* implement method `draw` in a manner specific to that shape. Each object in the `Shape` inheritance hierarchy knows how to draw itself. The drawing program does not have to worry about the type of each object or whether the drawing program has ever encountered objects of that type.

Polymorphism is particularly effective for implementing so-called layered software systems. In operating systems, for example, each type of physical device could operate quite differently from the others. Even so, commands to read or write data from and to devices may have a certain uniformity. For each device, the operating system uses a piece of software called a device driver to control all communication between the system and the device. The write message sent to a device-driver object needs to be interpreted specifically in the context of that driver and how it manipulates devices of a specific type. However, the write call itself really is no different from the write to any other device in the system: Place some number of bytes from memory onto that device. An object-oriented operating system might use an abstract superclass to provide an “interface” appropriate for all device drivers. Then, through inheritance from that abstract superclass, subclasses are formed that all behave similarly. The device-driver methods are declared as abstract methods in

480 Chapter 10 Object-Oriented Programming: Polymorphism

the abstract superclass. The implementations of these abstract methods are provided in the subclasses that correspond to the specific types of device drivers. New devices are always being developed, and often long after the operating system has been released. When you buy a new device, it comes with a device driver provided by the device vendor. The device is immediately operational after you connect it to your computer and install the driver. This is another elegant example of how polymorphism makes systems extensible.

It is common in object-oriented programming to declare an **iterator class** that can traverse all the objects in a collection, such as an array (Chapter 7) or an **ArrayList** (Chapter 19, Collections). For example, a program can print an **ArrayList** of objects by creating an iterator object and using it to obtain the next list element each time the iterator is called. Iterators often are used in polymorphic programming to traverse a collection that contains references to objects from various levels of a hierarchy. (Chapter 19 presents a thorough treatment of **ArrayList**, iterators and “generics” capabilities.) An **ArrayList** of objects of class **TwoDimensionalShape**, for example, could contain objects from subclasses **Square**, **Circle**, **Triangle** and so on. Calling method **draw** for each **TwoDimensionalShape** object off a **TwoDimensionalShape** variable would polymorphically draw each object correctly on the screen.

10.5 Case Study: Payroll System Using Polymorphism

This section reexamines the **CommissionEmployee**-**BasePlusCommissionEmployee** hierarchy that we explored throughout Section 9.4. Now we use an abstract method and polymorphism to perform payroll calculations based on the type of employee. We create an enhanced employee hierarchy to solve the following problem:

A company pays its employees on a weekly basis. The employees are of four types: Salaried employees are paid a fixed weekly salary regardless of the number of hours worked, hourly employees are paid by the hour and receive overtime pay for all hours worked in excess of 40 hours, commission employees are paid a percentage of their sales and salaried-commission employees receive a base salary plus a percentage of their sales. For the current pay period, the company has decided to reward salaried-commission employees by adding 10% to their base salaries. The company wants to implement a Java application that performs its payroll calculations polymorphically.

We use abstract class **Employee** to represent the general concept of an employee. The classes that extend **Employee** are **SalariedEmployee**, **CommissionEmployee** and **HourlyEmployee**. Class **BasePlusCommissionEmployee**—which extends **CommissionEmployee**—represents the last employee type. The UML class diagram in Fig. 10.2 shows the inheritance hierarchy for our polymorphic employee-payroll application. Note that abstract class **Employee** is italicized, as per the convention of the UML.

Abstract superclass **Employee** declares the “interface” to the hierarchy—that is, the set of methods that a program can invoke on all **Employee** objects. We use the term “interface” here in a general sense to refer to the various ways programs can communicate with objects of any **Employee** subclass. Be careful not to confuse the general notion of an “interface” to something with the formal notion of a Java interface, the subject of Section 10.7. Each employee, regardless of the way his or her earnings are calculated, has a first name, a last name and a social security number, so private instance variables **firstName**, **lastName** and **socialSecurityNumber** appear in abstract superclass **Employee**.

10.5 Case Study: Payroll System Using Polymorphism

481

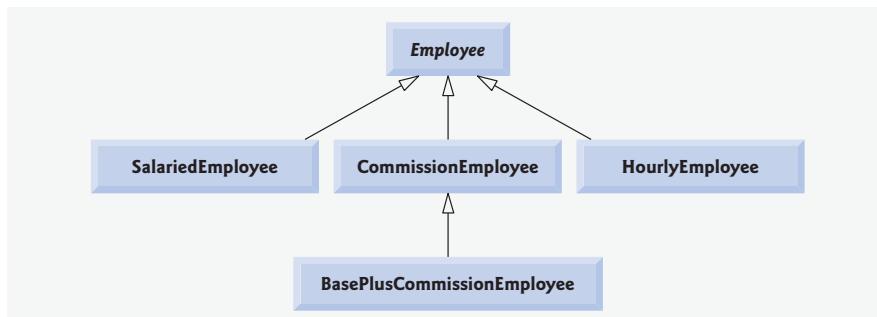

Fig. 10.2 | Employee hierarchy UML class diagram.

Software Engineering Observation 10.4

A subclass can inherit “interface” or “implementation” from a superclass. Hierarchies designed for **implementation inheritance** tend to have their functionality high in the hierarchy—each new subclass inherits one or more methods that were implemented in a superclass, and the subclass uses the superclass implementations. Hierarchies designed for **interface inheritance** tend to have their functionality lower in the hierarchy—a superclass specifies one or more abstract methods that must be declared for each concrete class in the hierarchy, and the individual subclasses override these methods to provide subclass-specific implementations.

The following sections implement the `Employee` class hierarchy. Each of the first four sections implements one of the concrete classes. The last section implements a test program that builds objects of all these classes and processes those objects polymorphically.

10.5.1 Creating Abstract Superclass `Employee`

Class `Employee` (Fig. 10.4) provides methods `earnings` and `toString`, in addition to the `get` and `set` methods that manipulate `Employee`'s instance variables. An `earnings` method certainly applies generically to all employees. But each `earnings` calculation depends on the employee's class. So we declare `earnings` as **abstract** in superclass `Employee` because a default implementation does not make sense for that method—there is not enough information to determine what amount `earnings` should return. Each subclass overrides `earnings` with an appropriate implementation. To calculate an employee's `earnings`, the program assigns a reference to the employee's object to a superclass `Employee` variable, then invokes the `earnings` method on that variable. We maintain an array of `Employee` variables, each of which holds a reference to an `Employee` object (of course, there cannot be `Employee` objects because `Employee` is an abstract class—because of inheritance, however, all objects of all subclasses of `Employee` may nevertheless be thought of as `Employee` objects). The program iterates through the array and calls method `earnings` for each `Employee` object. Java processes these method calls polymorphically. Including `earnings` as an abstract method in `Employee` forces every direct subclass of `Employee` to override `earnings` in order to become a concrete class. This enables the designer of the class hierarchy to demand that each concrete subclass provide an appropriate pay calculation.

482 Chapter 10 Object-Oriented Programming: Polymorphism

Method `toString` in class `Employee` returns a `String` containing the first name, last name and social security number of the employee. As we will see, each subclass of `Employee` overrides method `toString` to create a string representation of an object of that class that contains the employee's type (e.g., "salaried employee:") followed by the rest of the employee's information.

The diagram in Fig. 10.3 shows each of the five classes in the hierarchy down the left side and methods `earnings` and `toString` across the top. For each class, the diagram shows the desired results of each method. [Note: We do not list superclass `Employee`'s `get` and `set` methods because they are not overridden in any of the subclasses—each of these methods is inherited and used "as is" by each of the subclasses.]

Let us consider class `Employee`'s declaration (Fig. 10.4). The class includes a constructor that takes the first name, last name and social security number as arguments (lines 11–16); `get` methods that return the first name, last name and social security number (lines 25–28, 37–40 and 49–52, respectively); `set` methods that set the first name, last name and social security number (lines 19–22, 31–34 and 43–46, respectively); method `toString` (lines 55–59), which returns the string representation of `Employee`; and abstract method `earnings` (line 62), which will be implemented by subclasses. Note that the `Employee` constructor does not validate the social security number in this example. Normally, such validation should be provided.

	<code>earnings</code>	<code>toString</code>
<code>Employee</code>	<code>abstract</code>	<code>firstName lastName social security number: SSN</code>
<code>Salaried-Employee</code>	<code>weeklySalary</code>	<code>salaried employee: firstName lastName social security number: SSN weekly salary: weeklySalary</code>
<code>Hourly-Employee</code>	<code>if hours <= 40 wage * hours else if hours > 40 40 * wage + (hours - 40) * wage * 1.5</code>	<code>hourly employee: firstName lastName social security number: SSN hourly wage: wage; hours worked: hours</code>
<code>Commission-Employee</code>	<code>commissionRate * grossSales</code>	<code>commission employee: firstName lastName social security number: SSN gross sales: grossSales; commission rate: commissionRate</code>
<code>BasePlus-Commission-Employee</code>	<code>(commissionRate * grossSales) + baseSalary</code>	<code>base salaried commission employee: firstName lastName social security number: SSN gross sales: grossSales; commission rate: commissionRate; base salary: baseSalary</code>

Fig. 10.3 | Polymorphic interface for the `Employee` hierarchy classes.

10.5 Case Study: Payroll System Using Polymorphism

483

```

1 // Fig. 10.4: Employee.java
2 // Employee abstract superclass.
3
4 public abstract class Employee
5 {
6     private String firstName;
7     private String lastName;
8     private String socialSecurityNumber;
9
10    // three-argument constructor
11    public Employee( String first, String last, String ssn )
12    {
13        firstName = first;
14        lastName = last;
15        socialSecurityNumber = ssn;
16    } // end three-argument Employee constructor
17
18    // set first name
19    public void setFirstName( String first )
20    {
21        firstName = first;
22    } // end method setFirstName
23
24    // return first name
25    public String getFirstName()
26    {
27        return firstName;
28    } // end method getFirstName
29
30    // set last name
31    public void setLastName( String last )
32    {
33        lastName = last;
34    } // end method setLastName
35
36    // return last name
37    public String getLastname()
38    {
39        return lastName;
40    } // end method getLastname
41
42    // set social security number
43    public void setSocialSecurityNumber( String ssn )
44    {
45        socialSecurityNumber = ssn; // should validate
46    } // end method setSocialSecurityNumber
47
48    // return social security number
49    public String getSocialSecurityNumber()
50    {
51        return socialSecurityNumber;
52    } // end method getSocialSecurityNumber
53

```

Fig. 10.4 | Employee abstract superclass. (Part I of 2.)

484 Chapter 10 Object-Oriented Programming: Polymorphism

```

54  // return String representation of Employee object
55  public String toString()
56  {
57      return String.format( "%s %s\nsocial security number: %s",
58          getFirstName(), getLastName(), getSocialSecurityNumber() );
59  } // end method toString
60
61  // abstract method overridden by subclasses
62  public abstract double earnings(); // no implementation here
63 } // end abstract class Employee

```

Fig. 10.4 | Employee abstract superclass. (Part 2 of 2.)

Why did we decide to declare `earnings` as an `abstract` method? It simply does not make sense to provide an implementation of this method in class `Employee`. We cannot calculate the earnings for a general `Employee`—we first must know the specific `Employee` type to determine the appropriate `earnings` calculation. By declaring this method `abstract`, we indicate that each concrete subclass *must* provide an appropriate `earnings` implementation and that a program will be able to use superclass `Employee` variables to invoke method `earnings` polymorphically for any type of `Employee`.

10.5.2 Creating Concrete Subclass `SalariedEmployee`

Class `SalariedEmployee` (Fig. 10.5) extends class `Employee` (line 4) and overrides `earnings` (lines 29–32), which makes `SalariedEmployee` a concrete class. The class includes a constructor (lines 9–14) that takes a first name, a last name, a social security number and a weekly salary as arguments; a `set` method to assign a new nonnegative value to instance variable `weeklySalary` (lines 17–20); a `get` method to return `weeklySalary`'s value (lines 23–26); a method `earnings` (lines 29–32) to calculate a `SalariedEmployee`'s earnings; and a method `toString` (lines 35–39), which returns a `String` including the employee's type, namely, "salaried employee: " followed by employee-specific information produced by superclass `Employee`'s `toString` method and `SalariedEmployee`'s `getWeeklySalary` method. Class `SalariedEmployee`'s constructor passes the first name, last name and social security number to the `Employee` constructor (line 12) to initialize the private instance variables not inherited from the superclass. Method `earnings` overrides abstract method `earnings` in `Employee` to provide a concrete implementation that returns the `SalariedEmployee`'s weekly salary. If we do not implement `earnings`, class `SalariedEmployee` must be declared `abstract`—otherwise, a compilation error occurs (and, of course, we want `SalariedEmployee` here to be a concrete class).

Method `toString` (lines 35–39) of class `SalariedEmployee` overrides `Employee` method `toString`. If class `SalariedEmployee` did not override `toString`, `SalariedEmployee` would have inherited the `Employee` version of `toString`. In that case, `SalariedEmployee`'s `toString` method would simply return the employee's full name and social security number, which does not adequately represent a `SalariedEmployee`. To produce a complete string representation of a `SalariedEmployee`, the subclass's `toString` method returns "salaried employee: " followed by the superclass `Employee`-specific information (i.e., first name, last name and social security number) obtained by invoking the superclass's `toString` method (line 38)—this is a nice example of code reuse. The string repre-

36    {
37        return String.format( "salaried employee: %s\n%s: $%,.2f",
38                             super.toString(), "weekly salary", getWeeklySalary() );
39    } // end method toString
40 } // end class SalariedEmployee

```

Fig. 10.5 | SalariedEmployee class derived from Employee.

resentation of a SalariedEmployee also contains the employee's weekly salary obtained by invoking the class's `getWeeklySalary` method.

10.5.3 Creating Concrete Subclass HourlyEmployee

Class `HourlyEmployee` (Fig. 10.6) also extends `Employee` (line 4). The class includes a constructor (lines 10–16) that takes as arguments a first name, a last name, a social security number, an hourly wage and the number of hours worked. Lines 19–22 and 31–35 declare *set* methods that assign new values to instance variables `wage` and `hours`, respectively. Method `setWage` (lines 19–22) ensures that `wage` is nonnegative, and method `setHours`

486 Chapter 10 Object-Oriented Programming: Polymorphism

```

1 // Fig. 10.6: HourlyEmployee.java

3
4 public class HourlyEmployee extends Employee
5 {
6     private double wage; // wage per hour
7     private double hours; // hours worked for week
8
9     // five-argument constructor
10    public HourlyEmployee( String first, String last, String ssn,
11                           double hourlyWage, double hoursWorked )
12    {
13        super( first, last, ssn );
14        setWage( hourlyWage ); // validate hourly wage
15        setHours( hoursWorked ); // validate hours worked
16    } // end five-argument HourlyEmployee constructor
17
18    // set wage
19    public void setWage( double hourlyWage )
20    {
21        wage = ( hourlyWage < 0.0 ) ? 0.0 : hourlyWage;
22    } // end method setWage
23
24    // return wage
25    public double getWage()
26    {
27        return wage;
28    } // end method getWage
29
30    // set hours worked
31    public void setHours( double hoursWorked )
32    {
33        hours = ( ( hoursWorked >= 0.0 ) && ( hoursWorked <= 168.0 ) ) ?
34                  hoursWorked : 0.0;
35    } // end method setHours
36
37    // return hours worked
38    public double getHours()
39    {
40        return hours;
41    } // end method getHours
42
43    // calculate earnings; override abstract method earnings in Employee
44    public double earnings()
45    {
46        if ( getHours() <= 40 ) // no overtime
47            return getWage() * getHours();
48        else
49            return 40 * getWage() + ( gethours() - 40 ) * getWage() * 1.5;
50    } // end method earnings
51

```

Fig. 10.6 | HourlyEmployee class derived from Employee. (Part I of 2.)

10.5 Case Study: Payroll System Using Polymorphism

487

```

52     // return String representation of HourlyEmployee object
53     public String toString()
54     {
55         return String.format( "hourly employee: %s\n%s: $%,.2f; %s: %,.2f",
56             super.toString(), "hourly wage", getWage(),
57             "hours worked", getHours() );
58     } // end method toString
59 } // end class HourlyEmployee

```

Fig. 10.6 | HourlyEmployee class derived from Employee. (Part 2 of 2.)

(lines 31–35) ensures that `hours` is between 0 and 168 (the total number of hours in a week) inclusive. Class `HourlyEmployee` also includes `get` methods (lines 25–28 and 38–41) to return the values of `wage` and `hours`, respectively; a method `earnings` (lines 44–50) to calculate an `HourlyEmployee`'s earnings; and a method `toString` (lines 53–58), which returns the employee's type, namely, "hourly employee: " and `Employee`-specific information. Note that the `HourlyEmployee` constructor, like the `SalariedEmployee` constructor, passes the first name, last name and social security number to the superclass `Employee` constructor (line 13) to initialize the private instance variables. In addition, method `toString` calls superclass method `toString` (line 56) to obtain the `Employee`-specific information (i.e., first name, last name and social security number)—this is another nice example of code reuse.

10.5.4 Creating Concrete Subclass `CommissionEmployee`

Class `CommissionEmployee` (Fig. 10.7) extends class `Employee` (line 4). The class includes a constructor (lines 10–16) that takes a first name, a last name, a social security number, a sales amount and a commission rate; `set` methods (lines 19–22 and 31–34) to assign new values to instance variables `commissionRate` and `grossSales`, respectively; `get` methods (lines 25–28 and 37–40) that retrieve the values of these instance variables; method `earnings` (lines 43–46) to calculate a `CommissionEmployee`'s earnings; and method `toString` (lines 49–55), which returns the employee's type, namely, "commission employee: " and `Employee`-specific information. The constructor also passes the first name, last name and social security number to `Employee`'s constructor (line 13) to initialize `Employee`'s private instance variables. Method `toString` calls superclass method `toString` (line 52) to obtain the `Employee`-specific information (i.e., first name, last name and social security number).

```

45     return getCommissionRate() * getGrossSales();
46 } // end method earnings
47
48 // return String representation of CommissionEmployee object
49 public String toString()
50 {
51     return String.format( "%s: %s\n%s: $%,.2f; %s: %.2f",
52                         "commission employee", super.toString(),
53                         "gross sales", getGrossSales(),
54                         "commission rate", getCommissionRate() );
55 } // end method toString
56 } // end class CommissionEmployee

```

Fig. 10.7 | CommissionEmployee class derived from Employee. (Part 2 of 2.)

10.5.5 Creating Indirect Concrete Subclass BasePlusCommissionEmployee

Class `BasePlusCommissionEmployee` (Fig. 10.8) extends class `CommissionEmployee` (line 4) and therefore is an indirect subclass of class `Employee`. Class `BasePlusCommissionEmployee` has a constructor (lines 9–14) that takes as arguments a first name, a last name, a social security number, a sales amount, a commission rate and a base salary. It then passes

10.5 Case Study: Payroll System Using Polymorphism **489**

the first name, last name, social security number, sales amount and commission rate to the `CommissionEmployee` constructor (line 12) to initialize the inherited members. `BasePlusCommissionEmployee` also contains a `set` method (lines 17–20) to assign a new value to instance variable `baseSalary` and a `get` method (lines 23–26) to return `baseSalary`'s value. Method `earnings` (lines 29–32) calculates a `BasePlusCommissionEmployee`'s earnings. Note that line 31 in method `earnings` calls superclass `CommissionEmployee`'s `earnings` method to calculate the commission-based portion of the employee's earnings. This is a nice example of code reuse. `BasePlusCommissionEmployee`'s `toString` method (lines 35–40) creates a string representation of a `BasePlusCommissionEmployee` that contains "base-salaried", followed by the `String` obtained by invoking superclass `CommissionEmployee`'s `toString` method (another example of code reuse), then the base salary. The result is a `String` beginning with "base-salaried commission employee" followed by the rest of the `BasePlusCommissionEmployee`'s information. Recall that `CommissionEmployee`'s `toString` obtains the employee's first name, last name and social security number by invoking the `toString` method of its superclass (i.e., `Employee`)—yet another example of code reuse. Note that `BasePlusCommissionEmployee`'s `toString` initiates a chain of method calls that span all three levels of the `Employee` hierarchy.

```

10.5.6 Demonstrating Polymorphic Processing, Operator instanceof and Downcasting

To test our Employee hierarchy, the application in Fig. 10.9 creates an object of each of the four concrete classes SalariedEmployee, HourlyEmployee, CommissionEmployee and BasePlusCommissionEmployee. The program manipulates these objects, first via variables of each object's own type, then polymorphically, using an array of Employee variables. While processing the objects polymorphically, the program increases the base salary of each BasePlusCommissionEmployee by 10% (this, of course, requires determining the object's type at execution time). Finally, the program polymorphically determines and outputs the type of each object in the Employee array. Lines 9–18 create objects of each of the four concrete Employee subclasses. Lines 22–30 output the string representation and earnings of each of these objects. Note that each object's `toString` method is called implicitly by `printf` when the object is output as a `String` with the `%s` format specifier.

```

1 // Fig. 10.9: PayrollSystemTest.java
2 // Employee hierarchy test program.
3
4 public class PayrollSystemTest
5 {
6     public static void main( String args[] )
7     {
8         // create subclass objects
9         SalariedEmployee salariedEmployee =
10            new SalariedEmployee( "John", "Smith", "111-11-1111", 800.00 );
11         HourlyEmployee hourlyEmployee =
12            new HourlyEmployee( "Karen", "Price", "222-22-2222", 16.75, 40 );
13         CommissionEmployee commissionEmployee =
14            new CommissionEmployee(
15                "Sue", "Jones", "333-33-3333", 10000, .06 );
16         BasePlusCommissionEmployee basePlusCommissionEmployee =
17            new BasePlusCommissionEmployee(
18                "Bob", "Lewis", "444-44-4444", 5000, .04, 300 );
19

```

72 } // end class PayrollSystemTest

```

Fig. 10.9 | Employee class hierarchy test program. (Part 2 of 3.)

492 Chapter 10 Object-Oriented Programming: Polymorphism

```

Employees processed individually:

salaried employee: John Smith
social security number: 111-11-1111
weekly salary: $800.00
earned: $800.00

hourly employee: Karen Price
social security number: 222-22-2222
hourly wage: $16.75; hours worked: 40.00
earned: $670.00

commission employee: Sue Jones
social security number: 333-33-3333
gross sales: $10,000.00; commission rate: 0.06
earned: $600.00

base-salaried commission employee: Bob Lewis
social security number: 444-44-4444
gross sales: $5,000.00; commission rate: 0.04; base salary: $300.00
earned: $500.00

Employees processed polymorphically:

salaried employee: John Smith
social security number: 111-11-1111
weekly salary: $800.00
earned $800.00

hourly employee: Karen Price
social security number: 222-22-2222
hourly wage: $16.75; hours worked: 40.00
earned $670.00

commission employee: Sue Jones
social security number: 333-33-3333
gross sales: $10,000.00; commission rate: 0.06
earned $600.00

base-salaried commission employee: Bob Lewis
social security number: 444-44-4444
gross sales: $5,000.00; commission rate: 0.04; base salary: $300.00
new base salary with 10% increase is: $330.00
earned $530.00

Employee 0 is a SalariedEmployee
Employee 1 is a HourlyEmployee
Employee 2 is a CommissionEmployee
Employee 3 is a BasePlusCommissionEmployee

```

Fig. 10.9 | Employee class hierarchy test program. (Part 3 of 3.)

Line 33 declares `employees` and assigns it an array of four `Employee` variables. Line 36 assigns the reference to a `SalariedEmployee` object to `employees[0]`. Line 37 assigns the reference to an `HourlyEmployee` object to `employees[1]`. Line 38 assigns the reference to a `CommissionEmployee` object to `employees[2]`. Line 39 assigns the reference to a `BasePlusCommissionEmployee` object to `employee[3]`. Each assignment is allowed, because a `SalariedEmployee` is an `Employee`, an `HourlyEmployee` is an `Employee`, a `Com-`

10.5 Case Study: Payroll System Using Polymorphism 493

`missionEmployee` is an `Employee` and a `BasePlusCommissionEmployee` is an `Employee`. Therefore, we can assign the references of `SalariedEmployee`, `HourlyEmployee`, `CommissionEmployee` and `BasePlusCommissionEmployee` objects to superclass `Employee` variables, even though `Employee` is an abstract class.

Lines 44–65 iterate through array `employees` and invoke methods `toString` and `earnings` with `Employee` variable `currentEmployee`, which is assigned the reference to a different `Employee` in the array during each iteration. The output illustrates that the appropriate methods for each class are indeed invoked. All calls to method `toString` and `earnings` are resolved at execution time, based on the type of the object to which `currentEmployee` refers. This process is known as **dynamic binding** or **late binding**. For example, line 46 implicitly invokes method `toString` of the object to which `currentEmployee` refers. As a result of dynamic binding, Java decides which class's `toString` method to call at execution time rather than at compile time. Note that only the methods of class `Employee` can be called via an `Employee` variable (and `Employee`, of course, includes the methods of class `Object`). (Section 9.7 discusses the set of methods that all classes inherit from class `Object`.) A superclass reference can be used to invoke only methods of the superclass (and the superclass can invoke overridden versions of these in the subclass).

We perform special processing on `BasePlusCommissionEmployee` objects—as we encounter these objects, we increase their base salary by 10%. When processing objects polymorphically, we typically do not need to worry about the “specifics,” but to adjust the base salary, we do have to determine the specific type of `Employee` object at execution time. Line 49 uses the `instanceof` operator to determine whether a particular `Employee` object's type is `BasePlusCommissionEmployee`. The condition in line 49 is true if the object referenced by `currentEmployee` is a `BasePlusCommissionEmployee`. This would also be true for any object of a `BasePlusCommissionEmployee` subclass because of the *is-a* relationship a subclass has with its superclass. Lines 53–54 downcast `currentEmployee` from type `Employee` to type `BasePlusCommissionEmployee`—this cast is allowed only if the object has an *is-a* relationship with `BasePlusCommissionEmployee`. The condition at line 49 ensures that this is the case. This cast is required if we are to invoke subclass `BasePlusCommissionEmployee` methods `getBaseSalary` and `setBaseSalary` on the current `Employee` object—as you'll see momentarily, attempting to invoke a subclass-only method directly on a superclass reference is a compilation error.

Common Programming Error 10.3

Assigning a superclass variable to a subclass variable (without an explicit cast) is a compilation error.

Software Engineering Observation 10.5

If at execution time the reference of a subclass object has been assigned to a variable of one of its direct or indirect superclasses, it is acceptable to cast the reference stored in that superclass variable back to a reference of the subclass type. Before performing such a cast, use the `instanceof` operator to ensure that the object is indeed an object of an appropriate subclass type.

Common Programming Error 10.4

When downcasting an object, a `ClassCastException` occurs if at execution time the object does not have an *is-a* relationship with the type specified in the cast operator. An object can be cast only to its own type or to the type of one of its superclasses.

494 [Chapter 10 Object-Oriented Programming: Polymorphism](#)

If the `instanceof` expression in line 49 is `true`, the body of the `if` statement (lines 49–61) performs the special processing required for the `BasePlusCommissionEmployee` object. Using `BasePlusCommissionEmployee` variable `employee`, lines 56 and 57 invoke subclass-only methods `getBaseSalary` and `setBaseSalary` to retrieve and update the employee's base salary with the 10% raise.

Lines 63–64 invoke method `earnings` on `currentEmployee`, which calls the appropriate subclass object's `earnings` method polymorphically. As you can see, obtaining the earnings of the `SalariedEmployee`, `HourlyEmployee` and `CommissionEmployee` polymorphically in lines 63–64 produces the same result as obtaining these employees' earnings individually in lines 22–27. However, the earnings amount obtained for the `BasePlusCommissionEmployee` in lines 63–64 is higher than that obtained in lines 28–30, due to the 10% increase in its base salary.

Lines 68–70 display each employee's type as a string. Every object in Java knows its own class and can access this information through the `getClass` method, which all classes inherit from class `Object`. The `getClass` method returns an object of type `Class` (from package `java.lang`), which contains information about the object's type, including its class name. Line 70 invokes the `getClass` method on the object to get its runtime class (i.e., a `Class` object that represents the object's type). Then method `getName` is invoked on the object returned by `getClass` to get the class's name. To learn more about class `Class`, see its online documentation at java.sun.com/javase/6/docs/api/java/lang/Class.html.

In the previous example, we avoided several compilation errors by downcasting an `Employee` variable to a `BasePlusCommissionEmployee` variable in lines 53–54. If you remove the cast operator (`BasePlusCommissionEmployee`) from line 54 and attempt to assign `Employee` variable `currentEmployee` directly to `BasePlusCommissionEmployee` variable `employee`, you will receive an “incompatible types” compilation error. This error indicates that the attempt to assign the reference of superclass object `commissionEmployee` to subclass variable `basePlusCommissionEmployee` is not allowed. The compiler prevents this assignment because a `CommissionEmployee` is not a `BasePlusCommissionEmployee`—the *is-a* relationship applies only between the subclass and its superclasses, not vice versa.

Similarly, if lines 56, 57 and 60 used superclass variable `currentEmployee`, rather than subclass variable `employee`, to invoke subclass-only methods `getBaseSalary` and `setBaseSalary`, we would receive a “cannot find symbol” compilation error on each of these lines. Attempting to invoke subclass-only methods on a superclass reference is not allowed. While lines 56, 57 and 60 execute only if `instanceof` in line 49 returns `true` to indicate that `currentEmployee` has been assigned a reference to a `BasePlusCommissionEmployee` object, we cannot attempt to invoke subclass `BasePlusCommissionEmployee` methods `getBaseSalary` and `setBaseSalary` on superclass `Employee` reference `currentEmployee`. The compiler would generate errors in lines 56, 57 and 60, because `getBaseSalary` and `setBaseSalary` are not superclass methods and cannot be invoked on a superclass variable. Although the actual method that is called depends on the object's type at execution time, a variable can be used to invoke only those methods that are members of that variable's type, which the compiler verifies. Using a superclass `Employee` variable, we can invoke only methods found in class `Employee`—`earnings`, `toString` and `Employee`'s `get` and `set` methods.

10.5.7 Summary of the Allowed Assignments Between Superclass and Subclass Variables

Now that you have seen a complete application that processes diverse subclass objects polymorphically, we summarize what you can and cannot do with superclass and subclass objects and variables. Although a subclass object also *is a* superclass object, the two objects are nevertheless different. As discussed previously, subclass objects can be treated as if they are superclass objects. But because the subclass can have additional subclass-only members, assigning a superclass reference to a subclass variable is not allowed without an explicit cast—such an assignment would leave the subclass members undefined for the superclass object.

In the current section and in Section 10.3 and Chapter 9, we have discussed four ways to assign superclass and subclass references to variables of superclass and subclass types:

1. Assigning a superclass reference to a superclass variable is straightforward.
2. Assigning a subclass reference to a subclass variable is straightforward.
3. Assigning a subclass reference to a superclass variable is safe, because the subclass object *is an* object of its superclass. However, this reference can be used to refer only to superclass members. If this code refers to subclass-only members through the superclass variable, the compiler reports errors.
4. Attempting to assign a superclass reference to a subclass variable is a compilation error. To avoid this error, the superclass reference must be cast to a subclass type explicitly. At execution time, if the object to which the reference refers is not a subclass object, an exception will occur. (For more on exception handling, see Chapter 13, Exception Handling.) The `instanceof` operator can be used to ensure that such a cast is performed only if the object is a subclass object.

10.6 final Methods and Classes

We saw in Section 6.10 that variables can be declared `final` to indicate that they cannot be modified after they are initialized—such variables represent constant values. It is also possible to declare methods and classes with the `final` modifier.

A method that is declared `final` in a superclass cannot be overridden in a subclass. Methods that are declared `private` are implicitly `final`, because it is impossible to override them in a subclass. Methods that are declared `static` are also implicitly `final`. A `final` method's declaration can never change, so all subclasses use the same method implementation, and calls to `final` methods are resolved at compile time—this is known as **static binding**. Since the compiler knows that `final` methods cannot be overridden, it can optimize programs by removing calls to `final` methods and replacing them with the expanded code of their declarations at each method call location—a technique known as **inlining the code**.

Performance Tip 10.1

The compiler can decide to inline a final method call and will do so for small, simple final methods. Inlining does not violate encapsulation or information hiding, but does improve performance because it eliminates the overhead of making a method call.

496 Chapter 10 Object-Oriented Programming: Polymorphism

A class that is declared `final` cannot be a superclass (i.e., a class cannot extend a `final` class). All methods in a `final` class are implicitly `final`. Class `String` is an example of a `final` class. This class cannot be extended, so programs that use `Strings` can rely on the functionality of `String` objects as specified in the Java API. Making the class `final` also prevents programmers from creating subclasses that might bypass security restrictions. For more information on `final` classes and methods, visit java.sun.com/docs/books/tutorial/java/IandI/final.html. This site contains additional insights into using `final` classes to improve the security of a system.

Common Programming Error 10.5

Attempting to declare a subclass of a `final` class is a compilation error.

Software Engineering Observation 10.6

In the Java API, the vast majority of classes are not declared `final`. This enables inheritance and polymorphism—the fundamental capabilities of object-oriented programming. However, in some cases, it is important to declare classes `final`—typically for security reasons.

10.7 Case Study: Creating and Using Interfaces

Our next example (Figs. 10.11–10.13) reexamines the payroll system of Section 10.5. Suppose that the company involved wishes to perform several accounting operations in a single accounts payable application—in addition to calculating the earnings that must be paid to each employee, the company must also calculate the payment due on each of several invoices (i.e., bills for goods purchased). Though applied to unrelated things (i.e., employees and invoices), both operations have to do with obtaining some kind of payment amount. For an employee, the payment refers to the employee's earnings. For an invoice, the payment refers to the total cost of the goods listed on the invoice. Can we calculate such different things as the payments due for employees and invoices in a single application polymorphically? Does Java offer a capability that requires that unrelated classes implement a set of common methods (e.g., a method that calculates a payment amount)? Java `interfaces` offer exactly this capability.

Interfaces define and standardize the ways in which things such as people and systems can interact with one another. For example, the controls on a radio serve as an interface between radio users and a radio's internal components. The controls allow users to perform only a limited set of operations (e.g., changing the station, adjusting the volume, choosing between AM and FM), and different radios may implement the controls in different ways (e.g., using push buttons, dials, voice commands). The interface specifies *what* operations a radio must permit users to perform but does not specify *how* the operations are performed. Similarly, the interface between a driver and a car with a manual transmission includes the steering wheel, the gear shift, the clutch pedal, the gas pedal and the brake pedal. This same interface is found in nearly all manual transmission cars, enabling someone who knows how to drive one particular manual transmission car to drive just about any manual transmission car. The components of each individual car may look different, but their general purpose is the same—to allow people to drive the car.

Software objects also communicate via interfaces. A Java interface describes a set of methods that can be called on an object, to tell the object to perform some task or return

10.7 Case Study: Creating and Using Interfaces 497

some piece of information, for example. The next example introduces an interface named `Payable` to describe the functionality of any object that must be capable of being paid and thus must offer a method to determine the proper payment amount due. An [interface declaration](#) begins with the keyword `interface` and contains only constants and abstract methods. Unlike classes, all interface members must be `public`, and interfaces may not specify any implementation details, such as concrete method declarations and instance variables. So all methods declared in an interface are implicitly `public abstract` methods and all fields are implicitly `public static final`.

Good Programming Practice 10.1

According to Chapter 9 of the Java Language Specification, it is proper style to declare an interface's methods without keywords `public` and `abstract` because they are redundant in interface method declarations. Similarly, constants should be declared without keywords `public`, `static` and `final` because they, too, are redundant.

To use an interface, a concrete class must specify that it [implements](#) the interface and must declare each method in the interface with the signature specified in the interface declaration. A class that does not implement all the methods of the interface is an abstract class and must be declared `abstract`. Implementing an interface is like signing a contract with the compiler that states, “I will declare all the methods specified by the interface or I will declare my class `abstract`.”

Common Programming Error 10.6

Failing to implement any method of an interface in a concrete class that implements the interface results in a compilation error indicating that the class must be declared `abstract`.

An interface is typically used when disparate (i.e., unrelated) classes need to share common methods and constants. This allows objects of unrelated classes to be processed polymorphically—objects of classes that implement the same interface can respond to the same method calls. You can create an interface that describes the desired functionality, then implement this interface in any classes that require that functionality. For example, in the accounts payable application developed in this section, we implement interface `Payable` in any class that must be able to calculate a payment amount (e.g., `Employee`, `Invoice`).

An interface is often used in place of an `abstract` class when there is no default implementation to inherit—that is, no fields and no default method implementations. Like `public abstract` classes, interfaces are typically `public` types, so they are normally declared in files by themselves with the same name as the interface and the `.java` file-name extension.

10.7.1 Developing a Payable Hierarchy

To build an application that can determine payments for employees and invoices alike, we first create interface `Payable`, which contains method `getPaymentAmount` that returns a `double` amount that must be paid for an object of any class that implements the interface. Method `getPaymentAmount` is a general purpose version of method `earnings` of the `Employee` hierarchy—method `earnings` calculates a payment amount specifically for an `Employee`, while `getPaymentAmount` can be applied to a broad range of unrelated objects. After declaring interface `Payable`, we introduce class `Invoice`, which [implements](#) interface `Payable`. We then modify class `Employee` such that it also implements interface `Payable`.

498 Chapter 10 Object-Oriented Programming: Polymorphism

able. Finally, we update Employee subclass SalariedEmployee to “fit” into the Payable hierarchy (i.e., we rename SalariedEmployee method `earnings` as `getPaymentAmount`).

Good Programming Practice 10.2

When declaring a method in an interface, choose a method name that describes the method's purpose in a general manner, because the method may be implemented by many unrelated classes.

Classes `Invoice` and `Employee` both represent things for which the company must be able to calculate a payment amount. Both classes implement `Payable`, so a program can invoke method `getPaymentAmount` on `Invoice` objects and `Employee` objects alike. As we will soon see, this enables the polymorphic processing of `Invoices` and `Employees` required for our company’s accounts payable application.

The UML class diagram in Fig. 10.10 shows the hierarchy used in our accounts payable application. The hierarchy begins with interface `Payable`. The UML distinguishes an interface from other classes by placing the word “interface” in guillemets (« and ») above the interface name. The UML expresses the relationship between a class and an interface through a relationship known as a **realization**. A class is said to “realize,” or implement, the methods of an interface. A class diagram models a realization as a dashed arrow with a hollow arrowhead pointing from the implementing class to the interface. The diagram in Fig. 10.10 indicates that classes `Invoice` and `Employee` each realize (i.e., implement) interface `Payable`. Note that, as in the class diagram of Fig. 10.2, class `Employee` appears in italics, indicating that it is an abstract class. Concrete class `SalariedEmployee` extends `Employee` and inherits its superclass’s realization relationship with interface `Payable`.

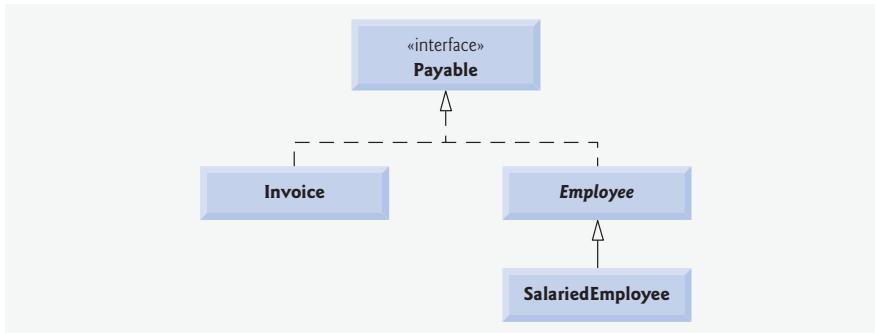

Fig. 10.10 | Payable interface hierarchy UML class diagram.

10.7.2 Declaring Interface Payable

The declaration of interface `Payable` begins in Fig. 10.11 at line 4. Interface `Payable` contains `public abstract` method `getPaymentAmount` (line 6). Note that the method is not explicitly declared `public` or `abstract`. Interface methods must be `public` and `abstract`, so they do not need to be declared as such. Interface `Payable` has only one method—interfaces can have any number of methods. (We will see later in the book the notion of “tagging interfaces”—these actually have *no* methods. In fact, a tagging interface contains no constant values, either—it simply contains an empty interface declaration.) In addition, method `getPaymentAmount` has no parameters, but interface methods can have parameters.

10.7 Case Study: Creating and Using Interfaces **499**

```

1 // Fig. 10.11: Payable.java
2 // Payable interface declaration.
3
4 public interface Payable
5 {
6     double getPaymentAmount(); // calculate payment; no implementation
7 } // end interface Payable

```

Fig. 10.11 | Payable interface declaration.**10.7.3 Creating Class Invoice**

We now create class `Invoice` (Fig. 10.12) to represent a simple invoice that contains billing information for only one kind of part. The class declares private instance variables `partNumber`, `partDescription`, `quantity` and `pricePerItem` (in lines 6–9) that indicate the part number, a description of the part, the quantity of the part ordered and the price per item. Class `Invoice` also contains a constructor (lines 12–19), `get` and `set` methods (lines 22–67) that manipulate the class's instance variables and a `toString` method (lines 70–75) that returns a string representation of an `Invoice` object. Note that methods `setQuantity` (lines 46–49) and `setPricePerItem` (lines 58–61) ensure that `quantity` and `pricePerItem` obtain only nonnegative values.

Line 4 of Fig. 10.12 indicates that class `Invoice` implements interface `Payable`. Like all classes, class `Invoice` also implicitly extends `Object`. Java does not allow subclasses to inherit from more than one superclass, but it does allow a class to inherit from a superclass and implement more than one interface. In fact, a class can implement as many interfaces as it needs, in addition to extending one other class. To implement more than one interface, use a comma-separated list of interface names after keyword `implements` in the class declaration, as in:

```
public class ClassName extends SuperclassName implements FirstInterface,
    SecondInterface, ...
```

All objects of a class that implement multiple interfaces have the *is-a* relationship with each implemented interface type.

```

1 // Fig. 10.12: Invoice.java
2 // Invoice class implements Payable.
3
4 public class Invoice implements Payable
5 {
6     private String partNumber;
7     private String partDescription;
8     private int quantity;
9     private double pricePerItem;
10
11    // four-argument constructor
12    public Invoice( String part, String description, int count,
13                    double price )
14    {

```

Fig. 10.12 | `Invoice` class that implements `Payable`. (Part I of 3.)

500 Chapter 10 Object-Oriented Programming: Polymorphism

```

15     partNumber = part;
16     partDescription = description;
17     setQuantity( count ); // validate and store quantity
18     setPricePerItem( price ); // validate and store price per item
19 } // end four-argument Invoice constructor
20
21 // set part number
22 public void setPartNumber( String part )
23 {
24     partNumber = part;
25 } // end method setPartNumber
26
27 // get part number
28 public String getPartNumber()
29 {
30     return partNumber;
31 } // end method getPartNumber
32
33 // set description
34 public void setPartDescription( String description )
35 {
36     partDescription = description;
37 } // end method setPartDescription
38
39 // get description
40 public String getPartDescription()
41 {
42     return partDescription;
43 } // end method getPartDescription
44
45 // set quantity
46 public void setQuantity( int count )
47 {
48     quantity = ( count < 0 ) ? 0 : count; // quantity cannot be negative
49 } // end method setQuantity
50
51 // get quantity
52 public int getQuantity()
53 {
54     return quantity;
55 } // end method getQuantity
56
57 // set price per item
58 public void setPricePerItem( double price )
59 {
60     pricePerItem = ( price < 0.0 ) ? 0.0 : price; // validate price
61 } // end method setPricePerItem
62
63 // get price per item
64 public double getPricePerItem()
65 {
66     return pricePerItem;
67 } // end method getPricePerItem

```

Fig. 10.12 | Invoice class that implements Payable. (Part 2 of 3.)

10.7 Case Study: Creating and Using Interfaces **501**

```

68 // return String representation of Invoice object
69 public String toString()
70 {
71     return String.format( "%s: \n%s: %s (%s) \n%s: %d \n%s: $%,.2f",
72         "invoice", "part number", getPartNumber(), getPartDescription(),
73         "quantity", getQuantity(), "price per item", getPricePerItem() );
74 } // end method toString
75
76 // method required to carry out contract with interface Payable
77 public double getPaymentAmount()
78 {
79     return getQuantity() * getPricePerItem(); // calculate total cost
80 } // end method getPaymentAmount
81 } // end class Invoice
82 }
```

Fig. 10.12 | Invoice class that implements Payable. (Part 3 of 3.)

Class `Invoice` implements the one method in interface `Payable`. Method `getPaymentAmount` is declared in lines 78–81. The method calculates the total payment required to pay the invoice. The method multiplies the values of `quantity` and `pricePerItem` (obtained through the appropriate `get` methods) and returns the result (line 80). This method satisfies the implementation requirement for this method in interface `Payable`—we have fulfilled the interface contract with the compiler.

10.7.4 Modifying Class Employee to Implement Interface Payable

We now modify class `Employee` such that it implements interface `Payable`. Figure 10.13 contains the modified `Employee` class. This class declaration is identical to that of Fig. 10.4 with only two exceptions. First, line 4 of Fig. 10.13 indicates that class `Employee` now implements interface `Payable`. Second, since `Employee` now implements interface `Payable`, we must rename `earnings` to `getPaymentAmount` throughout the `Employee` hierarchy. As with method `earnings` in the version of class `Employee` in Fig. 10.4, however, it does not make sense to implement method `getPaymentAmount` in class `Employee` because we cannot calculate the earnings payment owed to a general `Employee`—first we must know the specific type of `Employee`. In Fig. 10.4, we declared method `earnings` as `abstract` for this reason, and as a result class `Employee` had to be declared `abstract`. This forced each `Employee` subclass to override `earnings` with a concrete implementation.

```

1 // Fig. 10.13: Employee.java
2 // Employee abstract superclass implements Payable.
3
4 public abstract class Employee implements Payable
5 {
6     private String firstName;
7     private String lastName;
8     private String socialSecurityNumber;
9
10    // three-argument constructor
```

Fig. 10.13 | Employee class that implements Payable. (Part 1 of 2.)

502 Chapter 10 Object-Oriented Programming: Polymorphism

```

11  public Employee( String first, String last, String ssn )
12  {
13      firstName = first;
14      lastName = last;
15      socialSecurityNumber = ssn;
16  } // end three-argument Employee constructor
17
18  // set first name
19  public void setFirstName( String first )
20  {
21      firstName = first;
22  } // end method setFirstName
23
24  // return first name
25  public String getFirstName()
26  {
27      return firstName;
28  } // end method getFirstName
29
30  // set last name
31  public void setLastName( String last )
32  {
33      lastName = last;
34  } // end method setLastName
35
36  // return last name
37  public String getLastname()
38  {
39      return lastName;
40  } // end method getLastname
41
42  // set social security number
43  public void setSocialSecurityNumber( String ssn )
44  {
45      socialSecurityNumber = ssn; // should validate
46  } // end method setSocialSecurityNumber
47
48  // return social security number
49  public String getSocialSecurityNumber()
50  {
51      return socialSecurityNumber;
52  } // end method getSocialSecurityNumber
53
54  // return String representation of Employee object
55  public String toString()
56  {
57      return String.format( "%s %s\nsocial security number: %s",
58          getFirstName(), getLastname(), getSocialSecurityNumber() );
59  } // end method toString
60
61  // Note: We do not implement Payable method getPaymentAmount here so
62  // this class must be declared abstract to avoid a compilation error.
63 } // end abstract class Employee

```

Fig. 10.13 | Employee class that implements Payable. (Part 2 of 2.)

10.7 Case Study: Creating and Using Interfaces **503**

In Fig. 10.13, we handle this situation differently. Recall that when a class implements an interface, the class makes a contract with the compiler stating either that the class will implement each of the methods in the interface or that the class will be declared `abstract`. If the latter option is chosen, we do not need to declare the interface methods as `abstract` in the abstract class—they are already implicitly declared as such in the interface. Any concrete subclass of the abstract class must implement the interface methods to fulfill the superclass's contract with the compiler. If the subclass does not do so, it too must be declared `abstract`. As indicated by the comments in lines 61–62, class `Employee` of Fig. 10.13 does not implement method `getPaymentAmount`, so the class is declared `abstract`. Each direct `Employee` subclass inherits the superclass's contract to implement method `getPaymentAmount` and thus must implement this method to become a concrete class for which objects can be instantiated. A class that extends one of `Employee`'s concrete subclasses will inherit an implementation of `getPaymentAmount` and thus will also be a concrete class.

10.7.5 Modifying Class `SalariedEmployee` for Use in the `Payable` Hierarchy

Figure 10.14 contains a modified version of class `SalariedEmployee` that extends `Employee` and fulfills superclass `Employee`'s contract to implement method `getPaymentAmount` of interface `Payable`. This version of `SalariedEmployee` is identical to that of Fig. 10.5 with the exception that the version here implements method `getPaymentAmount` (lines 30–33) instead of method `earnings`. The two methods contain the same functionality but have different names. Recall that the `Payable` version of the method has a more general name to be applicable to possibly disparate classes. The remaining `Employee` subclasses (e.g., `HourlyEmployee`, `CommissionEmployee` and `BasePlusCommissionEmployee`) also must be modified to contain method `getPaymentAmount` in place of `earnings` to reflect the fact that `Employee` now implements `Payable`. We leave these modifications as an exercise and use only `SalariedEmployee` in our test program in this section.

```

1 // Fig. 10.14: SalariedEmployee.java
2 // SalariedEmployee class extends Employee, which implements Payable.
3
4 public class SalariedEmployee extends Employee
5 {
6     private double weeklySalary;
7
8     // four-argument constructor
9     public SalariedEmployee( String first, String last, String ssn,
10         double salary )
11    {
12        super( first, last, ssn ); // pass to Employee constructor
13        setWeeklySalary( salary ); // validate and store salary
14    } // end four-argument SalariedEmployee constructor
15
16    // set salary
17    public void setWeeklySalary( double salary )
18    {

```

Fig. 10.14 | `SalariedEmployee` class that implements interface `Payable` method `getPaymentAmount`. (Part I of 2.)

504 Chapter 10 Object-Oriented Programming: Polymorphism

```

19     weeklySalary = salary < 0.0 ? 0.0 : salary;
20 } // end method setWeeklySalary
21
22 // return salary
23 public double getWeeklySalary()
24 {
25     return weeklySalary;
26 } // end method getWeeklySalary
27
28 // calculate earnings; implement interface Payable method that was
29 // abstract in superclass Employee
30 public double getPaymentAmount()
31 {
32     return getWeeklySalary();
33 } // end method getPaymentAmount
34
35 // return String representation of SalariedEmployee object
36 public String toString()
37 {
38     return String.format("salaried employee: %s\n%s: $%,.2f",
39             super.toString(), "weekly salary", getWeeklySalary());
40 } // end method toString
41 } // end class SalariedEmployee

```

Fig. 10.14 | SalariedEmployee class that implements interface Payable method getPaymentAmount. (Part 2 of 2.)

When a class implements an interface, the same *is-a* relationship provided by inheritance applies. For example, class `Employee` implements `Payable`, so we can say that an `Employee` is *a* `Payable`. In fact, objects of any classes that extend `Employee` are also `Payable` objects. `SalariedEmployee` objects, for instance, are `Payable` objects. As with inheritance relationships, an object of a class that implements an interface may be thought of as an object of the interface type. Objects of any subclasses of the class that implements the interface can also be thought of as objects of the interface type. Thus, just as we can assign the reference of a `SalariedEmployee` object to a superclass `Employee` variable, we can assign the reference of a `SalariedEmployee` object to an interface `Payable` variable. `Invoice` implements `Payable`, so an `Invoice` object also is *a* `Payable` object, and we can assign the reference of an `Invoice` object to a `Payable` variable.

Software Engineering Observation 10.7

Inheritance and interfaces are similar in their implementation of the is-a relationship. An object of a class that implements an interface may be thought of as an object of that interface type. An object of any subclasses of a class that implements an interface also can be thought of as an object of the interface type.

Software Engineering Observation 10.8

The is-a relationship that exists between superclasses and subclasses, and between interfaces and the classes that implement them, holds when passing an object to a method. When a method parameter receives a variable of a superclass or interface type, the method processes the object received as an argument polymorphically.

10.7 Case Study: Creating and Using Interfaces **505****Software Engineering Observation 10.9**

Using a superclass reference, we can polymorphically invoke any method specified in the superclass declaration (and in class Object). Using an interface reference, we can polymorphically invoke any method specified in the interface declaration (and in class Object—because a variable of an interface type must refer to an object to call methods, and all objects contain the methods of class Object).

10.7.6 Using Interface Payable to Process Invoices and Employees Polymorphically

PayableInterfaceTest (Fig. 10.15) illustrates that interface `Payable` can be used to process a set of `Invoices` and `Employees` polymorphically in a single application. Line 9 declares `payableObjects` and assigns it an array of four `Payable` variables. Lines 12–13 assign the references of `Invoice` objects to the first two elements of `payableObjects`. Lines 14–17 then assign the references of `SalariedEmployee` objects to the remaining two elements of `payableObjects`. These assignments are allowed because an `Invoice` is a `Payable`, a `SalariedEmployee` is an `Employee` and an `Employee` is a `Payable`. Lines 23–29 use the enhanced for statement to polymorphically process each `Payable` object in `payableObjects`, printing the object as a `String`, along with the payment amount due. Note that line 27 invokes method `toString` off a `Payable` interface reference, even though `toString` is not declared in interface `Payable`—all references (including those of interface types) refer to objects that extend `Object` and therefore have a `toString` method. (Note that `toString` also can be invoked implicitly here.) Line 28 invokes `Payable` method `getPaymentAmount` to obtain the payment amount for each object in `payableObjects`, regardless of the actual type of the object. The output reveals that the method calls in lines 27–28 invoke the appropriate class's implementation of methods `toString` and `getPaymentAmount`. For instance, when `currentEmployee` refers to an `Invoice` during the first iteration of the for loop, class `Invoice`'s `toString` and `getPaymentAmount` execute.

```

1 // Fig. 10.15: PayableInterfaceTest.java
2 // Tests interface Payable.
3
4 public class PayableInterfaceTest
5 {
6     public static void main( String args[] )
7     {
8         // create four-element Payable array
9         Payable payableObjects[] = new Payable[ 4 ];
10
11        // populate array with objects that implement Payable
12        payableObjects[ 0 ] = new Invoice( "01234", "seat", 2, 375.00 );
13        payableObjects[ 1 ] = new Invoice( "56789", "tire", 4, 79.95 );
14        payableObjects[ 2 ] =
15            new SalariedEmployee( "John", "Smith", "111-11-1111", 800.00 );
16        payableObjects[ 3 ] =
17            new SalariedEmployee( "Lisa", "Barnes", "888-88-8888", 1200.00 );

```

Fig. 10.15 | Payable interface test program processing `Invoices` and `Employees` polymorphically. (Part 1 of 2.)

506 Chapter 10 Object-Oriented Programming: Polymorphism

```

18     System.out.println(
19         "Invoices and Employees processed polymorphically:\n");
20
21     // generically process each element in array payableObjects
22     for ( Payable currentPayable : payableObjects )
23     {
24         // output currentPayable and its appropriate payment amount
25         System.out.printf( "%s \n%: $%,.2f\n\n",
26             currentPayable.toString(),
27             "payment due", currentPayable.getPaymentAmount() );
28     } // end for
29 } // end main
30 } // end class PayableInterfaceTest

```

Invoices and Employees processed polymorphically:

```

invoice:
part number: 01234 (seat)
quantity: 2
price per item: $375.00
payment due: $750.00

invoice:
part number: 56789 (tire)
quantity: 4
price per item: $79.95
payment due: $319.80

salaried employee: John Smith
social security number: 111-11-1111
weekly salary: $800.00
payment due: $800.00

salaried employee: Lisa Barnes
social security number: 888-88-8888
weekly salary: $1,200.00
payment due: $1,200.00

```

Fig. 10.15 | Payable interface test program processing Invoices and Employees polymorphically. (Part 2 of 2.)

Software Engineering Observation 10.10

All methods of class `Object` can be called by using a reference of an interface type. A reference refers to an object, and all objects inherit the methods of class `Object`.

10.7.7 Declaring Constants with Interfaces

As we mentioned in Section 10.7, an interface can declare constants. The constants are implicitly `public`, `static` and `final`—again, these keywords are not required in the interface declaration. One popular use of an interface is to declare a set of constants that can be used in many class declarations. Consider interface `Constants`:

10.7 Case Study: Creating and Using Interfaces **507**

```
public interface Constants
{
    int ONE = 1;
    int TWO = 2;
    int THREE = 3;
}
```

A class can use these constants by importing the interface, then referring to each constant as `Constants.ONE`, `Constants.TWO` and `Constants.THREE`. Note that a class can refer to the imported constants with just their names (i.e., `ONE`, `TWO` and `THREE`) if it uses a `static import` declaration (presented in Section 8.12) to import the interface.

**Software Engineering Observation 10.11**

As of Java SE 5.0, it became a better programming practice to create sets of constants as enumerations with keyword enum. See Section 6.10 for an introduction to enum and Section 8.9 for additional enum details.

10.7.8 Common Interfaces of the Java API

In this section, we overview several common interfaces found in the Java API. The power and flexibility of interfaces is used frequently throughout the Java API. These interfaces are implemented and used in the same manner as the interfaces you create (e.g., interface `Payable` in Section 10.7.2). As you'll see throughout this book, the Java API's interfaces enable you to use your own classes within the frameworks provided by Java, such as comparing objects of your own types and creating tasks that can execute concurrently with other tasks in the same program. Figure 10.16 presents a brief overview of a few of the more popular interfaces of the Java API that we use in *Java How to Program, Seventh Edition*.

Interface	Description
<code>Comparable</code>	As you learned in Chapter 2, Java contains several comparison operators (e.g., <code><</code> , <code><=</code> , <code>></code> , <code>>=</code> , <code>==</code> , <code>!=</code>) that allow you to compare primitive values. However, these operators cannot be used to compare the contents of objects. Interface <code>Comparable</code> is used to allow objects of a class that implements the interface to be compared to one another. The interface contains one method, <code>compareTo</code> , that compares the object that calls the method to the object passed as an argument to the method. Classes must implement <code>compareTo</code> such that it returns a value indicating whether the object on which it is invoked is less than (negative integer return value), equal to (0 return value) or greater than (positive integer return value) the object passed as an argument, using any criteria specified by the programmer. For example, if class <code>Employee</code> implements <code>Comparable</code> , its <code>compareTo</code> method could compare <code>Employee</code> objects by their earnings amounts. Interface <code>Comparable</code> is commonly used for ordering objects in a collection such as an array. We use <code>Comparable</code> in Chapter 18, Generics, and Chapter 19, Collections.

Fig. 10.16 | Common interfaces of the Java API. (Part 1 of 2.)

508 Chapter 10 Object-Oriented Programming: Polymorphism

Interface	Description
Serializable	An interface used to identify classes whose objects can be written to (i.e., serialized) or read from (i.e., deserialized) some type of storage (e.g., file on disk, database field) or transmitted across a network. We use <code>Serializable</code> in Chapter 14, Files and Streams, and Chapter 24, Networking.
Runnable	Implemented by any class for which objects of that class should be able to execute in parallel using a technique called multithreading (discussed in Chapter 23, Multithreading). The interface contains one method, <code>run</code> , which describes the behavior of an object when executed.
GUI event-listener interfaces	You work with graphical user interfaces (GUIs) every day. For example, in your web browser, you might type in a text field the address of a website to visit, or you might click a button to return to the previous site you visited. When you type a website address or click a button in the web browser, the browser must respond to your interaction and perform the desired task for you. Your interaction is known as an event, and the code that the browser uses to respond to an event is known as an event handler. In Chapter 11, GUI Components: Part 1, and Chapter 22, GUI Components: Part 2, you will learn how to build Java GUIs and how to build event handlers to respond to user interactions. The event handlers are declared in classes that implement an appropriate event-listener interface. Each event-listener interface specifies one or more methods that must be implemented to respond to user interactions.
SwingConstants	Contains a set of constants used in GUI programming to position GUI elements on the screen. We explore GUI programming in Chapters 11 and 22.

Fig. 10.16 | Common interfaces of the Java API. (Part 2 of 2.)

10.8 (Optional) GUI and Graphics Case Study: Drawing with Polymorphism

You may have noticed in the drawing program created in Exercise 8.1 (and modified in Exercise 9.1) that there are many similarities between the shape classes. Using inheritance, we can “factor out” the common features from all three classes and place them in a single shape superclass. We can then manipulate objects of all three shape types polymorphically using variables of the superclass type. Removing the redundancy in the code will result in a smaller, more flexible program that is easier to maintain.

GUI and Graphics Case Study Exercises

10.1 Modify the `MyLine`, `MyOval` and `MyRectangle` classes of Exercise 8.1 and Exercise 9.1 to create the class hierarchy in Fig. 10.17. Classes of the `MyShape` hierarchy should be “smart” shape classes that know how to draw themselves (if provided with a `Graphics` object that tells them where to draw). Once the program creates an object from this hierarchy, it can manipulate it polymorphically for the rest of its lifetime as a `MyShape`.

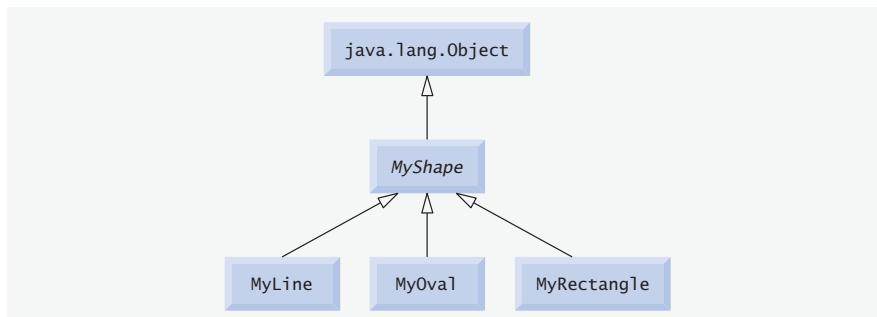

10.8 (Optional) GUI and Graphics Case Study: Drawing with Polymorphism **509**

Fig. 10.17 | MyShape hierarchy.

In your solution, class `MyShape` in Fig. 10.17 *must* be abstract. Since `MyShape` represents any shape in general, you cannot implement a `draw` method without knowing exactly what shape it is. The data representing the coordinates and color of the shapes in the hierarchy should be declared as `private` members of class `MyShape`. In addition to the common data, class `MyShape` should declare the following methods:

- A no-argument constructor that sets all the coordinates of the shape to 0 and the color to `Color.BLACK`.
- A constructor that initializes the coordinates and color to the values of the arguments supplied.
- Set* methods for the individual coordinates and color that allow the programmer to set any piece of data independently for a shape in the hierarchy.
- Get* methods for the individual coordinates and color that allow the programmer to retrieve any piece of data independently for a shape in the hierarchy.
- The `abstract` method

```
public abstract void draw( Graphics g );
```

which will be called from the program's `paintComponent` method to draw a shape on the screen.

To ensure proper encapsulation, all data in class `MyShape` must be `private`. This requires declaring proper *set* and *get* methods to manipulate the data. Class `MyLine` should provide a no-argument constructor and a constructor with arguments for the coordinates and color. Classes `MyOval` and `MyRect` should provide a no-argument constructor and a constructor with arguments for the coordinates, color and determining whether the shape is filled. The no-argument constructor should, in addition to setting the default values, set the shape to be an unfilled shape.

You can draw lines, rectangles and ovals if you know two points in space. Lines require `x1`, `y1`, `x2` and `y2` coordinates. The `drawLine` method of the `Graphics` class will connect the two points supplied with a line. If you have the same four coordinate values (`x1`, `y1`, `x2` and `y2`) for ovals and rectangles, you can calculate the four arguments needed to draw them. Each requires an upper-left *x*-coordinate value (the smaller of the two *x*-coordinate values), an upper-left *y*-coordinate value (the smaller of the two *y*-coordinate values), a *width* (the absolute value of the difference between the two *x*-coordinate values) and a *height* (the absolute value of the difference between the two *y*-coordinate values). Rectangles and ovals should also have a *filled* flag that determines whether to draw the shape as a filled shape.

There should be no `MyLine`, `MyOval` or `MyRectangle` variables in the program—only `MyShape` variables that contain references to `MyLine`, `MyOval` and `MyRectangle` objects. The program should generate random shapes and store them in an array of type `MyShape`. Method `paintComponent`

510 Chapter 10 Object-Oriented Programming: Polymorphism

should walk through the `MyShape` array and draw every shape (i.e., polymorphically calling every shape's `draw` method).

Allow the user to specify (via an input dialog) the number of shapes to generate. The program will then generate and display the shapes along with a status bar that informs the user how many of each shape were created.

10.2 (Drawing Application Modification) In Exercise 10.1, you created a `MyShape` hierarchy in which classes `MyLine`, `MyOval` and `MyRectangle` extend `MyShape` directly. If your hierarchy was properly designed, you should be able to see the similarities between the `MyOval` and `MyRectangle` classes. Redesign and reimplement the code for the `MyOval` and `MyRectangle` classes to “factor out” the common features into the abstract class `MyBoundedShape` to produce the hierarchy in Fig. 10.18.

Class `MyBoundedShape` should declare two constructors that mimic those of class `MyShape`, only with an added parameter to set whether the shape is filled. Class `MyBoundedShape` should also declare `get` and `set` methods for manipulating the filled flag and methods that calculate the upper-left *x*-coordinate, upper-left *y*-coordinate, width and height. Remember, the values needed to draw an oval or a rectangle can be calculated from two (*x*, *y*) coordinates. If designed properly, the new `MyOval` and `MyRectangle` classes should each have two constructors and a `draw` method.

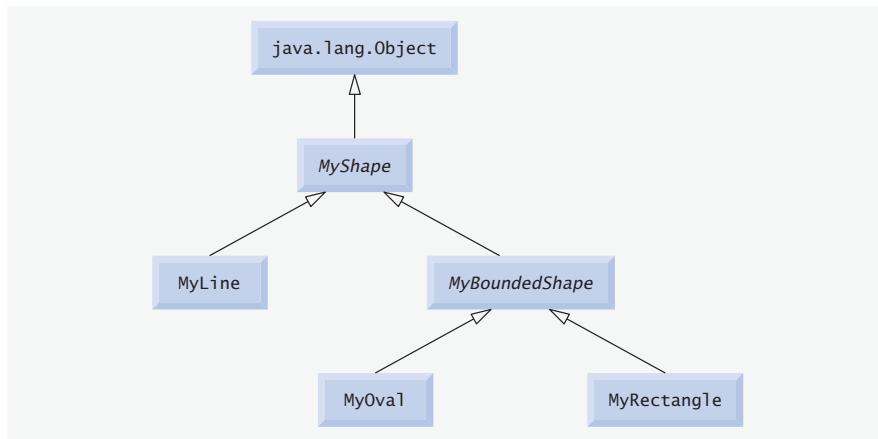

Fig. 10.18 | `MyShape` hierarchy with `MyBoundedShape`.

10.9 (Optional) Software Engineering Case Study: Incorporating Inheritance into the ATM System

We now revisit our ATM system design to see how it might benefit from inheritance. To apply inheritance, we first look for commonality among classes in the system. We create an inheritance hierarchy to model similar (yet not identical) classes in a more elegant and efficient manner. We then modify our class diagram to incorporate the new inheritance relationships. Finally, we demonstrate how our updated design is translated into Java code.

In Section 3.10, we encountered the problem of representing a financial transaction in the system. Rather than create one class to represent all transaction types, we decided to create three individual transaction classes—`BalanceInquiry`, `Withdrawal` and `Deposit`—to represent the transactions that the ATM system can perform. Figure 10.19 shows the attributes and operations of classes `BalanceInquiry`, `Withdrawal` and `Deposit`. Note that

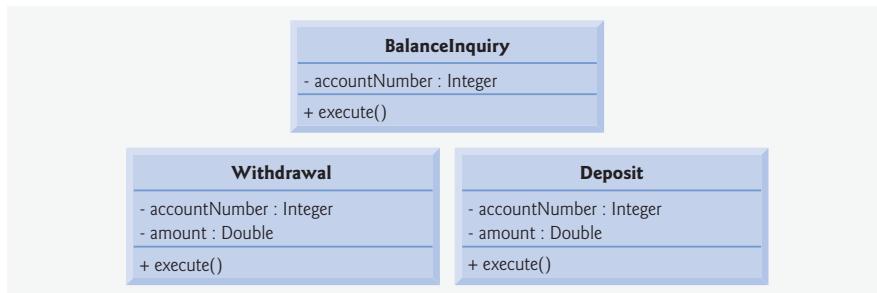

10.9 Incorporating Inheritance into the ATM System **511**

Fig. 10.19 | Attributes and operations of classes `BalanceInquiry`, `Withdrawal` and `Deposit`.

these classes have one attribute (`accountNumber`) and one operation (`execute`) in common. Each class requires attribute `accountNumber` to specify the account to which the transaction applies. Each class contains operation `execute`, which the ATM invokes to perform the transaction. Clearly, `BalanceInquiry`, `Withdrawal` and `Deposit` represent *types of transactions*. Figure 10.19 reveals commonality among the transaction classes, so using inheritance to factor out the common features seems appropriate for designing classes `BalanceInquiry`, `Withdrawal` and `Deposit`. We place the common functionality in a superclass, `Transaction`, that classes `BalanceInquiry`, `Withdrawal` and `Deposit` extend.

The UML specifies a relationship called a **generalization** to model inheritance. Figure 10.20 is the class diagram that models the generalization of superclass `Transaction` and subclasses `BalanceInquiry`, `Withdrawal` and `Deposit`. The arrows with triangular hollow arrowheads indicate that classes `BalanceInquiry`, `Withdrawal` and `Deposit` extend class `Transaction`. Class `Transaction` is said to be a generalization of classes `BalanceInquiry`, `Withdrawal` and `Deposit`. Class `BalanceInquiry`, `Withdrawal` and `Deposit` are said to be **specializations** of class `Transaction`.

Classes `BalanceInquiry`, `Withdrawal` and `Deposit` share integer attribute `accountNumber`, so we factor out this common attribute and place it in superclass `Transaction`. We no longer list `accountNumber` in the second compartment of each subclass, because the three subclasses inherit this attribute from `Transaction`. Recall, however, that subclasses cannot access **private** attributes of a superclass. We therefore include **public** method `getAccountNumber` in class `Transaction`. Each subclass will inherit this method, enabling the subclass to access its `accountNumber` as needed to execute a transaction.

According to Fig. 10.19, classes `BalanceInquiry`, `Withdrawal` and `Deposit` also share operation `execute`, so we decided that superclass `Transaction` should contain public method `execute`. However, it does not make sense to implement `execute` in class `Transaction`, because the functionality that this method provides depends on the type of the actual transaction. We therefore declare method `execute` as **abstract** in superclass `Transaction`. Any class that contains at least one abstract method must also be declared **abstract**. This forces any subclass of `Transaction` that must be a concrete class (i.e., `BalanceInquiry`, `Withdrawal` and `Deposit`) to implement method `execute`. The UML requires that we place abstract class names (and abstract methods) in **italics**, so `Transaction` and its method `execute` appear in **italics** in Fig. 10.20. Note that method `execute`

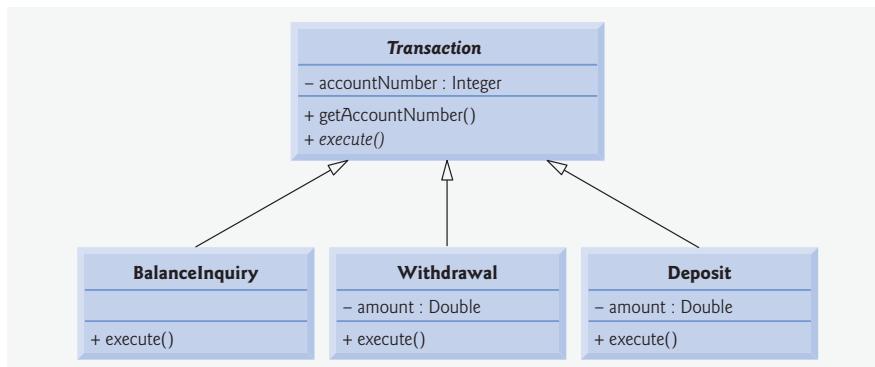

512 Chapter 10 Object-Oriented Programming: Polymorphism

Fig. 10.20 | Class diagram modeling generalization of superclass `Transaction` and subclasses `BalanceInquiry`, `Withdrawal` and `Deposit`. Note that abstract class names (e.g., `Transaction`) and method names (e.g., `execute` in class `Transaction`) appear in italics.

is not italicized in subclasses `BalanceInquiry`, `Withdrawal` and `Deposit`. Each subclass overrides superclass `Transaction`'s `execute` method with a concrete implementation that performs the steps appropriate for completing that type of transaction. Note that Fig. 10.20 includes operation `execute` in the third compartment of classes `BalanceInquiry`, `Withdrawal` and `Deposit`, because each class has a different concrete implementation of the overridden method.

Incorporating inheritance provides the ATM with an elegant way to execute all transactions “in the general.” For example, suppose a user chooses to perform a balance inquiry. The ATM sets a `Transaction` reference to a new object of class `BalanceInquiry`. When the ATM uses its `Transaction` reference to invoke method `execute`, `BalanceInquiry`'s version of `execute` is called.

This polymorphic approach also makes the system easily extensible. Should we wish to create a new transaction type (e.g., funds transfer or bill payment), we would just create an additional `Transaction` subclass that overrides the `execute` method with a version of the method appropriate for executing the new transaction type. We would need to make only minimal changes to the system code to allow users to choose the new transaction type from the main menu and for the ATM to instantiate and execute objects of the new subclass. The ATM could execute transactions of the new type using the current code, because it executes all transactions polymorphically using a general `Transaction` reference.

As you learned earlier in the chapter, an abstract class like `Transaction` is one for which the programmer never intends to instantiate objects. An abstract class simply declares common attributes and behaviors of its subclasses in an inheritance hierarchy. Class `Transaction` defines the concept of what it means to be a transaction that has an account number and executes. You may wonder why we bother to include `abstract` method `execute` in class `Transaction` if it lacks a concrete implementation. Conceptually, we include this method because it corresponds to the defining behavior of all transactions—executing. Technically, we must include method `execute` in superclass `Transac-`

10.9 Incorporating Inheritance into the ATM System **513**

tion so that the ATM (or any other class) can polymorphically invoke each subclass's overridden version of this method through a *Transaction* reference. Also, from a software engineering perspective, including an abstract method in a superclass forces the implementor of the subclasses to override that method with concrete implementations in the subclasses, or else the subclasses, too, will be abstract, preventing objects of those subclasses from being instantiated.

Subclasses *BalanceInquiry*, *Withdrawal* and *Deposit* inherit attribute *accountNumber* from superclass *Transaction*, but classes *Withdrawal* and *Deposit* contain the additional attribute *amount* that distinguishes them from class *BalanceInquiry*. Classes *Withdrawal* and *Deposit* require this additional attribute to store the amount of money that the user wishes to withdraw or deposit. Class *BalanceInquiry* has no need for such an attribute and requires only an account number to execute. Even though two of the three *Transaction* subclasses share this attribute, we do not place it in superclass *Transaction*—we place only features common to all the subclasses in the superclass, otherwise subclasses could inherit attributes (and methods) that they do not need and should not have.

Figure 10.21 presents an updated class diagram of our model that incorporates inheritance and introduces class *Transaction*. We model an association between class *ATM* and

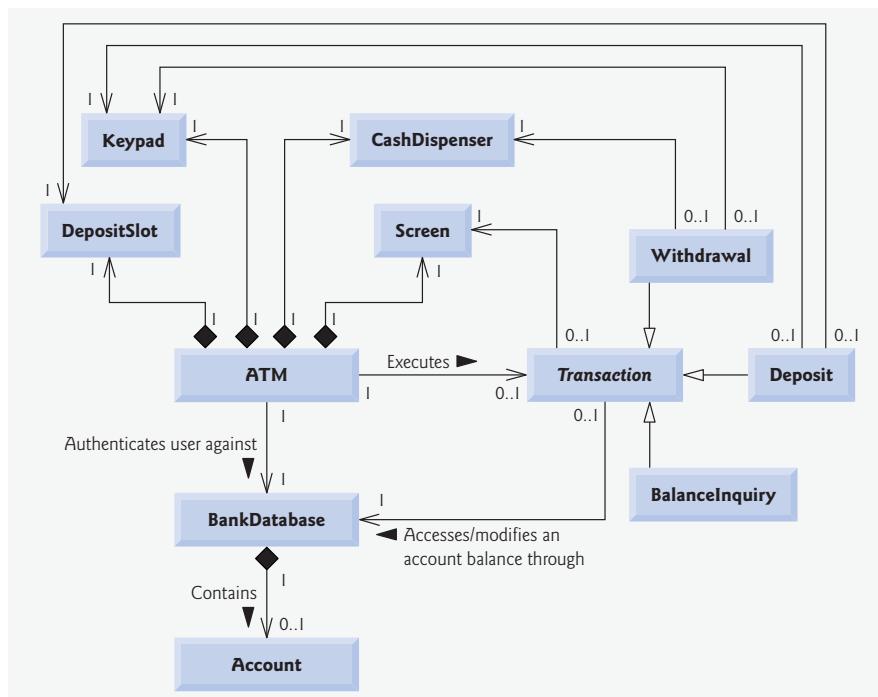

Fig. 10.21 | Class diagram of the ATM system (incorporating inheritance). Note that abstract class names (e.g., *Transaction*) appear in italics.

514 Chapter 10 Object-Oriented Programming: Polymorphism

class `Transaction` to show that the ATM, at any given moment is either executing a transaction or it is not (i.e., zero or one objects of type `Transaction` exist in the system at a time). Because a `Withdrawal` is a type of `Transaction`, we no longer draw an association line directly between class `ATM` and class `Withdrawal`. Subclass `Withdrawal` inherits superclass `Transaction`'s association with class `ATM`. Subclasses `BalanceInquiry` and `Deposit` inherit this association, too, so the previously omitted associations between `ATM` and classes `BalanceInquiry` and `Deposit` no longer exist either.

We also add an association between class `Transaction` and the `BankDatabase` (Fig. 10.21). All `Transactions` require a reference to the `BankDatabase` so they can access and modify account information. Because each `Transaction` subclass inherits this reference, we no longer model the association between class `Withdrawal` and the `BankDatabase`. Similarly, the previously omitted associations between the `BankDatabase` and classes `BalanceInquiry` and `Deposit` no longer exist.

We show an association between class `Transaction` and the `Screen`. All `Transactions` display output to the user via the `Screen`. Thus, we no longer include the association previously modeled between `Withdrawal` and the `Screen`, although `Withdrawal` still participates in associations with the `CashDispenser` and the `Keypad`. Our class diagram incorporating inheritance also models `Deposit` and `BalanceInquiry`. We show associations between `Deposit` and both the `DepositSlot` and the `Keypad`. Note that class `BalanceInquiry` takes part in no associations other than those inherited from class `Transaction`—a `BalanceInquiry` needs to interact only with the `BankDatabase` and with the `Screen`.

The class diagram of Fig. 8.24 showed attributes and operations with visibility markers. Now we present a modified class diagram that incorporates inheritance in Fig. 10.22. This abbreviated diagram does not show inheritance relationships, but instead shows the attributes and methods after we have employed inheritance in our system. To save space, as we did in Fig. 4.24, we do not include those attributes shown by associations in Fig. 10.21—we do, however, include them in the Java implementation in Appendix J. We also omit all operation parameters, as we did in Fig. 8.24—incorporating inheritance does not affect the parameters already modeled in Figs. 6.22–6.25.

Software Engineering Observation 10.12

A complete class diagram shows all the associations among classes and all the attributes and operations for each class. When the number of class attributes, methods and associations is substantial (as in Figs. 10.21 and 10.22), a good practice that promotes readability is to divide this information between two class diagrams—one focusing on associations and the other on attributes and methods.

Implementing the ATM System Design (Incorporating Inheritance)

In Section 8.19, we began implementing the ATM system design in Java code. We now modify our implementation to incorporate inheritance, using class `Withdrawal` as an example.

1. If a class A is a generalization of class B, then class B extends class A in the class declaration. For example, abstract superclass `Transaction` is a generalization of class `Withdrawal`. Figure 10.23 contains the shell of class `Withdrawal` containing the appropriate class declaration.

10.9 Incorporating Inheritance into the ATM System

515

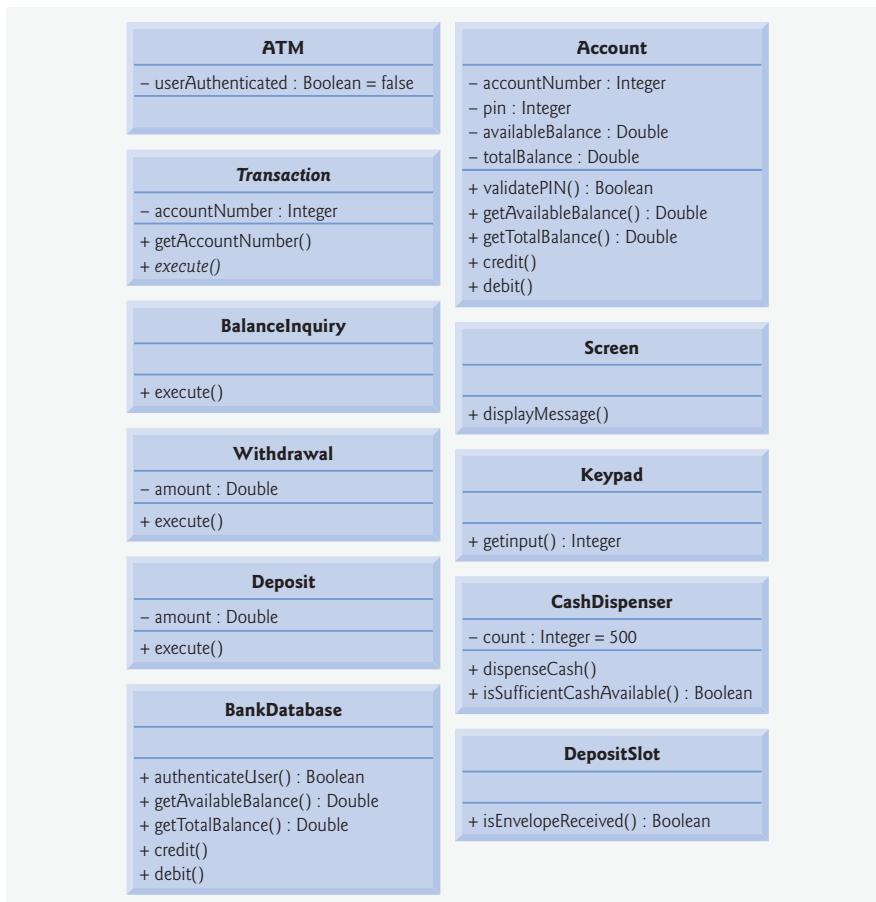

Fig. 10.22 | Class diagram with attributes and operations (incorporating inheritance). Note that abstract class names (e.g., *Transaction*) and method names (e.g., *execute* in class *Transaction*) appear in italics.

```

1 // Class Withdrawal represents an ATM withdrawal transaction
2 public class Withdrawal extends Transaction
3 {
4 } // end class Withdrawal

```

Fig. 10.23 | Java code for shell of class *Withdrawal*.

2. If class A is an abstract class and class B is a subclass of class A, then class B must implement the abstract methods of class A if class B is to be a concrete class. For example, class *Transaction* contains abstract method *execute*, so class *Withdrawal*

516 Chapter 10 Object-Oriented Programming: Polymorphism

must implement this method if we want to instantiate a `Withdrawal` object. Figure 10.24 is the Java code for class `Withdrawal` from Fig. 10.21 and Fig. 10.22. Class `Withdrawal` inherits field `accountNumber` from superclass `Transaction`, so `Withdrawal` does not need to declare this field. Class `Withdrawal` also inherits references to the `Screen` and the `BankDatabase` from its superclass `Transaction`, so we do not include these references in our code. Figure 10.22 specifies attribute `amount` and operation `execute` for class `Withdrawal`. Line 6 of Fig. 10.24 declares a field for attribute `amount`. Lines 16–18 declare the shell of a method for operation `execute`. Recall that subclass `Withdrawal` must provide a concrete implementation of the abstract method `execute` in superclass `Transaction`. The `keypad` and `cashDispenser` references (lines 7–8) are fields derived from `Withdrawal`'s associations in Fig. 10.21. [Note: The constructor in the complete working version of this class will initialize these references to actual objects.]

Software Engineering Observation 10.13

Several UML modeling tools convert UML-based designs into Java code and can speed the implementation process considerably. For more information on these tools, refer to the web resources listed at the end of Section 2.9.

Congratulations on completing the design portion of the case study! This concludes our object-oriented design of the ATM system. We completely implement the ATM system in 670 lines of Java code in Appendix J. We recommend that you carefully read the code and its description. The code is abundantly commented and precisely follows the design with which you are now familiar. The accompanying description is carefully written to guide your understanding of the implementation based on the UML design. Mastering this code is a wonderful culminating accomplishment after studying Chapters 1–8.

```

1 // Withdrawal.java
2 // Generated using the class diagrams in Fig. 10.21 and Fig. 10.22
3 public class Withdrawal extends Transaction
4 {
5     // attributes
6     private double amount; // amount to withdraw
7     private Keypad keypad; // reference to keypad
8     private CashDispenser cashDispenser; // reference to cash dispenser
9
10    // no-argument constructor
11    public Withdrawal()
12    {
13        // end no-argument Withdrawal constructor
14    }
15    // method overriding execute
16    public void execute()
17    {
18        // end method execute
19    } // end class Withdrawal

```

Fig. 10.24 | Java code for class `Withdrawal` based on Figs. 10.21 and 10.22.

10.9 Incorporating Inheritance into the ATM System **517*****Software Engineering Case Study Self-Review Exercises***

- 10.1** The UML uses an arrow with a _____ to indicate a generalization relationship.
- solid filled arrowhead
 - triangular hollow arrowhead
 - diamond-shaped hollow arrowhead
 - stick arrowhead
- 10.2** State whether the following statement is *true* or *false*, and if *false*, explain why: The UML requires that we underline abstract class names and method names.
- 10.3** Write Java code to begin implementing the design for class `Transaction` specified in Figs. 10.21 and 10.22. Be sure to include private reference-type attributes based on class `Transaction`'s associations. Also be sure to include public `get` methods that provide access to any of these private attributes that the subclasses require to perform their tasks.

Answers to Software Engineering Case Study Self-Review Exercises

10.1 b.

10.2 False. The UML requires that we italicize abstract class names and method names.

10.3 The design for class `Transaction` yields the code in Fig. 10.25. The bodies of the class constructor and methods will be completed in Appendix J. When fully implemented, methods `getScreen` and `getBankDatabase` will return superclass `Transaction`'s private reference attributes `screen` and `bankDatabase`, respectively. These methods allow the `Transaction` subclasses to access the ATM's screen and interact with the bank's database.

```

1 // Abstract class Transaction represents an ATM transaction
2 public abstract class Transaction
3 {
4     // attributes
5     private int accountNumber; // indicates account involved
6     private Screen screen; // ATM's screen
7     private BankDatabase bankDatabase; // account info database
8
9     // no-argument constructor invoked by subclasses using super()
10    public Transaction()
11    {
12    } // end no-argument Transaction constructor
13
14    // return account number
15    public int getAccountNumber()
16    {
17    } // end method getAccountNumber
18
19    // return reference to screen
20    public Screen getScreen()
21    {
22    } // end method getScreen
23
24    // return reference to bank database
25    public BankDatabase getBankDatabase()
26    {
27    } // end method getBankDatabase

10.10 Wrap-Up

This chapter introduced polymorphism—the ability to process objects that share the same superclass in a class hierarchy as if they are all objects of the superclass. The chapter discussed how polymorphism makes systems extensible and maintainable, then demonstrated how to use overridden methods to effect polymorphic behavior. We introduced abstract classes, which allow programmers to provide an appropriate superclass from which other classes can inherit. You learned that an abstract class can declare abstract methods that each subclass must implement to become a concrete class and that a program can use variables of an abstract class to invoke the subclasses' implementations of abstract methods polymorphically. You also learned how to determine an object's type at execution time. Finally, the chapter discussed declaring and implementing an interface as another way to achieve polymorphic behavior.

You should now be familiar with classes, objects, encapsulation, inheritance, interfaces and polymorphism—the most essential aspects of object-oriented programming. In the next chapter, we take a deeper look at graphical user interfaces (GUIs).

Summary

Section 10.1 Introduction

- Polymorphism enables us to write programs that process objects that share the same superclass in a class hierarchy as if they are all objects of the superclass; this can simplify programming.
- With polymorphism, we can design and implement systems that are easily extensible—new classes can be added with little or no modification to the general portions of the program, as long as the new classes are part of the inheritance hierarchy that the program processes generically. The only parts of a program that must be altered to accommodate new classes are those that require direct knowledge of the new classes that the programmer adds to the hierarchy.

Section 10.3 Demonstrating Polymorphic Behavior

- When the compiler encounters a method call made through a variable, the compiler determines if the method can be called by checking the variable's class type. If that class contains the proper method declaration (or inherits one), the call is compiled. At execution time, the type of the object to which the variable refers determines the actual method to use.

Section 10.4 Abstract Classes and Methods

- In some cases, it is useful to declare classes for which you never intend to instantiate objects. Such classes are called abstract classes. Because they are used only as superclasses in inheritance hierarchies, we refer to them as abstract superclasses. These classes cannot be used to instantiate objects, because they are incomplete.
- The purpose of an abstract class is primarily to provide an appropriate superclass from which other classes can inherit and thus share a common design.

[Summary](#) **519**

- Classes that can be used to instantiate objects are called concrete classes. Such classes provide implementations of every method they declare (some of the implementations can be inherited).
- Not all inheritance hierarchies contain abstract classes. However, programmers often write client code that uses only abstract superclass types to reduce client code's dependencies on a range of specific subclass types.
- Abstract classes sometimes constitute several levels of the hierarchy.
- You make a class abstract by declaring it with keyword `abstract`. An abstract class normally contains one or more abstract methods.
- Abstract methods do not provide implementations.
- A class that contains any abstract methods must be declared as an abstract class even if that class contains some concrete (nonabstract) methods. Each concrete subclass of an abstract superclass also must provide concrete implementations of each of the superclass's abstract methods.
- Constructors and `static` methods cannot be declared `abstract`.
- Although you cannot instantiate objects of abstract superclasses, you *can* use abstract superclasses to declare variables that can hold references to objects of any concrete class derived from those abstract superclasses. Programs typically use such variables to manipulate subclass objects polymorphically.
- Polymorphism is particularly effective for implementing layered software systems.

Section 10.5 Case Study: Payroll System Using Polymorphism

- Including an abstract method in a superclass forces every direct subclass of the superclass to override the abstract method in order to become a concrete class. This enables the designer of the class hierarchy to demand that each concrete subclass provide an appropriate method implementation.
- Most method calls are resolved at execution time, based on the type of the object being manipulated. This process is known as dynamic binding or late binding.
- A superclass reference can be used to invoke only methods of the superclass (and the superclass can invoke overridden versions of these in the subclass).
- The `instanceof` operator can be used to determine whether a particular object's type has the *is-a* relationship with a specific type.
- Every object in Java knows its own class and can access this information through method `getClass`, which all classes inherit from class `Object`. Method `getClass` returns an object of type `Class` (package `java.lang`), which contains information about the object's type, including its class name.
- The *is-a* relationship applies only between the subclass and its superclasses, not vice versa.
- Attempting to invoke subclass-only methods on a superclass reference is not allowed. Although the actual method that is called depends on the object's type at execution time, a variable can be used to invoke only those methods that are members of that variable's type, which the compiler verifies.

Section 10.6 Final Methods and Classes

- A method that is declared `final` in a superclass cannot be overridden in a subclass.
- Methods that are declared `private` are implicitly `final`, because it is impossible to override them in a subclass.
- Methods that are declared `static` are implicitly `final`.
- A `final` method's declaration can never change, so all subclasses use the same method implementation, and calls to `final` methods are resolved at compile time—this is known as static binding.

520 Chapter 10 Object-Oriented Programming: Polymorphism

- Since the compiler knows that `final` methods cannot be overridden, it can optimize programs by removing calls to `final` methods and replacing them with the expanded code of their declarations at each method-call location—a technique known as *inlining* the code.
- A class that is declared `final` cannot be a superclass (i.e., a class cannot extend a `final` class).
- All methods in a `final` class are implicitly `final`.

Section 10.7 Case Study: Creating and Using Interfaces

- Interfaces define and standardize the ways in which things such as people and systems can interact with one another.
- An interface specifies *what* operations are allowed but does not specify *how* the operations are performed.
- A Java interface describes a set of methods that can be called on an object.
- An interface declaration begins with the keyword `interface` and contains only constants and abstract methods.
- All interface members must be `public`, and interfaces may not specify any implementation details, such as concrete method declarations and instance variables.
- All methods declared in an interface are implicitly `public abstract` methods and all fields are implicitly `public static final`.
- To use an interface, a concrete class must specify that it implements the interface and must declare each interface method with the signature specified in the interface declaration. A class that does not implement all the interface's methods is an abstract class and must be declared `abstract`.
- Implementing an interface is like signing a contract with the compiler that states, “I will declare all the methods specified by the interface or I will declare my class `abstract`.”
- An interface is typically used when disparate (i.e., unrelated) classes need to share common methods and constants. This allows objects of unrelated classes to be processed polymorphically—objects of classes that implement the same interface can respond to the same method calls.
- You can create an interface that describes the desired functionality, then implement the interface in any classes that require that functionality.
- An interface is often used in place of an abstract class when there is no default implementation to inherit—that is, no fields and no default method implementations.
- Like `public abstract` classes, interfaces are typically `public` types, so they are normally declared in files by themselves with the same name as the interface and the `.java` file-name extension.
- Java does not allow subclasses to inherit from more than one superclass, but it does allow a class to inherit from a superclass and implement more than one interface. To implement more than one interface, use a comma-separated list of interface names after keyword `implements` in the class declaration.
- All objects of a class that implement multiple interfaces have the *is-a* relationship with each implemented interface type.
- An interface can declare constants. The constants are implicitly `public static final`.

Terminology

abstract class	concrete class
abstract keyword	constants declared in an interface
abstract method	downcasting
abstract superclass	dynamic binding
Class class	<code>final</code> class

Self-Review Exercises **521**

final method	interface inheritance
generalization in the UML	interface keyword
getClass method of Object	iterator class
getName method of Class	late binding
implement an interface	polymorphism
implementation inheritance	realization in the UML
implements keyword	specialization in the UML
inlining method calls	static binding
instanceof operator	subclass reference
interface declaration	superclass reference

Self-Review Exercises

- 10.1** Fill in the blanks in each of the following statements:
- Polymorphism helps eliminate _____ logic.
 - If a class contains at least one abstract method, it is a(n) _____ class.
 - Classes from which objects can be instantiated are called _____ classes.
 - _____ involves using a superclass variable to invoke methods on superclass and subclass objects, enabling you to “program in the general.”
 - Methods that are not interface methods and that do not provide implementations must be declared using keyword _____.
 - Casting a reference stored in a superclass variable to a subclass type is called _____.
- 10.2** State whether each of the statements that follows is *true* or *false*. If *false*, explain why.
- It is possible to treat superclass objects and subclass objects similarly.
 - All methods in an abstract class must be declared as *abstract* methods.
 - It is dangerous to try to invoke a subclass-only method through a subclass variable.
 - If a superclass declares an *abstract* method, a subclass must implement that method.
 - An object of a class that implements an interface may be thought of as an object of that interface type.

Answers to Self-Review Exercises

- 10.1** a) switch. b) abstract. c) concrete. d) Polymorphism. e) *abstract*. f) downcasting.
- 10.2** a) True. b) False. An abstract class can include methods with implementations and *abstract* methods. c) False. Trying to invoke a subclass-only method with a superclass variable is dangerous. d) False. Only a concrete subclass must implement the method. e) True.

Exercises

- 10.3** How does polymorphism enable you to program “in the general” rather than “in the specific”? Discuss the key advantages of programming “in the general.”
- 10.4** A subclass can inherit “interface” or “implementation” from a superclass. How do inheritance hierarchies designed for inheriting interface differ from those designed for inheriting implementation?
- 10.5** What are abstract methods? Describe the circumstances in which an abstract method would be appropriate.
- 10.6** How does polymorphism promote extensibility?
- 10.7** Discuss four ways in which you can assign superclass and subclass references to variables of superclass and subclass types.

522 Chapter 10 Object-Oriented Programming: Polymorphism

10.8 Compare and contrast abstract classes and interfaces. Why would you use an abstract class? Why would you use an interface?

10.9 (*Payroll System Modification*) Modify the payroll system of Figs. 10.4–10.9 to include private instance variable `birthDate` in class `Employee`. Use class `Date` of Fig. 8.7 to represent an employee's birthday. Add `get` methods to class `Date` and replace method `toDateString` with method `toString`. Assume that payroll is processed once per month. Create an array of `Employee` variables to store references to the various employee objects. In a loop, calculate the payroll for each `Employee` (polymorphically), and add a \$100.00 bonus to the person's payroll amount if the current month is the one in which the `Employee`'s birthday occurs.

10.10 (*Shape Hierarchy*) Implement the Shape hierarchy shown in Fig. 9.3. Each `TwoDimensionalShape` should contain method `getArea` to calculate the area of the two-dimensional shape. Each `ThreeDimensionalShape` should have methods `getArea` and `getVolume` to calculate the surface area and volume, respectively, of the three-dimensional shape. Create a program that uses an array of `Shape` references to objects of each concrete class in the hierarchy. The program should print a text description of the object to which each array element refers. Also, in the loop that processes all the shapes in the array, determine whether each shape is a `TwoDimensionalShape` or a `ThreeDimensionalShape`. If it is a `TwoDimensionalShape`, display its area. If it is a `ThreeDimensionalShape`, display its area and volume.

10.11 (*Payroll System Modification*) Modify the payroll system of Figs. 10.4–10.9 to include an additional `Employee` subclass `PieceWorker` that represents an employee whose pay is based on the number of pieces of merchandise produced. Class `PieceWorker` should contain private instance variables `wage` (to store the employee's wage per piece) and `pieces` (to store the number of pieces produced). Provide a concrete implementation of method `earnings` in class `PieceWorker` that calculates the employee's earnings by multiplying the number of pieces produced by the wage per piece. Create an array of `Employee` variables to store references to objects of each concrete class in the new `Employee` hierarchy. For each `Employee`, display its string representation and earnings.

10.12 (*Accounts Payable System Modification*) In this exercise, we modify the accounts payable application of Figs. 10.11–10.15 to include the complete functionality of the payroll application of Figs. 10.4–10.9. The application should still process two `Invoice` objects, but now should process one object of each of the four `Employee` subclasses. If the object currently being processed is a `BasePlusCommissionEmployee`, the application should increase the `BasePlusCommissionEmployee`'s base salary by 10%. Finally, the application should output the payment amount for each object. Complete the following steps to create the new application:

- Modify classes `HourlyEmployee` (Fig. 10.6) and `CommissionEmployee` (Fig. 10.7) to place them in the `Payable` hierarchy as subclasses of the version of `Employee` (Fig. 10.13) that implements `Payable`. [Hint: Change the name of method `earnings` to `getPaymentAmount` in each subclass so that the class satisfies its inherited contract with interface `Payable`.]
- Modify class `BasePlusCommissionEmployee` (Fig. 10.8) such that it extends the version of class `CommissionEmployee` created in Part a.
- Modify `PayableInterfaceTest` (Fig. 10.15) to polymorphically process two `Invoices`, one `SalariedEmployee`, one `HourlyEmployee`, one `CommissionEmployee` and one `BasePlusCommissionEmployee`. First output a string representation of each `Payable` object. Next, if an object is a `BasePlusCommissionEmployee`, increase its base salary by 10%. Finally, output the payment amount for each `Payable` object.

Do you think I can listen all day to such stuff?

—Lewis Carroll

Even a minor event in the life of a child is an event of that child's world and thus a world event.

—Gaston Bachelard

You pays your money and you takes your choice.

—Punch

Guess if you can, choose if you dare.

—Pierre Corneille

GUI Components: Part I

OBJECTIVES

In this chapter you will learn:

- The design principles of graphical user interfaces (GUIs).
- To build GUIs and handle events generated by user interactions with GUIs.
- To understand the packages containing GUI components, event-handling classes and interfaces.
- To create and manipulate buttons, labels, lists, text fields and panels.
- To handle mouse events and keyboard events.
- To use layout managers to arrange GUI components

524 Chapter 11 GUI Components: Part I

Outline

- 11.1** Introduction
- 11.2** Simple GUI-Based Input/Output with JOptionPane
- 11.3** Overview of Swing Components
- 11.4** Displaying Text and Images in a Window
- 11.5** Text Fields and an Introduction to Event Handling with Nested Classes
- 11.6** Common GUI Event Types and Listener Interfaces
- 11.7** How Event Handling Works
- 11.8** JButton
- 11.9** Buttons That Maintain State
 - 11.9.1** JCheckBox
 - 11.9.2** JRadioButton
- 11.10** JComboBox and Using an Anonymous Inner Class for Event Handling
- 11.11** JList
- 11.12** Multiple-Selection Lists
- 11.13** Mouse Event Handling
- 11.14** Adapter Classes
- 11.15** JPanel Subclass for Drawing with the Mouse
- 11.16** Key-Event Handling
- 11.17** Layout Managers
 - 11.17.1** FlowLayout
 - 11.17.2** BorderLayout
 - 11.17.3** GridLayout
- 11.18** Using Panels to Manage More Complex Layouts
- 11.19** JTextArea
- 11.20** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

11.1 Introduction

A **graphical user interface (GUI)** presents a user-friendly mechanism for interacting with an application. A GUI (pronounced “GOO-ee”) gives an application a distinctive “look” and “feel.” Providing different applications with consistent, intuitive user interface components allows users to be somewhat familiar with an application, so that they can learn it more quickly and use it more productively.

Look-and-Feel Observation 11.1

Consistent user interfaces enable a user to learn new applications faster.

As an example of a GUI, Fig. 11.1 contains an Internet Explorer web-browser window with some of its GUI components labeled. At the top is a **title bar** that contains the window’s title. Below that is a **menu bar** containing **menus** (File, Edit, View, etc.).

11.2 Simple GUI-Based Input/Output with JOptionPane

525

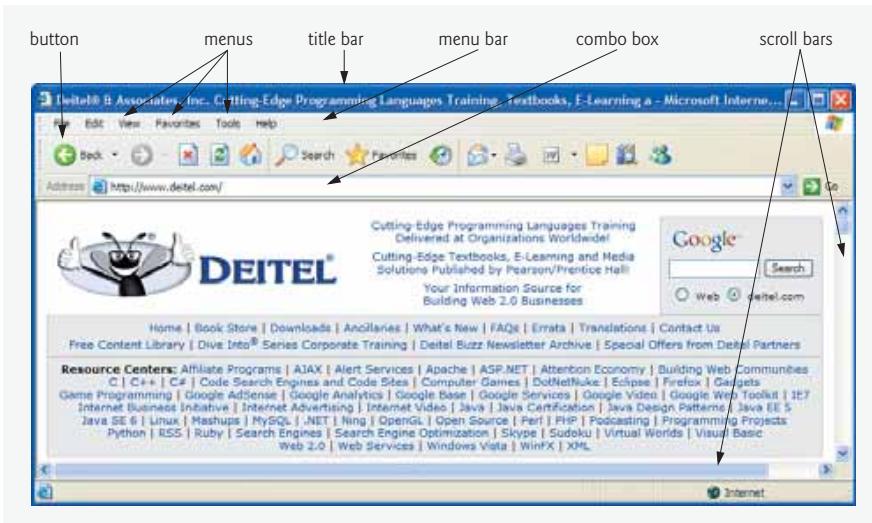

Fig. 11.1 | Internet Explorer window with GUI components.

Below the menu bar is a set of **buttons** that the user can click to perform tasks in Internet Explorer. Below the buttons is a **combo box**; the user can type into it the name of a website to visit or can click the down arrow at the right side of the box to select from a list of sites previously visited. The menus, buttons and combo box are part of Internet Explorer's GUI. They enable you to interact with Internet Explorer.

GUIs are built from **GUI components**. These are sometimes called **controls** or **widglets**—short for **window gadgets**—in other languages. A GUI component is an object with which the user interacts via the mouse, the keyboard or another form of input, such as voice recognition. In this chapter and Chapter 22, GUI Components: Part 2, you will learn about many of Java's GUI components. [Note: Several concepts covered in this chapter have already been covered in the optional GUI and Graphics Case Study of Chapters 3–10. So, some material will be repetitive if you read the case study. You do not need to read the case study to understand this chapter.]

11.2 Simple GUI-Based Input/Output with JOptionPane

The applications in Chapters 2–10 display text at the command window and obtain input from the command window. Most applications you use on a daily basis use windows or **dialog boxes** (also called **dialogs**) to interact with the user. For example, e-mail programs allow you to type and read messages in a window provided by the e-mail program. Typically, dialog boxes are windows in which programs display important messages to the user or obtain information from the user. Java's **JOptionPane** class (package `javax.swing`) provides prepackaged dialog boxes for both input and output. These dialogs are displayed by invoking **static JOptionPane** methods. Figure 11.2 presents a simple addition application that uses two **input dialogs** to obtain integers from the user and a **message dialog** to display the sum of the integers the user enters.

526 Chapter 11 GUI Components: Part I

Input Dialogs

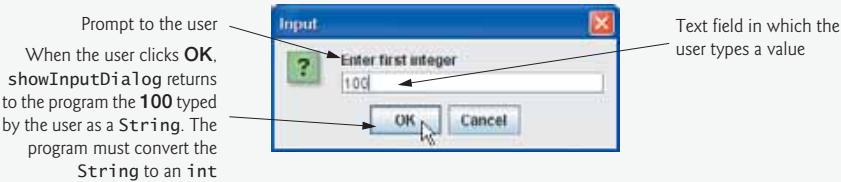

Line 3 imports class `JOptionPane` for use in this application. Lines 10–11 declare the local `String` variable `firstNumber` and assign it the result of the call to `JOptionPane` static method `showInputDialog`. This method displays an input dialog (see the first screen capture in Fig. 11.2), using the method's `String` argument ("Enter first integer") as a prompt.

```

1 // Fig. 11.2: Addition.java
2 // Addition program that uses JOptionPane for input and output.
3 import javax.swing.JOptionPane; // program uses JOptionPane
4
5 public class Addition
6 {
7     public static void main( String args[] )
8     {
9         // obtain user input from JOptionPane input dialogs
10        String firstNumber =
11            JOptionPane.showInputDialog( "Enter first integer" );
12        String secondNumber =
13            JOptionPane.showInputDialog( "Enter second integer" );
14
15        // convert String inputs to int values for use in a calculation
16        int number1 = Integer.parseInt( firstNumber );
17        int number2 = Integer.parseInt( secondNumber );
18
19        int sum = number1 + number2; // add numbers
20
21        // display result in a JOptionPane message dialog
22        JOptionPane.showMessageDialog( null, "The sum is " + sum,
23            "Sum of Two Integers", JOptionPane.PLAIN_MESSAGE );
24    } // end method main
25 } // end class Addition

```

Input dialog displayed by lines 10–11

Input dialog displayed by lines 12–13

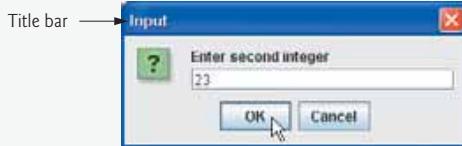

Fig. 11.2 | Addition program that uses `JOptionPane` for input and output. (Part I of 2.)

11.2 Simple GUI-Based Input/Output with JOptionPane 527

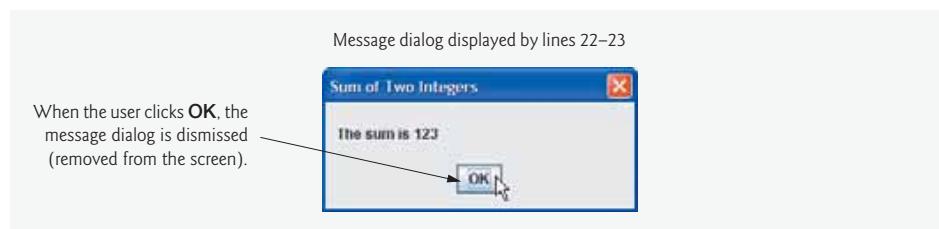

Fig. 11.2 | Addition program that uses JOptionPane for input and output. (Part 2 of 2.)

Look-and-Feel Observation 11.2

The prompt in an input dialog typically uses *sentence-style capitalization*—a style that capitalizes only the first letter of the first word in the text unless the word is a proper noun (for example, Deitel).

The user types characters in the text field, then clicks the **OK** button or presses the **Enter** key to submit the `String` to the program. Clicking **OK** also **dismisses (hides) the dialog**. [Note: If you type in the text field and nothing appears, activate the text field by clicking it with the mouse.] Unlike Scanner, which can be used to input values of several types from the user at the keyboard, an input dialog can input only `String`s. This is typical of most GUI components. Technically, the user can type anything in the input dialog's text field. Our program assumes that the user enters a valid integer value. If the user clicks the **Cancel** button, `showInputDialog` returns `null`. If the user either types a noninteger value or clicks the **Cancel** button in the input dialog, a runtime logic error will occur in this program and it will not operate correctly. Chapter 13, Exception Handling, discusses how to handle such errors. Lines 12–13 display another input dialog that prompts the user to enter the second integer.

Converting `Strings` to `int` Values

To perform the calculation in this application, we must convert the `String`s that the user entered to `int` values. Recall from Section 7.12 that the `Integer` class's `static` method `parseInt` converts its `String` argument to an `int` value. Lines 16–17 assign the converted values to local variables `number1` and `number2`. Then, line 19 sums these values and assigns the result to local variable `sum`.

Message Dialogs

Lines 22–23 use `JOptionPane` `static` method `showMessageDialog` to display a message dialog (the last screen capture of Fig. 11.2) containing the sum. The first argument helps the Java application determine where to position the dialog box. The value `null` indicates that the dialog should appear in the center of the computer screen. The first argument can also be used to specify that the dialog should appear centered over a particular window, which we will demonstrate later in Section 11.8. The second argument is the message to display—in this case, the result of concatenating the `String` "The sum is " and the value of `sum`. The third argument—"Sum of Two Integers"—represents the string that should appear in the dialog's title bar at the top of the dialog. The fourth argument—`JOptionPane.PLAIN_MESSAGE`—is the type of message dialog to display. A `PLAIN_MESSAGE` dialog does not display an icon to the left of the message. Class `JOptionPane` provides several

528 Chapter 11 GUI Components: Part I

overloaded versions of methods `showInputDialog` and `showMessageDialog`, as well as methods that display other dialog types. For complete information on class `JOptionPane`, visit java.sun.com/javase/6/docs/api/javax/swing/JOptionPane.html.

Look-and-Feel Observation 11.3

The title bar of a window typically uses **book-title capitalization**—a style that capitalizes the first letter of each significant word in the text and does not end with any punctuation (for example, *Capitalization in a Book Title*).

JOptionPane Message Dialog Constants

The constants that represent the message dialog types are shown in Fig. 11.3. All message dialog types except `PLAIN_MESSAGE` display an icon to the left of the message. These icons provide a visual indication of the message's importance to the user. Note that a `QUESTION_MESSAGE` icon is the default icon for an input dialog box (see Fig. 11.2).

Message dialog type	Icon	Description
<code>ERROR_MESSAGE</code>		A dialog that indicates an error to the user.
<code>INFORMATION_MESSAGE</code>		A dialog with an informational message to the user.
<code>WARNING_MESSAGE</code>		A dialog warning the user of a potential problem.
<code>QUESTION_MESSAGE</code>		A dialog that poses a question to the user. This dialog normally requires a response, such as clicking a Yes or a No button.
<code>PLAIN_MESSAGE</code>	no icon	A dialog that contains a message, but no icon.

Fig. 11.3 | `JOptionPane` static constants for message dialogs.

11.3 Overview of Swing Components

Though it is possible to perform input and output using the `JOptionPane` dialogs presented in Section 11.2, most GUI applications require more elaborate, customized user interfaces. The remainder of this chapter discusses many GUI components that enable application developers to create robust GUIs. Figure 11.4 lists several **Swing GUI components** from package `javax.swing` that are used to build Java GUIs. Most Swing components are **pure Java** components—they are written, manipulated and displayed completely in Java. They are part of the **Java Foundation Classes (JFC)**—Java's libraries for cross-platform GUI development. Visit java.sun.com/products/jfc for more information on JFC.

Swing vs. AWT

There are actually two sets of GUI components in Java. Before Swing was introduced in Java SE 1.2, Java GUIs were built with components from the **Abstract Window Toolkit**

11.3 Overview of Swing Components **529**

Component	Description
JLabel	Displays uneditable text or icons.
JTextField	Enables user to enter data from the keyboard. Can also be used to display editable or uneditable text.
JButton	Triggers an event when clicked with the mouse.
JCheckBox	Specifies an option that can be selected or not selected.
JComboBox	Provides a drop-down list of items from which the user can make a selection by clicking an item or possibly by typing into the box.
JList	Provides a list of items from which the user can make a selection by clicking on any item in the list. Multiple elements can be selected.
JPanel	Provides an area in which components can be placed and organized. Can also be used as a drawing area for graphics.

Fig. 11.4 | Some basic GUI components.

(**AWT**) in package `java.awt`. When a Java application with an AWT GUI executes on different Java platforms, the application's GUI components display differently on each platform. Consider an application that displays an object of type `Button` (package `java.awt`). On a computer running the Microsoft Windows operating system, the `Button` will have the same appearance as the buttons in other Windows applications. Similarly, on a computer running the Apple Mac OS X operating system, the `Button` will have the same look and feel as the buttons in other Macintosh applications. Sometimes, the manner in which a user can interact with a particular AWT component differs between platforms.

Together, the appearance and the way in which the user interacts with the application are known as that application's **look-and-feel**. Swing GUI components allow you to specify a uniform look-and-feel for your application across all platforms or to use each platform's custom look-and-feel. An application can even change the look-and-feel during execution to enable users to choose their own preferred look-and-feel.

**Portability Tip 11.1**

Swing components are implemented in Java, so they are more portable and flexible than the original Java GUI components from package `java.awt`, which were based on the GUI components of the underlying platform. For this reason, Swing GUI components are generally preferred.

Lightweight vs. Heavyweight GUI Components

Most Swing components are not tied to actual GUI components supported by the underlying platform on which an application executes. Such GUI components are known as **lightweight components**. AWT components (many of which parallel the Swing components) are tied to the local platform and are called **heavyweight components**, because they rely on the local platform's **windowing system** to determine their functionality and their look-and-feel.

530 Chapter 11 GUI Components: Part I

Several Swing components are heavyweight components. Like AWT components, heavyweight Swing GUI components require direct interaction with the local windowing system, which may restrict their appearance and functionality, making them less flexible than lightweight components.

Look-and-Feel Observation 11.4

The look-and-feel of a GUI defined with heavyweight GUI components from package `java.awt` may vary across platforms. Because heavyweight components are tied to the local-platform GUI, the look-and-feel varies from platform to platform.

Superclasses of Swing's Lightweight GUI Components

The UML class diagram of Fig. 11.5 shows an inheritance hierarchy containing classes from which lightweight Swing components inherit their common attributes and behaviors. As discussed in Chapter 9, class `Object` is the superclass of the Java class hierarchy.

Software Engineering Observation 11.1

Study the attributes and behaviors of the classes in the class hierarchy of Fig. 11.5. These classes declare the features that are common to most Swing components.

Class `Component` (package `java.awt`) is a subclass of `Object` that declares many of the attributes and behaviors common to the GUI components in packages `java.awt` and `javax.swing`. Most GUI components extend class `Component` directly or indirectly. Visit java.sun.com/javase/6/docs/api/java.awt/Component.html for a complete list of these common features.

Class `Container` (package `java.awt`) is a subclass of `Component`. As you will soon see, Components are attached to Containers (such as windows) so the Components can be organized and displayed on the screen. Any object that is a `Container` can be used to organize other Components in a GUI. Because a `Container` is a `Component`, you can attach Containers to other Containers to help organize a GUI. Visit java.sun.com/javase/6/docs/api/java.awt/Container.html for a complete list of the `Container` features that are common to Swing lightweight components.

Class `JComponent` (package `javax.swing`) is a subclass of `Container`. `JComponent` is the superclass of all lightweight Swing components and declares their common attributes

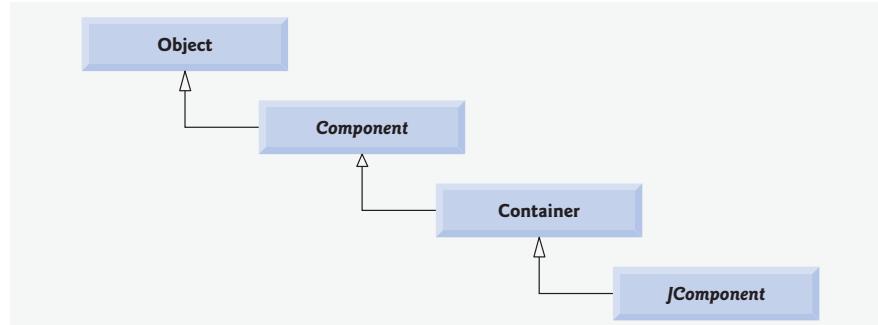

Fig. 11.5 | Common superclasses of many of the Swing components.

11.4 Displaying Text and Images in a Window 531

and behaviors. Because `JComponent` is a subclass of `Container`, all lightweight Swing components are also Containers. Some common lightweight component features supported by `JComponent` include:

1. A **pluggable look-and-feel** that can be used to customize the appearance of components (e.g., for use on particular platforms). You will see an example of this in Section 22.6.
2. Shortcut keys (called **mnemonics**) for direct access to GUI components through the keyboard. You will see an example of this in Section 22.4.
3. Common event-handling capabilities for cases where several GUI components initiate the same actions in an application.
4. Brief descriptions of a GUI component's purpose (called **tool tips**) that are displayed when the mouse cursor is positioned over the component for a short time. You will see an example of this in the next section.
5. Support for assistive technologies, such as braille screen readers for the visually impaired.
6. Support for user-interface **localization**—that is, customizing the user interface to display in different languages and use local cultural conventions.

These are just some of the many features of the Swing components. Visit java.sun.com/javase/6/docs/api/javax/swing/JComponent.html for more details of the common lightweight component features.

11.4 Displaying Text and Images in a Window

Our next example introduces a framework for building GUI applications. This framework uses several concepts that you will see in many of our GUI applications. This is our first example in which the application appears in its own window. Most windows you will create are an instance of class `JFrame` or a subclass of `JFrame`. `JFrame` provides the basic attributes and behaviors of a window—a title bar at the top of the window, and buttons to minimize, maximize and close the window. Since an application's GUI is typically specific to the application, most of our examples will consist of two classes—a subclass of `JFrame` that helps us demonstrate new GUI concepts and an application class in which `main` creates and displays the application's primary window.

Labeling GUI Components

A typical GUI consists of many components. In a large GUI, it can be difficult to identify the purpose of every component unless the GUI designer provides text instructions or information stating the purpose of each component. Such text is known as a **label** and is created with class `JLabel`—a subclass of `JComponent`. A `JLabel` displays a single line of read-only text, an image, or both text and an image. Applications rarely change a label's contents after creating it.

Look-and-Feel Observation 11.5

Text in a `JLabel` normally uses sentence-style capitalization.

532 Chapter 11 GUI Components: Part I

The application of Figs. 11.6–11.7 demonstrates several `JLabel` features and presents the framework we use in most of our GUI examples. We did not highlight the code in this example, since most of it is new. [Note: There are many more features for each GUI component than we can cover in our examples. To learn the complete details of each GUI component, visit its page in the online documentation. For class `JLabel`, visit java.sun.com/javase/6/docs/api/javax/swing/JLabel.html.]

Class `LabelFrame` (Fig. 11.6) is a subclass of `JFrame`. We will use an instance of class `LabelFrame` to display a window containing three `JLabel`s. Lines 3–8 import the classes used in class `LabelFrame`. The class extends `JFrame` to inherit the features of a window. Lines 12–14 declare the three `JLabel` instance variables, each of which is instantiated in the `LabelFrame` constructor (lines 17–41). Typically, the `JFrame` subclass's constructor builds the GUI that is displayed in the window when the application executes. Line 19 invokes superclass `JFrame`'s constructor with the argument "Testing `JLabel`". `JFrame`'s constructor uses this `String` as the text in the window's title bar.

```

1 // Fig. 11.6: LabelFrame.java
2 // Demonstrating the JLabel class.
3 import java.awt.FlowLayout; // specifies how components are arranged
4 import javax.swing.JFrame; // provides basic window features
5 import javax.swing.JLabel; // displays text and images
6 import javax.swing.SwingConstants; // common constants used with Swing
7 import javax.swing.Icon; // interface used to manipulate images
8 import javax.swing.ImageIcon; // loads images
9
10 public class LabelFrame extends JFrame
11 {
12     private JLabel label1; // JLabel with just text
13     private JLabel label2; // JLabel constructed with text and icon
14     private JLabel label3; // JLabel with added text and icon
15
16     // LabelFrame constructor adds JLabels to JFrame
17     public LabelFrame()
18     {
19         super( "Testing JLabel" );
20         setLayout( new FlowLayout() ); // set frame layout
21
22         // JLabel constructor with a string argument
23         label1 = new JLabel( "Label with text" );
24         label1.setToolTipText( "This is label1" );
25         add( label1 ); // add label1 to JFrame
26
27         // JLabel constructor with string, Icon and alignment arguments
28         Icon bug = new ImageIcon( getClass().getResource( "bug1.gif" ) );
29         label2 = new JLabel( "Label with text and icon", bug,
30             SwingConstants.LEFT );
31         label2.setToolTipText( "This is label2" );
32         add( label2 ); // add label2 to JFrame
33
34         label3 = new JLabel(); // JLabel constructor no arguments
35         label3.setText( "Label with icon and text at bottom" );

```

```

1 // Fig. 11.7: LabelTest.java
2 // Testing LabelFrame.
3 import javax.swing.JFrame;
4
5 public class LabelTest
6 {
7     public static void main( String args[] )
8     {
9         LabelFrame labelFrame = new LabelFrame(); // create LabelFrame
10        labelFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        labelFrame.setSize( 275, 180 ); // set frame size
12        labelFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class LabelTest

```

**Fig. 11.7** | Test class for `LabelFrame`.*Specifying the Layout*

When building a GUI, each GUI component must be attached to a container, such as a window created with a `JFrame`. Also, you typically must decide where to position each GUI component. This is known as specifying the layout of the GUI components. As you will learn at the end of this chapter and in Chapter 22, GUI Components: Part 2, Java provides several **layout managers** that can help you position components.

Many integrated development environments provide GUI design tools in which you can specify the exact size and location of a component in a visual manner by using the mouse, then the IDE will generate the GUI code for you. Though such IDEs can greatly simplify GUI creation, they are each different in capability.

To ensure that the code in this book can be used with any IDE, we did not use an IDE to create the GUI code in most of our examples. For this reason, we use Java's layout

534 Chapter 11 GUI Components: Part I

managers in our GUI examples. One such layout manager is `FlowLayout`, in which GUI components are placed on a container from left to right in the order in which the program attaches them to the container. When there is no more room to fit components left to right, components continue to display left to right on the next line. If the container is resized, a `FlowLayout` reflows (i.e., rearranges) the components to accommodate the new width of the container, possibly with fewer or more rows of GUI components. Line 20 specifies that the layout of the `LabelFrame` should be a `FlowLayout`. Method `setLayout` is inherited into class `LabelFrame` indirectly from class `Container`. The argument to the method must be an object of a class that implements the `LayoutManager` interface (e.g., `FlowLayout`). Line 20 creates a new `FlowLayout` object and pass its reference as the argument to `setLayout`.

Creating and Attaching `label1`

Now that we have specified the window's layout, we can begin creating and attaching GUI components to the window. Line 23 creates a `JLabel` object and passes "Label with text" to the constructor. The `JLabel` displays this text on the screen as part of the application's GUI. Line 24 uses method `setToolTipText` (inherited by `JLabel` from `JComponent`) to specify the tool tip that is displayed when the user positions the mouse cursor over the `JLabel` in the GUI. You can see a sample tool tip in the second screen capture of Fig. 11.7. When you execute this application, try positioning the mouse over each `JLabel` to see its tool tip. Line 25 attaches `label1` to the `LabelFrame` by passing `label1` to the `add` method, which is inherited indirectly from class `Container`.

Common Programming Error 11.1

If you do not explicitly add a GUI component to a container, the GUI component will not be displayed when the container appears on the screen.

Look-and-Feel Observation 11.6

Use tool tips to add descriptive text to your GUI components. This text helps the user determine the GUI component's purpose in the user interface.

Creating and Attaching `label2`

Icons are a popular way to enhance the look-and-feel of an application and are also commonly used to indicate functionality. For examples, most of today's VCRs and DVD players use the same icon to play a tape or DVD. Several Swing components can display images. An icon is normally specified with an `Icon` argument to a constructor or to the component's `setIcon` method. An `Icon` is an object of any class that implements interface `Icon` (package `javax.swing`). One such class is `ImageIcon` (package `javax.swing`), which supports several image formats, including **Graphics Interchange Format (GIF)**, **Portable Network Graphics (PNG)** and **Joint Photographic Experts Group (JPEG)**. File names for each of these types end with `.gif`, `.png` or `.jpg` (or `.jpeg`), respectively. We discuss images in more detail in Chapter 21, Multimedia: Applets and Applications.

Line 28 declares an `ImageIcon` object. The file `bug1.gif` contains the image to load and store in the `ImageIcon` object. (This image is included in the directory for this example on the CD that accompanies this book.) The `ImageIcon` object is assigned to `Icon` reference `bug`. Remember, class `ImageIcon` implements interface `Icon`; an `ImageIcon` is an `Icon`.

11.4 Displaying Text and Images in a Window **535**

In line 28, the expression `getClass().getResource("bug1.gif")` invokes method `getClass` (inherited from class `Object`) to retrieve a reference to the `Class` object that represents the `LabelFrame` class declaration. That reference is then used to invoke `Class` method `getResource`, which returns the location of the image as a URL. The `ImageIcon` constructor uses the URL to locate the image, then loads it into memory. As we discussed in Chapter 1, the JVM loads class declarations into memory, using a class loader. The class loader knows where each class it loads is located on disk. Method `getResource` uses the `Class` object's class loader to determine the location of a resource, such as an image file. In this example, the image file is stored in the same location as the `LabelFrame.class` file. The techniques described here enable an application to load image files from locations that are relative to `LabelFrame`'s `.class` file on disk.

A `JLabel` can display an `Icon`. Lines 29–30 use another `JLabel` constructor to create a `JLabel` that displays the text "Label with text and icon" and the `Icon` bug created in line 28. The last constructor argument indicates that the label's contents are left justified, or `left aligned` (i.e., the icon and text are at the left side of the label's area on the screen). Interface `SwingConstants` (package `javax.swing`) declares a set of common integer constants (such as `SwingConstants.LEFT`) that are used with many Swing components. By default, the text appears to the right of the image when a label contains both text and an image. Note that the horizontal and vertical alignments of a `JLabel` can be set with methods `setHorizontalAlignment` and `setVerticalAlignment`, respectively. Line 31 specifies the tool-tip text for `label2`, and line 32 adds `label2` to the `JFrame`.

Creating and Attaching `label3`

Class `JLabel` provides many methods to change a label's appearance after the label has been instantiated. Line 34 creates a `JLabel` and invokes its no-argument constructor. Such a label initially has no text or `Icon`. Line 35 uses `JLabel` method `setText` to set the text displayed on the label. The corresponding method `getText` retrieves the current text displayed on a label. Line 36 uses `JLabel` method `setIcon` to specify the `Icon` to display on the label. The corresponding method `getIcon` retrieves the current `Icon` displayed on a label. Lines 37–38 use `JLabel` methods `setHorizontalTextPosition` and `setVerticalTextPosition` to specify the text position in the label. In this case, the text will be centered horizontally and will appear at the bottom of the label. Thus, the `Icon` will appear above the text. The horizontal-position constants in `SwingConstants` are `LEFT`, `CENTER` and `RIGHT` (Fig. 11.8). The vertical-position constants in `SwingConstants` are `TOP`, `CENTER` and `BOTTOM` (Fig. 11.8). Line 39 sets the tool-tip text for `label3`. Line 40 adds `label3` to the `JFrame`.

Constant	Description
<i>Horizontal-position constants</i>	
<code>SwingConstants.LEFT</code>	Place text on the left.
<code>SwingConstants.CENTER</code>	Place text in the center.
<code>SwingConstants.RIGHT</code>	Place text on the right.

Fig. 11.8 | Some basic GUI components. (Part I of 2.)

536 Chapter 11 GUI Components: Part I

Constant	Description
<i>Vertical-position constants</i>	
<code>SwingConstants.TOP</code>	Place text at the top.
<code>SwingConstants.CENTER</code>	Place text in the center.
<code>SwingConstants.BOTTOM</code>	Place text at the bottom.

Fig. 11.8 | Some basic GUI components. (Part 2 of 2.)*Creating and Displaying a `LabelFrame` Window*

Class `LabelTest` (Fig. 11.7) creates an object of class `LabelFrame` (line 9), then specifies the default close operation for the window. By default, closing a window simply hides the window. However, when the user closes the `LabelFrame` window, we would like the application to terminate. Line 10 invokes `LabelFrame`'s `setDefaultCloseOperation` method (inherited from class `JFrame`) with constant `JFrame.EXIT_ON_CLOSE` as the argument to indicate that the program should terminate when the window is closed by the user. This line is important. Without it the application will not terminate when the user closes the window. Next, line 11 invokes `LabelFrame`'s `setSize` method to specify the width and height of the window. Finally, line 12 invokes `LabelFrame`'s `setVisible` method with the argument `true` to display the window on the screen. Try resizing the window to see how the `FlowLayout` changes the `JLabel` positions as the window width changes.

11.5 Text Fields and an Introduction to Event Handling with Nested Classes

Normally, a user interacts with an application's GUI to indicate the tasks that the application should perform. For example, when you write an e-mail in an e-mail application, clicking the `Send` button tells the application to send the e-mail to the specified e-mail addresses. GUIs are **event driven**. When the user interacts with a GUI component, the interaction—known as an **event**—drives the program to perform a task. Some common events (user interactions) that might cause an application to perform a task include clicking a button, typing in a text field, selecting an item from a menu, closing a window and moving the mouse. The code that performs a task in response to an event is called an **event handler** and the overall process of responding to events is known as **event handling**.

In this section, we introduce two new GUI components that can generate events—`JTextFields` and `JPasswordFields` (package `javax.swing`). Class `JTextField` extends class `JTextComponent` (package `javax.swing.text`), which provides many features common to Swing's text-based components. Class `JPasswordField` extends `JTextField` and adds several methods that are specific to processing passwords. Each of these components is a single-line area in which the user can enter text via the keyboard. Applications can also display text in a `JTextField` (see the output of Fig. 11.10). A `JPasswordField` shows that characters are being typed as the user enters them, but hides the actual characters with an **echo character**, assuming that they represent a password that should remain known only to the user.

11.5 Text Fields and an Introduction to Event Handling with Nested Classes **537**

When the user types data into a `JTextField` or a `JPasswordField`, then presses *Enter*, an event occurs. Our next example demonstrates how a program can perform a task in response to that event. The techniques shown here are applicable to all GUI components that generate events.

The application of Figs. 11.9–11.10 uses classes `JTextField` and `JPasswordField` to create and manipulate four text fields. When the user types in one of the text fields, then presses *Enter*, the application displays a message dialog box containing the text the user typed. You can only type in the text field that is “in focus.” A component receives the focus when the user clicks the component. This is important, because the text field with the focus is the one that generates an event when the user presses *Enter*. In this example, when the user presses *Enter* in the `JPasswordField`, the password is revealed. We begin by discussing the setup of the GUI, then discuss the event-handling code.

```

14     private JTextField textField2; // text field constructed with text
15     private JTextField textField3; // text field with text and size
16     private JPasswordField passwordField; // password field with text
17
18     // TextFieldFrame constructor adds JTextFields to JFrame
19     public TextFieldFrame()
20     {
21         super( "Testing JTextField and JPasswordField" );
22         setLayout( new FlowLayout() ); // set frame layout
23
24         // constructtextfield with 10 columns
25         textField1 = new JTextField( 10 );
26         add( textField1 ); // add textField1 to JFrame
27
28         // constructtextfield with default text
29         textField2 = new JTextField( "Enter text here" );
30         add( textField2 ); // add textField2 to JFrame
31
32         // constructtextfield with default text and 21 columns
33         textField3 = new JTextField( "Uneditable text field", 21 );
34         textField3.setEditable( false ); // disable editing
35         add( textField3 ); // add textField3 to JFrame
36

```

Fig. 11.9 | `JTextFields` and `JPasswordFields`. (Part I of 2.)

538 Chapter 11 GUI Components: Part I

```

37  // construct passwordfield with default text
38  passwordField = new JPasswordField( "Hidden text" );
39  add( passwordField ); // add passwordField to JFrame
40
41  // register event handlers
42  TextFieldHandler handler = new TextFieldHandler();
43  textField1.addActionListener( handler );
44  textField2.addActionListener( handler );
45  textField3.addActionListener( handler );
46  passwordField.addActionListener( handler );
47 } // end TextFieldFrame constructor
48
49 // private inner class for event handling
50 private class TextFieldHandler implements ActionListener
51 {
52     // process text field events
53     public void actionPerformed( ActionEvent event )
54     {
55         String string = ""; // declare string to display
56
57         // user pressed Enter in JTextField textField1
58         if ( event.getSource() == textField1 )
59             string = String.format( "textField1: %s",
60             event.getActionCommand() );
61
62         // user pressed Enter in JTextField textField2
63         else if ( event.getSource() == textField2 )
64             string = String.format( "textField2: %s",
65             event.getActionCommand() );
66
67         // user pressed Enter in JTextField textField3
68         else if ( event.getSource() == textField3 )
69             string = String.format( "textField3: %s",
70             event.getActionCommand() );
71
72         // user pressed Enter in JTextField passwordField
73         else if ( event.getSource() == passwordField )
74             string = String.format( "passwordField: %s",
75             new String( passwordField.getPassword() ) );
76
77         // display JTextField content
78         JOptionPane.showMessageDialog( null, string );
79     } // end method actionPerformed
80 } // end private inner class TextFieldHandler
81 } // end class TextFieldFrame

```

Fig. 11.9 | JTextFields and JPasswordFields. (Part 2 of 2.)

Lines 3–9 import the classes and interfaces we use in this example. Class `TextFieldFrame` extends `JFrame` and declares three `JTextField` variables and a `JPasswordField` variable (lines 13–16). Each of the corresponding text fields is instantiated and attached to the `TextFieldFrame` in the constructor (lines 19–47).

11.5 Text Fields and an Introduction to Event Handling with Nested Classes **539**

```

1 // Fig. 11.10: TextFieldTest.java
2 // Testing JTextFieldFrame.
3 import javax.swing.JFrame;
4
5 public class JTextFieldTest
6 {
7     public static void main( String args[] )
8     {
9         JTextFieldFrame textFieldFrame = new JTextFieldFrame();
10        textFieldFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        textFieldFrame.setSize( 350, 100 ); // set frame size
12        textFieldFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class JTextFieldTest

```

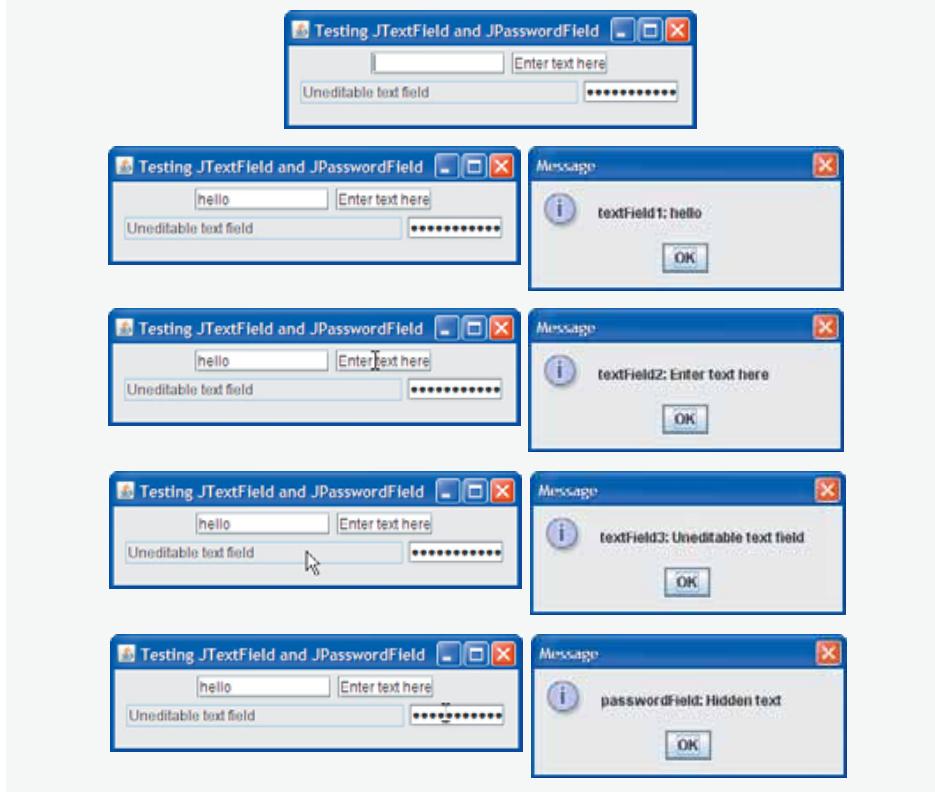

Fig. 11.10 | Test class for JTextFieldFrame.

Creating the GUI

Line 22 sets the layout of the JTextFieldFrame to FlowLayout. Line 25 creates textField1 with 10 columns of text. The width in pixels of a text column is determined by the average width of a character in the text field's current font. When text is displayed in a text field

540 Chapter 11 GUI Components: Part I

and the text is wider than the text field itself, a portion of the text at the right side is not visible. If you are typing in a text field and the cursor reaches the right edge of the text field, the text at the left edge is pushed off the left side of the text field and will no longer be visible. Users can use the left and right arrow keys to move through the complete text even though the entire text will not be visible at one time. Line 26 adds `textField1` to the `JFrame`.

Line 29 creates `textField2` with the initial text "Enter text here" to display in the text field. The width of the text field is determined by the width of the default text specified in the constructor. Line 30 adds `textField2` to the `JFrame`.

Line 33 creates `textField3` and calls the `JTextField` constructor with two arguments—the default text "Uneditable text field" to display and the number of columns (21). The width of the text field is determined by the number of columns specified. Line 34 uses method `setEditable` (inherited by `JTextField` from class `JTextComponent`) to make the text field uneditable—i.e., the user cannot modify the text in the text field. Line 35 adds `textField3` to the `JFrame`.

Line 38 creates `passwordField` with the text "Hidden text" to display in the text field. The width of the text field is determined by the width of the default text. When you execute the application, notice that the text is displayed as a string of asterisks. Line 39 adds `passwordField` to the `JFrame`.

Steps Required to Set Up Event Handling for a GUI Component

This example should display a message dialog containing the text from a text field when the user presses *Enter* in that text field. Before an application can respond to an event for a particular GUI component, you must perform several coding steps:

1. Create a class that represents the event handler.
2. Implement an appropriate interface, known as an **event-listener interface**, in the class from *Step 1*.
3. Indicate that an object of the class from *Steps 1* and *2* should be notified when the event occurs. This is known as **registering the event handler**.

Using a Nested Class to Implement an Event Handler

All the classes discussed so far were so-called **top-level classes**—that is, the classes were not declared inside another class. Java allows you to declare classes inside other classes—these are called **nested classes**. Nested classes can be **static** or **non-static**. Non-**static** nested classes are called **inner classes** and are frequently used for event handling.

Software Engineering Observation 11.2

An inner class is allowed to directly access its top-level class's variables and methods, even if they are private.

Before an object of an inner class can be created, there must first be an object of the top-level class that contains the inner class. This is required because an inner-class object implicitly has a reference to an object of its top-level class. There is also a special relationship between these objects—the inner-class object is allowed to directly access all the instance variables and methods of the outer class. A nested class that is **static** does not require an object of its top-level class and does not implicitly have a reference to an object

11.5 Text Fields and an Introduction to Event Handling with Nested Classes 541

of the top-level class. As you will see in Chapter 12, Graphics and Java 2D™, the Java 2D graphics API uses `static` nested classes extensively.

The event handling in this example is performed by an object of the `private` inner class `TextFieldHandler` (lines 50–80). This class is `private` because it will be used only to create event handlers for the text fields in top-level class `TextFieldFrame`. As with other members of a class, inner classes can be declared `public`, `protected` or `private`.

GUI components can generate a variety of events in response to user interactions. Each event is represented by a class and can be processed only by the appropriate type of event handler. In most cases, the events a GUI component supports are described in the Java API documentation for that component's class and its superclasses. When the user presses *Enter* in a `JTextField` or `JPasswordField`, the GUI component generates an `ActionEvent` (package `java.awt.event`). Such an event is processed by an object that implements the interface `ActionListener` (package `java.awt.event`). The information discussed here is available in the Java API documentation for classes `JTextField` and `ActionEvent`. Since `JPasswordField` is a subclass of `JTextField`, `JPasswordField` supports the same events.

To prepare to handle the events in this example, inner class `TextFieldHandler` implements interface `ActionListener` and declares the only method in that interface—`actionPerformed` (lines 53–79). This method specifies the tasks to perform when an `ActionEvent` occurs. So inner class `TextFieldHandler` satisfies *Steps 1* and *2* listed earlier in this section. We'll discuss the details of method `actionPerformed` shortly.

Registering the Event Handler for Each Text Field

In the `TextFieldFrame` constructor, line 42 creates a `TextFieldHandler` object and assigns it to variable `handler`. This object's `actionPerformed` method will be called automatically when the user presses *Enter* in any of the GUI's text fields. However, before this can occur, the program must register this object as the event handler for each text field. Lines 43–46 are the event-registration statements that specify `handler` as the event handler for the three `JTextFields` and the `JPasswordField`. The application calls `JTextField` method `addActionListener` to register the event handler for each component. This method receives as its argument an `ActionListener` object, which can be an object of any class that implements `ActionListener`. The object `handler` is an `ActionListener`, because class `TextFieldHandler` implements `ActionListener`. After lines 43–46 execute, the object `handler` **listens for events**. Now, when the user presses *Enter* in any of these four text fields, method `actionPerformed` (line 53–79) in class `TextFieldHandler` is called to handle the event. If an event handler is not registered for a particular text field, the event that occurs when the user presses *Enter* in that text field is **consumed**—i.e., it is simply ignored by the application.

Software Engineering Observation 11.3

The event listener for an event must implement the appropriate event-listener interface.

Common Programming Error 11.2

Forgetting to register an event-handler object for a particular GUI component's event type causes events of that type to be ignored.

542 Chapter 11 GUI Components: Part I

Details of Class `TextFieldHandler`'s `actionPerformed` Method

In this example, we are using one event-handling object's `actionPerformed` method (lines 53–79) to handle the events generated by four text fields. Since we'd like to output the name of each text field's instance variable for demonstration purposes, we must determine which text field generated the event each time `actionPerformed` is called. The GUI component with which the user interacts is the `event source`. In this example, the event source is one of the text fields or the password field. When the user presses *Enter* while one of these GUI components has the focus, the system creates a unique `ActionEvent` object that contains information about the event that just occurred, such as the event source and the text in the text field. The system then passes this `ActionEvent` object in a method call to the event listener's `actionPerformed` method. In this example, we display some of that information in a message dialog. Line 55 declares the `String` that will be displayed. The variable is initialized with the `empty string`—a string containing no characters. The compiler requires this in case none of the branches of the nested `if` in lines 58–75 executes.

`ActionEvent` method `getSource` (called in lines 58, 63, 68 and 73) returns a reference to the event source. The condition in line 58 asks, “Is the `event source` `textField1`? ” This condition compares the references on either side of the `==` operator to determine whether they refer to the same object. If they both refer to `textField1`, then the program knows that the user pressed *Enter* in `textField1`. In this case, lines 59–60 create a `String` containing the message that line 78 will display in a message dialog. Line 60 uses `ActionEvent` method `getActionCommand` to obtain the text the user typed in the text field that generated the event.

If the user interacted with the `JPasswordField`, lines 74–75 use `JPasswordField` method `getPassword` to obtain the password and create the `String` to display. This method returns the password as an array of type `char` that is used as an argument to a `String` constructor to create a string containing the characters in the array.

Class `TextFieldTest`

Class `TextFieldTest` (Fig. 11.10) contains the `main` method that executes this application and displays an object of class `TextFieldFrame`. When you execute the application, note that even the uneditable `JTextField` (`textField3`) can generate an `ActionEvent`. To test this, click the text field to give it the focus, then press *Enter*. Also note that the actual text of the password is displayed when you press *Enter* in the `JPasswordField`. Of course, you would normally not display the password!

This application used a single object of class `TextFieldHandler` as the event listener for four text fields. Starting in Section 11.9, you will see that it is possible to declare several event-listener objects of the same type and register each individual object for a separate GUI component's event. This technique enables us to eliminate the `if...else` logic used in this example's event handler by providing separate event handlers for each component's events.

11.6 Common GUI Event Types and Listener Interfaces

In Section 11.5, you learned that information about the event that occurs when the user presses *Enter* in a text field is stored in an `ActionEvent` object. Many different types of events can occur when the user interacts with a GUI. The information about any GUI event that occurs is stored in an object of a class that extends `AWTEvent`. Figure 11.11 il-

11.6 Common GUI Event Types and Listener Interfaces **543**

lustrates a hierarchy containing many event classes from the package `java.awt.event`. Some of these are discussed in this chapter and Chapter 22. These event types are used with both AWT and Swing components. Additional event types that are specific to Swing GUI components are declared in package `javax.swing.event`.

Let's summarize the three parts to the event-handling mechanism that you saw in Section 11.5—the event source, the event object and the event listener. The event source is the particular GUI component with which the user interacts. The event object encapsulates information about the event that occurred, such as a reference to the event source and any event-specific information that may be required by the event listener for it to handle the event. The event listener is an object that is notified by the event source when an event occurs; in effect, it “listens” for an event, and one of its methods executes in response to the event. A method of the event listener receives an event object when the event listener is notified of the event. The event listener then uses the event object to respond to the event. The event-handling model described here is known as the **delegation event model**—an event’s processing is delegated to a particular object (the event listener) in the application.

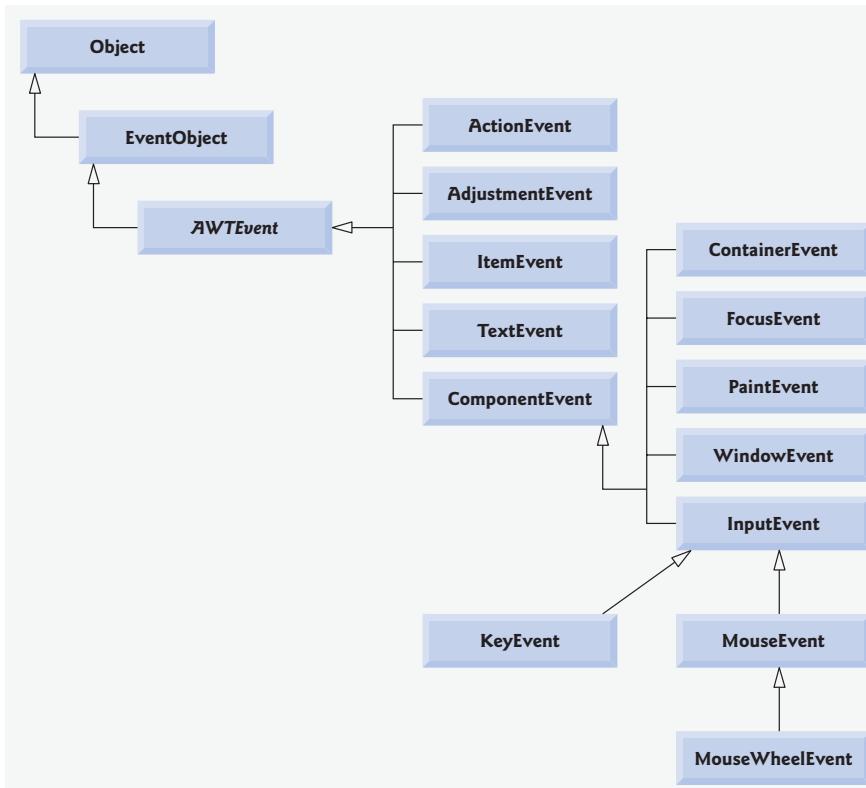

Fig. 11.11 | Some event classes of package `java.awt.event`.

544 Chapter 11 GUI Components: Part I

For each event-object type, there is typically a corresponding event-listener interface. An event listener for a GUI event is an object of a class that implements one or more of the event-listener interfaces from packages `java.awt.event` and `javax.swing.event`. Many of the event-listener types are common to both Swing and AWT components. Such types are declared in package `java.awt.event`, and some of them are shown in Fig. 11.12. Additional event-listener types that are specific to Swing components are declared in package `javax.swing.event`.

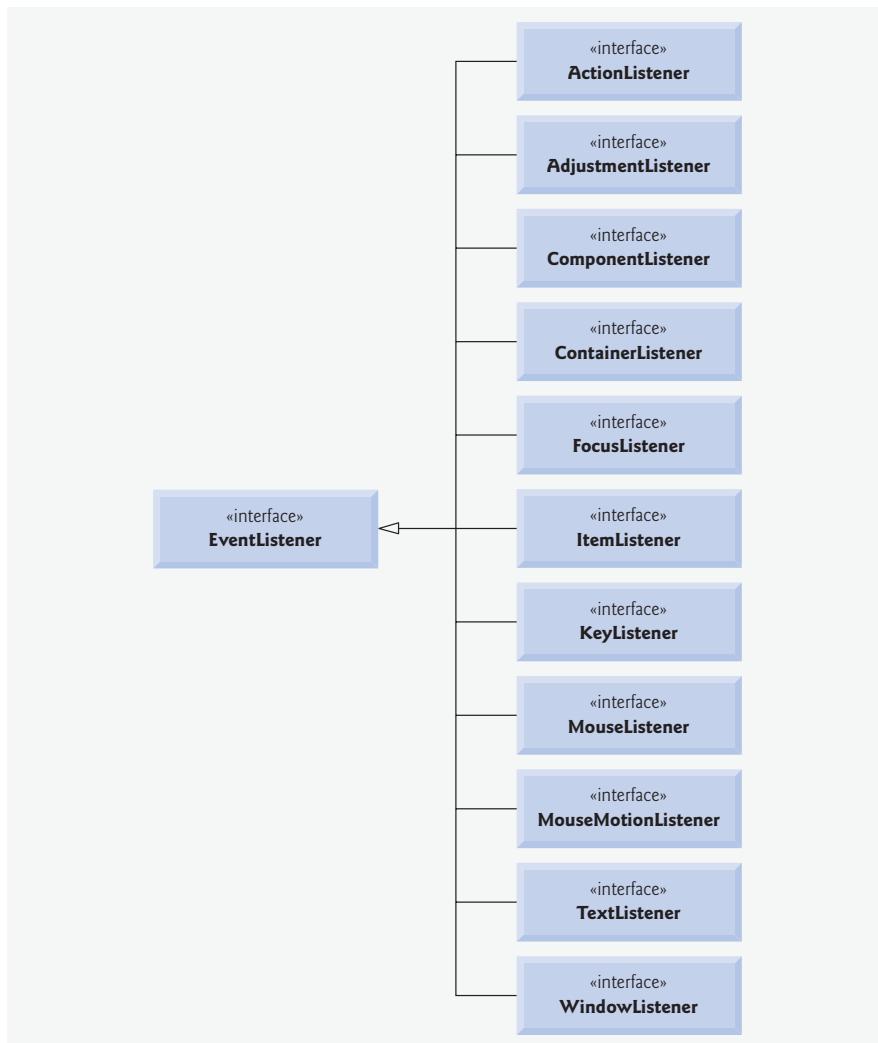

Fig. 11.12 | Some common event-listener interfaces of package `java.awt.event`.

11.7 How Event Handling Works 545

Each event-listener interface specifies one or more event-handling methods that must be declared in the class that implements the interface. Recall from Section 10.7 that any class which implements an interface must declare all the **abstract** methods of that interface; otherwise, the class is an **abstract** class and cannot be used to create objects.

When an event occurs, the GUI component with which the user interacted notifies its registered listeners by calling each listener's appropriate event-handling method. For example, when the user presses the *Enter* key in a `JTextField`, the registered listener's `actionPerformed` method is called. How did the event handler get registered? How does the GUI component know to call `actionPerformed` rather than another event-handling method? We answer these questions and diagram the interaction in the next section.

11.7 How Event Handling Works

Let us illustrate how the event-handling mechanism works, using `textField1` from the example of Fig. 11.9. We have two remaining open questions from Section 11.5:

1. How did the event handler get registered?
2. How does the GUI component know to call `actionPerformed` rather than some other event-handling method?

The first question is answered by the event registration performed in lines 43–46 of the application. Figure 11.13 diagrams `JTextField` variable `textField1`, `TextFieldHandler` variable `handler` and the objects to which they refer.

Registering Events

Every `JComponent` has an instance variable called `listenerList` that refers to an object of class `EventListenerList` (package `javax.swing.event`). Each object of a `JComponent` subclass maintains a references to all its registered listeners in the `listenerList`. For simplicity, we have diagrammed `listenerList` as an array below the `JTextField` object in Fig. 11.13.

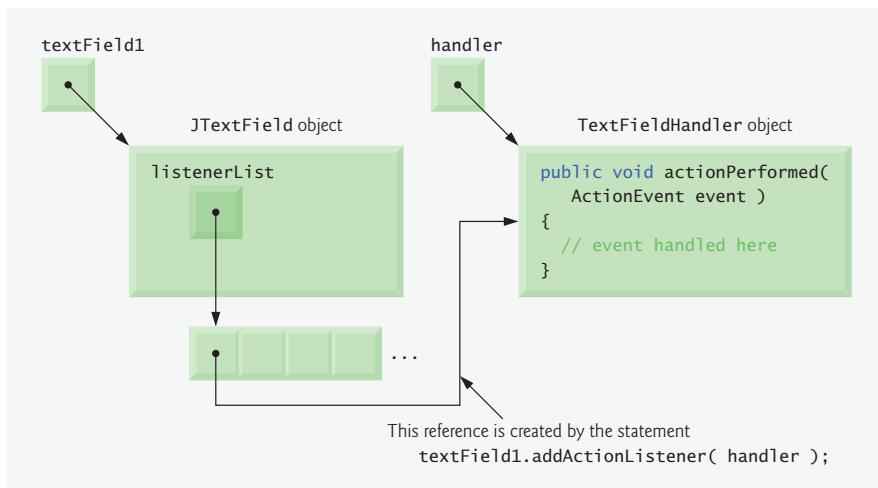

Fig. 11.13 | Event registration for `JTextField` `textField1`.

546 Chapter 11 GUI Components: Part I

When line 43 of Fig. 11.9

```
textField1.addActionListener( handler );
```

executes, a new entry containing a reference to the `TextFieldHandler` object is placed in `textField1`'s `listenerList`. Although not shown in the diagram, this new entry also includes the listener's type (in this case, `ActionListener`). Using this mechanism, each lightweight Swing GUI component maintains its own list of listeners that were registered to handle the component's events.

Event-Handler Invocation

The event-listener type is important in answering the second question: How does the GUI component know to call `actionPerformed` rather than another method? Every GUI component supports several event types, including [mouse events](#), [key events](#) and others. When an event occurs, the event is [dispatched](#) to only the event listeners of the appropriate type. Dispatching is simply the process by which the GUI component calls an event-handling method on each of its listeners that are registered for the particular event type that occurred.

Each event type has one or more corresponding event-listener interfaces. For example, `ActionEvents` are handled by `ActionListeners`, `MouseEvent`s are handled by `MouseListeners` and `MouseMotionListeners`, and `KeyEvents` are handled by `KeyListeners`. When an event occurs, the GUI component receives (from the JVM) a unique `event ID` specifying the event type. The GUI component uses the event ID to decide the listener type to which the event should be dispatched and to decide which method to call on each listener object. For an `ActionEvent`, the event is dispatched to every registered `ActionListener`'s `actionPerformed` method (the only method in interface `ActionListener`). For a `MouseEvent`, the event is dispatched to every registered `MouseListener` or `MouseMotionListener`, depending on the mouse event that occurs. The `MouseEvent`'s event ID determines which of the several mouse event-handling methods are called. All these decisions are handled for you by the GUI components. All you need to do is register an event handler for the particular event type that your application requires, and the GUI component will ensure that the event handler's appropriate method gets called when the event occurs. [Note: We discuss other event types and event-listener interfaces as they are needed with each new component we introduce.]

11.8 JButton

A [button](#) is a component the user clicks to trigger a specific action. A Java application can use several types of buttons, including [command buttons](#), [checkboxes](#), [toggle buttons](#) and [radio buttons](#). Figure 11.14 shows the inheritance hierarchy of the Swing buttons we cover in this chapter. As you can see, all the button types are subclasses of `AbstractButton` (package `javax.swing`), which declares the common features of Swing buttons. In this section, we concentrate on buttons that are typically used to initiate a command.

Look-and-Feel Observation 11.7

Buttons typically use book-title capitalization.

11.8 JButton 547

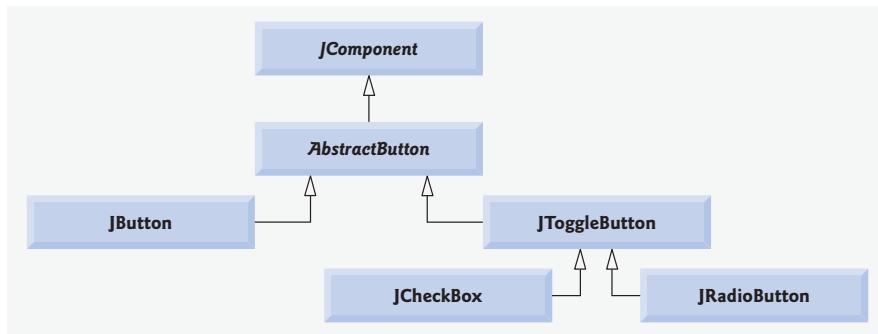

Fig. 11.14 | Swing button hierarchy.

A command button (see the output of Fig. 11.15) generates an **ActionEvent** when the user clicks the button. Command buttons are created with class **JButton**. The text on the face of a **JButton** is called a **button label**. A GUI can have many **JButtons**, but each button label typically should be unique in the portion of the GUI that is currently displayed.

Look-and-Feel Observation 11.8

Having more than one JButton with the same label makes the JButton ambiguous to the user. Provide a unique label for each button.

The application of Figs. 11.15 and 11.16 creates two **JButtons** and demonstrates that **JButtons** support the display of **Icons**. Event handling for the buttons is performed by a single instance of inner class **ButtonHandler** (lines 39–47).

```

4
5 public class ButtonTest
6 {
7     public static void main( String args[] )
8     {
9         ButtonFrame buttonFrame = new ButtonFrame(); // create ButtonFrame
10        buttonFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        buttonFrame.setSize( 275, 110 ); // set frame size
12        buttonFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class ButtonTest

```

**Fig. 11.16** | Test class for ButtonFrame. (Part 1 of 2.)

11.8 JButton 549

Fig. 11.16 | Test class for ButtonFrame. (Part 2 of 2.)

Lines 14–15 declare JButton variables plainButton and fancyButton. The corresponding objects are instantiated in the constructor. Line 23 creates plainButton with the button label "Plain Button". Line 24 adds the button to the JFrame.

A JButton can display an Icon. To provide the user with an extra level of visual interaction with the GUI, a JButton can also have a **rollover** Icon—an Icon that is displayed when the user positions the mouse over the button. The icon on the button changes as the mouse moves in and out of the button's area on the screen. Lines 26–27 create two ImageIcon objects that represent the default Icon and rollover Icon for the JButton created at line 28. Both statements assume that the image files are stored in the same directory as the application (which is commonly the case for applications that use images). These image files have been provided for you.

Line 28 creates fancyButton with the text "Fancy Button" and the icon bug1. By default, the text is displayed to the right of the icon. Line 29 uses **setRolloverIcon** (inherited from class AbstractButton) to specify the image displayed on the button when the user positions the mouse over it. Line 30 adds the button to the JFrame.

Look-and-Feel Observation 11.9

Because class AbstractButton supports displaying text and images on a button, all subclasses of AbstractButton also support displaying text and images.

Look-and-Feel Observation 11.10

Using rollover icons for JButtons provides users with visual feedback indicating that when they click the mouse while the cursor is positioned over the button, an action will occur.

JButtons, like JTextFields, generate ActionEvents that can be processed by any ActionListener object. Lines 33–35 create an object of private inner class ButtonHandler and register it as the event handler for each JButton. Class ButtonHandler (lines 39–47) declares actionPerformed to display a message dialog box containing the label for the

550 Chapter 11 GUI Components: Part I

button the user pressed. For a JButton event, ActionEvent method `getActionCommand` returns the label on the button.

Accessing the `this` Reference in an Object of a Top-Level Class From an Inner Class

When you execute this application and click one of its buttons, notice that the message dialog that appears is centered over the application's window. This occurs because the call to JOptionPane method `showMessageDialog` (lines 44–45 of Fig. 11.15) uses `ButtonFrame.this` rather than `null` as the first argument. When this argument is not `null`, it represents the so-called parent GUI component of the message dialog (in this case the application window is the parent component) and enables the dialog to be centered over that component when the dialog is displayed. `ButtonFrame.this` represents the `this` reference of the object of top-level class `ButtonFrame`.

Software Engineering Observation 11.4

When used in an inner class, keyword `this` refers to the current inner-class object being manipulated. An inner-class method can use its outer-class object's `this` by preceding `this` with the outer-class name and a dot, as in `ButtonFrame.this`.

11.9 Buttons That Maintain State

The Swing GUI components contain three types of **state buttons**—**JToggleButton**, **JCheckBox** and **JRadioButton**—that have on/off or true/false values. Classes **JCheckBox** and **JRadioButton** are subclasses of **JToggleButton** (Fig. 11.14). A **JRadioButton** is different from a **JCheckBox** in that normally several **JRadioButtons** are grouped together, and are mutually exclusive—only one in the group can be selected at any time, just like the buttons on a car radio. We first discuss class **JCheckBox**. The next two subsections also demonstrate that an inner class can access the members of its top-level class.

11.9.1 JCheckBox

The application of Figs. 11.17–11.18 uses two **JCheckBox** objects to select the desired font style of the text displayed in a **JTextField**. When selected, one applies a bold style and the other an italic style. If both are selected, the style of the font is bold and italic. When the application initially executes, neither **JCheckBox** is checked (i.e., they are both `false`), so the font is plain. Class **CheckBoxTest** (Fig. 11.18) contains the `main` method that executes this application.

```

1 // Fig. 11.17: CheckBoxFrame.java
2 // Creating JCheckBox buttons.
3 import java.awt.FlowLayout;
4 import java.awt.Font;
5 import java.awt.event.ItemListener;
6 import java.awt.event.ItemEvent;
7 import javax.swing.JFrame;
8 import javax.swing.JTextField;
9 import javax.swing.JCheckBox;
10

```

Fig. 11.17 | **JCheckBox** buttons and item events. (Part 1 of 2.)

11.9 Buttons That Maintain State **551**

```

11  public class CheckBoxFrame extends JFrame
12  {
13      private JTextField textField; // displays text in changing fonts
14      private JCheckBox boldJCheckBox; // to select/deselect bold
15      private JCheckBox italicJCheckBox; // to select/deselect italic
16
17      // CheckBoxFrame constructor adds JCheckboxes to JFrame
18      public CheckBoxFrame()
19      {
20          super( "JCheckBox Test" );
21          setLayout( new FlowLayout() ); // set frame layout
22
23          // set up JTextField and set its font
24          textField = new JTextField( "Watch the font style change", 20 );
25          textField.setFont( new Font( "Serif", Font.PLAIN, 14 ) );
26          add( textField ); // add textField to JFrame
27
28          boldJCheckBox = new JCheckBox( "Bold" ); // create bold checkbox
29          italicJCheckBox = new JCheckBox( "Italic" ); // create italic
30          add( boldJCheckBox ); // add bold checkbox to JFrame
31          add( italicJCheckBox ); // add italic checkbox to JFrame
32
33          // register listeners for JCheckboxes
34          CheckBoxHandler handler = new CheckBoxHandler();
35          boldJCheckBox.addItemListener( handler );
36          italicJCheckBox.addItemListener( handler );
37      } // end CheckBoxFrame constructor
38
39      // private inner class for ItemListener event handling
40      private class CheckBoxHandler implements ItemListener
41      {
42          private int valBold = Font.PLAIN; // controls bold font style
43          private int valItalic = Font.PLAIN; // controls italic font style
44
45          // respond to checkbox events
46          public void itemStateChanged( ItemEvent event )
47          {
48              // process bold checkbox events
49              if ( event.getSource() == boldJCheckBox )
50                  valBold =
51                      boldJCheckBox.isSelected() ? Font.BOLD : Font.PLAIN;
52
53              // process italic checkbox events
54              if ( event.getSource() == italicJCheckBox )
55                  valItalic =
56                      italicJCheckBox.isSelected() ? Font.ITALIC : Font.PLAIN;
57
58              // set text field font
59              textField.setFont(
60                  new Font( "Serif", valBold + valItalic, 14 ) );
61          } // end method itemStateChanged
62      } // end private inner class CheckBoxHandler
63  } // end class CheckBoxFrame

```

1 // Fig. 11.18: CheckBoxTest.java
2 // Testing CheckBoxFrame.
3 import javax.swing.JFrame;
4
5 public class CheckBoxTest
6 {
7     public static void main( String args[] )
8     {
9         CheckBoxFrame checkBoxFrame = new CheckBoxFrame();
10        checkBoxFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        checkBoxFrame.setSize( 275, 100 ); // set frame size
12        checkBoxFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class CheckBoxTest

```

Fig. 11.18 | Test class for CheckBoxFrame.

After the JTextField is created and initialized (Fig. 11.17, line 24), line 25 uses method `setFont` (inherited by JTextField indirectly from class Component) to set the font of the JTextField to a new object of class `Font` (package java.awt). The new Font is initialized with "Serif" (a generic font name representing a font such as Times and is supported on all Java platforms), `Font.PLAIN` style and 14-point size. Next, lines 28–29 create two JCheckBox objects. The string passed to the JCheckBox constructor is the `checkboxLabel` that appears to the right of the JCheckBox by default.

When the user clicks a JCheckBox, an `ItemEvent` occurs. This event can be handled by an `ItemListener` object, which must implement method `itemStateChanged`. In this example, the event handling is performed by an instance of private inner class `CheckBoxHandler` (lines 40–62). Lines 34–36 create an instance of class `CheckBoxHandler` and register it with method `addItemListener` as the listener for both the JCheckBox objects.

Lines 42–43 declare instance variables for the inner class `CheckBoxHandler`. Together, these variables represent the font style for the text displayed in the JTextField. Initially both are `Font.PLAIN` to indicate that the font is not bold and is not italic. Method `itemStateChanged` (lines 46–61) is called when the user clicks the `bold` or the `italic` JCheckBox. The method uses `event.getSource()` to determine which JCheckBox the user clicked. If it was the `boldJCheckBox`, line 51 uses JCheckBox method `isSelected` to determine if the JCheckBox is selected (i.e., it is checked). If the checkbox is selected, local variable `valBold` is assigned `Font.BOLD`; otherwise, it is assigned `Font.PLAIN`. A similar statement executes if the user clicks the `italicJCheckBox`. If the `italicJCheckBox` is selected, local variable `valItalic` is assigned `Font.ITALIC`; otherwise, it is assigned

11.9 Buttons That Maintain State **553**

`Font.PLAIN`. Lines 59–60 change the font of the `JTextField`, using the same font name and point size. The sum of `valBold` and `valItalic` represents the `JTextField`'s new font style. Each of the `Font` constants represents a unique value. `Font.PLAIN` has the value 0, so if both `valBold` and `valItalic` are set to `Font.PLAIN`, the font will have the plain style. If one of the values is `Font.BOLD` or `Font.ITALIC`, the font will be bold or italic accordingly. If one is `BOLD` and the other is `ITALIC`, the font will be both bold and italic.

Relationship Between an Inner Class and Its Top-Level Class

You may have noticed that class `CheckBoxHandler` used variables `boldJCheckBox` (Fig. 11.17, lines 49 and 51), `italicJCheckBox` (lines 54 and 56) and `textField` (line 59) even though these variables are not declared in the inner class. An inner class has a special relationship with its top-level class—the inner class is allowed to access directly all the instance variables and methods of the top-level class. Method `itemStateChanged` (line 46–61) of class `CheckBoxHandler` uses this relationship to determine which `JCheckBox` is the event source, to determine the state of a `JCheckBox` and to set the font on the `JTextField`. Notice that none of the code in inner class `CheckBoxHandler` requires a reference to the top-level class object.

11.9.2 JRadioButton

Radio buttons (declared with class `JRadioButton`) are similar to checkboxes in that they have two states—selected and not selected (also called deselected). However, radio buttons normally appear as a **group** in which only one button can be selected at a time (see the output of Fig. 11.20). Selecting a different radio button forces all others to be deselected. Radio buttons are used to represent **mutually exclusive** options (i.e., multiple options in the group cannot be selected at the same time). The logical relationship between radio buttons is maintained by a `ButtonGroup` object (package `javax.swing`), which itself is not a GUI component. A `ButtonGroup` object organizes a group of buttons and is not itself displayed in a user interface. Rather, the individual `JRadioButton` objects from the group are displayed in the GUI.

Common Programming Error 11.3

Adding a `ButtonGroup` object (or an object of any other class that does not derive from `Component`) to a container results in a compilation error.

The application of Figs. 11.19–11.20 is similar to that of Figs. 11.17–11.18. The user can alter the font style of a `JTextField`'s text. The application uses radio buttons that permit only a single font style in the group to be selected at a time. Class `RadioButtonTest` (Fig. 11.20) contains the `main` method that executes this application.

```

**Fig. 11.20** | Test class for RadioButtonFrame. (Part 1 of 2.)

556 Chapter 11 GUI Components: Part I

Fig. 11.20 | Test class for RadioButtonFrame. (Part 2 of 2.)

Lines 35–42 in the constructor (Fig. 11.19) create four `JRadioButton` objects and add them to the `JFrame`. Each `JRadioButton` is created with a constructor call like that in line 35. This constructor specifies the label that appears to the right of the `JRadioButton` by default and the initial state of the `JRadioButton`. A true second argument indicates that the `JRadioButton` should appear selected when it is displayed.

Line 45 instantiates `ButtonGroup` object `radioGroup`. This object is the “glue” that forms the logical relationship between the four `JRadioButton` objects and allows only one of the four to be selected at a time. It is possible that no `JRadioButtons` in a `ButtonGroup` are selected, but this can occur only if no preselected `JRadioButtons` are added to the `ButtonGroup` and the user has not selected a `JRadioButton` yet. Lines 46–49 use `ButtonGroup` method `add` to associate each of the `JRadioButtons` with `radioGroup`. If more than one selected `JRadioButton` object is added to the group, the selected one that was added first will be selected when the GUI is displayed.

`JRadioButtons`, like `JCheckboxes`, generate `ItemEvents` when they are clicked. Lines 59–66 create four instances of inner class `RadioButtonHandler` (declared at lines 70–84). In this example, each event-listener object is registered to handle the `ItemEvent` generated when the user clicks a particular `JRadioButton`. Notice that each `RadioButtonHandler` object is initialized with a particular `Font` object (created in lines 52–55).

Class `RadioButtonHandler` (line 70–84) implements interface `ItemListener` so it can handle `ItemEvents` generated by the `JRadioButtons`. The constructor stores the `Font` object it receives as an argument in the event-listener object’s instance variable `font` (declared at line 72). When the user clicks a `JRadioButton`, `radioGroup` turns off the previously selected `JRadioButton` and method `itemStateChanged` (line 80–83) sets the font in the `JTextField` to the `Font` stored in the `JRadioButton`’s corresponding event-listener object. Notice that line 82 of inner class `RadioButtonHandler` uses the top-level class’s `textField` instance variable to set the font.

11.10 JComboBox and Using an Anonymous Inner Class for Event Handling

A combo box (sometimes called a [drop-down list](#)) provides a list of items (Fig. 11.22) from which the user can make a single selection. Combo boxes are implemented with class `JComboBox`, which extends class `JComponent`. `JComboBoxes` generate `ItemEvents` like `JCheckboxes` and `JRadioButtons`. This example also demonstrates a special form of inner class that is used frequently in event handling.

The application of Figs. 11.21–11.22 uses a `JComboBox` to provide a list of four image file names from which the user can select one image to display. When the user selects a name, the application displays the corresponding image as an `Icon` on a `JLabel`. Class `ComboBoxTest` (Fig. 11.22) contains the `main` method that executes this application. The

11.10 JComboBox and Using an Anonymous Inner Class for Event Handling 557

screen captures for this application show the JComboBox list after the selection was made to illustrate which image file name was selected.

```

52 } // end class ComboBoxFrame

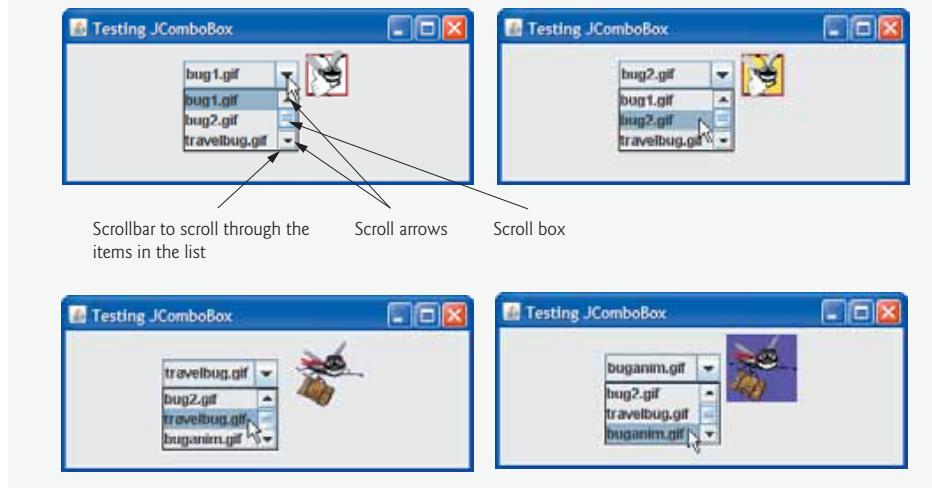

```

Fig. 11.21 | JComboBox that displays a list of image names. (Part 2 of 2.)

```

1 // Fig. 11.22: ComboBoxTest.java
2 // Testing ComboBoxFrame.
3 import javax.swing.JFrame;
4
5 public class ComboBoxTest
6 {
7     public static void main( String args[] )
8     {
9         ComboBoxFrame comboBoxFrame = new ComboBoxFrame();
10        comboBoxFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        comboBoxFrame.setSize( 350, 150 ); // set frame size
12        comboBoxFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class ComboBoxTest

```

**Fig. 11.22** | Test class for ComboBoxFrame.

Lines 19–23 (Fig. 11.21) declare and initialize array `icons` with four new `ImageIcon` objects. `String` array `names` (lines 17–18) contains the names of the four image files that are stored in the same directory as the application.

At line 31, the constructor creates a `JComboBox` object, using the `Strings` in array `names` as the elements in the list. Each item in the list has an `index`. The first item is added at index 0, the next at index 1 and so forth. The first item added to a `JComboBox` appears as the currently selected item when the `JComboBox` is displayed. Other items are selected by clicking the `JComboBox`, which expands into a list from which the user can make a selection.

11.10 JComboBox and Using an Anonymous Inner Class for Event Handling 559

Line 32 uses JComboBox method `setMaximumRowCount` to set the maximum number of elements that are displayed when the user clicks the JComboBox. If there are additional items, the JComboBox provides a `scrollbar` (see the first screen capture) that allows the user to scroll through all the elements in the list. The user can click the `scroll arrows` at the top and bottom of the scrollbar to move up and down through the list one element at a time, or else drag the `scroll box` in the middle of the scrollbar up and down. To drag the scroll box, position the mouse cursor on it, hold the mouse button down and move the mouse.

Look-and-Feel Observation 11.11

Set the maximum row count for a JComboBox to a number of rows that prevents the list from expanding outside the bounds of the window in which it is used. This configuration will ensure that the list displays correctly when it is expanded by the user.

Line 48 attaches the JComboBox to the ComboBoxFrame's FlowLayout (set in line 29). Line 49 creates the JLabel that displays ImageIcons and initializes it with the first ImageIcon in array icons. Line 50 attaches the JLabel to the ComboBoxFrame's FlowLayout.

Using an Anonymous Inner Class for Event Handling

Lines 34–46 are one statement that declares the event listener's class, creates an object of that class and registers that object as the listener for imagesJComboBox's ItemEvents. In this example, the event-listener object is an instance of an **anonymous inner class**—a special form of inner class that is declared without a name and typically appears inside a method declaration. As with other inner classes, an anonymous inner class can access its top-level class's members. However, an anonymous inner class has limited access to the local variables of the method in which it is declared. Since an anonymous inner class has no name, one object of the anonymous inner class must be created at the point where the class is declared (starting at line 35).

Software Engineering Observation 11.5

An anonymous inner class declared in a method can access the instance variables and methods of the top-level class object that declared it, as well as the method's final local variables, but cannot access the method's non-final local variables.

Lines 34–46 are a call to imagesJComboBox's addItemListener method. The argument to this method must be an object that is an ItemListener (i.e., any object of a class that implements ItemListener). Lines 35–45 are a class-instance creation expression that declares an anonymous inner class and creates one object of that class. A reference to that object is then passed as the argument to addItemListener. The syntax ItemListener() after new begins the declaration of an anonymous inner class that implements interface ItemListener. This is similar to beginning a class declaration with

```
public class MyHandler implements ItemListener
```

The parentheses after ItemListener indicate a call to the default constructor of the anonymous inner class.

The opening left brace {} at 36 and the closing right brace {} at line 45 delimit the body of the anonymous inner class. Lines 38–44 declare the ItemListener's itemStateChanged method. When the user makes a selection from imagesJComboBox, this method sets label's Icon. The Icon is selected from array icons by determining the index of the

560 Chapter 11 GUI Components: Part I

selected item in the JComboBox with method `getSelectedIndex` in line 43. Note that for each item selected from a JComboBox, another item is first deselected—so two ItemEvents occur when an item is selected. We wish to display only the icon for the item the user just selected. For this reason, line 41 determines whether ItemEvent method `getStateChange` returns `ItemEvent.SELECTED`. If so, lines 42–43 set `label`'s icon.

Software Engineering Observation 11.6

Like any other class, when an anonymous inner class implements an interface, the class must implement every method in the interface.

The syntax shown in lines 35–45 for creating an event handler with an anonymous inner class is similar to the code that would be generated by a Java integrated development environment (IDE). Typically, an IDE enables the programmer to design a GUI visually, then the IDE generates code that implements the GUI. The programmer simply inserts statements in the event-handling methods that declare how to handle each event.

11.11 JList

A *list* displays a series of items from which the user may select one or more items (see the output of Fig. 11.23). Lists are created with class `JList`, which directly extends class `JComponent`. Class `JList` supports **single-selection lists** (which allow only one item to be selected at a time) and **multiple-selection lists** (which allow any number of items to be selected). In this section, we discuss single-selection lists.

The application of Figs. 11.23–11.24 creates a `JList` containing 13 color names. When a color name is clicked in the `JList`, a `ListSelectionEvent` occurs and the application changes the background color of the application window to the selected color. Class `ListTest` (Fig. 11.24) contains the `main` method that executes this application.

```

1 // Fig. 11.23: ListFrame.java
2 // Selecting colors from a JList.
3 import java.awt.FlowLayout;
4 import java.awt.Color;
5 import javax.swing.JFrame;
6 import javax.swing.JList;
7 import javax.swing.JScrollPane;
8 import javax.swing.event.ListSelectionListener;
9 import javax.swing.event.ListSelectionEvent;
10 import javax.swing.ListSelectionModel;
11
12 public class ListFrame extends JFrame
13 {
14     private JList colorJList; // List to display colors
15     private final String colorNames[] = { "Black", "Blue", "Cyan",
16         "Dark Gray", "Gray", "Green", "Light Gray", "Magenta",
17         "Orange", "Pink", "Red", "White", "Yellow" };
18     private final Color colors[] = { Color.BLACK, Color.BLUE, Color.CYAN,
19         Color.DARK_GRAY, Color.GRAY, Color.GREEN, Color.LIGHT_GRAY,
20         Color.MAGENTA, Color.ORANGE, Color.PINK, Color.RED, Color.WHITE,
21         Color.YELLOW };

```

Fig. 11.23 | `JList` that displays a list of colors. (Part 1 of 2.)

11.11 JList 561

```

22
23     // ListFrame constructor add JScrollPane containing JList to JFrame
24     public ListFrame()
25     {
26         super( "List Test" );
27         setLayout( new FlowLayout() ); // set frame layout
28
29         colorJList = new JList( colorNames ); // create with colorNames
30         colorJList.setVisibleRowCount( 5 ); // display five rows at once
31
32         // do not allow multiple selections
33         colorJList.setSelectionMode( ListSelectionModel.SINGLE_SELECTION );
34
35         // add a JScrollPane containing JList to frame
36         add( new JScrollPane( colorJList ) );
37
38         colorJList.addListSelectionListener(
39             new ListSelectionListener() // anonymous inner class
40             {
41                 // handle list selection events
42                 public void valueChanged( ListSelectionEvent event )
43                 {
44                     getContentPane().setBackground(
45                         colors[ colorJList.getSelectedIndex() ] );
46                 } // end method valueChanged
47             } // end anonymous inner class
48         ); // end call to addListSelectionListener
49     } // end ListFrame constructor
50 } // end class ListFrame

```

Fig. 11.23 | JList that displays a list of colors. (Part 2 of 2.)

Line 29 (Fig. 11.23) creates JList object `colorList`. The argument to the JList constructor is the array of Objects (in this case Strings) to display in the list. Line 30 uses JList method `setVisibleRowCount` to determine the number of items that are visible in the list.

Line 33 uses JList method `setSelectionMode` to specify the list's `selection mode`. Class `ListSelectionModel` (of package `javax.swing`) declares three constants that specify a JList's selection mode—`SINGLE_SELECTION` (which allows only one item to be selected at a time), `SINGLE_INTERVAL_SELECTION` (for a multiple-selection list that allows selection of several contiguous items) and `MULTIPLE_INTERVAL_SELECTION` (for a multiple-selection list that does not restrict the items that can be selected).

Unlike a JComboBox, a JList *does not* provide a scrollbar if there are more items in the list than the number of visible rows. In this case, a JScrollPane object is used to provide the scrolling capability. Line 36 adds a new instance of class JScrollPane to the JFrame. The JScrollPane constructor receives as its argument the JComponent that needs scrolling functionality (in this case, `colorList`). Notice in the screen captures that a scrollbar created by the JScrollPane appears at the right side of the JList. By default, the scrollbar appears only when the number of items in the JList exceeds the number of visible items.

Lines 38–48 use JList method `addListSelectionListener` to register an object that implements `ListSelectionListener` (package `javax.swing.event`) as the listener for the

562 Chapter 11 GUI Components: Part I

```

1 // Fig. 11.24: ListTest.java
2 // Selecting colors from a JList.
3 import javax.swing.JFrame;
4
5 public class ListTest
6 {
7     public static void main( String args[] )
8     {
9         ListFrame listFrame = new ListFrame(); // create ListFrame
10        listFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        listFrame.setSize( 350, 150 ); // set frame size
12        listFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class ListTest

```

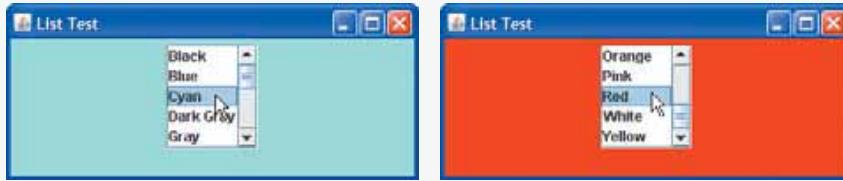

Fig. 11.24 | Test class for `ListFrame`.

`JList`'s selection events. Once again, we use an instance of an anonymous inner class (lines 39–47) as the listener. In this example, when the user makes a selection from `colorList`, method `valueChanged` (line 42–46) should change the background color of the `ListFrame` to the selected color. This is accomplished in lines 44–45. Note the use of `JFrame` method `getContentPane` in line 44. Each `JFrame` actually consists of three layers—the background, the content pane and the glass pane. The content pane appears in front of the background and is where the GUI components in the `JFrame` are displayed. The glass pane is used to display tool tips and other items that should appear in front of the GUI components on the screen. The content pane completely hides the background of the `JFrame`; thus, to change the background color behind the GUI components, you must change the content pane's background color. Method `getContentPane` returns a reference to the `JFrame`'s content pane (an object of class `Container`). In line 44, we then use that reference to call method `setBackground`, which sets the content pane's background color to an element in the `colors` array. The color is selected from the array by using the selected item's index. `JList` method `getSelectedIndex` returns the selected item's index. As with arrays and `JComboBoxes`, `JList` indexing is zero based.

11.12 Multiple-Selection Lists

A **multiple-selection list** enables the user to select many items from a `JList` (see the output of Fig. 11.26). A **SINGLE_INTERVAL_SELECTION** list allows selecting a contiguous range of items. To do so, click the first item, then press and hold the *Shift* key while clicking the last item in the range. A **MULTIPLE_INTERVAL_SELECTION** list allows continuous range selection as described for a **SINGLE_INTERVAL_SELECTION** list. Such a list allows miscellaneous items to be selected by pressing and holding the *Ctrl* key (sometimes called the

11.12 Multiple-Selection Lists **563**

Control key) while clicking each item to select. To deselect an item, press and hold the *Ctrl* key while clicking the item a second time.

The application of Figs. 11.25–11.26 uses multiple-selection lists to copy items from one `JList` to another. One list is a `MULTIPLE_INTERVAL_SELECTION` list and the other is a `SINGLE_INTERVAL_SELECTION` list. When you execute the application, try using the selection techniques described previously to select items in both lists.

```

1 // Fig. 11.26: MultipleSelectionTest.java
2 // Testing MultipleSelectionFrame.
3 import javax.swing.JFrame;
4
5 public class MultipleSelectionTest
6 {
7     public static void main( String args[] )
8     {
9         MultipleSelectionFrame multipleSelectionFrame =
10            new MultipleSelectionFrame();
11         multipleSelectionFrame.setDefaultCloseOperation(
12             JFrame.EXIT_ON_CLOSE );
13         multipleSelectionFrame.setSize( 350, 140 ); // set frame size
14         multipleSelectionFrame.setVisible( true ); // display frame
15     } // end main
16 } // end class MultipleSelectionTest

```

**Fig. 11.26** | Test class for `MultipleSelectionFrame`.

Line 27 of Fig. 11.25 creates `JList` `colorJList` and initializes it with the strings in the array `colorNames`. Line 28 sets the number of visible rows in `colorJList` to 5. Lines 29–30 specify that `colorList` is a `MULTIPLE_INTERVAL_SELECTION` list. Line 31 adds a new `JScrollPane` containing `colorJList` to the `JFrame`. Lines 49–55 perform similar tasks for `copyJList`, which is declared as a `SINGLE_INTERVAL_SELECTION` list. Line 51 uses `JList` method `setFixedCellWidth` to set `copyJList`'s width to 100 pixels. Line 52 uses `JList` method `setFixedCellHeight` to set the height of each item in the `JList` to 15 pixels.

There are no events to indicate that a user has made multiple selections in a multiple-selection list. Normally, an event generated by another GUI component (known as an **external event**) specifies when the multiple selections in a `JList` should be processed. In

11.13 Mouse Event Handling 565

In this example, the user clicks the JButton called `copyJButton` to trigger the event that copies the selected items in `colorJList` to `copyJList`.

Lines 39–45 declare, create and register an ActionListener for the `copyButton`. When the user clicks `copyJButton`, method `actionPerformed` (lines 39–43) uses `JList` method `setListData` to set the items displayed in `copyJList`. Line 42 calls `colorJList`'s method `getSelectedValues`, which returns an array of Objects representing the selected items in `colorJList`. In this example, the returned array is passed as the argument to `copyJList`'s `setListData` method.

You might be wondering why `copyJList` can be used in line 42 even though the application does not create the object to which it refers until line 49. Remember that method `actionPerformed` (lines 39–43) does not execute until the user presses the `copyJButton`, which cannot occur until after the constructor completes execution and the application displays the GUI. At that point in the application's execution, `copyJList` is already initialized with a new `JList` object.

11.13 Mouse Event Handling

This section presents the `MouseListener` and `MouseMotionListener` event-listener interfaces for handling `mouse events`. Mouse events can be trapped for any GUI component that derives from `java.awt.Component`. The methods of interfaces `MouseListener` and `MouseMotionListener` are summarized in Figure 11.27. Package `javax.swing.event` contains interface `MouseInputListener`, which extends interfaces `MouseListener` and `MouseMotionListener` to create a single interface containing all the `MouseListener` and `MouseMotionListener` methods. The `MouseListener` and `MouseMotionListener` methods are called when the mouse interacts with a Component if appropriate event-listener objects are registered for that Component.

MouseListener and MouseMotionListener interface methods	
<i>Methods of interface MouseListener</i>	
<code>public void mousePressed(MouseEvent event)</code>	Called when a mouse button is pressed while the mouse cursor is on a component.
<code>public void mouseClicked(MouseEvent event)</code>	Called when a mouse button is pressed and released while the mouse cursor remains stationary on a component. This event is always preceded by a call to <code>mousePressed</code> .
<code>public void mouseReleased(MouseEvent event)</code>	Called when a mouse button is released after being pressed. This event is always preceded by a call to <code>mousePressed</code> and one or more calls to <code>mouseDragged</code> .
<code>public void mouseEntered(MouseEvent event)</code>	Called when the mouse cursor enters the bounds of a component.

Fig. 11.27 | MouseListener and MouseMotionListener interface methods. (Part I of 2.)

566 Chapter 11 GUI Components: Part I**MouseListener and MouseMotionListener interface methods**

```
public void mouseExited( MouseEvent event )
```

Called when the mouse cursor leaves the bounds of a component.

Methods of interface MouseMotionListener

```
public void mouseDragged( MouseEvent event )
```

Called when the mouse button is pressed while the mouse cursor is on a component and the mouse is moved while the mouse button remains pressed. This event is always preceded by a call to `mousePressed`. All drag events are sent to the component on which the user began to drag the mouse.

```
public void mouseMoved( MouseEvent event )
```

Called when the mouse is moved when the mouse cursor is on a component. All move events are sent to the component over which the mouse is currently positioned.

Fig. 11.27 | MouseListener and MouseMotionListener interface methods. (Part I of 2.)

Each of the mouse event-handling methods takes a `MouseEvent` object as its argument. A `MouseEvent` object contains information about the mouse event that occurred, including the *x*- and *y*-coordinates of the location where the event occurred. These coordinates are measured from the upper-left corner of the GUI component on which the event occurred. The *x*-coordinates start at 0 and increase from left to right. The *y*-coordinates start at 0 and increase from top to bottom. In addition, the methods and constants of class `InputEvent` (`MouseEvent`'s superclass) enable an application to determine which mouse button the user clicked.

**Look-and-Feel Observation 11.12**

Method calls to `mouseDragged` and `mouseReleased` are sent to the `MouseMotionListener` for the Component on which a mouse drag operation started. Similarly, the `mouseReleased` method call at the end of a drag operation is sent to the `MouseListener` for the Component on which the drag operation started.

Java also provides interface `MouseWheelListener` to enable applications to respond to the rotation of a mouse wheel. This interface declares method `mouseWheelMoved`, which receives a `MouseWheelEvent` as its argument. Class `MouseWheelEvent` (a subclass of `MouseEvent`) contains methods that enable the event handler to obtain information about the amount of wheel rotation.

Tracking Mouse Events on a JPanel

The `MouseTracker` application (Figs. 11.28–11.29) demonstrates the `MouseListener` and `MouseMotionListener` interface methods. The application class implements both interfaces so it can listen for its own mouse events. Note that all seven methods from these two interfaces must be declared by the programmer when a class implements both interfaces. Each mouse event in this example displays a string in the `JLabel` called `statusBar` at the bottom of the window.

11.13 Mouse Event Handling **569**

```

11     mouseTrackerFrame.setSize( 300, 100 ); // set frame size
12     mouseTrackerFrame.setVisible( true ); // display frame
13 } // end main
14 } // end class MouseTracker

```

Fig. 11.29 | Test class for MouseTrackerFrame. (Part 2 of 2.)

Line 23 in Fig. 11.28 creates JPanel mousePanel1. This JPanel's mouse events will be tracked by the application. Line 24 sets mousePanel1's background color to white. When the user moves the mouse into the mousePanel1, the application will change mousePanel1's background color to green. When the user moves the mouse out of the mousePanel1, the application will change the background color back to white. Line 25 attaches mousePanel1 to the JFrame. As you learned in Section 11.4, you typically must specify the layout of the GUI components in a JFrame. In that section, we introduced the layout manager FlowLayout. Here we use the default layout of a JFrame's content pane—**BorderLayout**. This layout manager arranges components into five regions: **NORTH**, **SOUTH**, **EAST**, **WEST** and **CENTER**. NORTH corresponds to the top of the container. This example uses the CENTER and SOUTH regions. Line 25 uses a two-argument version of method add to place mousePanel1 in the CENTER region. The BorderLayout automatically sizes the component in the CENTER to use all the space in the JFrame that is not occupied by components in the other regions. Section 11.17.2 discusses BorderLayout in more detail.

Lines 27–28 in the constructor declare JLabel statusBar and attach it to the JFrame's SOUTH region. This JLabel occupies the width of the JFrame. The region's height is determined by the JLabel.

Line 31 creates an instance of inner class MouseHandler (lines 36–90) called handler that responds to mouse events. Lines 32–33 register handler as the listener for mousePanel1's mouse events. Methods **addMouseListener** and **addMouseMotionListener** are inherited indirectly from class Component and can be used to register MouseListeners and MouseMotionListeners, respectively. A MouseHandler object is both a MouseListener and a MouseMotionListener because the class implements both interfaces. [Note: In this example, we chose to implement both interfaces to demonstrate a class that implements more than one interface. However, we also could have implemented interface MouseInputListener here.]

570 Chapter 11 GUI Components: Part I

When the mouse enters and exits `mousePanel`'s area, methods `mouseEntered` (lines 62–67) and `mouseExited` (lines 70–74) are called, respectively. Method `mouseEntered` displays a message in the `statusBar` indicating that the mouse entered the `JPanel` and changes the background color to green. Method `mouseExited` displays a message in the `statusBar` indicating that the mouse is outside the `JPanel` (see the first sample output window) and changes the background color to white.

When any of the other five events occurs, it displays a message in the `statusBar` that includes a string containing the event and the coordinates at which it occurred. Mouse-Event methods `getX` and `getY` return the *x*- and *y*-coordinates, respectively, of the mouse at the time the event occurred.

11.14 Adapter Classes

Many event-listener interfaces, such as `MouseListener` and `MouseMotionListener`, contain multiple methods. It is not always desirable to declare every method in an event-listener interface. For instance, an application may need only the `mouseClicked` handler from `MouseListener` or the `mouseDragged` handler from `MouseMotionListener`. Interface `WindowListener` specifies seven window event-handling methods. For many of the listener interfaces that have multiple methods, packages `java.awt.event` and `javax.swing.event` provide event-listener adapter classes. An **adapter class** implements an interface and provides a default implementation (with an empty method body) of each method in the interface. Figure 11.30 shows several `java.awt.event` adapter classes and the interfaces they implement. You can extend an adapter class to inherit the default implementation of every method and subsequently override only the method(s) you need for event handling.

Software Engineering Observation 11.7

When a class implements an interface, the class has an is-a relationship with that interface. All direct and indirect subclasses of that class inherit this interface. Thus, an object of a class that extends an event-adapter class is an object of the corresponding event-listener type (e.g., an object of a subclass of `MouseAdapter` is a `MouseListener`).

Event-adapter class in <code>java.awt.event</code>	Implements interface
<code>ComponentAdapter</code>	<code>ComponentListener</code>
<code>ContainerAdapter</code>	<code>ContainerListener</code>
<code>FocusAdapter</code>	<code>FocusListener</code>
<code>KeyAdapter</code>	<code>KeyListener</code>
<code>MouseAdapter</code>	<code>MouseListener</code>
<code>MouseMotionAdapter</code>	<code>MouseMotionListener</code>
<code>WindowAdapter</code>	<code>WindowListener</code>

Fig. 11.30 | Event-adapter classes and the interfaces they implement in package `java.awt.event`.

11.14 Adapter Classes **571*****Extending MouseAdapter***

The application of Figs. 11.31–11.32 demonstrates how to determine the number of mouse clicks (i.e., the click count) and how to distinguish between the different mouse buttons. The event listener in this application is an object of inner class `MouseClickHandler` (lines 26–46) that extends `MouseAdapter`, so we can declare just the `mouseClicked` method we need in this example.

**Common Programming Error 11.4**

If you extend an adapter class and misspell the name of the method you are overriding, your method simply becomes another method in the class. This is a logic error that is difficult to detect, since the program will call the empty version of the method inherited from the adapter class.

6 {
7     public static void main( String args[] )
8     {
9         MouseDetailsFrame mouseDetailsFrame = new MouseDetailsFrame();
10        mouseDetailsFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        mouseDetailsFrame.setSize( 400, 150 ); // set frame size
12        mouseDetailsFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class MouseDetails

```

**Fig. 11.32** | Test class for MouseDetailsFrame.

A user of a Java application may be on a system with a one-, two- or three-button mouse. Java provides a mechanism to distinguish among mouse buttons. Class `MouseEvent` inherits several methods from class `InputEvent` that can distinguish among mouse buttons on a multi-button mouse or can mimic a multi-button mouse with a combined

11.15 JPanel Subclass for Drawing with the Mouse **573**

keystroke and mouse-button click. Figure 11.33 shows the `InputEvent` methods used to distinguish among mouse-button clicks. Java assumes that every mouse contains a left mouse button. Thus, it is simple to test for a left-mouse-button click. However, users with a one- or two-button mouse must use a combination of keystrokes and mouse-button clicks at the same time to simulate the missing buttons on the mouse. In the case of a one- or two-button mouse, a Java application assumes that the center mouse button is clicked if the user holds down the *Alt* key and clicks the left mouse button on a two-button mouse or the only mouse button on a one-button mouse. In the case of a one-button mouse, a Java application assumes that the right mouse button is clicked if the user holds down the *Meta* key and clicks the mouse button.

Line 22 of Fig. 11.31 registers a `MouseListener` for the `MouseDetailsFrame`. The event listener is an object of class `MouseClickedHandler`, which extends `MouseAdapter`. This enables us to declare only method `mouseClicked` (lines 29–45). This method first captures the coordinates where the event occurred and stores them in local variables `xPos` and `yPos` (lines 31–32). Lines 34–35 create a `String` called `details` containing the number of mouse clicks, which is returned by `MouseEvent` method `getClickCount` at line 35. Lines 37–42 use methods `isMetaDown` and `isAltDown` to determine which mouse button the user clicked and append an appropriate `String` to `details` in each case. The resulting `String` is displayed in the `statusBar`. Class `MouseDetails` (Fig. 11.32) contains the `main` method that executes the application. Try clicking with each of your mouse's buttons repeatedly to see the click count increment.

InputEvent method	Description
<code>isMetaDown()</code>	Returns <code>true</code> when the user clicks the right mouse button on a mouse with two or three buttons. To simulate a right-mouse-button click on a one-button mouse, the user can hold down the <i>Meta</i> key on the keyboard and click the mouse button.
<code>isAltDown()</code>	Returns <code>true</code> when the user clicks the middle mouse button on a mouse with three buttons. To simulate a middle-mouse-button click on a one- or two-button mouse, the user can press the <i>Alt</i> key on the keyboard and click the only or left mouse button, respectively.

Fig. 11.33 | InputEvent methods that help distinguish among left-, center- and right-mouse-button clicks.

11.15 JPanel Subclass for Drawing with the Mouse

Section 11.13 showed how to track mouse events in a `JPanel`. In this section, we use a `JPanel` as a **dedicated drawing area** in which the user can draw by dragging the mouse. In addition, this section demonstrates an event listener that extends an adapter class.

Method `paintComponent`

Lightweight Swing components that extend class `JComponent` (such as `JPanel`) contain method `paintComponent`, which is called when a lightweight Swing component is dis-

574 Chapter 11 GUI Components: Part I

played. By overriding this method, you can specify how to draw shapes using Java's graphics capabilities. When customizing a JPanel for use as a dedicated drawing area, the subclass should override method `paintComponent` and call the superclass version of `paintComponent` as the first statement in the body of the overridden method to ensure that the component displays correctly. The reason for this is that subclasses of JComponent support **transparency**. To display a component correctly, the program must determine whether the component is transparent. The code that determines this is in superclass JComponent's `paintComponent` implementation. When a component is transparent, `paintComponent` will not clear its background when the program displays the component. When a component is **opaque**, `paintComponent` clears the component's background before the component is displayed. If the superclass version of `paintComponent` is not called, an opaque GUI component typically will not display correctly on the user interface. Also, if the superclass version is called after performing the customized drawing statements, the results typically will be erased. The transparency of a Swing lightweight component can be set with method `setOpaque` (a `false` argument indicates that the component is transparent).

**Look-and-Feel Observation 11.13**

Most Swing GUI components can be transparent or opaque. If a Swing GUI component is opaque, its background will be cleared when its `paintComponent` method is called. Only opaque components can display a customized background color. JPanel objects are opaque by default.

**Error-Prevention Tip 11.1**

In a JComponent subclass's `paintComponent` method, the first statement should always be a call to the superclass's `paintComponent` method to ensure that an object of the subclass displays correctly.

**Common Programming Error 11.5**

If an overridden `paintComponent` method does not call the superclass's version, the subclass component may not display properly. If an overridden `paintComponent` method calls the superclass's version after other drawing is performed, the drawing will be erased.

Defining the Custom Drawing Area

The Painter application of Figs. 11.34–11.35 demonstrates a **customized subclass of JPanel** that is used to create a dedicated drawing area. The application uses the mouse-Dragged event handler to create a simple drawing application. The user can draw pictures by dragging the mouse on the JPanel. This example does not use method `mouseMoved`, so our event-listener class (the anonymous inner class at lines 22–34) extends `MouseMotionAdapter`. Since this class already declares both `mouseMoved` and `mouseDragged`, we can simply override `mouseDragged` to provide the event handling this application requires.

Class `PaintPanel` (Fig. 11.34) extends JPanel to create the dedicated drawing area. Lines 3–7 import the classes used in class `PaintPanel`. Class `Point` (package `java.awt`) represents an *x-y* coordinate. We use objects of this class to store the coordinates of each mouse drag event. Class `Graphics` is used to draw.

In this example, we use an array of 10,000 `Points` (line 14) to store the location at which each mouse-drag event occurs. As you will see, method `paintComponent` uses these `Points` to draw. Instance variable `pointCount` (line 11) maintains the total number of `Points` captured from mouse drag events so far.

41     super.paintComponent( g ); // clears drawing area
42
43     // draw all points in array
44     for ( int i = 0; i < pointCount; i++ )
45         g.fillOval( points[ i ].x, points[ i ].y, 4, 4 );
46 } // end method paintComponent
47 } // end class PaintPanel

```

Fig. 11.34 | Adapter classes used to implement event handlers.

Lines 20–35 register a `MouseMotionListener` to listen for the `PaintPanel`'s mouse-motion events. Lines 22–34 create an object of an anonymous inner class that extends the adapter class `MouseMotionAdapter`. Recall that `MouseMotionAdapter` implements `MouseMotionListener`, so the anonymous inner class object is a `MouseMotionListener`. The

```

Fig. 11.35 | Test class for PaintFrame.

anonymous inner class inherits a default implementation of methods `mouseMoved` and `mouseDragged`, so it already satisfies the requirement that all methods of the interface must be implemented. However, the default methods do nothing when they are called. So, we override method `mouseDragged` at lines 25–33 to capture the coordinates of a mouse-dragged event and store them as a `Point` object. Line 27 ensures that we store the event's coordinates only if there are still empty elements in the array. If so, line 29 invokes the `MouseEvent`'s `getPoint` method to obtain the `Point` where the event occurred and stores it in the array at index `pointCount`. Line 30 increments the `pointCount`, and line 31 calls method `repaint` (inherited indirectly from class `Component`) to indicate that the `PaintPanel` should be refreshed on the screen as soon as possible with a call to the `PaintPanel`'s `paintComponent` method.

Method `paintComponent` (lines 39–46), which receives a `Graphics` parameter, is called automatically any time the `PaintPanel` needs to be displayed on the screen (such as when the GUI is first displayed) or refreshed on the screen (such as when method `repaint`

11.16 Key-Event Handling **577**

is called or when the GUI component was hidden by another window on the screen and subsequently becomes visible again).

**Look-and-Feel Observation 11.14**

Calling repaint for a Swing GUI component indicates that the component should be refreshed on the screen as soon as possible. The background of the GUI component is cleared only if the component is opaque. JComponent method setOpaque can be passed a boolean argument indicating whether the component is opaque (true) or transparent (false).

Line 41 invokes the superclass version of `paintComponent` to clear the `PaintPanel`'s background (`JPanels` are opaque by default). Lines 44–45 draw an oval at the location specified by each `Point` in the array (up to the `pointCount`). `Graphics` method `fillOval` draws a solid oval. The method's four parameters represent a rectangular area (called the **bounding box**) in which the oval is displayed. The first two parameters are the upper-left *x*-coordinate and the upper-left *y*-coordinate of the rectangular area. The last two coordinates represent the rectangular area's width and height. Method `fillOval` draws the oval so it touches the middle of each side of the rectangular area. In line 45, the first two arguments are specified by using class `Point`'s two public instance variables—*x* and *y*. The loop terminates either when a null reference is encountered in the array or when the end of the array is reached. You will learn more `Graphics` features in Chapter 12.

**Look-and-Feel Observation 11.15**

Drawing on any GUI component is performed with coordinates that are measured from the upper-left corner (0, 0) of that GUI component, not the upper-left corner of the screen.

Using the Custom JPanel in an Application

Class `Painter` (Fig. 11.35) contains the main method that executes this application. Line 14 creates a `PaintPanel` object on which the user can drag the mouse to draw. Line 15 attaches the `PaintPanel` to the `JFrame`.

11.16 Key-Event Handling

This section presents the `KeyListener` interface for handling **key events**. Key events are generated when keys on the keyboard are pressed and released. A class that implements `KeyListener` must provide declarations for methods `keyPressed`, `keyReleased` and `keyTyped`, each of which receives a `KeyEvent` as its argument. Class `KeyEvent` is a subclass of `InputEvent`. Method `keyPressed` is called in response to pressing any key. Method `keyTyped` is called in response to pressing any key that is not an **action key**. (The action keys are any arrow key, *Home*, *End*, *Page Up*, *Page Down*, any function key, *Num Lock*, *Print Screen*, *Scroll Lock*, *Caps Lock* and *Pause*.) Method `keyReleased` is called when the key is released after any `keyPressed` or `keyTyped` event.

The application of Figs. 11.36–11.37 demonstrates the `KeyListener` methods. Class `KeyDemo` implements the `KeyListener` interface, so all three methods are declared in the application.

The constructor (Fig. 11.36, lines 17–28) registers the application to handle its own key events by using method `addKeyListener` at line 27. Method `addKeyListener` is declared in class `Component`, so every subclass of `Component` can notify `KeyListener` objects of key events for that `Component`.

14 } // end class KeyDemo

```

**Fig. 11.37** | Test class for KeyDemoFrame. (Part 1 of 2.)

580 Chapter 11 GUI Components: Part I

Fig. 11.37 | Test class for KeyDemoFrame. (Part 2 of 2.)

At line 25, the constructor adds `JTextArea textArea` (where the application's output is displayed) to the `JFrame`. Notice in the screen captures that `textArea` occupies the entire window. This is due to the `JFrame`'s default `BorderLayout` (discussed in Section 11.17.2 and demonstrated in Fig. 11.41). When a single Component is added to a `BorderLayout`, the Component occupies the entire Container. Note that line 24 uses method `setDisabledTextColor` to change the color of the text in the textarea to black.

Methods `keyPressed` (lines 31–36) and `keyReleased` (lines 39–44) use `KeyEvent` method `getKeyCode` to get the **virtual key code** of the key that was pressed. Class `KeyEvent` maintains a set of constants—the virtual key-code constants—that represents every key on the keyboard. These constants can be compared with the return value of `getKeyCode` to test for individual keys on the keyboard. The value returned by `getKeyCode` is passed to `KeyEvent` method `getKeyText`, which returns a string containing the name of the key that was pressed. For a complete list of virtual key constants, see the on-line documentation for class `KeyEvent` (package `java.awt.event`). Method `keyTyped` (lines 47–51) uses `KeyEvent` method `getKeyChar` to get the Unicode value of the character typed.

All three event-handling methods finish by calling method `setLines2and3` (lines 54–66) and passing it the `KeyEvent` object. This method uses `KeyEvent` method `isActionKey` (line 57) to determine whether the key in the event was an action key. Also, `InputEvent` method `getModifiers` is called (line 59) to determine whether any modifier keys (such as *Shift*, *Alt* and *Ctrl*) were pressed when the key event occurred. The result of this method is passed to `KeyEvent` method `getKeyModifiersText`, which produces a string containing the names of the pressed modifier keys.

[*Note:* If you need to test for a specific key on the keyboard, class `KeyEvent` provides a **key constant** for every key on the keyboard. These constants can be used from the key event handlers to determine whether a particular key was pressed. Also, to determine whether the *Alt*, *Ctrl*, *Meta* and *Shift* keys are pressed individually, `InputEvent` methods `isAltDown`, `isControlDown`, `isMetaDown` and `isShiftDown` each return a `boolean` indicating if the particular key was pressed during the key event.]

11.17 Layout Managers

Layout managers are provided to arrange GUI components in a container for presentation purposes. Programmers can use the layout managers for basic layout capabilities instead of determining the exact position and size of every GUI component. This functionality enables the programmer to concentrate on the basic look-and-feel and lets the layout managers process most of the layout details. All layout managers implement the interface `LayoutManager` (in package `java.awt`). Class `Container`'s `setLayout` method takes an ob-

11.17 Layout Managers **581**

ject that implements the `LayoutManager` interface as an argument. There are basically three ways for you to arrange components in a GUI:

1. Absolute positioning: This provides the greatest level of control over a GUI's appearance. By setting a Container's layout to `null`, you can specify the absolute position of each GUI component with respect to the upper-left corner of the Container. If you do this, you also must specify each GUI component's size. Programming a GUI with absolute positioning can be tedious, unless you have an integrated development environment (IDE) that can generate the code for you.
2. Layout managers: Using layout managers to position elements can be simpler and faster than creating a GUI with absolute positioning, but you lose some control over the size and the precise positioning of GUI components.
3. Visual programming in an IDE: IDEs provide tools that make it easy to create GUIs. Each IDE typically provides a **GUI design tool** that allows you to drag and drop GUI components from a tool box onto a design area. You can then position, size and align GUI components as you like. The IDE generates the Java code that creates the GUI. In addition, you can typically add event-handling code for a particular component by double-clicking the component. Some design tools also allow you to use the layout managers described in this chapter and in Chapter 22.

**Look-and-Feel Observation 11.16**

Most Java programming environments provide GUI design tools that help a programmer graphically design a GUI; the design tools then write the Java code to create the GUI. Such tools often provide greater control over the size, position and alignment of GUI components than do the built-in layout managers.

**Look-and-Feel Observation 11.17**

It is possible to set a Container's layout to `null`, which indicates that no layout manager should be used. In a Container without a layout manager, the programmer must position and size the components in the given container and take care that, on resize events, all components are repositioned as necessary. A component's resize events can be processed by a ComponentListener.

Figure 11.38 summarizes the layout managers presented in this chapter. Other layout managers are discussed in Chapter 22.

Layout manager	Description
FlowLayout	Default for <code>javax.swing.JPanel</code> . Places components sequentially (left to right) in the order they were added. It is also possible to specify the order of the components by using the <code>Container</code> method <code>add</code> , which takes a <code>Component</code> and an integer index position as arguments.
BorderLayout	Default for <code>JFrames</code> (and other windows). Arranges the components into five areas: NORTH, SOUTH, EAST, WEST and CENTER.
GridLayout	Arranges the components into rows and columns.

Fig. 11.38 | Layout managers.

582 Chapter 11 GUI Components: Part I

11.17.1 FlowLayout

`FlowLayout` is the simplest layout manager. GUI components are placed on a container from left to right in the order in which they are added to the container. When the edge of the container is reached, components continue to display on the next line. Class `FlowLayout` allows GUI components to be **left aligned**, **centered** (the default) and **right aligned**.

The application of Figs. 11.39–11.40 creates three `JButton` objects and adds them to the application, using a `FlowLayout` layout manager. The components are center aligned by default. When the user clicks **Left**, the alignment for the layout manager is changed to a left-aligned `FlowLayout`. When the user clicks **Right**, the alignment for the layout manager is changed to a right-aligned `FlowLayout`. When the user clicks **Center**, the alignment for the layout manager is changed to a center-aligned `FlowLayout`. Each button has its own event handler that is declared with an inner class that implements `ActionListener`. The sample output windows show each of the `FlowLayout` alignments. Also, the last sample output window shows the centered alignment after the window has been resized to a smaller width. Notice that the button **Right** flows onto a new line.

```

1 // Fig. 11.39: FlowLayoutFrame.java
2 // Demonstrating FlowLayout alignments.
3 import java.awt.FlowLayout;
4 import java.awt.Container;
5 import java.awt.event.ActionListener;
6 import java.awt.event.ActionEvent;
7 import javax.swing.JFrame;
8 import javax.swing.JButton;
9
10 public class FlowLayoutFrame extends JFrame
11 {
12     private JButton leftJButton; // button to set alignment left
13     private JButton centerJButton; // button to set alignment center
14     private JButton rightJButton; // button to set alignment right
15     private FlowLayout layout; // layout object
16     private Container container; // container to set layout
17
18     // set up GUI and register button listeners
19     public FlowLayoutFrame()
20     {
21         super( "FlowLayout Demo" );
22
23         layout = new FlowLayout(); // create FlowLayout
24         container = getContentPane(); // get container to layout
25         setLayout( layout ); // set frame layout
26
27         // set up leftJButton and register listener
28         leftJButton = new JButton( "Left" ); // create Left button
29         add( leftJButton ); // add Left button to frame
30         leftJButton.addActionListener(
31
32             new ActionListener() // anonymous inner class
33             {

```

Fig. 11.39 | `FlowLayout` allows components to flow over multiple lines. (Part I of 2.)

11.17 Layout Managers **583**

```

34         // process leftJButton event
35     public void actionPerformed( ActionEvent event )
36     {
37         layout.setAlignment( FlowLayout.LEFT );
38
39         // realign attached components
40         layout.layoutContainer( container );
41     } // end method actionPerformed
42 } // end anonymous inner class
43 ); // end call to addActionListener
44
45 // set up centerJButton and register listener
46 centerJButton = new JButton( "Center" ); // create Center button
47 add( centerJButton ); // add Center button to frame
48 centerJButton.addActionListener(
49
50     new ActionListener() // anonymous inner class
51     {
52         // process centerJButton event
53         public void actionPerformed( ActionEvent event )
54         {
55             layout.setAlignment( FlowLayout.CENTER );
56
57             // realign attached components
58             layout.layoutContainer( container );
59         } // end method actionPerformed
60     } // end anonymous inner class
61 ); // end call to addActionListener
62
63 // set up rightJButton and register listener
64 rightJButton = new JButton( "Right" ); // create Right button
65 add( rightJButton ); // add Right button to frame
66 rightJButton.addActionListener(
67
68     new ActionListener() // anonymous inner class
69     {
70         // process rightJButton event
71         public void actionPerformed( ActionEvent event )
72         {
73             layout.setAlignment( FlowLayout.RIGHT );
74
75             // realign attached components
76             layout.layoutContainer( container );
77         } // end method actionPerformed
78     } // end anonymous inner class
79 ); // end call to addActionListener
80 } // end FlowLayoutFrame constructor
81 } // end class FlowLayoutFrame

```

Fig. 11.39 | FlowLayout allows components to flow over multiple lines. (Part 2 of 2.)

As seen previously, a container's layout is set with method `setLayout` of class `Container`. Line 25 sets the layout manager to the `FlowLayout` declared at line 23. Normally, the layout is set before any GUI components are added to a container.

584 Chapter 11 GUI Components: Part I

```

1 // Fig. 11.40: FlowLayoutDemo.java
2 // Testing FlowLayoutFrame.
3 import javax.swing.JFrame;
4
5 public class FlowLayoutDemo
6 {
7     public static void main( String args[] )
8     {
9         FlowLayoutFrame flowLayoutFrame = new FlowLayoutFrame();
10        flowLayoutFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        flowLayoutFrame.setSize( 300, 75 ); // set frame size
12        flowLayoutFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class FlowLayoutDemo

```

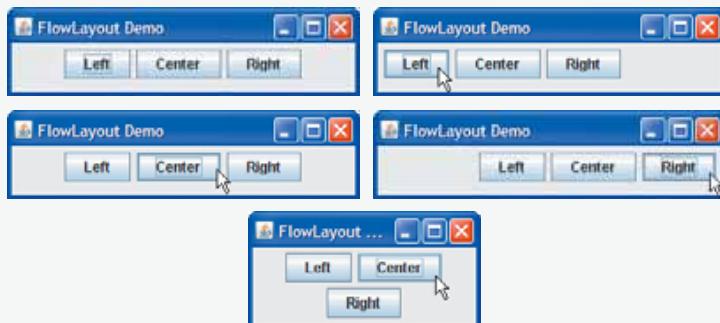

Fig. 11.40 | Test class for `FlowLayoutFrame`.

Look-and-Feel Observation 11.18

Each container can have only one layout manager. Separate containers in the same application can use different layout managers.

Note in this example that each button's event handler is specified with a separate anonymous inner-class object (lines 30–43, 48–61 and 66–71, respectively). Each button's `actionPerformed` event handler executes two statements. For example, line 37 in method `actionPerformed` for button `left` uses `FlowLayout` method `setAlignment` to change the alignment for the `FlowLayout` to a left-aligned (`FlowLayout.LEFT`) `FlowLayout`. Line 40 uses `LayoutManager` interface method `layoutContainer` (which is inherited by all layout managers) to specify that the `JFrame` should be rearranged based on the adjusted layout. According to which button was clicked, the `actionPerformed` method for each button sets the `FlowLayout`'s alignment to `FlowLayout.LEFT` (line 37), `FlowLayout.CENTER` (line 55) or `FlowLayout.RIGHT` (line 73).

11.17.2 BorderLayout

The `BorderLayout` layout manager (the default layout manager for a `JFrame`) arranges components into five regions: NORTH, SOUTH, EAST, WEST and CENTER. NORTH corresponds to the top of the container. Class `BorderLayout` extends `Object` and implements interface

11.17 Layout Managers **585**

`LayoutManager2` (a subinterface of `LayoutManager` that adds several methods for enhanced layout processing).

A `BorderLayout` limits a `Container` to containing at most five components—one in each region. The component placed in each region can be a container to which other components are attached. The components placed in the `NORTH` and `SOUTH` regions extend horizontally to the sides of the container and are as tall as the components placed in those regions. The `EAST` and `WEST` regions expand vertically between the `NORTH` and `SOUTH` regions and are as wide as the components placed in those regions. The component placed in the `CENTER` region expands to fill all remaining space in the layout (which is the reason the `JTextArea` in Fig. 11.36 occupies the entire window). If all five regions are occupied, the entire container's space is covered by GUI components. If the `NORTH` or `SOUTH` region is not occupied, the GUI components in the `EAST`, `CENTER` and `WEST` regions expand vertically to fill the remaining space. If the `EAST` or `WEST` region is not occupied, the GUI component in the `CENTER` region expands horizontally to fill the remaining space. If the `CENTER` region is not occupied, the area is left empty—the other GUI components do not expand to fill the remaining space. The application of Figs. 11.41–11.42 demonstrates the `BorderLayout` layout manager by using five `JButtons`.

```

1 // Fig. 11.41: BorderLayoutFrame.java

```

**Fig. 11.42** | Test class for BorderLayoutFrame. (Part 1 of 2.)

11.17 Layout Managers **587**

Fig. 11.42 | Test class for BorderLayoutFrame. (Part 2 of 2.)

Line 21 of Fig. 11.41 creates a `BorderLayout`. The constructor arguments specify the number of pixels between components that are arranged horizontally (**horizontal gap space**) and between components that are arranged vertically (**vertical gap space**), respectively. The default is one pixel of gap space horizontally and vertically. Line 22 uses method `setLayout` to set the content pane's layout to `layout`.

We add Components to a `BorderLayout` with another version of `Container` method `add` that takes two arguments—the Component to add and the region in which the Component should appear. For example, line 32 specifies that `buttons[0]` should appear in the `NORTH` region. The components can be added in any order, but only one component should be added to each region.

Look-and-Feel Observation 11.19

If no region is specified when adding a Component to a `BorderLayout`, the layout manager assumes that the Component should be added to region `BorderLayout.CENTER`.

Common Programming Error 11.6

When more than one component is added to a region in a `BorderLayout`, only the last component added to that region will be displayed. There is no error that indicates this problem.

Note that class `BorderLayoutFrame` implements `ActionListener` directly in this example, so the `BorderLayoutFrame` will handle the events of the `JButtons`. For this reason, line 29 passes the `this` reference to the `addActionListener` method of each `JButton`. When the user clicks a particular `JButton` in the layout, method `actionPerformed` (lines 40–52) executes. The enhanced `for` statement at lines 43–49 uses an `if...else` to hide the particular `JButton` that generated the event. Method `setVisible` (inherited into `JButton` from class `Component`) is called with a `false` argument (line 46) to hide the `JButton`. If the current `JButton` in the array is not the one that generated the

588 Chapter 11 GUI Components: Part I

event, method `setVisible` is called with a `true` argument (line 48) to ensure that the `JButton` is displayed on the screen. Line 51 uses `LayoutManager` method `layoutContainer` to recalculate the layout of the content pane. Notice in the screen captures of Fig. 11.41 that certain regions in the `BorderLayout` change shape as `JButtons` are hidden and displayed in other regions. Try resizing the application window to see how the various regions resize based on the window's width and height. For more complex layouts, group components in `JPanels`, each with a separate layout manager. Place the `JPanels` on the `JFrame` using either the default `BorderLayout` or some other layout.

11.17.3 GridLayout

The `GridLayout` layout manager divides the container into a grid so that components can be placed in rows and columns. Class `GridLayout` inherits directly from class `Object` and implements interface `LayoutManager`. Every `Component` in a `GridLayout` has the same width and height. Components are added to a `GridLayout` starting at the top-left cell of the grid and proceeding left to right until the row is full. Then the process continues left to right on the next row of the grid, and so on. The application of Figs. 11.43–11.44 demonstrates the `GridLayout` layout manager by using six `JButtons`.

```

1 // Fig. 11.43: GridLayoutFrame.java
2 // Demonstrating GridLayout.
3 import java.awt.GridLayout;
4 import java.awt.Container;
5 import java.awt.event.ActionListener;
6 import java.awt.event.ActionEvent;
7 import javax.swing.JFrame;
8 import javax.swing.JButton;
9
10 public class GridLayoutFrame extends JFrame implements ActionListener
11 {
12     private JButton buttons[]; // array of buttons
13     private final String names[] =
14         { "one", "two", "three", "four", "five", "six" };
15     private boolean toggle = true; // toggle between two layouts
16     private Container container; // frame container
17     private GridLayout gridLayout1; // first GridLayout
18     private GridLayout gridLayout2; // second GridLayout
19
20     // no-argument constructor
21     public GridLayoutFrame()
22     {
23         super( "GridLayout Demo" );
24         gridLayout1 = new GridLayout( 2, 3, 5, 5 ); // 2 by 3; gaps of 5
25         gridLayout2 = new GridLayout( 3, 2 ); // 3 by 2; no gaps
26         container = getContentPane(); // get content pane
27         setLayout( gridLayout1 ); // set JFrame layout
28         buttons = new JButton[ names.length ]; // create array of JButtons
29
30         for ( int count = 0; count < names.length; count++ )
31     }
```

Fig. 11.43 | `GridLayout` containing six buttons. (Part I of 2.)

11.17 Layout Managers **589**

```

32         buttons[ count ] = new JButton( names[ count ] );
33         buttons[ count ].addActionListener( this ); // register listener
34         add( buttons[ count ] ); // add button to JFrame
35     } // end for
36 } // end GridLayoutFrame constructor
37
38 // handle button events by toggling between layouts
39 public void actionPerformed( ActionEvent event )
40 {
41     if ( toggle )
42         container.setLayout( gridLayout2 ); // set layout to second
43     else
44         container.setLayout( gridLayout1 ); // set layout to first
45
46     toggle = !toggle; // set toggle to opposite value
47     container.validate(); // re-lay out container
48 } // end method actionPerformed
49 } // end class GridLayoutFrame

```

Fig. 11.43 | GridLayout containing six buttons. (Part 2 of 2.)

```

1 // Fig. 11.44: GridLayoutDemo.java
2 // Testing GridLayoutFrame.
3 import javax.swing.JFrame;
4
5 public class GridLayoutDemo
6 {
7     public static void main( String args[] )
8     {
9         GridLayoutFrame gridLayoutFrame = new GridLayoutFrame();
10        gridLayoutFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        gridLayoutFrame.setSize( 300, 200 ); // set frame size
12        gridLayoutFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class GridLayoutDemo

```

**Fig. 11.44** | Test class for GridLayoutFrame.

Lines 24–25 create two GridLayout objects. The GridLayout constructor used at line 24 specifies a GridLayout with 2 rows, 3 columns, 5 pixels of horizontal-gap space between Components in the grid and 5 pixels of vertical-gap space between Components in the grid. The GridLayout constructor used at line 25 specifies a GridLayout with 3 rows and 2 columns that uses the default gap space (1 pixel).

590 Chapter 11 GUI Components: Part I

The JButton objects in this example initially are arranged using gridLayout1 (set for the content pane at line 27 with method setLayout). The first component is added to the first column of the first row. The next component is added to the second column of the first row, and so on. When a JButton is pressed, method actionPerformed (lines 39–48) is called. Every call to actionPerformed toggles the layout between gridLayout2 and gridLayout1, using boolean variable toggle to determine the next layout to set.

Line 47 shows another way to reformat a container for which the layout has changed. Container method validate recomputes the container's layout based on the current layout manager for the Container and the current set of displayed GUI components.

11.18 Using Panels to Manage More Complex Layouts

Complex GUIs (like Fig. 11.1) require that each component be placed in an exact location. They often consist of multiple panels, with each panel's components arranged in a specific layout. Class JPanel extends JComponent and JComponent extends class Container, so every JPanel is a Container. Thus, every JPanel may have components, including other panels, attached to it with Container method add. The application of Figs. 11.45–11.46 demonstrates how a JPanel can be used to create a more complex layout in which several JButton objects are placed in the SOUTH region of a BorderLayout.

After JPanel buttonPanel is declared in line 11 and created at line 19, line 20 sets buttonPanel's layout to a GridLayout of one row and five columns (there are five JButton objects in array buttons). Lines 23–27 add the five JButton objects in array buttons to the JPanel in the loop. Line 26 adds the buttons directly to the JPanel—class JPanel does not have a content pane, unlike a JFrame. Line 29 uses the default BorderLayout to add buttonPanel to the SOUTH region. Note that the SOUTH region is as tall as the buttons on buttonPanel. A JPanel is sized to the components it contains. As more components are added, the JPanel grows (according to the restrictions of its layout manager) to accommodate the components. Resize the window to see how the layout manager affects the size of the JButton objects.

```

11.19 JTextArea 591

```

18     buttons = new JButton[ 5 ]; // create buttons array
19     buttonJPanel = new JPanel(); // set up panel
20     buttonJPanel.setLayout( new GridLayout( 1, buttons.length ) );
21
22     // create and add buttons
23     for ( int count = 0; count < buttons.length; count++ )
24     {
25         buttons[ count ] = new JButton( "Button " + ( count + 1 ) );
26         buttonJPanel.add( buttons[ count ] ); // add button to panel
27     } // end for
28
29     add( buttonJPanel, BorderLayout.SOUTH ); // add panel to JFrame
30 } // end JPanelFrame constructor
31 } // end class JPanelFrame

```

8     {
9         JPanelFrame panelFrame = new JPanelFrame();
10        panelFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        panelFrame.setSize( 450, 200 ); // set frame size
12        panelFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class PanelDemo

```

Fig. 11.46 | Test class for JPanelFrame.

11.19 JTextArea

A `JTextArea` provides an area for manipulating multiple lines of text. Like class `JTextField`, `JTextArea` is a subclass of `JTextComponent`, which declares common methods for `JTextFields`, `JTextAreas` and several other text-based GUI components.

The application in Figs. 11.47–11.48 demonstrates `JTextAreas`. One `JTextArea` displays text that the user can select. The other `JTextArea` is uneditable and is used to display

592 Chapter 11 GUI Components: Part I

the text the user selected in the first JTextArea. Unlike JTextField, JTextAreas do not have action events. As with multiple-selection JLists (Section 11.12), an external event from another GUI component indicates when to process the text in a JTextArea. For example, when typing an e-mail message, you normally click a **Send** button to send the text of the message to the recipient. Similarly, when editing a document in a word processor, you normally save the file by selecting a **Save** or **Save As...** menu item. In this program, the button **Copy >>>** generates the external event that copies the selected text in the left JTextArea and displays it in the right JTextArea.

```

1 // Fig. 11.47: TextAreaFrame.java
2 // Copying selected text from one textarea to another.
3 import java.awt.event.ActionListener;
4 import java.awt.event.ActionEvent;
5 import javax.swing.Box;
6 import javax.swing.JFrame;
7 import javax.swing.JTextArea;
8 import javax.swing.JButton;
9 import javax.swing.JScrollPane;
10
11 public class TextAreaFrame extends JFrame
12 {
13     private JTextArea textArea1; // displays demo string
14     private JTextArea textArea2; // highlighted text is copied here
15     private JButton copyJButton; // initiates copying of text
16
17     // no-argument constructor
18     public TextAreaFrame()
19     {
20         super( "TextArea Demo" );
21         Box box = Box.createHorizontalBox(); // create box
22         String demo = "This is a demo string to\n" +
23             "illustrate copying text\nfrom one textarea to \n" +
24             "another textarea using an\nexternal event\n";
25
26         textArea1 = new JTextArea( demo, 10, 15 ); // create textarea1
27         box.add( new JScrollPane( textArea1 ) ); // add scrollpane
28
29         copyJButton = new JButton( "Copy >>>" ); // create copy button
30         box.add( copyJButton ); // add copy button to box
31         copyJButton.addActionListener(
32
33             new ActionListener() // anonymous inner class
34             {
35                 // set text in textArea2 to selected text from textArea1
36                 public void actionPerformed( ActionEvent event )
37                 {
38                     textArea2.setText( textArea1.getSelectedText() );
39                 } // end method actionPerformed
40             } // end anonymous inner class
41         ); // end call to addActionListener
42

```

Fig. 11.47 | Copying selected text from one JTextArea to another. (Part I of 2.)

11.19 JTextArea 593

```

43     textArea2 = new JTextArea( 10, 15 ); // create second textarea
44     textArea2.setEditable( false ); // disable editing
45     box.add( new JScrollPane( textArea2 ) ); // add scrollpane
46
47     add( box ); // add box to frame
48 } // end TextAreaFrame constructor
49 } // end class TextAreaFrame

```

Fig. 11.47 | Copying selected text from one JTextArea to another. (Part 2 of 2.)

```

1 // Fig. 11.48: TextAreaDemo.java
2 // Copying selected text from one textarea to another.
3 import javax.swing.JFrame;
4
5 public class TextAreaDemo
6 {
7     public static void main( String args[] )
8     {
9         TextAreaFrame textAreaFrame = new TextAreaFrame();
10        textAreaFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        textAreaFrame.setSize( 425, 200 ); // set frame size
12        textAreaFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class TextAreaDemo

```

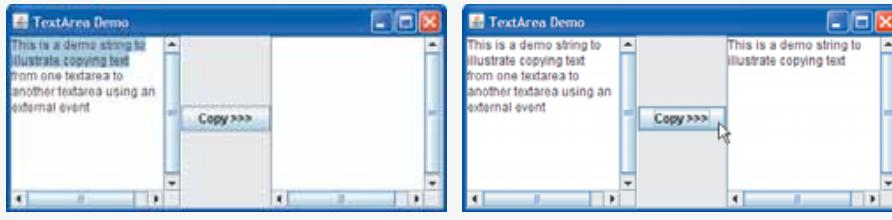

Fig. 11.48 | Test class for TextAreaFrame.

In the constructor (lines 18–48), line 21 creates a `Box` container (package `javax.swing`) to organize the GUI components. `Box` is a subclass of `Container` that uses a `BoxLayout` layout manager (discussed in detail in Section 22.9) to arrange the GUI components either horizontally or vertically. `Box`'s static method `createHorizontalBox` creates a `Box` that arranges components from left to right in the order that they are attached.

Lines 26 and 43 create `JTextAreas` `textArea1` and `textArea2`. Line 26 uses `JTextArea`'s three-argument constructor, which takes a `String` representing the initial text and two `ints` specifying that the `JTextArea` has 10 rows and 15 columns. Line 43 uses `JTextArea`'s two-argument constructor, specifying that the `JTextArea` has 10 rows and 15 columns. Line 26 specifies that `demo` should be displayed as the default `JTextArea` content. A `JTextArea` does not provide scrollbars if it cannot display its complete contents. So, line 27 creates a `JScrollPane` object, initializes it with `textArea1` and attaches it to container `box`. By default, horizontal and vertical scrollbars will appear as necessary in a `JScrollPane`.

594 Chapter 11 GUI Components: Part I

Lines 29–41 create JButton object copyButton with the label "Copy >>", add copyButton to container box and register the event handler for copyButton's ActionEvent. This button provides the external event that determines when the program should copy the selected text in textArea1 to textArea2. When the user clicks copyButton, line 38 in actionPerformed indicates that method `getSelectedText` (inherited into JTextArea from JTextComponent) should return the selected text from textArea1. The user selects text by dragging the mouse over the desired text to highlight it. Method setText changes the text in textArea2 to the string returned by `getSelectedText`.

Lines 43–45 create textArea2, set its editable property to `false` and add it to container box. Line 47 adds box to the JFrame. Recall from Section 11.17 that the default layout of a JFrame is a BorderLayout and that the add method by default attaches its argument to the CENTER of the BorderLayout.

It is sometimes desirable, when text reaches the right side of a JTextArea, to have the text wrap to the next line. This is referred to as **line wrapping**. By default, JTextArea does not wrap lines.

**Look-and-Feel Observation 11.20**

To provide line wrapping functionality for a JTextArea, invoke JTextArea method `setLineWrap` with a true argument.

JScrollPane Scrollbar Policies

This example uses a JScrollPane to provide scrolling for a JTextArea. By default, JScrollPane displays scrollbars only if they are required. You can set the horizontal and vertical **scrollbar policies** of a JScrollPane when it is constructed. If a program has a reference to a JScrollPane, the program can use JScrollPane methods `setHorizontalScrollBarPolicy` and `setVerticalScrollBarPolicy` to change the scrollbar policies at any time. Class JScrollPane declares the constants

```
JScrollPane.VERTICAL_SCROLLBAR_ALWAYS  
JScrollPane.HORIZONTAL_SCROLLBAR_ALWAYS
```

to indicate that a scrollbar should always appear, constants

```
JScrollPane.VERTICAL_SCROLLBAR_AS_NEEDED  
JScrollPane.HORIZONTAL_SCROLLBAR_AS_NEEDED
```

to indicate that a scrollbar should appear only if necessary (the defaults) and constants

```
JScrollPane.VERTICAL_SCROLLBAR_NEVER  
JScrollPane.HORIZONTAL_SCROLLBAR_NEVER
```

to indicate that a scrollbar should never appear. If the horizontal scrollbar policy is set to `JScrollPane.HORIZONTAL_SCROLLBAR_NEVER`, a JTextArea attached to the JScrollPane will automatically wrap lines.

11.20 Wrap-Up

In this chapter, you learned many GUI components and how to implement event handling. You also learned about nested classes, inner classes and anonymous inner classes. You saw the special relationship between an inner-class object and an object of its top-level class. You learned how to use JOptionPane dialogs to obtain text input from the user and

how to display messages to the user. You also learned how to create applications that execute in their own windows. We discussed class `JFrame` and components that enable a user to interact with an application. We also showed you how to display text and images to the user. You learned how to customize `JPanels` to create custom drawing areas, which you will use extensively in the next chapter. You saw how to organize components on a window using layout managers and how to creating more complex GUIs by using `JPanels` to organize components. Finally, you learned about the `JTextArea` component in which a user can enter text and an application can display text. In Chapter 22, GUI Components: Part 2, you will learn about more advanced GUI components, such as sliders, menus and more complex layout managers. In the next chapter, you will learn how to add graphics to your GUI application. Graphics allow you to draw shapes and text with colors and styles.

Summary

Section 11.1 Introduction

- A graphical user interface (GUI) presents a user-friendly mechanism for interacting with an application. A GUI gives an application a distinctive “look” and “feel.”
- Providing different applications with consistent, intuitive user interface components allows users to be somewhat familiar with an application, so that they can learn it more quickly.
- GUIs are built from GUI components—sometimes called controls or widgets.

Section 11.2 Simple GUI-Based Input/Output with `JOptionPane`

- Most applications use windows or dialog boxes (also called dialogs) to interact with the user.
- Class `JOptionPane` (package `javax.swing`) provides prepackaged dialog boxes for both input and output. `JOptionPane` static method `showInputDialog` displays an input dialog.
- A prompt typically uses sentence-style capitalization—a style that capitalizes only the first letter of the first word in the text unless the word is a proper noun.
- An input dialog can input only `String`s. This is typical of most GUI components.
- `JOptionPane` static method `showMessageDialog` displays a message dialog.

Section 11.3 Overview of Swing Components

- Most Swing GUI components are located in package `javax.swing`. They are part of the Java Foundation Classes (JFC)—Java’s libraries for cross-platform GUI development.
- Together, the appearance and the way in which the user interacts with the application are known as that application’s look-and-feel. Swing GUI components allow you to specify a uniform look-and-feel for your application across all platforms or to use each platform’s custom look-and-feel.
- Lightweight Swing components are not tied to actual GUI components supported by the underlying platform on which an application executes.
- Several Swing components are heavyweight components that require direct interaction with the local windowing system, which may restrict their appearance and functionality.
- Class `Component` (package `java.awt`) declares many of the attributes and behaviors common to the GUI components in packages `java.awt` and `javax.swing`.
- Class `Container` (package `java.awt`) is a subclass of `Component`. Components are attached to Containers so the Components can be organized and displayed on the screen.

596 [Chapter 11 GUI Components: Part I](#)

- Class `JComponent` (package `javax.swing`) is a subclass of `Container`. `JComponent` is the superclass of all lightweight Swing components and declares their common attributes and behaviors.
- Some common `JComponent` features include a pluggable look-and-feel, shortcut keys called mnemonics, tool tips, support for assistive technologies and support for user interface localization.

Section 11.4 Displaying Text and Images in a Window

- Most windows are instances of class `JFrame` or a subclass of `JFrame`. `JFrame` provides the basic attributes and behaviors of a window.
- A `JLabel` displays a single line of read-only text, an image, or both text and an image. Text in a `JLabel` normally uses sentence-style capitalization.
- When building a GUI, each GUI component must be attached to a container, such as a window created with a `JFrame`.
- Many IDEs provide GUI design tools in which you can specify the exact size and location of a component by using the mouse, then the IDE will generate the GUI code for you.
- `JComponent` method `setToolTipText` specifies the tool tip that is displayed when the user positions the mouse cursor over a lightweight component.
- `Container` method `add` attaches a GUI component to a `Container`.
- Class `ImageIcon` (package `javax.swing`) supports several image formats, including GIF, PNG and JPEG.
- Method `getClass` (of class `Object`) retrieves a reference to the `Class` object that represents the class declaration for the object on which the method is called.
- `Class` method `getResource` returns the location of its argument as a URL. Method `getResource` uses the `Class` object's class loader to determine the location of the resource.
- Interface `SwingConstants` (package `javax.swing`) declares a set of common integer constants that are used with many Swing components.
- The horizontal and vertical alignments of a `JLabel` can be set with methods `setHorizontalAlignment` and `setVerticalAlignment`, respectively.
- `JLabel` method `setText` sets the text displayed on a label. The corresponding method `getText` retrieves the current text displayed on a label.
- `JLabel` method `setIcon` specifies the `Icon` to display on a label. The corresponding method `getIcon` retrieves the current `Icon` displayed on a label.
- `JLabel` methods `setHorizontalTextPosition` and `setVerticalTextPosition` specify the text position in the label.
- `JFrame` method `setDefaultCloseOperation` with constant `JFrame.EXIT_ON_CLOSE` as the argument indicates that the program should terminate when the window is closed by the user.
- Component method `setSize` specifies the width and height of a component.
- Component method `setVisible` with the argument `true` displays a `JFrame` on the screen.

Section 11.5 Text Fields and an Introduction to Event Handling with Nested Classes

- GUIs are event driven—when the user interacts with a GUI component, events drive the program to perform tasks.
- The code that performs a task in response to an event is called an event handler and the overall process of responding to events is known as event handling.
- Class `JTextField` extends class `JTextComponent` (package `javax.swing.text`), which provides many features common to Swing's text-based components. Class `JPasswordField` extends `JTextField` and adds several methods that are specific to processing passwords.

Summary 597

- A `JPasswordField` shows that characters are being typed as the user enters them, but hides the actual characters with echo characters.
- A component receives the focus when the user clicks the component.
- `JTextComponent` method `setEditable` can be used to make a text field uneditable.
- Before an application can respond to an event for a particular GUI component, you must perform several coding steps: 1) Create a class that represents the event handler. 2) Implement an appropriate interface, known as an event-listener interface, in the class from *Step 1*. 3) Indicate that an object of the class from *Steps 1* and *2* should be notified when the event occurs. This is known as registering the event handler.
- Nested classes can be `static` or `non-static`. Non-`static` nested classes are called inner classes and are frequently used for event handling.
- Before an object of an inner class can be created, there must first be an object of the top-level class that contains the inner class, because an inner-class object implicitly has a reference to an object of its top-level class.
- An inner-class object is allowed to directly access all the instance variables and methods of its top-level class.
- A nested class that is `static` does not require an object of its top-level class and does not implicitly have a reference to an object of the top-level class.
- When the user presses *Enter* in a `JTextField` or `JPasswordField`, the GUI component generates an `ActionEvent` (package `java.awt.event`). Such an event is processed by an object that implements the interface `ActionListener` (package `java.awt.event`).
- `JTextField` method `addActionListener` registers the event handler for a component text field. This method receives as its argument an `ActionListener` object.
- The GUI component with which the user interacts is the event source.
- An `ActionEvent` object contains information about the event that just occurred, such as the event source and the text in the text field.
- `ActionEvent` method `getSource` returns a reference to the event source. `ActionEvent` method `getActionCommand` returns the text the user typed in a text field or the label on a `JButton`.
- `JPasswordField` method `getPassword` returns the password the user typed.

Section 11.6 Common GUI Event Types and Listener Interfaces

- For each event-object type, there is typically a corresponding event-listener interface. Each event-listener interface specifies one or more event-handling methods that must be declared in the class that implements the interface.

Section 11.7 How Event Handling Works

- When an event occurs, the GUI component with which the user interacted notifies its registered listeners by calling each listener's appropriate event-handling method.
- Every `JComponent` has an instance variable called `listenerList` that refers to an object of class `EventListenerList` (package `javax.swing.event`). Each object of a `JComponent` subclass maintains references to all of its registered listeners in the `listenerList`.
- Every GUI component supports several event types, including mouse events, key events and others. When an event occurs, the event is dispatched only to the event listeners of the appropriate type. The GUI component receives a unique event ID specifying the event type, which it uses to decide the listener type to which the event should be dispatched and which method to call on each listener object.

598 Chapter 11 GUI Components: Part I

Section 11.8 JButton

- A button is a component the user clicks to trigger a specific action. All the button types are subclasses of `AbstractButton` (package `javax.swing`), which declares the common features of Swing buttons. Button labels typically use book-title capitalization—a style that capitalizes the first letter of each significant word in the text and does not end with any punctuation.
- Command buttons are created with class `JButton`.
- A `JButton` can display an `Icon`. To provide the user with an extra level of visual interaction with the GUI, a `JButton` can also have a rollover `Icon`—an `Icon` that is displayed when the user positions the mouse over the button.
- Method `setRolloverIcon` (of class `AbstractButton`) specifies the image displayed on a button when the user positions the mouse over it.

Section 11.9 Buttons That Maintain State

- The Swing GUI components contain three types of state buttons—`JToggleButton`, `JCheckBox` and `JRadioButton`.
- Classes `JCheckBox` and `JRadioButton` are subclasses of `JToggleButton`. A `JRadioButton` is different from a `JCheckBox` in that normally several `JRadioButtons` are grouped together, and only one in the group can be selected at any time.
- Method `setFont` (of class `Component`) sets the font of a component to a new object of class `Font` (package `java.awt`).
- When the user clicks a `JCheckBox`, an `ItemEvent` occurs. This event can be handled by an `ItemListener` object, which must implement method `itemStateChanged`. Method `addItemListener` registers the listener for a `JCheckBox` or `JRadioButton` object.
- `JCheckBox` method `isSelected` determines whether a `JCheckBox` is selected.
- `JRadioButtons` are similar to `JCheckboxes` in that they have two states—selected and not selected. However, radio buttons normally appear as a group in which only one button can be selected at a time. Selecting a different radio button forces all others to be deselected.
- `JRadioButtons` are used to represent mutually exclusive options.
- The logical relationship between `JRadioButtons` is maintained by a `ButtonGroup` object (package `javax.swing`).
- `ButtonGroup` method `add` associates each a `JRadioButton` with a `ButtonGroup`. If more than one selected `JRadioButton` object is added to a group, the selected one that was added first will be selected when the GUI is displayed.
- `JRadioButtons` generate `ItemEvents` when they are clicked.

Section 11.10 JComboBox and Using an Anonymous Inner Class for Event Handling

- A `JComboBox` provides a list of items from which the user can make a single selection. `JComboBoxes` generate `ItemEvents`.
- Each item in a `JComboBox` has an index. The first item added to a `JComboBox` appears as the currently selected item when the `JComboBox` is displayed. Other items are selected by clicking the `JComboBox`, which expands into a list from which the user can make a selection.
- `JComboBox` method `setMaximumRowCount` sets the maximum number of elements that are displayed when the user clicks the `JComboBox`. If there are additional items, the `JComboBox` provides a scrollbar that allows the user to scroll through all the elements in the list.
- An anonymous inner class is a special form of inner class that is declared without a name and typically appears inside a method declaration. Since an anonymous inner class has no name, one object of the anonymous inner class must be created at the point where the class is declared.

Summary 599

- `JComboBox` method `getSelectedIndex` returns the index of the selected item.

Section 11.11 JList

- A `JList` displays a series of items from which the user may select one or more items. Class `JList` supports single-selection lists and multiple-selection lists.
- When the user clicks an item in a `JList`, a `ListSelectionEvent` occurs. `JList` method `addListSelectionListener` registers a `ListSelectionListener` for a `JList`'s selection events. A `ListSelectionListener` (package `javax.swing.event`) must implement method `valueChanged`.
- `JList` method `setVisibleRowCount` specifies the number of items that are visible in the list.
- `JList` method `setSelectionMode` specifies a list's selection mode.
- A `JList` does not provide a scrollbar if there are more items in the list than the number of visible rows. In this case, a `JScrollPane` object can be used to provide the scrolling capability.
- `JFrame` method `getContentPane` returns a reference to the `JFrame`'s content pane where GUI components are displayed.
- `JList` method `getSelectedIndex` returns the selected item's index.

Section 11.12 Multiple-Selection Lists

- A multiple-selection list enables the user to select many items from a `JList`.
- `JList` method `setFixedCellWidth` sets a `JList`'s width. Method `setFixedCellHeight` sets the height of each item in a `JList`.
- There are no events to indicate that a user has made multiple selections in a multiple-selection list. Normally, an external event generated by another GUI component specifies when the multiple selections in a `JList` should be processed.
- `JList` method `setListData` sets the items displayed in a `JList`. `JList` method `getSelectedValues` returns an array of `Objects` representing the selected items in a `JList`.

Section 11.13 Mouse Event Handling

- The `MouseListener` and `MouseMotionListener` event-listener interfaces are used to handle mouse events. Mouse events can be trapped for any GUI component that extends `Component`.
- Interface `MouseInputListener` (package `javax.swing.event`) extends interfaces `MouseListener` and `MouseMotionListener` to create a single interface containing all their methods.
- Each of the mouse event-handling methods takes a `MouseEvent` object as its argument. A `MouseEvent` object contains information about the mouse event that occurred, including the *x*- and *y*-coordinates of the location where the event occurred. These coordinates are measured from the upper-left corner of the GUI component on which the event occurred.
- The methods and constants of class `InputEvent` (`MouseEvent`'s superclass) enable an application to determine which mouse button the user clicked.
- Interface `MouseWheelListener` enables applications to respond to the rotation of a mouse wheel.
- GUI components inherit methods `addMouseListener` and `addMouseMotionListener` from class `Component`.

Section 11.14 Adapter Classes

- Many event-listener interfaces contain multiple methods. For many of these interfaces, packages `java.awt.event` and `javax.swing.event` provide event-listener adapter classes. An adapter class implements an interface and provides a default implementation of each method in the interface. You can extend an adapter class to inherit the default implementation of every method and subsequently override only the method(s) you need for event handling.

600 Chapter 11 GUI Components: Part I

- MouseEvent method `getClickCount` returns the number of mouse button clicks. Methods `isMetaDown` and `isAltDown` determine which mouse button the user clicked.

Section 11.15 JPanel Subclass for Drawing with the Mouse

- Lightweight Swing components that extend class `JComponent` contain method `paintComponent`, which is called when a lightweight Swing component is displayed. By overriding this method, you can specify how to draw shapes using Java's graphics capabilities.
- When customizing a `JPanel` for use as a dedicated drawing area, the subclass should override method `paintComponent` and call the superclass version of `paintComponent` as the first statement in the body of the overridden method.
- Subclasses of `JComponent` support transparency. When a component is opaque, `paintComponent` clears the component's background before the component is displayed.
- The transparency of a Swing lightweight component can be set with method `setOpaque` (a `false` argument indicates that the component is transparent).
- Class `Point` (package `java.awt`) represents an *x-y* coordinate.
- Class `Graphics` is used to draw.
- MouseEvent method `getPoint` obtains the `Point` where a mouse event occurred.
- Method `repaint` (inherited indirectly from class `Component`) indicates that a component should be refreshed on the screen as soon as possible.
- Method `paintComponent` receives a `Graphics` parameter and is called automatically any time a lightweight component needs to be displayed on the screen.
- `Graphics` method `fillOval` draws a solid oval. The method's four parameters represent the bounding box in which the oval is displayed. The first two parameters are the upper-left *x*-coordinate and the upper-left *y*-coordinate of the rectangular area. The last two coordinates represent the rectangular area's width and height.

Section 11.16 Key-Event Handling

- Interface `KeyListener` is used to handle key events that are generated when keys on the keyboard are pressed and released. Method `addKeyListener` of class `Component` registers a `KeyListener` for a component.
- `KeyEvent` method `getKeyCode` gets the virtual key code of the key that was pressed. Class `KeyEvent` maintains a set of virtual key-code constants that represent every key on the keyboard.
- `KeyEvent` method `getKeyText` returns a string containing the name of the key that was pressed.
- `KeyEvent` method `getKeyChar` gets the Unicode value of the character typed.
- `KeyEvent` method `isActionKey` determines whether the key in an event was an action key.
- `InputEvent` method `getModifiers` determines whether any modifier keys (such as *Shift*, *Alt* and *Ctrl*) were pressed when the key event occurred.
- `KeyEvent` method `getKeyModifiersText` produces a string containing the names of the pressed modifier keys.

Section 11.17 Layout Managers

- Layout managers arrange GUI components in a container for presentation purposes.
- All layout managers implement the interface `LayoutManager` (package `java.awt`).
- Container method `setLayout` specifies the layout of a container.
- `FlowLayout` is the simplest layout manager. GUI components are placed on a container from left to right in the order in which they are added to the container. When the edge of the container is

Terminology **601**

reached, components continue to display on the next line. Class `FlowLayout` allows GUI components to be left aligned, centered (the default) and right aligned.

- `FlowLayout` method `setAlignment` changes the alignment for a `FlowLayout`.
- The `BorderLayout` layout manager (the default for a `JFrame`) arranges components into five regions: NORTH, SOUTH, EAST, WEST and CENTER. NORTH corresponds to the top of the container.
- A `BorderLayout` limits a `Container` to containing at most five components—one in each region.
- The `GridLayout` layout manager divides the container into a grid so that components can be placed in rows and columns.
- `Container` method `validate` recomputes a container's layout based on the current layout manager for the `Container` and the current set of displayed GUI components.

Section 11.19 JTextArea

- A `JTextArea` provides an area for manipulating multiple lines of text. `JTextArea` is a subclass of `JTextComponent`, which declares common methods for `JTextFields`, `JTextAreas` and several other text-based GUI components.
- Class `Box` is a subclass of `Container` that uses a `BoxLayout` layout manager to arrange the GUI components either horizontally or vertically.
- `Box` static method `createHorizontalBox` creates a `Box` that arranges components from left to right in the order that they are attached.
- Method `getSelectedText` (inherited into `JTextArea` from `JTextComponent`) returns the selected text from a `JTextArea`.
- You can set the horizontal and vertical scrollbar policies of a `JScrollPane` when it is constructed. `JScrollPane` methods `setHorizontalScrollBarPolicy`, and `setVerticalScrollBarPolicy` can be used change the scrollbar policies at any time.

Terminology

AbstractButton class	BoxLayout class
ActionEvent class	ButtonGroup class
ActionListener interface	Class class
actionPerformed method of ActionListener	Component class
adapter class	Container class
add method of class ButtonGroup	content pane
add method of Container	createHorizontalBox method of class Box
addActionListener method of class JTextField	dedicated drawing area
addItemListener method of class	default constructor of an anonymous inner class
AbstractButton	delegation event model
addKeyListener method of class Component	dialog box
addListSelectionListener method of	dispatch an event
class JList	event
addMouseListener method of class Component	event driven
addMouseMotionListener method of class	event handler
Component	event handling
addWindowListener method of class JFrame	event listener
anonymous inner class	event-listener adapter class
AWTEvent class	event-listener interface
book-title capitalization	event object
BorderLayout class	event registration
Box class	event source

602 Chapter 11 GUI Components: Part I

EventListenerList class	javax.swing package
fillOval method of class Graphics	javax.swing.event package
FlowLayout class	JButton class
focus	JCheckBox class
Font class	JComboBox class
getActionCommand method of ActionEvent	JComponent class
getClass method of Object	JFrame class
getClickCount method of MouseEvent	JLabel class
getContentPane method of JFrame	JList class
getIcon method of JLabel	JOptionPane class
getKeyChar method of KeyEvent	JPanel class
getKeyCode method of KeyEvent	JPasswordField class
getKeyModifiersText method of KeyEvent	JRadioButton class
getKeyText method of KeyEvent	JScrollPane class
getModifiers method of InputEvent	JSlider class
getPassword method of JPasswordField	JTextArea class
getPoint method of MouseEvent	JTextComponent class
getResource method of Class	JTextField class
getSelectedIndex method of JList	JToggleButton class
getSelectedIndex method of JComboBox	KeyAdapter class
getSelectedText method of JTextComponent	KeyEvent class
getSelectedValues method of JList	KeyListener interface
getSource method of EventObject	keyPressed method of KeyListener
getStateChange method of ItemEvent	keyReleased method of KeyListener
getText method of JLabel	keyTyped method of KeyListener
getX method of MouseEvent	layout manager
getY method of MouseEvent	LayoutContainer method of LayoutManager
graphical user interface (GUI)	LayoutManager interface
Graphics class	LayoutManager2 interface
GridLayout class	lightweight GUI component
GUI component	listenerList field of JComponent
heavyweight GUI component	ListSelectionEvent class
Icon interface	ListSelectionListener interface
ImageIcon class	ListSelectionModel class
inner class	look-and-feel
input dialog	message dialog
InputEvent class	MouseAdapter class
isActionKey method of KeyEvent	mouseClicked method of MouseListener
isAltDown method of InputEvent	mouseDragged method of MouseMotionListener
isAltDown method of MouseEvent	mouseEntered method of MouseListener
isControlDown method of InputEvent	MouseEvent class
isMetaDown method of InputEvent	mouseExited method of MouseListener
isMetaDown method of MouseEvent	MouseListener interface
isSelected method of JCheckBox	MouseMotionAdapter class
isShiftDown method of InputEvent	MouseMotionListener interface
ItemEvent class	mouseMoved method of MouseMotionListener
ItemListener interface	mousePressed method of MouseListener
itemStateChanged method of ItemListener	mouseReleased method of MouseListener
java.awt package	MouseWheelEvent class
java.awt.event package

WindowAdapter class
windowClosing method of WindowListener
WindowListener interface

Self-Review Exercises

11.1 Fill in the blanks in each of the following statements:

- Method _____ is called when the mouse is moved with no buttons pressed and an event listener is registered to handle the event.
- Text that cannot be modified by the user is called _____ text.
- A(n) _____ arranges GUI components in a Container.
- The add method for attaching GUI components is a method of class _____.
- GUI is an acronym for _____.
- Method _____ is used to specify the layout manager for a container.
- A mouseDragged method call is preceded by a(n) _____ method call and followed by a(n) _____ method call.
- Class _____ contains methods that display message dialogs and input dialogs.
- An input dialog capable of receiving input from the user is displayed with method _____ of class _____.
- A dialog capable of displaying a message to the user is displayed with method _____ of class _____.
- Both JTextField and JTextArea directly extend class _____.

11.2 Determine whether each statement is *true* or *false*. If *false*, explain why.

- BorderLayout is the default layout manager for a JFrame's content pane.
- When the mouse cursor is moved into the bounds of a GUI component, method mouseOver is called.
- A JPanel cannot be added to another JPanel.

604 Chapter 11 GUI Components: Part I

- d) In a BorderLayout, two buttons added to the NORTH region will be placed side by side.
- e) When one is using BorderLayout, a maximum of five components can be displayed.
- f) Inner classes are not allowed to access the members of the enclosing class.
- g) A JTextArea's text is always read-only.
- h) Class JTextArea is a direct subclass of class Component.

11.3 Find the error(s) in each of the following statements, and explain how to correct it (them):

```
a) buttonName = JButton( "Caption" );
b) JLabel aLabel, JLabel; // create references
c) txtField = new JTextField( 50, "Default Text" );
d) Container container = getContentPane();
   setLayout( new BorderLayout() );
   button1 = new JButton( "North Star" );
   button2 = new JButton( "South Pole" );
   container.add( button1 );
   container.add( button2 );
```

Answers to Self-Review Exercises

11.1 a) mouseMoved. b) uneditable (read-only). c) layout manager. d) Container. e) graphical user interface. f) setLayout. g) mousePressed, mouseReleased. h) JOptionPane. i) showInputDialog, JOptionPane. j) showMessageDialog, JOptionPane. k) JTextComponent.

11.2 a) True.
 b) False. Method mouseEntered is called.
 c) False. A JPanel can be added to another JPanel, because JPanel is an indirect subclass of Component. So, a JPanel is a Component. Any Component can be added to a Container.
 d) False. Only the last button added will be displayed. Remember that only one component should be added to each region in a BorderLayout.
 e) True.
 f) False. Inner classes have access to all members of the enclosing class declaration.
 g) False. JTextAreas are editable by default.
 h) False. JTextArea derives from class JTextComponent.

11.3 a) new is needed to create an object.
 b) JLabel is a class name and cannot be used as a variable name.
 c) The arguments passed to the constructor are reversed. The String must be passed first.
 d) BorderLayout has been set, and components are being added without specifying the region, so both are added to the center region. Proper add statements might be
`container.add(button1, BorderLayout.NORTH);
 container.add(button2, BorderLayout.SOUTH);`

Exercises

11.4 Fill in the blanks in each of the following statements:

- a) The JTextField class directly extends class _____.
- b) Container method _____ attaches a GUI component to a container.
- c) Method _____ is called when a mouse button is released (without moving the mouse).
- d) The _____ class is used to create a group of JRadioButtons.

11.5 Determine whether each statement is *true* or *false*. If *false*, explain why.

- a) Only one layout manager can be used per Container.
- b) GUI components can be added to a Container in any order in a BorderLayout.

Exercises **605**

- c) JRadioButtons provide a series of mutually exclusive options (i.e., only one can be true at a time).
- d) Graphics method setFont is used to set the font for text fields.
- e) A JList displays a scrollbar if there are more items in the list than can be displayed.
- f) A Mouse object has a method called mouseDragged.

11.6 Determine whether each statement is *true* or *false*. If *false*, explain why.

- a) A JPanel is a JComponent.
- b) A JPanel is a Component.
- c) A JLabel is a Container.
- d) A JList is a JPanel.
- e) An AbstractButton is a JButton.
- f) A JTextField is an Object.
- g) ButtonGroup is a subclass of JComponent.

11.7 Find any errors in each of the following lines of code, and explain how to correct them.

- a) `import javax.swing.JFrame`
- b) `panelObject.setLayout(8, 8); // set GridLayout`
- c) `container.setLayout(new FlowLayout(FlowLayout.DEFAULT));`
- d) `container.add(eastButton, EAST); // BorderLayout`

11.8 Create the following GUI. You do not have to provide any functionality.

11.9 Create the following GUI. You do not have to provide any functionality.

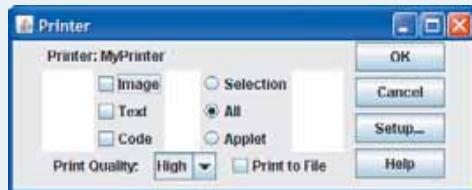

11.10 Create the following GUI. You do not have to provide any functionality.

606 Chapter 11 GUI Components: Part I

11.11 Create the following GUI. You do not have to provide any functionality.

11.12 Write a temperature conversion application that converts from Fahrenheit to Celsius. The Fahrenheit temperature should be entered from the keyboard (via a JTextField). A JLabel should be used to display the converted temperature. Use the following formula for the conversion:

$$\text{Celsius} = \frac{5}{9} \times (\text{Fahrenheit} - 32)$$

11.13 Enhance the temperature conversion application of Exercise 11.12 by adding the Kelvin temperature scale. The application should also allow the user to make conversions between any two scales. Use the following formula for the conversion between Kelvin and Celsius (in addition to the formula in Exercise 11.12):

$$\text{Kelvin} = \text{Celsius} + 273.15$$

11.14 Write an application that displays events as they occur in a JTextArea. Provide a JComboBox with a minimum of four items. The user should be able to choose an event to monitor from the JComboBox. When that particular event occurs, display information about the event in the JTextArea. Use method `toString` on the event object to convert it to a string representation.

11.15 Write an application that plays “guess the number” as follows: Your application chooses the number to be guessed by selecting an integer at random in the range 1–1000. The application then displays the following in a label:

```
I have a number between 1 and 1000. Can you guess my number?  
Please enter your first guess.
```

A JTextField should be used to input the guess. As each guess is input, the background color should change to either red or blue. Red indicates that the user is getting “warmer,” and blue indicates that the user is getting “colder.” A JLabel should display either “Too High” or “Too Low” to help the user zero in on the correct answer. When the user gets the correct answer, “Correct!” should be displayed, and the JTextField used for input should be changed to be uneditable. A JButton should be provided to allow the user to play the game again. When the JButton is clicked, a new random number should be generated and the input JTextField changed to be editable.

11.16 It is often useful to display the events that occur during the execution of an application. This can help you understand when the events occur and how they are generated. Write an application that enables the user to generate and process every event discussed in this chapter. The application should provide methods from the ActionListener, ItemListener, ListSelectionListener, MouseListener, MouseMotionListener and KeyListener interfaces to display messages when the events occur. Use method `toString` to convert the event objects received in each event handler into a String that can be displayed. Method `toString` creates a String containing all the information in the event object.

11.17 Modify the application of Section 6.10 to provide a GUI that enables the user to click a JButton to roll the dice. The application should also display four JLabels and four JTextFields,

Exercises **607**

with one `JLabel` for each `JTextField`. The `JTextFields` should be used to display the values of each die and the sum of the dice after each roll. The point should be displayed in the fourth `JTextField` when the user does not win or lose on the first roll and should continue to be displayed until the game is lost.

(Optional) GUI and Graphics Case Study Exercise: Expanding the Interface

11.18 In this exercise, you will implement a GUI application that uses the `MyShape` hierarchy from the GUI case study Exercise 10.2 to create an interactive drawing application. You will create two classes for the GUI and provide a test class that launches the application. The classes of the `MyShape` hierarchy require no additional changes.

The first class to create is a subclass of `JPanel` called `DrawPanel`, which represents the area on which the user draws the shapes. Class `DrawPanel` should have the following instance variables:

- An array `shapes` of type `MyShape` that will store all the shapes the user draws.
- An integer `shapeCount` that counts the number of shapes in the array.
- An integer `shapeType` that determines the type of shape to draw.
- A `MyShape` `currentShape` that represents the current shape the user is drawing.
- A `Color` `currentColor` that represents the current drawing color.
- A boolean `filledShape` that determines whether to draw a filled shape.
- A `JLabel` `statusLabel` that represents the status bar. The status bar will display the coordinates of the current mouse position.

Class `DrawPanel` should also declare the following methods:

- Overridden method `paintComponent` that draws the shapes in the array. Use instance variable `shapeCount` to determine how many shapes to draw. Method `paintComponent` should also call `currentShape`'s `draw` method, provided that `currentShape` is not `null`.
- Set methods for the `shapeType`, `currentColor` and `filledShape`.
- Method `clearLastShape` should clear the last shape drawn by decrementing instance variable `shapeCount`. Ensure that `shapeCount` is never less than zero.
- Method `clearDrawing` should remove all the shapes in the current drawing by setting `shapeCount` to zero.

Methods `clearLastShape` and `clearDrawing` should call method `repaint` (inherited from `JPanel`) to refresh the drawing on the `DrawPanel` by indicating that the system should call method `paintComponent`.

Class `DrawPanel` should also provide event handling to enable the user to draw with the mouse. Create a single inner class that both extends `MouseAdapter` and implements `MouseListener` to handle all mouse events in one class.

In the inner class, override method `mousePressed` so that it assigns `currentShape` a new shape of the type specified by `shapeType` and initializes both points to the mouse position. Next, override method `mouseReleased` to finish drawing the current shape and place it in the array. Set the second point of `currentShape` to the current mouse position and add `currentShape` to the array. Instance variable `shapeCount` determines the insertion index. Set `currentShape` to `null` and call method `repaint` to update the drawing with the new shape.

Override method `mouseMoved` to set the text of the `statusLabel` so that it displays the mouse coordinates—this will update the label with the coordinates every time the user moves (but does not drag) the mouse within the `DrawPanel`. Next, override method `mouseDragged` so that it sets the second point of the `currentShape` to the current mouse position and calls method `repaint`. This will allow the user to see the shape while dragging the mouse. Also, update the `JLabel` in `mouseDragged` with the current position of the mouse.

Create a constructor for `DrawPanel` that has a single `JLabel` parameter. In the constructor, initialize `statusLabel` with the value passed to the parameter. Also initialize array `shapes` with 100 entries, `shapeCount` to 0, `shapeType` to the value that represents a line, `currentShape` to `null` and

608 Chapter 11 GUI Components: Part I

currentColor to Color.BLACK. The constructor should then set the background color of the DrawPanel to Color.WHITE and register the MouseListener and MouseMotionListener so the JPanel properly handles mouse events.

Next, create a JFrame subclass called DrawFrame that provides a GUI that enables the user to control various aspects of drawing. For the layout of the DrawFrame, we recommend a BorderLayout, with the components in the NORTH region, the main drawing panel in the CENTER region, and a status bar in the SOUTH region, as in Fig. 11.49. In the top panel, create the components listed below. Each component's event handler should call the appropriate method in class DrawPanel.

- a) A button to undo the last shape drawn.
- b) A button to clear all shapes from the drawing.
- c) A combo box for selecting the color from the 13 predefined colors.
- d) A combo box for selecting the shape to draw.
- e) A checkbox that specifies whether a shape should be filled or unfilled.

Declare and create the interface components in DrawFrame's constructor. You will need to create the status bar JLabel before you create the DrawPanel, so you can pass the JLabel as an argument to DrawPanel's constructor. Finally, create a test class that initializes and displays the DrawFrame to execute the application.

Fig. 11.49 | Interface for drawing shapes.

One picture is worth ten thousand words.

—Chinese proverb

Treat nature in terms of the cylinder, the sphere, the cone, all in perspective.

—Paul Cézanne

Colors, like features, follow the changes of the emotions.

—Pablo Picasso

Nothing ever becomes real till it is experienced—even a proverb is no proverb to you till your life has illustrated it.

—John Keats

Graphics and Java 2D™

OBJECTIVES

In this chapter you will learn:

- To understand graphics contexts and graphics objects.
- To manipulate colors.
- To manipulate fonts.
- To use methods of class `Graphics` to draw lines, rectangles, rectangles with rounded corners, three-dimensional rectangles, ovals, arcs and polygons.
- To use methods of class `Graphics2D` from the Java 2D API to draw lines, rectangles, rectangles with rounded corners, ellipses, arcs and general paths.
- To specify `Paint` and `Stroke` characteristics of shapes displayed with `Graphics2D`.

610 Chapter 12 Graphics and Java 2D™**Outline**

- 12.1** Introduction
- 12.2** Graphics Contexts and Graphics Objects
- 12.3** Color Control
- 12.4** Font Control
- 12.5** Drawing Lines, Rectangles and Ovals
- 12.6** Drawing Arcs
- 12.7** Drawing Polygons and Polylines
- 12.8** Java 2D API
- 12.9** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

12.1 Introduction

In this chapter, we overview several of Java's capabilities for drawing two-dimensional shapes, controlling colors and controlling fonts. One of Java's initial appeals was its support for graphics that enabled programmers to visually enhance their applications. Java now contains many more sophisticated drawing capabilities as part of the Java 2D™ API. This chapter begins with an introduction to many of Java's original drawing capabilities. Next we present several of the more powerful Java 2D capabilities, such as controlling the style of lines used to draw shapes and the way shapes are filled with color and patterns. [Note: Several concepts covered in this chapter have already been covered in the optional GUI and Graphics Case Study of Chapters 3–10. So, some material will be repetitive if you read the case study. You do not need to read the case study to understand this chapter.]

Figure 12.1 shows a portion of the Java class hierarchy that includes several of the basic graphics classes and Java 2D API classes and interfaces covered in this chapter. Class **Color** contains methods and constants for manipulating colors. Class **JComponent** contains method **paintComponent**, which is used to draw graphics on a component. Class **Font** contains methods and constants for manipulating fonts. Class **FontMetrics** contains methods for obtaining font information. Class **Graphics** contains methods for drawing strings, lines, rectangles and other shapes. Class **Graphics2D**, which extends class **Graphics**, is used for drawing with the Java 2D API. Class **Polygon** contains methods for creating polygons. The bottom half of the figure lists several classes and interfaces from the Java 2D API. Class **BasicStroke** helps specify the drawing characteristics of lines. Classes **GradientPaint** and **TexturePaint** help specify the characteristics for filling shapes with colors or patterns. Classes **GeneralPath**, **Line2D**, **Arc2D**, **Ellipse2D**, **Rectangle2D** and **RoundRectangle2D** represent several Java 2D shapes. [Note: We begin the chapter by discussing Java's original graphics capabilities, then move on to the Java 2D API. Now, the classes that were part of Java's original graphics capabilities are considered to be part of the Java 2D API.]

To begin drawing in Java, we must first understand Java's **coordinate system** (Fig. 12.2), which is a scheme for identifying every point on the screen. By default, the upper-left corner of a GUI component (e.g., a window) has the coordinates (0, 0). A coordinate pair is composed of an **x-coordinate** (the **horizontal coordinate**) and a **y-coordinate** (the **vertical coordinate**). The **x**-coordinate is the horizontal distance moving right from the left of the screen. The **y**-coordinate is the vertical distance moving down from the top

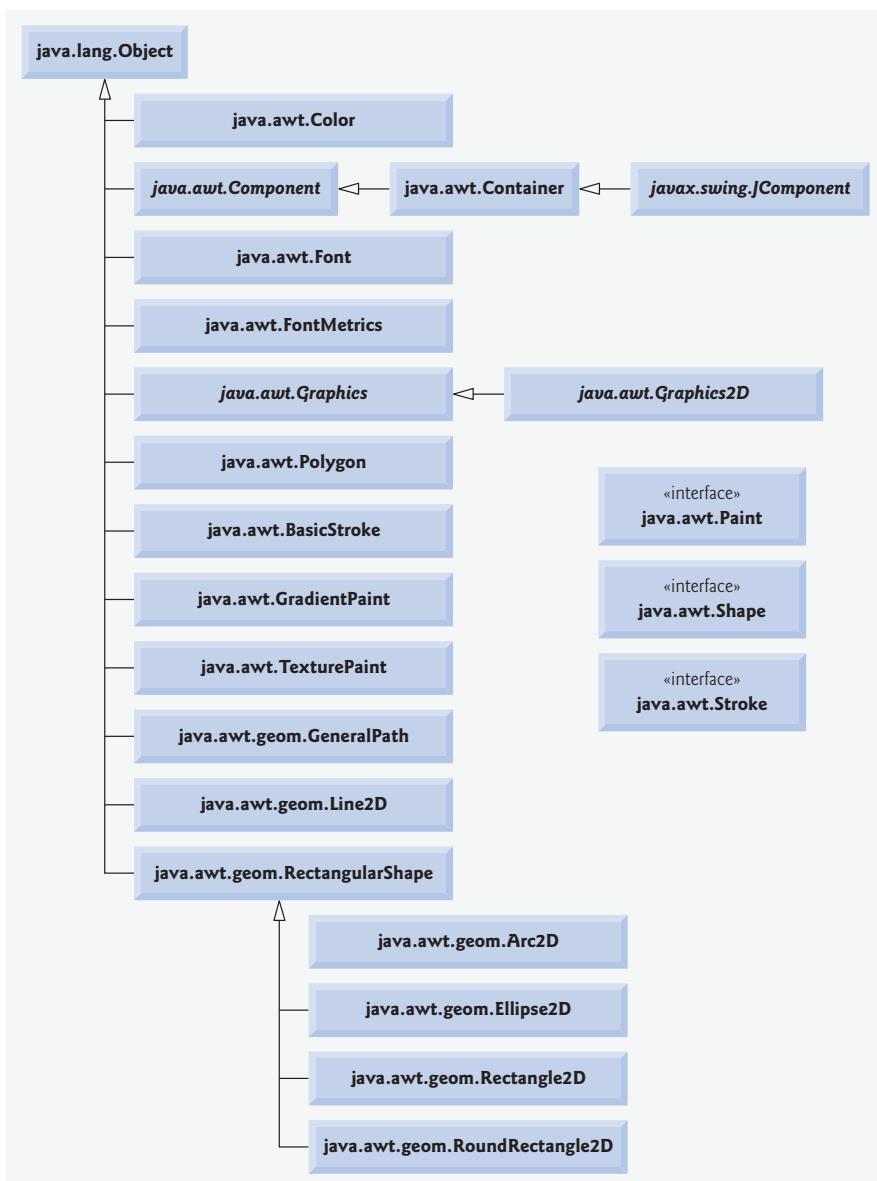

12.1 Introduction **611**

Fig. 12.1 | Classes and interfaces used in this chapter from Java's original graphics capabilities and from the Java 2D API. [Note: Class `Object` appears here because it is the superclass of the Java class hierarchy. Also, abstract classes appear in italics.]

612 Chapter 12 Graphics and Java 2D™

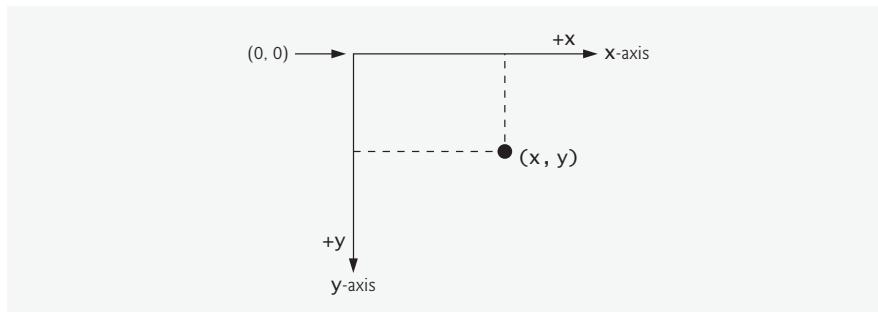

Fig. 12.2 | Java coordinate system. Units are measured in pixels.

of the screen. The *x-axis* describes every horizontal coordinate, and the *y-axis* every vertical coordinate. The coordinates are used to indicate where graphics should be displayed on a screen. Coordinate units are measured in *pixels* (which stands for “picture element”). A pixel is a display monitor’s smallest unit of resolution.

Portability Tip 12.1

Different display monitors have different resolutions (i.e., the density of the pixels varies). This can cause graphics to appear in different sizes on different monitors or on the same monitor with different settings.

12.2 Graphics Contexts and Graphics Objects

A *graphics context* enables drawing on the screen. A *Graphics* object manages a graphics context and draws pixels on the screen that represent text and other graphical objects (e.g., lines, ellipses, rectangles and other polygons). *Graphics* objects contain methods for drawing, font manipulation, color manipulation and the like.

Class *Graphics* is an abstract class (i.e., *Graphics* objects cannot be instantiated). This contributes to Java’s portability. Because drawing is performed differently on every platform that supports Java, there cannot be only one implementation of the drawing capabilities across all systems. For example, the graphics capabilities that enable a PC running Microsoft Windows to draw a rectangle are different from those that enable a Linux workstation to draw a rectangle—and they are both different from the graphics capabilities that enable a Macintosh to draw a rectangle. When Java is implemented on each platform, a subclass of *Graphics* is created that implements the drawing capabilities. This implementation is hidden by class *Graphics*, which supplies the interface that enables us to use graphics in a platform-independent manner.

Class *Component* is the superclass for many of the classes in the *java.awt* package. (We introduced class *Component* in Chapter 11.) Class *JComponent*, which inherits indirectly from class *Component*, contains a *paintComponent* method that can be used to draw graphics. Method *paintComponent* takes a *Graphics* object as an argument. This object is passed to the *paintComponent* method by the system when a lightweight Swing component needs to be repainted. The header for the *paintComponent* method is

```
public void paintComponent( Graphics g )
```

12.3 Color Control **613**

Parameter `g` receives a reference to an instance of the system-specific subclass that `Graphics` extends. The preceding method header should look familiar to you—it is the same one we used in some of the applications in Chapter 11. Actually, class `JComponent` is a superclass of `JPanel`. Many capabilities of class `JPanel` are inherited from class `JComponent`.

Method `paintComponent` is seldom called directly by the programmer because drawing graphics is an event-driven process. When a GUI application executes, the application container calls method `paintComponent` for each lightweight component as the GUI is displayed. For `paintComponent` to be called again, an event must occur (such as covering and uncovering the component with another window).

If the programmer needs to have `paintComponent` execute (i.e., if the programmer wants to update the graphics drawn on the Swing component), a call is made to method `repaint`, which is inherited by all `JComponents` indirectly from class `Component` (package `java.awt`). Method `repaint` is frequently called to request a call to method `paintComponent`. The header for `repaint` is

```
public void repaint()
```

12.3 Color Control

Class `Color` declares methods and constants for manipulating colors in a Java program. The predeclared color constants are summarized in Fig. 12.3, and several color methods and constructors are summarized in Fig. 12.4. Note that two of the methods in Fig. 12.4 are `Graphics` methods that are specific to colors.

Color constant	RGB value
<code>public final static Color RED</code>	255, 0, 0
<code>public final static Color GREEN</code>	0, 255, 0
<code>public final static Color BLUE</code>	0, 0, 255
<code>public final static Color ORANGE</code>	255, 200, 0
<code>public final static Color PINK</code>	255, 175, 175
<code>public final static Color CYAN</code>	0, 255, 255
<code>public final static Color MAGENTA</code>	255, 0, 255
<code>public final static Color YELLOW</code>	255, 255, 0
<code>public final static Color BLACK</code>	0, 0, 0
<code>public final static Color WHITE</code>	255, 255, 255
<code>public final static Color GRAY</code>	128, 128, 128
<code>public final static Color LIGHT_GRAY</code>	192, 192, 192
<code>public final static Color DARK_GRAY</code>	64, 64, 64

Fig. 12.3 | Color constants and their RGB values.

614 Chapter 12 Graphics and Java 2D™

Method	Description
<i>Color constructors and methods</i>	
<code>public Color(int r, int g, int b)</code>	Creates a color based on red, green and blue components expressed as integers from 0 to 255.
<code>public Color(float r, float g, float b)</code>	Creates a color based on red, green and blue components expressed as floating-point values from 0.0 to 1.0.
<code>public int getRed()</code>	Returns a value between 0 and 255 representing the red content.
<code>public int getGreen()</code>	Returns a value between 0 and 255 representing the green content.
<code>public int getBlue()</code>	Returns a value between 0 and 255 representing the blue content.
<i>Graphics methods for manipulating Colors</i>	
<code>public Color getColor()</code>	Returns Color object representing current color for the graphics context.
<code>public void setColor(Color c)</code>	Sets the current color for drawing with the graphics context.

Fig. 12.4 | Color methods and color-related Graphics methods .

Every color is created from a red, a green and a blue component. Together these components are called **RGB values**. All three RGB components can be integers in the range from 0 to 255, or they can be floating-point values in the range 0.0 to 1.0. The first RGB component specifies the amount of red, the second the amount of green and the third the amount of blue. The larger the RGB value, the greater the amount of that particular color. Java enables the programmer to choose from $256 \times 256 \times 256$ (approximately 16.7 million) colors. Not all computers are capable of displaying all these colors. The computer will display the closest color it can.

Two of class `Color`'s constructors are shown in Fig. 12.4—one that takes three `int` arguments and one that takes three `float` arguments, with each argument specifying the amount of red, green and blue. The `int` values must be in the range 0–255 and the `float` values must be in the range 0.0–1.0. The new `Color` object will have the specified amounts of red, green and blue. `Color` methods `getRed`, `getGreen` and `getBlue` return integer values from 0 to 255 representing the amount of red, green and blue, respectively. `Graphics` method `getColor` returns a `Color` object representing the current drawing color. `Graphics` method `setColor` sets the current drawing color.

Figures 12.5–12.6 demonstrates several methods from Fig. 12.4 by drawing filled rectangles and strings in several different colors. When the application begins execution, class `Color JPanel`'s `paintComponent` method (lines 10–37 of Fig. 12.5) is called to paint the window. Line 17 uses `Graphics` method `setColor` to set the drawing color. Method

12.3 Color Control **615**

`setColor` receives a `Color` object. The expression `new Color(255, 0, 0)` creates a new `Color` object that represents red (red value 255, and 0 for the green and blue values). Line 18 uses `Graphics` method `fillRect` to draw a filled rectangle in the current color. Method `fillRect` draws a rectangle based on its four arguments. The first two integer values represent the upper-left *x*-coordinate and upper-left *y*-coordinate, where the `Graphics` object begins drawing the rectangle. The third and fourth arguments are nonnegative integers that represent the width and the height of the rectangle in pixels, respectively. A rectangle drawn using method `fillRect` is filled by the current color of the `Graphics` object.

Line 19 uses `Graphics` method `drawString` to draw a `String` in the current color. The expression `g.getColor()` retrieves the current color from the `Graphics` object. The returned `Color` object is concatenated with string "Current RGB: ", resulting in an

19 } // end class ShowColors

```

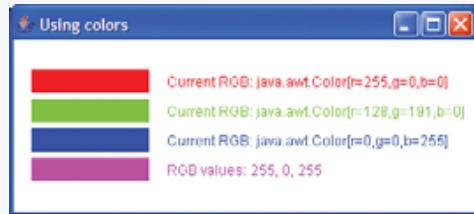

Fig. 12.6 | Creating JFrame to display colors on JPanel.

implicit call to class Color's `toString` method. The String representation of a Color contains the class name and package (`java.awt.Color`), and the red, green and blue values.

Look-and-Feel Observation 12.1

Everyone perceives colors differently. Choose your colors carefully to ensure that your application is readable, both for people who can perceive color and for people who are color blind. Try to avoid using many different colors in close proximity.

Lines 22–24 and lines 27–29 perform the same tasks again. Line 22 uses the `Color` constructor with three `float` arguments to create a dark green color (0.50f for red, 0.75f for green and 0.0f for blue). Note the syntax of the values. The letter `f` appended to a floating-point literal indicates that the literal should be treated as type `float`. Recall that by default, floating-point literals are treated as type `double`.

Line 27 sets the current drawing color to one of the predeclared `Color` constants (`Color.BLUE`). The `Color` constants are `static`, so they are created when class `Color` is loaded into memory at execution time.

The statement in lines 35–36 makes calls to `Color` methods `getRed`, `getGreen` and `getBlue` on the predeclared `Color.MAGENTA` constant. Method `main` of class `ShowColors`

12.3 Color Control 617

(lines 8–18 of Fig. 12.6) creates the `JFrame` that will contain a `ColorJPanel` object where the colors will be displayed.

**Software Engineering Observation 12.1**

To change the color, you must create a new `Color` object (or use one of the predeclared `Color` constants). Like `String` objects, `Color` objects are immutable (not modifiable).

Package `javax.swing` provides the `JColorChooser` GUI component that enables application users to select colors. The application of Figs. 12.7–12.8 demonstrates a `JColorChooser` dialog. When you click the **Change Color** button, a `JColorChooser` dialog appears. When you select a color and press the dialog's **OK** button, the background color of the application window changes.

53 setVisible( true ); // display frame
54 } // end ShowColor2JFrame constructor
55 } // end class ShowColors2JFrame

```

Fig. 12.7 | JColorChooser dialog. (Part 2 of 2.)

Class `JColorChooser` provides static method `showDialog`, which creates a `JColorChooser` object, attaches it to a dialog box and displays the dialog. Lines 36–37 of Fig. 12.7 invoke this method to display the color chooser dialog. Method `showDialog` returns the selected `Color` object, or `null` if the user presses `Cancel` or closes the dialog without pressing `OK`. The method takes three arguments—a reference to its parent `Component`, a `String` to display in the title bar of the dialog and the initial selected `Color` for the dialog. The parent component is a reference to the window from which the dialog is displayed (in this case the `JFrame`, with the reference name `frame`). The dialog will be centered on the parent. If the parent is `null`, the dialog is centered on the screen. While the color chooser dialog is on the screen, the user cannot interact with the parent component. This type of dialog is called a **modal dialog** (discussed in Chapter 22, GUI Components: Part 2).

After the user selects a color, lines 40–41 determine whether `color` is `null`, and, if so, set `color` to `Color.LIGHT_GRAY`. Line 44 invokes method `setBackground` to change the background color of the `JPanel`. Method `setBackground` is one of the many `Component`

```

12.3 Color Control **619**

Fig. 12.8 | Choosing colors with `JColorChooser`. (Part 2 of 2.)

methods that can be used on most GUI components. Note that the user can continue to use the `Change Color` button to change the background color of the application. Figure 12.8 contains method `main`, which executes the program.

The second screen capture of Fig. 12.8 demonstrates the default `JColorChooser` dialog that allows the user to select a color from a variety of [color swatches](#). Note that there are actually three tabs across the top of the dialog—**Swatches**, **HSB** and **RGB**. These represent three different ways to select a color. The **HSB** tab allows you to select a color based on **hue**, **saturation** and **brightness**—values that are used to define the amount of light in a color. We do not discuss HSB values. For more information on hue, saturation and brightness, visit whatis.techtarget.com/definition/0,,sid9_gci212262,00.html. The **RGB** tab allows you to select a color by using sliders to select the red, green and blue components. The **HSB** and **RGB** tabs are shown in Fig. 12.9.

620 Chapter 12 Graphics and Java 2D™

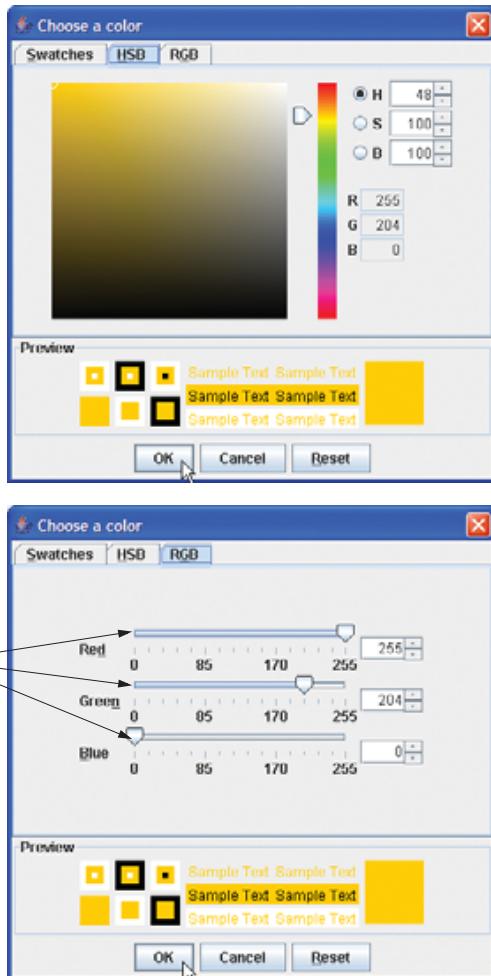

Fig. 12.9 | HSB and RGB tabs of the JColorChooser dialog.

12.4 Font Control

This section introduces methods and constants for font control. Most font methods and font constants are part of class `Font`. Some methods of class `Font` and class `Graphics` are summarized in Fig. 12.10.

Class `Font`'s constructor takes three arguments—the `font name`, `font style` and `font size`. The font name is any font currently supported by the system on which the program is running, such as standard Java fonts `Monospaced`, `SansSerif` and `Serif`. The font style is `Font.PLAIN`, `Font.ITALIC` or `Font.BOLD` (each is a static field of class `Font`). Font styles

12.4 Font Control **621**

Method or constant	Description
<i>Font constants, constructors and methods</i>	
<code>public final static int PLAIN</code>	A constant representing a plain font style.
<code>public final static int BOLD</code>	A constant representing a bold font style.
<code>public final static int ITALIC</code>	A constant representing an italic font style.
<code>public Font(String name, int style, int size)</code>	Creates a <code>Font</code> object with the specified font name, style and size.
<code>public int getStyle()</code>	Returns an integer value indicating the current font style.
<code>public int getSize()</code>	Returns an integer value indicating the current font size.
<code>public String getName()</code>	Returns the current font name as a string.
<code>public String getFamily()</code>	Returns the font's family name as a string.
<code>public boolean isPlain()</code>	Returns <code>true</code> if the font is plain, else <code>false</code> .
<code>public boolean isBold()</code>	Returns <code>true</code> if the font is bold, else <code>false</code> .
<code>public boolean isItalic()</code>	Returns <code>true</code> if the font is italic, else <code>false</code> .
<i>Graphics methods for manipulating Fonts</i>	
<code>public Font getFont()</code>	Returns a <code>Font</code> object reference representing the current font.
<code>public void setFont(Font f)</code>	Sets the current font to the font, style and size specified by the <code>Font</code> object reference <code>f</code> .

Fig. 12.10 | Font-related methods and constants.

can be used in combination (e.g., `Font.ITALIC + Font.BOLD`). The font size is measured in points. A `point` is 1/72 of an inch. Graphics method `setFont` sets the current drawing font—the font in which text will be displayed—to its `Font` argument.

Portability Tip 12.2

The number of fonts varies greatly across systems. Java provides five font names—`Serif`, `Monospaced`, `SansSerif`, `Dialog` and `DialogInput`—that can be used on all Java platforms. The Java runtime environment (JRE) on each platform maps these logical font names to actual fonts installed on the platform. The actual fonts used may vary by platform.

The application of Figs. 12.11–12.12 displays text in four different fonts, with each font in a different size. Figure 12.11 uses the `Font` constructor to initialize `Font` objects (in lines 16, 20, 24 and 29) that are each passed to `Graphics` method `setFont` to change the drawing font. Each call to the `Font` constructor passes a font name (`Serif`, `Monospaced` or `SansSerif`) as a string, a font style (`Font.PLAIN`, `Font.ITALIC` or `Font.BOLD`) and a font

17     frame.setVisible( true ); // display frame
18 } // end main
19 } // end class Fonts

```

Fig. 12.12 | Creating a JFrame to display fonts. (Part 2 of 2.)

size. Once `Graphics` method `setFont` is invoked, all text displayed following the call will appear in the new font until the font is changed. Each font's information is displayed in lines 17, 21, 25 and 30–31 using method `drawString`. Note that the coordinate passed to `drawString` corresponds to the lower-left corner of the baseline of the font. Line 28 changes the drawing color to red, so the next string displayed appears in red. Lines 30–31 display information about the final `Font` object. Method `getFont` of class `Graphics` returns a `Font` object representing the current font. Method `getName` returns the current font name as a string. Method `getSize` returns the font size in points.

Figure 12.12 contains method `main`, which creates a `JFrame`. We add a `Font JPanel` object to this `JFrame` (line 15), which displays the graphics created in Fig. 12.11.

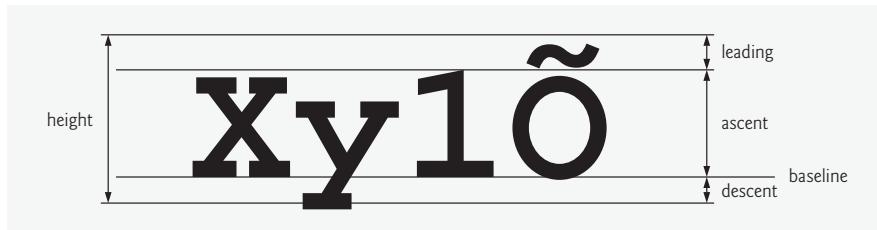

Software Engineering Observation 12.2

To change the font, you must create a new Font object. Font objects are immutable—class Font has no set methods to change the characteristics of the current font.

Font Metrics

Sometimes it is necessary to get information about the current drawing font, such as its name, style and size. Several `Font` methods used to get font information are summarized in Fig. 12.10. Method `getStyle` returns an integer value representing the current style. The integer value returned is either `Font.PLAIN`, `Font.ITALIC`, `Font.BOLD` or the combination of `Font.ITALIC` and `Font.BOLD`. Method `getFamily` returns the name of the font family to which the current font belongs. The name of the font family is platform specific. `Font` methods are also available to test the style of the current font, and these too are summarized in Fig. 12.10. Methods `isPlain`, `isBold` and `isItalic` return `true` if the current font style is plain, bold or italic, respectively.

Sometimes precise information about a font's metrics must be known—such as `height`, `descent` (the amount a character dips below the baseline), `ascent` (the amount a character rises above the baseline) and `leading` (the difference between the descent of one line of text and the ascent of the line of text below it—that is, the interline spacing). Figure 12.13 illustrates some of the common `font metrics`.

624 Chapter 12 Graphics and Java 2D™**Fig. 12.13** | Font metrics.

Class `FontMetrics` declares several methods for obtaining font metrics. These methods and `Graphics` method `getFontMetrics` are summarized in Fig. 12.14. The application of Figs. 12.15–12.16 uses the methods of Fig. 12.14 to obtain font metric information for two fonts.

Method	Description
<i>FontMetrics methods</i>	
<code>public int getAscent()</code>	Returns the ascent of a font in points.
<code>public int getDescent()</code>	Returns the descent of a font in points.
<code>public int getLeading()</code>	Returns the leading of a font in points.
<code>public int getHeight()</code>	Returns the height of a font in points.
<i>Graphics methods for getting a Font's FontMetrics</i>	
<code>public FontMetrics getFontMetrics()</code>	Returns the <code>FontMetrics</code> object for the current drawing <code>Font</code> .
<code>public FontMetrics getFontMetrics(Font f)</code>	Returns the <code>FontMetrics</code> object for the specified <code>Font</code> argument.

Fig. 12.16 | Creating JFrame to display font metric information. (Part I of 2.)

626 Chapter 12 Graphics and Java 2D™

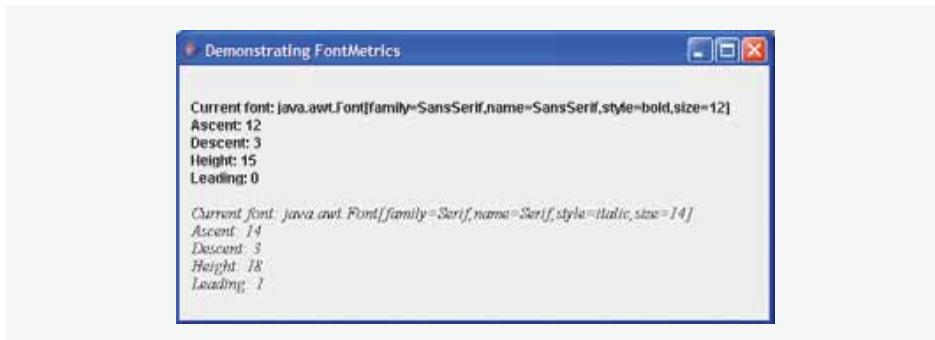

Fig. 12.16 | Creating JFrame to display font metric information. (Part I of 2.)

Line 15 of Fig. 12.15 creates and sets the current drawing font to a SansSerif, bold, 12-point font. Line 16 uses `Graphics` method `getFontMetrics` to obtain the `FontMetrics` object for the current font. Line 17 outputs the `String` representation of the `Font` returned by `g.getFont()`. Lines 18–21 use `FontMetric` methods to obtain the ascent, descent, height and leading for the font.

Line 23 creates a new Serif, italic, 14-point font. Line 24 uses a second version of `Graphics` method `getFontMetrics`, which accepts a `Font` argument and returns a corresponding `FontMetrics` object. Lines 27–30 obtain the ascent, descent, height and leading for the font. Note that the font metrics are slightly different for the two fonts.

12.5 Drawing Lines, Rectangles and Ovals

This section presents `Graphics` methods for drawing lines, rectangles and ovals. The methods and their parameters are summarized in Fig. 12.17. For each drawing method that requires a `width` and `height` parameter, the `width` and `height` must be nonnegative values. Otherwise, the shape will not display.

Method	Description
<code>public void drawLine(int x1, int y1, int x2, int y2)</code>	Draws a line between the point (<code>x1, y1</code>) and the point (<code>x2, y2</code>).
<code>public void drawRect(int x, int y, int width, int height)</code>	Draws a rectangle of the specified <code>width</code> and <code>height</code> . The top-left corner of the rectangle has the coordinates (<code>x, y</code>). Only the outline of the rectangle is drawn using the <code>Graphics</code> object's color—the body of the rectangle is not filled with this color.
<code>public void fillRect(int x, int y, int width, int height)</code>	Draws a filled rectangle with the specified <code>width</code> and <code>height</code> . The top-left corner of the rectangle has the coordinates (<code>x, y</code>). The rectangle is filled with the <code>Graphics</code> object's color.

Fig. 12.17 | `Graphics` methods that draw lines, rectangles and ovals. (Part I of 2.)

12.5 Drawing Lines, Rectangles and Ovals **627**

Method	Description
<code>public void clearRect(int x, int y, int width, int height)</code>	Draws a filled rectangle with the specified width and height in the current background color. The top-left corner of the rectangle has the coordinates (x, y). This method is useful if the programmer wants to remove a portion of an image.
<code>public void drawRoundRect(int x, int y, int width, int height, int arcWidth, int arcHeight)</code>	Draws a rectangle with rounded corners in the current color with the specified width and height. The arcWidth and arcHeight determine the rounding of the corners (see Fig. 12.20). Only the outline of the shape is drawn.
<code>public void fillRoundRect(int x, int y, int width, int height, int arcWidth, int arcHeight)</code>	Draws a filled rectangle with rounded corners in the current color with the specified width and height. The arcWidth and arcHeight determine the rounding of the corners (see Fig. 12.20).
<code>public void draw3DRect(int x, int y, int width, int height, boolean b)</code>	Draws a three-dimensional rectangle in the current color with the specified width and height. The top-left corner of the rectangle has the coordinates (x, y). The rectangle appears raised when b is true and lowered when b is false. Only the outline of the shape is drawn.
<code>public void fill3DRect(int x, int y, int width, int height, boolean b)</code>	Draws a filled three-dimensional rectangle in the current color with the specified width and height. The top-left corner of the rectangle has the coordinates (x, y). The rectangle appears raised when b is true and lowered when b is false.
<code>public void drawOval(int x, int y, int width, int height)</code>	Draws an oval in the current color with the specified width and height. The bounding rectangle's top-left corner is at the coordinates (x, y). The oval touches all four sides of the bounding rectangle at the center of each side (see Fig. 12.21). Only the outline of the shape is drawn.
<code>public void fillOval(int x, int y, int width, int height)</code>	Draws a filled oval in the current color with the specified width and height. The bounding rectangle's top-left corner is at the coordinates (x, y). The oval touches all four sides of the bounding rectangle at the center of each side (see Fig. 12.21).

Fig. 12.17 | Graphics methods that draw lines, rectangles and ovals. (Part 2 of 2.)

The application of Figs. 12.18–12.19 demonstrates drawing a variety of lines, rectangles, three-dimensional rectangles, rounded rectangles and ovals.

In Fig. 12.18, line 17 draws a red line, line 20 draws an empty blue rectangle and line 21 draws a filled blue rectangle. Methods `fillRoundRect` (line 24) and `drawRoundRect` (line 25) draw rectangles with rounded corners. Their first two arguments specify the coordinates of the upper-left corner of the **bounding rectangle**—the area in which the rounded rectangle will be drawn. Note that the upper-left corner coordinates are not the edge of

21
22 } // end main
23 } // end class LinesRectsOvals

```

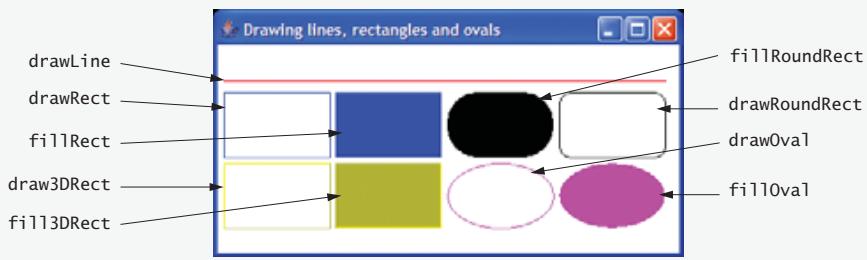

Fig. 12.19 | Creating JFrame to display lines, rectangles and ovals. (Part 2 of 2.)

the rounded rectangle, but the coordinates where the edge would be if the rectangle had square corners. The third and fourth arguments specify the width and height of the rectangle. The last two arguments determine the horizontal and vertical diameters of the arc (i.e., the arc width and arc height) used to represent the corners.

Figure 12.20 labels the arc width, arc height, width and height of a rounded rectangle. Using the same value for the arc width and arc height produces a quarter-circle at each corner. When the arc width, arc height, width and height have the same values, the result is a circle. If the values for width and height are the same and the values of arcWidth and arcHeight are 0, the result is a square.

Methods `draw3DRect` (line 28) and `fill3DRect` (line 29) take the same arguments. The first two arguments specify the top-left corner of the rectangle. The next two arguments specify the width and height of the rectangle, respectively. The last argument deter-

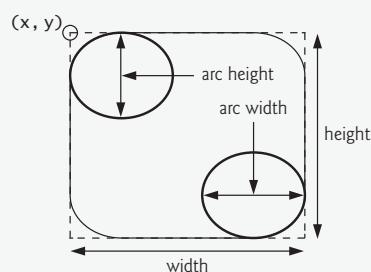

Fig. 12.20 | Arc width and arc height for rounded rectangles.

630 Chapter 12 Graphics and Java 2D™

mines whether the rectangle is **raised** (true) or **lowered** (false). The three-dimensional effect of `draw3DRect` appears as two edges of the rectangle in the original color and two edges in a slightly darker color. The three-dimensional effect of `fill3DRect` appears as two edges of the rectangle in the original drawing color and the fill and other two edges in a slightly darker color. Raised rectangles have the original drawing color edges at the top and left of the rectangle. Lowered rectangles have the original drawing color edges at the bottom and right of the rectangle. The three-dimensional effect is difficult to see in some colors.

Methods `drawOval` and `fillOval` (lines 32–33) take the same four arguments. The first two arguments specify the top-left coordinate of the bounding rectangle that contains the oval. The last two arguments specify the width and height of the bounding rectangle, respectively. Figure 12.21 shows an oval bounded by a rectangle. Note that the oval touches the center of all four sides of the bounding rectangle. (The bounding rectangle is not displayed on the screen.)

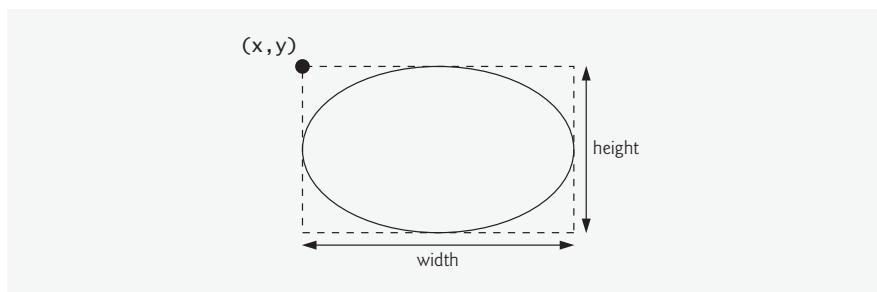

Fig. 12.21 | Oval bounded by a rectangle.

12.6 Drawing Arcs

An **arc** is drawn as a portion of an oval. Arc angles are measured in degrees. Arcs **sweep** (i.e., move along a curve) from a **starting angle** by the number of degrees specified by their **arc angle**. The starting angle indicates in degrees where the arc begins. The arc angle specifies the total number of degrees through which the arc sweeps. Figure 12.22 illustrates two arcs. The left set of axes shows an arc sweeping from zero degrees to approximately 110 degrees. Arcs that sweep in a counterclockwise direction are measured in **positive**

Fig. 12.22 | Positive and negative arc angles.

12.6 Drawing Arcs **631**

degrees. The set of axes on the right shows an arc sweeping from zero degrees to approximately -110 degrees. Arcs that sweep in a clockwise direction are measured in **negative degrees**. Note the dashed boxes around the arcs in Fig. 12.22. When drawing an arc, we specify a bounding rectangle for an oval. The arc will sweep along part of the oval. **Graphics** methods **drawArc** and **fillArc** for drawing arcs are summarized in Fig. 12.23.

The application of Fig. 12.24–Fig. 12.25 demonstrates the arc methods of Fig. 12.23. The application draws six arcs (three unfilled and three filled). To illustrate the bounding rectangle that helps determine where the arc appears, the first three arcs are displayed inside a red rectangle that has the same **x**, **y**, **width** and **height** arguments as the arcs.

Method	Description
<code>public void drawArc(int x, int y, int width, int height, int startAngle, int arcAngle)</code>	Draws an arc relative to the bounding rectangle's top-left x - and y -coordinates with the specified width and height . The arc segment is drawn starting at startAngle and sweeps arcAngle degrees.
<code>public void fillArc(int x, int y, int width, int height, int startAngle, int arcAngle)</code>	Draws a filled arc (i.e., a sector) relative to the bounding rectangle's top-left x - and y -coordinates with the specified width and height . The arc segment is drawn starting at startAngle and sweeps arcAngle degrees.

**Fig. 12.25** | Creating JFrame to display arcs.

12.7 Drawing Polygons and Polylines

Polygons are closed multisided shapes composed of straight-line segments. **Polylines** are sequences of connected points. Figure 12.26 discusses methods for drawing polygons and polylines. Note that some methods require a **Polygon** object (package `java.awt`). Class **Polygon**'s constructors are also described in Fig. 12.26. The application of Figs. 12.27–12.28 draws polygons and polylines.

Method	Description
<i>Graphics methods for drawing polygons</i>	
<code>public void drawPolygon(int xPoints[], int yPoints[], int points)</code>	Draws a polygon. The <i>x</i> -coordinate of each point is specified in the <i>xPoints</i> array, and the <i>y</i> -coordinate of each point in the <i>yPoints</i> array. The last argument specifies the number of points. This method draws a closed polygon. If the last point is different from the first, the polygon is closed by a line that connects the last point to the first.
<code>public void drawPolyline(int xPoints[], int yPoints[], int points)</code>	Draws a sequence of connected lines. The <i>x</i> -coordinate of each point is specified in the <i>xPoints</i> array, and the <i>y</i> -coordinate of each point in the <i>yPoints</i> array. The last argument specifies the number of points. If the last point is different from the first, the polyline is not closed.
<code>public void drawPolygon(Polygon p)</code>	Draws the specified polygon.
<code>public void fillPolygon(int xPoints[], int yPoints[], int points)</code>	Draws a filled polygon. The <i>x</i> -coordinate of each point is specified in the <i>xPoints</i> array, and the <i>y</i> -coordinate of each point in the <i>yPoints</i> array. The last argument specifies the number of points. This method draws a closed polygon. If the last point is different from the first, the polygon is closed by a line that connects the last point to the first.
<code>public void fillPolygon(Polygon p)</code>	Draws the specified filled polygon. The polygon is closed.
<i>Polygon constructors and methods</i>	
<code>public Polygon()</code>	Constructs a new polygon object. The polygon does not contain any points.
<code>public Polygon(int xValues[], int yValues[], int numberOfPoints)</code>	Constructs a new polygon object. The polygon has <i>numberOfPoints</i> sides, with each point consisting of an <i>x</i> -coordinate from <i>xValues</i> and a <i>y</i> -coordinate from <i>yValues</i> .
<code>public void addPoint(int x, int y)</code>	Adds pairs of <i>x</i> - and <i>y</i> -coordinates to the Polygon .

12.7 Drawing Polygons and Polylines **635**

```

10  // create frame for PolygonsJPanel
11 JFrame frame = new JFrame( "Drawing Polygons" );
12 frame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
13
14 PolygonsJPanel polygonsJPanel = new PolygonsJPanel();
15 frame.add( polygonsJPanel ); // add polygonsJPanel to frame
16 frame.setSize( 280, 270 ); // set frame size
17 frame.setVisible( true ); // display frame
18 } // end main
19 } // end class DrawPolygons

```

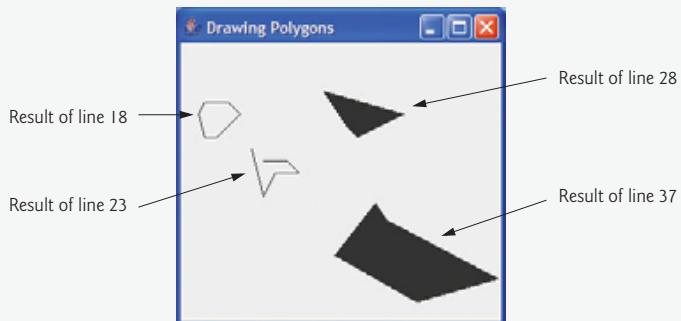

Fig. 12.28 | Creating JFrame to display polygons. (Part 2 of 2.)

Lines 15–16 of Fig. 12.27 create two int arrays and use them to specify the points for `Polygon` `polygon1`. The `Polygon` constructor call in line 17 receives array `xValues`, which contains the *x*-coordinate of each point; array `yValues`, which contains the *y*-coordinate of each point and 6 (the number of points in the polygon). Line 18 displays `polygon1` by passing it as an argument to `Graphics` method `drawPolygon`.

Lines 21–22 create two int arrays and use them to specify the points for a series of connected lines. Array `xValues2` contains the *x*-coordinate of each point and array `yValues2` the *y*-coordinate of each point. Line 23 uses `Graphics` method `drawPolyline` to display the series of connected lines specified with the arguments `xValues2`, `yValues2` and 7 (the number of points).

Lines 26–27 create two int arrays and use them to specify the points of a polygon. Array `xValues3` contains the *x*-coordinate of each point and array `yValues3` the *y*-coordinate of each point. Line 28 displays a polygon by passing to `Graphics` method `fillPolygon` the two arrays (`xValues3` and `yValues3`) and the number of points to draw (4).

Common Programming Error 12.1

An `ArrayIndexOutOfBoundsException` is thrown if the number of points specified in the third argument to method `drawPolygon` or method `fillPolygon` is greater than the number of elements in the arrays of coordinates that specify the polygon to display.

Line 31 creates `Polygon` `polygon2` with no points. Lines 32–36 use `Polygon` method `addPoint` to add pairs of *x*- and *y*-coordinates to the `Polygon`. Line 37 displays `Polygon` `polygon2` by passing it to `Graphics` method `fillPolygon`.

636 Chapter 12 Graphics and Java 2D™

12.8 Java 2D API

The [Java 2D API](#) provides advanced two-dimensional graphics capabilities for programmers who require detailed and complex graphical manipulations. The API includes features for processing line art, text and images in packages `java.awt`, `java.awt.image`, `java.awt.color`, `java.awt.font`, `java.awt.geom`, `java.awt.print` and `java.awt.image.renderable`. The capabilities of the API are far too broad to cover in this textbook. For an overview of the capabilities, see the Java 2D demo (discussed in Chapter 20, Introduction to Java Applets) or visit java.sun.com/products/java-media/2D/index.html.

In this section, we overview several Java 2D capabilities.

Drawing with the Java 2D API is accomplished with a [Graphics2D](#) reference (package `java.awt`). `Graphics2D` is an abstract subclass of class `Graphics`, so it has all the graphics capabilities demonstrated earlier in this chapter. In fact, the actual object used to draw in every `paintComponent` method is an instance of a subclass of `Graphics2D` that is passed to method `paintComponent` and accessed via the superclass `Graphics`. To access `Graphics2D` capabilities, we must cast the `Graphics` reference (`g`) passed to `paintComponent` into a `Graphics2D` reference with a statement such as

```
Graphics2D g2d = (Graphics2D) g;
```

The next two examples use this technique.

Lines, Rectangles, Round Rectangles, Arcs and Ellipses

The next example demonstrates several Java 2D shapes from package `java.awt.geom`, including `Line2D.Double`, `Rectangle2D.Double`, `RoundRectangle2D.Double`, `Arc2D.Double` and `Ellipse2D.Double`. Note the syntax of each class name. Each of these classes represents a shape with dimensions specified as double-precision floating-point values. There is a separate version of each represented with single-precision floating-point values (e.g., `Ellipse2D.Float`). In each case, `Double` is a static nested class of the class specified to the left of the dot (e.g., `Ellipse2D`). To use the static nested class, we simply qualify its name with the outer class name.

In Figs. 12.29–12.30, we draw Java 2D shapes and modify their drawing characteristics, such as changing line thickness, filling shapes with patterns and drawing dashed lines. These are just a few of the many capabilities provided by Java 2D.

```

1 // Fig. 12.29: Shapes JPanel.java
2 // Demonstrating some Java 2D shapes.
3 import java.awt.Color;
4 import java.awt.Graphics;

16 import javax.swing.JPanel;
17
18 public class ShapesJPanel extends JPanel
19 {
20     // draw shapes with Java 2D API
21     public void paintComponent( Graphics g )
22     {
23         super.paintComponent( g ); // call superclass's paintComponent
24
25         Graphics2D g2d = ( Graphics2D ) g; // cast g to Graphics2D
26
27         // draw 2D ellipse filled with a blue-yellow gradient
28         g2d.setPaint( new GradientPaint( 5, 30, Color.BLUE, 35, 100,
29             Color.YELLOW, true ) );
30         g2d.fill( new Ellipse2D.Double( 5, 30, 65, 100 ) );
31
32         // draw 2D rectangle in red
33         g2d.setPaint( Color.RED );
34         g2d.setStroke( new BasicStroke( 10.0f ) );
35         g2d.draw( new Rectangle2D.Double( 80, 30, 65, 100 ) );
36
37         // draw 2D rounded rectangle with a buffered background
38         BufferedImage buffImage = new BufferedImage( 10, 10,
39             BufferedImage.TYPE_INT_RGB );
40
41         // obtain Graphics2D from buffImage and draw on it
42         Graphics2D gg = buffImage.createGraphics();
43         gg.setColor( Color.YELLOW ); // draw in yellow
44         gg.fillRect( 0, 0, 10, 10 ); // draw a filled rectangle
45         gg.setColor( Color.BLACK ); // draw in black
46         gg.drawRect( 1, 1, 6, 6 ); // draw a rectangle
47         gg.setColor( Color.BLUE ); // draw in blue
48         gg.fillRect( 1, 1, 3, 3 ); // draw a filled rectangle
49         gg.setColor( Color.RED ); // draw in red
50         gg.fillRect( 4, 4, 3, 3 ); // draw a filled rectangle
51
52         // paint buffImage onto the JFrame
53         g2d.setPaint( new TexturePaint( buffImage,
54             new Rectangle( 10, 10 ) ) );
55         g2d.fill(
56             new RoundRectangle2D.Double( 155, 30, 75, 100, 50, 50 ) );
57
58         // draw 2D pie-shaped arc in white
59         g2d.setPaint( Color.WHITE );
60         g2d.setStroke( new BasicStroke( 6.0f ) );
61         g2d.draw(
62             new Arc2D.Double( 240, 30, 75, 100, 0, 270, Arc2D.PIE ) );
63
64         // draw 2D lines in green and yellow
65         g2d.setPaint( Color.GREEN );
66         g2d.draw( new Line2D.Double( 395, 30, 320, 150 ) );

20    } // end main
21 } // end class Shapes

```

**Fig. 12.30** | Creating JFrame to display shapes.

Line 25 of Fig. 12.29 casts the `Graphics` reference received by `paintComponent` to a `Graphics2D` reference and assigns it to `g2d` to allow access to the Java 2D features.

Ovals, Gradient Fills and Paint Objects

The first shape we draw is an oval filled with gradually changing colors. Lines 28–29 invoke `Graphics2D` method `setPaint` to set the `Paint` object that determines the color for

the shape to display. A `Paint` object implements interface `java.awt.Paint`. It can be something as simple as one of the predeclared `Color` objects introduced in Section 12.3 (class `Color` implements `Paint`), or it can be an instance of the Java 2D API's `GradientPaint`, `SystemColor`, `TexturePaint`, `LinearGradientPaint` or `RadialGradientPaint` classes. In this case, we use a `GradientPaint` object.

Class `GradientPaint` helps draw a shape in gradually changing colors—called a **gradient**. The `GradientPaint` constructor used here requires seven arguments. The first two specify the starting coordinate for the gradient. The third specifies the starting `Color` for the gradient. The fourth and fifth specify the ending coordinate for the gradient. The sixth specifies the ending `Color` for the gradient. The last argument specifies whether the gradient is **cyclic** (`true`) or **acyclic** (`false`). The two sets of coordinates determine the direction of the gradient. Because the second coordinate (35, 100) is down and to the right of the first coordinate (5, 30), the gradient goes down and to the right at an angle. Because this gradient is cyclic (`true`), the color starts with blue, gradually becomes yellow, then gradually returns to blue. If the gradient is acyclic, the color transitions from the first color specified (e.g., blue) to the second color (e.g., yellow).

Line 30 uses `Graphics2D` method `fill` to draw a filled `Shape` object—an object that implements interface `Shape` (package `java.awt`). In this case, we display an `Ellipse2D.Double` object. The `Ellipse2D.Double` constructor receives four arguments specifying the bounding rectangle for the ellipse to display.

Rectangles, Strokes

Next we draw a red rectangle with a thick border. Line 33 invokes `setPaint` to set the `Paint` object to `Color.RED`. Line 34 uses `Graphics2D` method `setStroke` to set the characteristics of the rectangle's border (or the lines for any other shape). Method `setStroke` requires as its argument an object that implements interface `Stroke` (package `java.awt`). In this case, we use an instance of class `BasicStroke`. Class `BasicStroke` provides several constructors to specify the width of the line, how the line ends (called the **end caps**), how lines join together (called **line joins**) and the dash attributes of the line (if it is a dashed line). The constructor here specifies that the line should be 10 pixels wide.

Line 35 uses `Graphics2D` method `draw` to draw a `Shape` object—in this case, a `Rectangle2D.Double`. The `Rectangle2D.Double` constructor receives four arguments specifying the upper-left *x*-coordinate, upper-left *y*-coordinate, width and height of the rectangle.

Rounded Rectangles, `BufferedImage` and `TexturePaint` Objects

Next we draw a rounded rectangle filled with a pattern created in a `BufferedImage` (package `java.awt.image`) object. Lines 38–39 create the `BufferedImage` object. Class `BufferedImage` can be used to produce images in color and grayscale. This particular `BufferedImage` is 10 pixels wide and 10 pixels tall (as specified by the first two arguments of the constructor). The third argument `BufferedImage.TYPE_INT_RGB` indicates that the image is stored in color using the RGB color scheme.

To create the rounded rectangle's fill pattern, we must first draw into the `BufferedImage`. Line 42 creates a `Graphics2D` object (with a call to `BufferedImage` method `createGraphics`) that can be used to draw into the `BufferedImage`. Lines 43–50 use methods `setColor`, `fillRect` and `drawRect` (discussed earlier in this chapter) to create the pattern.

640 Chapter 12 Graphics and Java 2D™

Lines 53–54 set the `Paint` object to a new `TexturePaint` (package `java.awt`) object. A `TexturePaint` object uses the image stored in its associated `BufferedImage` (the first constructor argument) as the fill texture for a filled-in shape. The second argument specifies the `Rectangle` area from the `BufferedImage` that will be replicated through the texture. In this case, the `Rectangle` is the same size as the `BufferedImage`. However, a smaller portion of the `BufferedImage` can be used.

Lines 55–56 use `Graphics2D` method `fill` to draw a filled `Shape` object—in this case, a `RoundRectangle2D.Double`. The constructor for class `RoundRectangle2D.Double` receives six arguments specifying the rectangle dimensions and the arc width and arc height used to determine the rounding of the corners.

Arcs

Next we draw a pie-shaped arc with a thick white line. Line 59 sets the `Paint` object to `Color.WHITE`. Line 60 sets the `Stroke` object to a new `BasicStroke` for a line 6 pixels wide. Lines 61–62 use `Graphics2D` method `draw` to draw a `Shape` object—in this case, an `Arc2D.Double`. The `Arc2D.Double` constructor's first four arguments specify the upper-left `x`-coordinate, upper-left `y`-coordinate, width and height of the bounding rectangle for the arc. The fifth argument specifies the start angle. The sixth argument specifies the arc angle. The last argument specifies how the arc is closed. Constant `Arc2D.PIE` indicates that the arc is closed by drawing two lines—one line from the arc's starting point to the center of the bounding rectangle and one line from the center of the bounding rectangle to the ending point. Class `Arc2D` provides two other static constants for specifying how the arc is closed. Constant `Arc2D.CHORD` draws a line from the starting point to the ending point. Constant `Arc2D.OPEN` specifies that the arc should not be closed.

Lines

Finally, we draw two lines using `Line2D` objects—one solid and one dashed. Line 65 sets the `Paint` object to `Color.GREEN`. Line 66 uses `Graphics2D` method `draw` to draw a `Shape` object—in this case, an instance of class `Line2D.Double`. The `Line2D.Double` constructor's arguments specify the starting coordinates and ending coordinates of the line.

Line 69 declares a one-element `float` array containing the value 10. This array will be used to describe the dashes in the dashed line. In this case, each dash will be 10 pixels long. To create dashes of different lengths in a pattern, simply provide the length of each dash as an element in the array. Line 70 sets the `Paint` object to `Color.YELLOW`. Lines 71–72 set the `Stroke` object to a new `BasicStroke`. The line will be 4 pixels wide and will have rounded ends (`BasicStroke.CAP_ROUND`). If lines join together (as in a rectangle at the corners), their joining will be rounded (`BasicStroke.JOIN_ROUND`). The `dashes` argument specifies the dash lengths for the line. The last argument indicates the starting index in the `dashes` array for the first dash in the pattern. Line 73 then draws a line with the current `Stroke`.

Creating Your Own Shapes with General Paths

Next we present a **general path**—a shape constructed from straight lines and complex curves. A general path is represented with an object of class `GeneralPath` (package `java.awt.geom`). The application of Figs. 12.31 and 12.32 demonstrates drawing a general path in the shape of a five-pointed star.

12.8 Java 2D API **641**

```

1 // Fig. 12.31: Shapes2JPanel.java
2 // Demonstrating a general path.
3 import java.awt.Color;
4 import java.awt.Graphics;
5 import java.awt.Graphics2D;
6 import java.awt.geom.GeneralPath;
7 import java.util.Random;
8 import javax.swing.JPanel;
9
10 public class Shapes2JPanel extends JPanel
11 {
12     // draw general paths
13     public void paintComponent( Graphics g )
14     {
15         super.paintComponent( g ); // call superclass's paintComponent
16         Random random = new Random(); // get random number generator
17
18         int xPoints[] = { 55, 67, 109, 73, 83, 55, 27, 37, 1, 43 };
19         int yPoints[] = { 0, 36, 36, 54, 96, 72, 96, 54, 36, 36 };
20
21         Graphics2D g2d = ( Graphics2D ) g;
22         GeneralPath star = new GeneralPath(); // create GeneralPath object
23
24         // set the initial coordinate of the General Path
25         star.moveTo( xPoints[ 0 ], yPoints[ 0 ] );
26
27         // create the star--this does not draw the star
28         for ( int count = 1; count < xPoints.length; count++ )
29             star.lineTo( xPoints[ count ], yPoints[ count ] );
30
31         star.closePath(); // close the shape
32
33         g2d.translate( 200, 200 ); // translate the origin to (200, 200)
34
35         // rotate around origin and draw stars in random colors
36         for ( int count = 1; count <= 20; count++ )
37         {
38             g2d.rotate( Math.PI / 10.0 ); // rotate coordinate system
39
40             // set random drawing color
41             g2d.setColor( new Color( random.nextInt( 256 ),
42                 random.nextInt( 256 ), random.nextInt( 256 ) ) );
43
44             g2d.fill( star ); // draw filled star
45         } // end for
46     } // end method paintComponent
47 } // end class Shapes2JPanel

```

Fig. 12.31 | Java 2D general paths.

Lines 18–19 declare two `int` arrays representing the *x*- and *y*-coordinates of the points in the star. Line 22 creates `GeneralPath` object `star`. Line 25 uses `GeneralPath` method `moveTo` to specify the first point in the star. The `for` statement in lines 28–29 uses `GeneralPath` method `lineTo` to draw a line to the next point in the star. Each new call to

642 Chapter 12 Graphics and Java 2D™

```

1 // Fig. 12.32: Shapes2.java
2 // Demonstrating a general path.
3 import java.awt.Color;
4 import javax.swing.JFrame;
5
6 public class Shapes2
7 {
8     // execute application
9     public static void main( String args[] )
10    {
11        // create frame for Shapes2JPanel
12        JFrame frame = new JFrame( "Drawing 2D Shapes" );
13        frame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
14
15        Shapes2 JPanel shapes2 JPanel = new Shapes2 JPanel();
16        frame.add( shapes2 JPanel ); // add shapes2 JPanel to frame
17        frame.setBackground( Color.WHITE ); // set frame background color
18        frame.setSize( 400, 400 ); // set frame size
19        frame.setVisible( true ); // display frame
20    } // end main
21 } // end class Shapes2

```

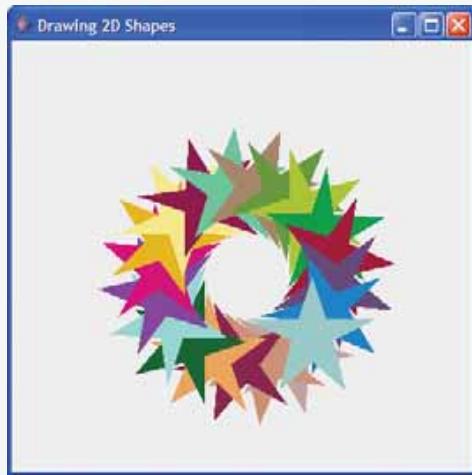

Fig. 12.32 | Creating JFrame to display stars.

LineTo draws a line from the previous point to the current point. Line 31 uses GeneralPath method `closePath` to draw a line from the last point to the point specified in the last call to `moveTo`. This completes the general path.

Line 33 uses Graphics2D method `translate` to move the drawing origin to location (200, 200). All drawing operations now use location (200, 200) as (0, 0).

The for statement in lines 36–45 draws the star 20 times by rotating it around the new origin point. Line 38 uses Graphics2D method `rotate` to rotate the next displayed shape. The argument specifies the rotation angle in radians (with $360^\circ = 2\pi$ radians). Line 44 uses Graphics2D method `fill` to draw a filled version of the star.

12.9 Wrap-Up

In this chapter, you learned how to use Java's graphics capabilities to produce colorful drawings. You learned how to specify the location of an object using Java's coordinate system, and how to draw on a window using the `paintComponent` method. You were introduced to class `Color`, and learned how to use this class to specify different colors using their RGB components. You used the `JColorChooser` dialog to allow users to select colors in a program. You then learned how to work with fonts when drawing text on a window. You learned how to create a `Font` object from a font name, style and size, as well as how to access the metrics of a font. From there, you learned how to draw various shapes on a window, such as rectangles (regular, rounded and 3D), ovals and polygons, as well as lines and arcs. You then used the Java 2D API to create more complex shapes and to fill them with gradients or patterns. The chapter concluded with a discussion of general paths, used to construct shapes from straight lines and complex curves. In the next chapter, you will learn about exceptions, useful for handling errors during a program's execution. Handling errors in this way provides for more robust programs.

Summary

Section 12.1 Introduction

- Java's coordinate system is a scheme for identifying every point on the screen.
- A coordinate pair is composed of an *x*-coordinate (the horizontal coordinate) and a *y*-coordinate (the vertical coordinate).
- Text and shapes are displayed on the screen by specifying coordinates. The coordinates are used to indicate where graphics should be displayed on a screen.
- Coordinate units are measured in pixels. A pixel is a display monitor's smallest unit of resolution.

Section 12.2 Graphics Contexts and Graphics Objects

- A Java graphics context enables drawing on the screen.
- Class `Graphics` contains methods for drawing strings, lines, rectangles and other shapes. Methods are also included for font manipulation and color manipulation.
- A `Graphics` object manages a graphics context and draws pixels on the screen that represent text and other graphical object (e.g., lines, ellipses, rectangles and other polygons).
- Class `Graphics` is an abstract class. This contributes to Java's portability—when Java is implemented on a platform, a subclass of `Graphics` is created that implements the drawing capabilities. This implementation is hidden from us by class `Graphics`, which supplies the interface that enables us to use graphics in a platform-independent manner.
- Class `JComponent` contains a `paintComponent` method that can be used to draw graphics in a Swing component.
- Method `paintComponent` takes as an argument a `Graphics` object that is passed to the `paintComponent` method by the system when a lightweight Swing component needs to be repainted.
- Method `paintComponent` is seldom called directly by the programmer because drawing graphics is an event-driven process. When an application executes, the application container calls method `paintComponent`. For `paintComponent` to be called again, an event must occur.
- When a `JComponent` is displayed, its `paintComponent` method is called.
- Programmers call method `repaint` to update the graphics drawn on the Swing component.

644 Chapter 12 Graphics and Java 2D™

Section 12.3 Color Control

- Class `Color` declares methods and constants for manipulating colors in a Java program.
- Every color is created from a red, a green and a blue component. Together these components are called RGB values.
- The RGB components specify the amount of red, green and blue in a color, respectively. The larger the RGB value, the greater the amount of that particular color.
- `Color` methods `getRed`, `getGreen` and `getBlue` return integer values from 0 to 255 representing the amount of red, green and blue, respectively.
- `Graphics` method `getColor` returns a `Color` object representing the current drawing color.
- `Graphics` method `setColor` sets the current drawing color.
- `Graphics` method `fillRect` draws a rectangle filled by the current color of the `Graphics` object.
- `Graphics` method `drawString` draws a `String` in the current color.
- The `JColorChooser` GUI component enables application users to select colors.
- Class `JColorChooser` provides the static convenience method `showDialog` that creates a `JColorChooser` object, attaches it to a dialog box and displays the dialog.
- While the color chooser dialog is on the screen, the user cannot interact with the parent component. This type of dialog is called a modal dialog.

Section 12.4 Font Control

- Class `Font` contains methods and constants for manipulating fonts.
- Class `Font`'s constructor takes three arguments—the font name, font style and font size.
- A `Font`'s font style can be `Font.PLAIN`, `Font.ITALIC` or `Font.BOLD` (each is a static field of class `Font`). Font styles can be used in combination (e.g., `Font.ITALIC + Font.BOLD`).
- The font size is measured in points. A point is 1/72 of an inch.
- `Graphics` method `setFont` sets the drawing font in which text will be displayed.
- `Font` method `getStyle` returns an integer value representing the current `Font`'s style.
- `Font` method `getSize` returns the font size in points.
- `Font` method `getName` returns the current font name as a string.
- `Font` method `getFamily` returns the name of the font family to which the current font belongs. The name of the font family is platform specific.
- Class `FontMetrics` contains methods for obtaining font information.
- Font metrics include height, descent (the amount a character dips below the baseline), ascent (the amount a character rises above the baseline) and leading (the difference between the descent of one line of text and the ascent of the line of text below it—that is, the interline spacing).

Section 12.5 Drawing Lines, Rectangles and Ovals

- `Graphics` methods `fillRoundRect` and `drawRoundRect` draw rectangles with rounded corners.
- `Graphics` methods `draw3DRect` and `fill3DRect` draw three-dimensional rectangles.
- `Graphics` methods `drawOval` and `fillOval` draw ovals.

Section 12.6 Drawing Arcs

- An arc is drawn as a portion of an oval.
- Arcs sweep from a starting angle by the number of degrees specified by their arc angle.
- `Graphics` methods `drawArc` and `fillArc` are used for drawing arcs.

Section 12.7 Drawing Polygons and Polylines

- Class `Polygon` contains methods for creating polygons.
- Polygons are closed multisided shapes composed of straight-line segments.
- Polylines are a sequence of connected points.
- `Graphics` method `drawPolyline` displays a series of connected lines.
- `Graphics` methods `drawPolygon` and `fillPolygon` are used to draw polygons.
- `Polygon` method `addPoint` of class `Polygon` adds pairs of *x*- and *y*-coordinates to the `Polygon`.

Section 12.8 Java 2D API

- The Java 2D API provides advanced two-dimensional graphics capabilities for programmers who require detailed and complex graphical manipulations.
- Class `Graphics2D`, which extends class `Graphics`, is used for drawing with the Java 2D API.
- The Java 2D API contains several classes for drawing shapes, including `Line2D.Double`, `Rectangle2D.Double`, `RoundRectangle2D.Double`, `Arc2D.Double` and `Ellipse2D.Double`.
- Class `GradientPaint` helps draw a shape in gradually changing colors—called a gradient.
- `Graphics2D` method `fill` draws a filled `Shape` object—an object that implements interface `Shape`.
- Class `BasicStroke` helps specify the drawing characteristics of lines.
- `Graphics2D` method `draw` is used to draw a `Shape` object.
- Classes `GradientPaint` and `TexturePaint` help specify the characteristics for filling shapes with colors or patterns.
- A general path is a shape constructed from straight lines and complex curves.
- A general path is represented with an object of class `GeneralPath`.
- `GeneralPath` method `moveTo` specifies the first point in a general path.
- `GeneralPath` method `lineTo` draws a line to the next point in the path. Each new call to `lineTo` draws a line from the previous point to the current point.
- `GeneralPath` method `closePath` draws a line from the last point to the point specified in the last call to `moveTo`. This completes the general path.
- `Graphics2D` method `translate` is used to move the drawing origin to a new location.
- `Graphics2D` method `rotate` is used to rotate the next displayed shape.

Terminology

acyclic gradient	color manipulation
<code>addPoint</code> method of class <code>Polygon</code>	color swatches
arc	complex curve
arc angle	connected lines
ascent (font metrics)	coordinate system
baseline (font metrics)	<code>createGraphics</code> method of class <code>BufferedImage</code>
<code>BasicStroke</code> class	cyclic gradient
<code>BOLD</code> constant of class <code>Font</code>	dashed lines
bounding rectangle	descent (font metrics)
<code>CAP_ROUND</code> constant of class <code>BasicStroke</code>	<code>draw</code> method of class <code>Graphics2D</code>
<code>clearRect</code> method of class <code>Graphics</code>	<code>draw3DRect</code> method of class <code>Graphics</code>
closed polygons	<code>drawArc</code> method of class <code>Graphics</code>
<code>closePath</code> method of class <code>GeneralPath</code>	<code>drawLine</code> method of class <code>Graphics</code>
<code>Color</code> class	<code>drawOval</code> method of class <code>Graphics</code>

Self-Review Exercises

- 12.1** Fill in the blanks in each of the following statements:
- In Java 2D, method _____ of class _____ sets the characteristics of a line used to draw a shape.

Answers to Self-Review Exercises 647

- b) Class _____ helps specify the fill for a shape such that the fill gradually changes from one color to another.
- c) The _____ method of class `Graphics` draws a line between two points.
- d) RGB is short for _____, _____ and _____.
- e) Font sizes are measured in units called _____.
- f) Class _____ helps specify the fill for a shape using a pattern drawn in a `BufferedImage`.

12.2 State whether each of the following is *true* or *false*. If *false*, explain why.

- a) The first two arguments of `Graphics` method `drawOval` specify the center coordinate of the oval.
- b) In the Java coordinate system, *x*-values increase from left to right.
- c) `Graphics` method `fillPolygon` draws a filled polygon in the current color.
- d) `Graphics` method `drawArc` allows negative angles.
- e) `Graphics` method `getSize` returns the size of the current font in centimeters.
- f) Pixel coordinate (0, 0) is located at the exact center of the monitor.

12.3 Find the error(s) in each of the following and explain how to correct the error(s). Assume that `g` is a `Graphics` object.

- a) `g.setFont("SansSerif");`
- b) `g.erase(x, y, w, h); // clear rectangle at (x, y)`
- c) `Font f = new Font("Serif", Font.BOLDITALIC, 12);`
- d) `g.setColor(255, 255, 0); // change color to yellow`

Answers to Self-Review Exercises

12.1 a) `setStroke`, `Graphics2D`. b) `GradientPaint`. c) `drawLine`. d) red, green, blue. e) points. f) `TexturePaint`.

12.2 a) False. The first two arguments specify the upper-left corner of the bounding rectangle.
 b) True.
 c) True.
 d) True.
 e) False. Font sizes are measured in points.
 f) False. The coordinate (0,0) corresponds to the upper-left corner of a GUI component on which drawing occurs.

12.3 a) The `setFont` method takes a `Font` object as an argument—not a `String`.
 b) The `Graphics` class does not have an `erase` method. The `clearRect` method should be used.
 c) `Font.BOLDITALIC` is not a valid font style. To get a bold italic font, use `Font.BOLD + Font.ITALIC`.
 d) Method `setColor` takes a `Color` object as an argument, not three integers.

Exercises

12.4 Fill in the blanks in each of the following statements:

- a) Class _____ of the Java 2D API is used to draw ovals.
- b) Methods `draw` and `fill` of class `Graphics2D` require an object of type _____ as their argument.
- c) The three constants that specify font style are _____, _____ and _____.
- d) `Graphics2D` method _____ sets the painting color for Java 2D shapes.

12.5 State whether each of the following is *true* or *false*. If *false*, explain why.

- a) `Graphics` method `drawPolygon` automatically connects the endpoints of the polygon.

648 Chapter 12 Graphics and Java 2D™

- b) Graphics method `drawLine` draws a line between two points.
- c) Graphics method `fillArc` uses degrees to specify the angle.
- d) In the Java coordinate system, values on the *y*-axis increase from left to right.
- e) Graphics inherits directly from class `Object`.
- f) Graphics is an abstract class.
- g) The `Font` class inherits directly from class `Graphics`.

12.6 (*Concentric Circles Using Method `drawArc`*) Write an application that draws a series of eight concentric circles. The circles should be separated by 10 pixels. Use Graphics method `drawArc`.

12.7 (*Concentric Circles Using Class `Ellipse2D.Double`*) Modify your solution to Exercise 12.6 to draw the ovals by using class `Ellipse2D.Double` and method `draw` of class `Graphics2D`.

12.8 (*Random Lines Using Class `Line2D.Double`*) Modify your solution to Exercise 12.7 to draw random lines, in random colors and random line thicknesses. Use class `Line2D.Double` and method `draw` of class `Graphics2D` to draw the lines.

12.9 (*Random Triangles*) Write an application that displays randomly generated triangles in different colors. Each triangle should be filled with a different color. Use class `GeneralPath` and method `fill` of class `Graphics2D` to draw the triangles.

12.10 (*Random Characters*) Write an application that randomly draws characters in different font sizes and colors.

12.11 (*Grid Using Method `drawLine`*) Write an application that draws an 8-by-8 grid. Use Graphics method `drawLine`.

12.12 (*Grid Using Class `Line2D.Double`*) Modify your solution to Exercise 12.11 to draw the grid using instances of class `Line2D.Double` and method `draw` of class `Graphics2D`.

12.13 (*Grid Using Method `drawRect`*) Write an application that draws a 10-by-10 grid. Use the Graphics method `drawRect`.

12.14 (*Grid Using Class `Rectangle2D.Double`*) Modify your solution to Exercise 12.13 to draw the grid by using class `Rectangle2D.Double` and method `draw` of class `Graphics2D`.

12.15 (*Drawing Tetrahedrons*) Write an application that draws a tetrahedron (a three-dimensional shape with four triangular faces). Use class `GeneralPath` and method `draw` of class `Graphics2D`.

12.16 (*Drawing Cubes*) Write an application that draws a cube. Use class `GeneralPath` and method `draw` of class `Graphics2D`.

12.17 (*Circles Using Class `Ellipse2D.Double`*) Write an application that asks the user to input the radius of a circle as a floating-point number and draws the circle, as well as the values of the circle's diameter, circumference and area. Use the value 3.14159 for π . [Note: You may also use the pre-defined constant `Math.PI` for the value of π . This constant is more precise than the value 3.14159. Class `Math` is declared in the `java.lang` package, so you do not need to import it.] Use the following formulas (r is the radius):

$$\begin{aligned} \text{diameter} &= 2r \\ \text{circumference} &= 2\pi r \\ \text{area} &= \pi r^2 \end{aligned}$$

The user should also be prompted for a set of coordinates in addition to the radius. Then draw the circle, and display the circle's diameter, circumference and area, using an `Ellipse2D.Double` object to represent the circle and method `draw` of class `Graphics2D` to display the circle.

12.18 (*Screen Saver*) Write an application that simulates a screen saver. The application should randomly draw lines using method `drawLine` of class `Graphics`. After drawing 100 lines, the application should clear itself and start drawing lines again. To allow the program to draw continuously,

Exercises **649**

place a call to `repaint` as the last line in method `paintComponent`. Do you notice any problems with this on your system?

12.19 (*Screen Saver Using Timer*) Package `javax.swing` contains a class called `Timer` that is capable of calling method `actionPerformed` of interface `ActionListener` at a fixed time interval (specified in milliseconds). Modify your solution to Exercise 12.18 to remove the call to `repaint` from method `paintComponent`. Declare your class to implement `ActionListener`. (The `actionPerformed` method should simply call `repaint`.) Declare an instance variable of type `Timer` called `timer` in your class. In the constructor for your class, write the following statements:

```
timer = new Timer( 1000, this );
timer.start();
```

This creates an instance of class `Timer` that will call `this` object's `actionPerformed` method every 1000 milliseconds (i.e., every second).

12.20 (*Screen Saver for a Random Number of Lines*) Modify your solution to Exercise 12.19 to enable the user to enter the number of random lines that should be drawn before the application clears itself and starts drawing lines again. Use a `JTextField` to obtain the value. The user should be able to type a new number into the `JTextField` at any time during the program's execution. Use an inner class to perform event handling for the `JTextField`.

12.21 (*Screen Saver with Shapes*) Modify your solution to Exercise 12.19 such that it uses random-number generation to choose different shapes to display. Use methods of class `Graphics`.

12.22 (*Screen Saver Using the Java 2D API*) Modify your solution to Exercise 12.21 to use classes and drawing capabilities of the Java 2D API. Draw shapes like rectangles and ellipses, with randomly generated gradients. Use class `GradientPaint` to generate the gradient.

12.23 (*Turtle Graphics*) Modify your solution to Exercise 7.21—*Turtle Graphics*—to add a graphical user interface using `JTextFields` and `JButtons`. Draw lines rather than asterisks (*). When the turtle graphics program specifies a move, translate the number of positions into a number of pixels on the screen by multiplying the number of positions by 10 (or any value you choose). Implement the drawing with Java 2D API features.

12.24 (*Knight's Tour*) Produce a graphical version of the Knight's Tour problem (Exercise 7.22, Exercise 7.23 and Exercise 7.26). As each move is made, the appropriate cell of the chessboard should be updated with the proper move number. If the result of the program is a *full tour* or a *closed tour*, the program should display an appropriate message. If you like, use class `Timer` (see Exercise 12.19) to help animate the Knight's Tour.

12.25 (*Tortoise and Hare*) Produce a graphical version of the *Tortoise and Hare* simulation (Exercise 7.28). Simulate the mountain by drawing an arc that extends from the bottom-left corner of the window to the top-right corner of the window. The tortoise and the hare should race up the mountain. Implement the graphical output to actually print the tortoise and the hare on the arc for every move. [Hint: Extend the length of the race from 70 to 300 to allow yourself a larger graphics area.]

12.26 (*Drawing Spirals*) Write an application that uses `Graphics` method `drawPolyline` to draw a spiral similar to the one shown in Fig. 12.33.

12.27 (*Pie Chart*) Write a program that inputs four numbers and graphs them as a pie chart. Use class `Arc2D.Double` and method `fill` of class `Graphics2D` to perform the drawing. Draw each piece of the pie in a separate color.

12.28 (*Selecting Shapes*) Write an application that allows the user to select a shape from a `JComboBox` and draws it 20 times with random locations and dimensions in method `paintComponent`. The first item in the `JComboBox` should be the default shape that is displayed the first time `paintComponent` is called.

650 Chapter 12 Graphics and Java 2D™

Fig. 12.33 | Spiral drawn using method `drawPolyline`.

12.29 (*Random Colors*) Modify Exercise 12.28 to draw each of the 20 randomly sized shapes in a randomly selected color. Use all 13 predefined `Color` objects in an array of `Colors`.

12.30 (*JColorChooser Dialog*) Modify Exercise 12.28 to allow the user to select the color in which shapes should be drawn from a `JColorChooser` dialog.

(Optional) GUI and Graphics Case Study: Adding Java2D

12.31 Java2D introduces many new capabilities for creating unique and impressive graphics. We will add a small subset of these features to the drawing application you created in Exercise 11.18. In this version of the drawing application, you will enable the user to specify gradients for filling shapes and to change stroke characteristics for drawing lines and outlines of shapes. The user will be able to choose which colors compose the gradient and set the width and dash length of the stroke.

First, you must update the `MyShape` hierarchy to support Java2D functionality. Make the following changes in class `MyShape`:

- Change abstract method `draw`'s parameter type from `Graphics` to `Graphics2D`.
- Change all variables of type `Color` to type `Paint` to enable support for gradients. [Note: Recall that class `Color` implements interface `Paint`.]
- Add an instance variable of type `Stroke` in class `MyShape` and a `Stroke` parameter in the constructor to initialize the new instance variable. The default stroke should be an instance of class `BasicStroke`.

Classes `MyLine`, `MyBoundedShape`, `MyOval` and `MyRect` should each add a `Stroke` parameter to their constructors. In the `draw` methods, each shape should set the `Paint` and the `Stroke` before drawing or filling a shape. Since `Graphics2D` is a subclass of `Graphics`, we can continue to use `Graphics` methods `drawLine`, `drawOval`, `fillOval`, and so on. to draw the shapes. When these methods are called, they will draw the appropriate shape using the specified `Paint` and `Stroke` settings.

Next, you will update the `DrawPanel` to handle the Java2D features. Change all `Color` variables to `Paint` variables. Declare an instance variable `currentStroke` of type `Stroke` and provide a *set* method for it. Update the calls to the individual shape constructors to include the `Paint` and `Stroke` arguments. In method `paintComponent`, cast the `Graphics` reference to type `Graphics2D` and use the `Graphics2D` reference in each call to `MyShape` method `draw`.

Next, make the new Java2D features accessible from the GUI. Create a `JPanel` of GUI components for setting the Java2D options. Add these components at the top of the `DrawFrame` below

Exercises **651**

the panel that currently contains the standard shape controls (see Fig. 12.34). These GUI components should include:

- A check box to specify whether to paint using a gradient
- Two JButtons that each show a JColorChooser dialog to allow the user to choose the first and second color in the gradient. (These will replace the JComboBox used for choosing the color in Exercise 11.18.)
- A text field for entering the Stroke width
- A text field for entering the Stroke dash length
- A check box for selecting whether to draw a dashed or solid line

If the user selects to draw with a gradient, set the Paint on the DrawPanel to be a gradient of the two colors chosen by the user. The expression

```
new GradientPaint( 0, 0, color1, 50, 50, color2, true )
```

creates a GradientPaint that cycles diagonally from the upper-left to the bottom-right every 50 pixels. Variables color1 and color2 represent the colors chosen by the user. If the user does not select to use a gradient, then simply set the Paint on the DrawPanel to be the first Color chosen by the user.

For strokes, if the user chooses a solid line, then create the Stroke with the expression

```
new BasicStroke( width, BasicStroke.CAP_ROUND, BasicStroke.JOIN_ROUND )
```

where variable width is the width specified by the user in the line-width text field. If the user chooses a dashed line, then create the Stroke with the expression

```
new BasicStroke( width, BasicStroke.CAP_ROUND, BasicStroke.JOIN_ROUND,
    10, dashes, 0 )
```

where width again is the width in the line-width field, and dashes is an array with one element whose value is the length specified in the dash-length field. The Panel and Stroke objects should be passed to the shape object's constructor when the shape is created in DrawPanel.

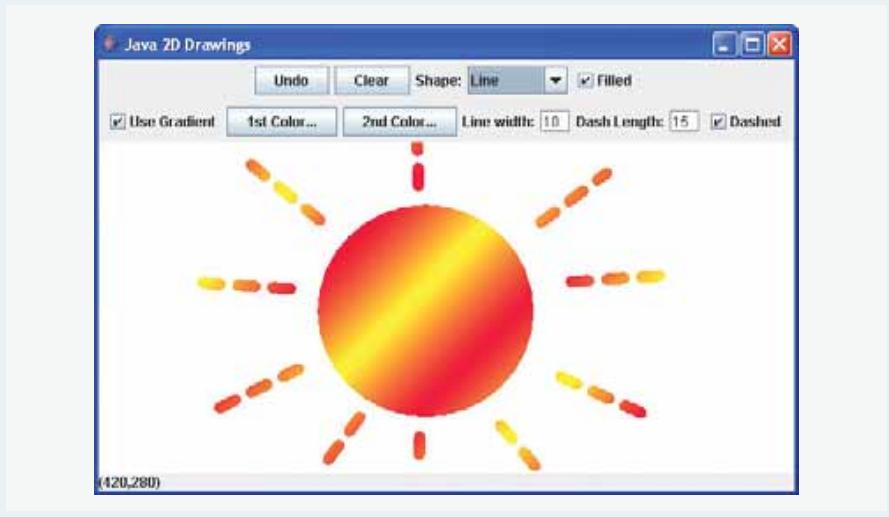

Fig. 12.34 | Drawing with Java2D.

13

Exception Handling

OBJECTIVES

In this chapter you will learn:

- How exception and error handling works.
- To use `try`, `throw` and `catch` to detect, indicate and handle exceptions, respectively.
- To use the `finally` block to release resources.
- How stack unwinding enables exceptions not caught in one scope to be caught in another scope.
- How stack traces help in debugging.
- How exceptions are arranged in an exception-class hierarchy.
- To declare new exception classes.
- To create chained exceptions that maintain complete stack-trace information.

It is common sense to take a method and try it. If it fails, admit it frankly and try another. But above all, try something.

—Franklin Delano Roosevelt

*O! throw away the worser part of it,
And live the purer with the other half.*

—William Shakespeare

*If they're running and they don't look where they're going
I have to come out from somewhere and catch them.*

—Jerome David Salinger

O infinite virtue! com'st thou smiling from the world's great snare uncaught?

—William Shakespeare

Outline

- 13.1** Introduction
- 13.2** Exception-Handling Overview
- 13.3** Example: Divide by Zero without Exception Handling
- 13.4** Example: Handling `ArithmeticExceptions` and `InputMismatchExceptions`
- 13.5** When to Use Exception Handling
- 13.6** Java Exception Hierarchy
- 13.7** `finally` Block
- 13.8** Stack Unwinding
- 13.9** `printStackTrace`, `getStackTrace` and `getMessage`
- 13.10** Chained Exceptions

- 13.12** Preconditions and Postconditions
- 13.13** Assertions
- 13.14** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

13.1 Introduction

In this chapter, we introduce **exception handling**. An **exception** is an indication of a problem that occurs during a program’s execution. The name “exception” implies that the problem occurs infrequently—if the “rule” is that a statement normally executes correctly, then the “exception to the rule” is that a problem occurs. Exception handling enables you to create applications that can resolve (or handle) exceptions. In many cases, handling an exception allows a program to continue executing as if no problem had been encountered. A more severe problem could prevent a program from continuing normal execution, instead requiring it to notify the user of the problem before terminating in a controlled manner. The features presented in this chapter enable programmers to write **robust** and **fault-tolerant programs** (i.e., programs that are able to deal with problems that may arise and continue executing). The style and details of Java exception handling are based in part on Andrew Koenig’s and Bjarne Stroustrup’s paper, “Exception Handling for C++ (revised).”¹

Error-Prevention Tip 13.1

Exception handling helps improve a program’s fault tolerance.

You have already been briefly introduced to exceptions in earlier chapters. In Chapter 7 you learned that an `ArrayIndexOutOfBoundsException` occurs when an attempt is made to access an element past the end of an array. Such a problem may occur if there is an “off-by-one” error in a `for` statement that manipulates an array. In Chapter 10, we introduced the `ClassCastException`, which occurs when an attempt is made to cast an object that does not have an *is-a* relationship with the type specified in the cast operator. Chapter 11

1. Koenig, A., and B. Stroustrup. “Exception Handling for C++ (revised),” *Proceedings of the Usenix C++ Conference*, pp. 149–176, San Francisco, April 1990.

654 Chapter 13 Exception Handling

briefly mentioned the `NullPointerException`, which occurs whenever a `null` reference is used where an object is expected (for example, when an attempt is made to attach a GUI component to a `Container`, but the GUI component has not yet been created). Throughout this text you have also used class `Scanner`—which, as you will see in this chapter, also may cause exceptions.

The chapter begins with an overview of exception-handling concepts, then demonstrates basic exception-handling techniques. We show these techniques in action by handling an exception that occurs when a method attempts to divide an integer by zero. Next, we introduce several classes at the top of Java’s class hierarchy for exception handling. As you will see, only classes that extend `Throwable` (package `java.lang`) directly or indirectly can be used with exception handling. We then discuss the chained exception feature that allows programmers to wrap information about an exception that occurred in another exception object to provide more detailed information about a problem in a program. Next, we discuss additional exception-handling issues, such as how to handle exceptions that occur in a constructor. We introduce preconditions and postconditions, which must be true when your methods are called and when those methods return, respectively. Finally, we present assertions, which programmers use at development time to help debug their code.

13.2 Exception-Handling Overview

Programs frequently test conditions to determine how program execution should proceed. Consider the following pseudocode:

```
Perform a task
If the preceding task did not execute correctly
    Perform error processing
Perform next task
If the preceding task did not execute correctly
    Perform error processing
...

```

In this pseudocode, we begin by performing a task; then we test whether that task executed correctly. If not, we perform error processing. Otherwise, we continue with the next task. Although this form of error handling works, intermixing program logic with error-handling logic can make programs difficult to read, modify, maintain and debug—especially in large applications.

Performance Tip 13.1

If the potential problems occur infrequently, intermixing program and error-handling logic can degrade a program’s performance, because the program must perform (potentially frequent) tests to determine whether the task executed correctly and the next task can be performed.

Exception handling enables programmers to remove error-handling code from the “main line” of the program’s execution, improving program clarity and enhancing modifiability. You can decide to handle any exceptions you choose—all exceptions, all exceptions of a certain type or all exceptions of a group of related types (i.e., exception types that

13.3 Example: Divide by Zero without Exception Handling **655**

are related through an inheritance hierarchy). Such flexibility reduces the likelihood that errors will be overlooked, thus making programs more robust.

With programming languages that do not support exception handling, programmers often delay writing error-processing code or sometimes forget to include it. This results in less robust software products. Java enables programmers to deal with exception handling easily from the inception of a project.

13.3 Example: Divide by Zero without Exception Handling

First we demonstrate what happens when errors arise in an application that does not use exception handling. Figure 13.1 prompts the user for two integers and passes them to method `quotient`, which calculates the quotient and returns an `int` result. In this example, we'll see that exceptions are `thrown` (i.e., the exception occurs) when a method detects a problem and is unable to handle it.

The first of the three sample executions in Fig. 13.1 shows a successful division. In the second sample execution, the user enters the value 0 as the denominator. Notice that sev-

```

```

Fig. 13.1 | Integer division without exception handling. (Part 2 of 2.)

erally lines of information are displayed in response to this invalid input. This information is known as the **stack trace**, which includes the name of the exception (`java.lang.ArithmetricException`) in a descriptive message that indicates the problem that occurred and the complete method-call stack (i.e., the call chain) at the time the exception occurred. The stack trace includes the path of execution that led to the exception method by method. This information helps in debugging a program. The first line specifies that an `ArithmetricException` has occurred. The text after the name of the exception ("`/ by zero`") indicates that this exception occurred as a result of an attempt to divide by zero. Java does not allow division by zero in integer arithmetic. [Note: Java *does* allow division by zero with floating-point values. Such a calculation results in the value infinity, which is represented in Java as a floating-point value (but actually displays as the string `Infinity`).] When division by zero in integer arithmetic occurs, Java throws an `ArithmetricException`. `ArithmetricExceptions` can arise from a number of different problems in arithmetic, so the extra data ("`/ by zero`") gives us more information about this specific exception.

Starting from the last line of the stack trace, we see that the exception was detected in line 22 of method `main`. Each line of the stack trace contains the class name and method (`DivideByZeroNoExceptionHandling.main`) followed by the file name and line number (`DivideByZeroNoExceptionHandling.java:22`). Moving up the stack trace, we see that the exception occurs in line 10, in method `quotient`. The top row of the call chain indicates the **throw point**—the initial point at which the exception occurs. The throw point of this exception is in line 10 of method `quotient`.

In the third execution, the user enters the string "`hello`" as the denominator. Notice again that a stack trace is displayed. This informs us that an `InputMismatchException` has occurred (package `java.util`). Our prior examples that read numeric values from the user assumed that the user would input a proper integer value. However, users sometimes make mistakes and input noninteger values. An `InputMismatchException` occurs when `Scanner` method `nextInt` receives a string that does not represent a valid integer. Starting from the end of the stack trace, we see that the exception was detected in line 20 of method `main`.

13.4 ArithmeticExceptions and InputMismatchExceptions 657

Moving up the stack trace, we see that the exception occurs in method `nextInt`. Notice that in place of the file name and line number, we are provided with the text Unknown Source. This means that the JVM does not have access to the source code for where the exception occurred.

Notice that in the sample executions of Fig. 13.1 when exceptions occur and stack traces are displayed, the program also exits. This does not always occur in Java—sometimes a program may continue even though an exception has occurred and a stack trace has been printed. In such cases, the application may produce unexpected results. The next section demonstrates how to handle these exceptions and keep the program running successfully.

In Fig. 13.1 both types of exceptions were detected in method `main`. In the next example, we will see how to handle these exceptions to enable the program to run to normal completion.

13.4 Example: Handling ArithmeticExceptions and InputMismatchExceptions

The application in Fig. 13.2, which is based on Fig. 13.1, uses exception handling to process any `ArithmeticException` and `InputMismatchException` that arise. The application still prompts the user for two integers and passes them to method `quotient`, which calculates the quotient and returns an `int` result. This version of the application uses exception handling so that if the user makes a mistake, the program `catches` and `handles` (i.e., deals with) the exception—in this case, allowing the user to try to enter the input again.

The first sample execution in Fig. 13.2 shows a successful execution that does not encounter any problems. In the second execution, the user enters a zero denominator and an `ArithmeticException` exception occurs. In the third execution, the user enters the string "hello" as the denominator, and an `InputMismatchException` occurs. For each exception, the user is informed of the mistake and asked to try again, then is prompted for two new integers. In each sample execution, the program runs successfully to completion.

```

Please enter an integer denominator: 7

Result: 100 / 7 = 14
```

Fig. 13.2 | Handling `ArithmeticExceptions` and `InputMismatchExceptions`. (Part 3 of 3.)

Class `InputMismatchException` is imported in line 3. Class `ArithmeticException` does not need to be imported because it is located in package `java.lang`. Method `main` (lines 15–49) creates a `Scanner` object at line 17. Line 18 creates the boolean variable `continueLoop`, which is true if the user has not yet entered valid input. Lines 20–48 repeatedly ask users for input until a valid input is received.

Enclosing Code in a `try` Block

Lines 22–33 contain a `try block`, which encloses the code that might throw an exception and the code that should not execute if an exception occurs (i.e., if an exception occurs, the remaining code in the `try` block will be skipped). A `try` block consists of the keyword `try` followed by a block of code enclosed in curly braces (`{}`). [Note: The term “`try block`” sometimes refers only to the block of code that follows the `try` keyword (not including the `try` keyword itself). For simplicity, we use the term “`try block`” to refer to the block of code that follows the `try` keyword, as well as the `try` keyword.] The statements that read the integers from the keyboard (lines 25 and 27) each use method `nextInt` to read an `int` value. Method `nextInt` throws an `InputMismatchException` if the value read in is not a valid integer.

The division that can cause an `ArithmeticException` is not performed in the `try` block. Rather, the call to method `quotient` (line 29) invokes the code that attempts the division (line 12); the JVM throws an `ArithmeticException` object when the denominator is zero.

Software Engineering Observation 13.1

Exceptions may surface through explicitly mentioned code in a try block, through calls to other methods, through deeply nested method calls initiated by code in a try block or from the Java Virtual Machine as it executes Java bytecodes.

Catching Exceptions

The `try` block in this example is followed by two `catch` blocks—one that handles an `InputMismatchException` (lines 34–41) and one that handles an `ArithmeticException` (lines 42–47). A `catch block` (also called a `catch clause` or `exception handler`) catches (i.e., receives) and handles an exception. A `catch` block begins with the keyword `catch` and is followed by a parameter in parentheses (called the exception parameter, discussed shortly) and a block of code enclosed in curly braces. [Note: The term “`catch clause`” is sometimes used to refer to the keyword `catch` followed by a block of code, where the term “`catch`

660 Chapter 13 Exception Handling

block” refers to only the block of code following the `catch` keyword, but not including it. For simplicity, we use the term “`catch` block” to refer to the block of code following the `catch` keyword, as well as the keyword itself.]

At least one `catch` block or a **`finally` block** (discussed in Section 13.7) must immediately follow the `try` block. Each `catch` block specifies in parentheses an **exception parameter** that identifies the exception type the handler can process. When an exception occurs in a `try` block, the `catch` block that executes is the one whose type matches the type of the exception that occurred (i.e., the type in the `catch` block matches the thrown exception type exactly or is a superclass of it). The exception parameter’s name enables the `catch` block to interact with a caught exception object—e.g., to implicitly invoke the caught exception’s `toString` method (as in lines 37 and 44), which displays basic information about the exception. Line 38 of the first `catch` block calls `Scanner` method `nextLine`. Because an `InputMismatchException` occurred, the call to method `nextInt` never successfully read in the user’s data—so we read that input with a call to method `nextLine`. We do not do anything with the input at this point, because we know that it is invalid. Each `catch` block displays an error message and asks the user to try again. After either `catch` block terminates, the user is prompted for input. We will soon take a deeper look at how this flow of control works in exception handling.

Common Programming Error 13.1

It is a syntax error to place code between a `try` block and its corresponding `catch` blocks.

Common Programming Error 13.2

Each `catch` block can have only a single parameter—specifying a comma-separated list of exception parameters is a syntax error.

An **uncaught exception** is an exception that occurs for which there are no matching `catch` blocks. You saw uncaught exceptions in the second and third outputs of Fig. 13.1. Recall that when exceptions occurred in that example, the application terminated early (after displaying the exception’s stack trace). This does not always occur as a result of uncaught exceptions. As you will learn in Chapter 23, Multithreading, Java uses a multi-threaded model of program execution. Each `thread` is a parallel activity. One program can have many threads. If a program has only one thread, an uncaught exception will cause the program to terminate. If a program has multiple threads, an uncaught exception will terminate only the thread where the exception occurred. In such programs, however, certain threads may rely on others and if one thread terminates due to an uncaught exception, there may be adverse effects to the rest of the program.

Termination Model of Exception Handling

If an exception occurs in a `try` block (such as an `InputMismatchException` being thrown as a result of the code at line 25 of Fig. 13.2), the `try` block terminates immediately and program control transfers to the first of the following `catch` blocks in which the exception parameter’s type matches the thrown exception’s type. In Fig. 13.2, the first `catch` block catches `InputMismatchExceptions` (which occur if invalid input is entered) and the second `catch` block catches `ArithmeticsExceptions` (which occur if an attempt is made to divide by zero). After the exception is handled, program control does not return to the throw point because the `try` block has expired (and its local variables have been lost). Rather, con-

13.4 ArithmeticExceptions and InputMismatchExceptions 661

trol resumes after the last catch block. This is known as the **termination model of exception handling**. [Note: Some languages use the **resumption model of exception handling**, in which, after an exception is handled, control resumes just after the throw point.]

Common Programming Error 13.3

Logic errors can occur if you assume that after an exception is handled, control will return to the first statement after the throw point.

Error-Prevention Tip 13.2

With exception handling, a program can continue executing (rather than terminating) after dealing with a problem. This helps ensure the kind of robust applications that contribute to what is called mission-critical computing or business-critical computing.

Notice that we name our exception parameters (`inputMismatchException` and `arithmeticException`) based on their type. Java programmers often simply use the letter `e` as the name of their exception parameters.

Good Programming Practice 13.1

Using an exception parameter name that reflects the parameter's type promotes clarity by reminding the programmer of the type of exception being handled.

After executing a catch block, this program's flow of control proceeds to the first statement after the last catch block (line 48 in this case). The condition in the `do...while` statement is `true` (variable `continueLoop` contains its initial value of `true`), so control returns to the beginning of the loop and the user is once again prompted for input. This control statement will loop until valid input is entered. At that point, program control reaches line 32, which assigns `false` to variable `continueLoop`. The try block then terminates. If no exceptions are thrown in the try block, the catch blocks are skipped and control continues with the first statement after the catch blocks (we'll learn about another possibility when we discuss the `finally` block in Section 13.7). Now the condition for the `do...while` loop is `false`, and method `main` ends.

The try block and its corresponding catch and/or finally blocks together form a **try statement**. It is important not to confuse the terms "try block" and "try statement"—the term "try block" refers to the keyword `try` followed by a block of code, while "try statement" includes the try block as well as the following catch blocks and/or finally block.

As with any other block of code, when a try block terminates, local variables declared in the block are destroyed. When a catch block terminates, local variables declared within the catch block (including the exception parameter of that catch block) also go out of scope and are destroyed. Any remaining catch blocks in the try statement are ignored, and execution resumes at the first line of code after the try...catch sequence—this will be a finally block, if one is present.

Using the throws Clause

Now let us examine method `quotient` (Fig. 13.2; lines 9–13). The portion of the method declaration located at line 10 is known as a **throws clause**. A throws clause specifies the exceptions the method throws. This clause appears after the method's parameter list and before the method's body. It contains a comma-separated list of the exceptions that the

662 Chapter 13 Exception Handling

method will throw if a problem occurs. Such exceptions may be thrown by statements in the method's body or by methods called from the body. A method can throw exceptions of the classes listed in its `throws` clause or of their subclasses. We have added the `throws` clause to this application to indicate to the rest of the program that this method may throw an `ArithmetcException`. Clients of method `quotient` are thus informed that the method may throw an `ArithmetcException`. You will learn more about the `throws` clause in Section 13.6.

**Error-Prevention Tip 13.3**

If you know that a method might throw an exception, include appropriate exception-handling code in your program to make it more robust.

**Error-Prevention Tip 13.4**

Read the online API documentation for a method before using that method in a program. The documentation specifies the exceptions thrown by the method (if any) and indicates reasons why such exceptions may occur. Then provide for handling those exceptions in your program.

**Error-Prevention Tip 13.5**

Read the online API documentation for an exception class before writing exception-handling code for that type of exception. The documentation for an exception class typically contains potential reasons that such exceptions occur during program execution.

When line 12 executes, if the denominator is zero, the JVM throws an `ArithmetcException` object. This object will be caught by the catch block at lines 42–47, which displays basic information about the exception by implicitly invoking the exception's `toString` method, then asks the user to try again.

If the denominator is not zero, method `quotient` performs the division and returns the result to the point of invocation of method `quotient` in the `try` block (line 29). Lines 30–31 display the result of the calculation and line 32 sets `continueLoop` to `false`. In this case, the `try` block completes successfully, so the program skips the catch blocks and fails the condition at line 48, and method `main` completes execution normally.

Note that when `quotient` throws an `ArithmetcException`, `quotient` terminates and does not return a value, and `quotient`'s local variables go out of scope (and the variables are destroyed). If `quotient` contained local variables that were references to objects and there were no other references to those objects, the objects would be marked for garbage collection. Also, when an exception occurs, the `try` block from which `quotient` was called terminates before lines 30–32 can execute. Here, too, if local variables were created in the `try` block prior to the exception being thrown, these variables would go out of scope.

If an `InputMismatchException` is generated by lines 25 or 27, the `try` block terminates and execution continues with the catch block at lines 34–41. In this case, method `quotient` is not called. Then method `main` continues after the last catch block (line 48).

13.5 When to Use Exception Handling

Exception handling is designed to process `synchronous errors`, which occur when a statement executes. Common examples we will see throughout the book are out-of-range array indices, arithmetic overflow (i.e., a value outside the representable range of values), division by zero, invalid method parameters, thread interruption and unsuccessful memory al-

13.6 Java Exception Hierarchy **663**

location (due to lack of memory). Exception handling is not designed to process problems associated with [asynchronous events](#) (e.g., disk I/O completions, network message arrivals, mouse clicks and keystrokes), which occur in parallel with, and independent of, the program's flow of control.

**Software Engineering Observation 13.2**

Incorporate your exception-handling strategy into your system from the inception of the design process. Including effective exception handling after a system has been implemented can be difficult.

**Software Engineering Observation 13.3**

Exception handling provides a single, uniform technique for processing problems. This helps programmers working on large projects understand each other's error-processing code.

**Software Engineering Observation 13.4**

Avoid using exception handling as an alternate form of flow of control. These "additional" exceptions can "get in the way" of genuine error-type exceptions.

**Software Engineering Observation 13.5**

Exception handling simplifies combining software components and enables them to work together effectively by enabling predefined components to communicate problems to application-specific components, which can then process the problems in an application-specific manner.

13.6 Java Exception Hierarchy

All Java exception classes inherit, either directly or indirectly, from class [Exception](#), forming an inheritance hierarchy. Programmers can extend this hierarchy to create their own exception classes.

Figure 13.3 shows a small portion of the inheritance hierarchy for class [Throwable](#) (a subclass of [Object](#)), which is the superclass of class [Exception](#). Only [Throwable](#) objects can be used with the exception-handling mechanism. Class [Throwable](#) has two subclasses: [Exception](#) and [Error](#). Class [Exception](#) and its subclasses—for instance, [RuntimeException](#) (package `java.lang`) and [IOException](#) (package `java.io`)—represent exceptional situations that can occur in a Java program and that can be caught by the application. Class [Error](#) and its subclasses (e.g., [OutOfMemoryError](#)) represent abnormal situations that could happen in the JVM. Errors happen infrequently and should not be caught by applications—it is usually not possible for applications to recover from Errors. [Note: The Java exception hierarchy contains hundreds of classes. Information about Java's exception classes can be found throughout the Java API. The documentation for class [Throwable](#) can be found at java.sun.com/javase/6/docs/api/java/lang/Throwable.html. From there, you can look at this class's subclasses to get more information about Java's Exceptions and Errors.]

Java distinguishes between two categories of exceptions: [checked exceptions](#) and [unchecked exceptions](#). This distinction is important, because the Java compiler enforces a [catch-or-declare requirement](#) for checked exceptions. An exception's type determines whether the exception is checked or unchecked. All exception types that are direct or indirect subclasses of class [RuntimeException](#) (package `java.lang`) are unchecked exceptions.

664 Chapter 13 Exception Handling

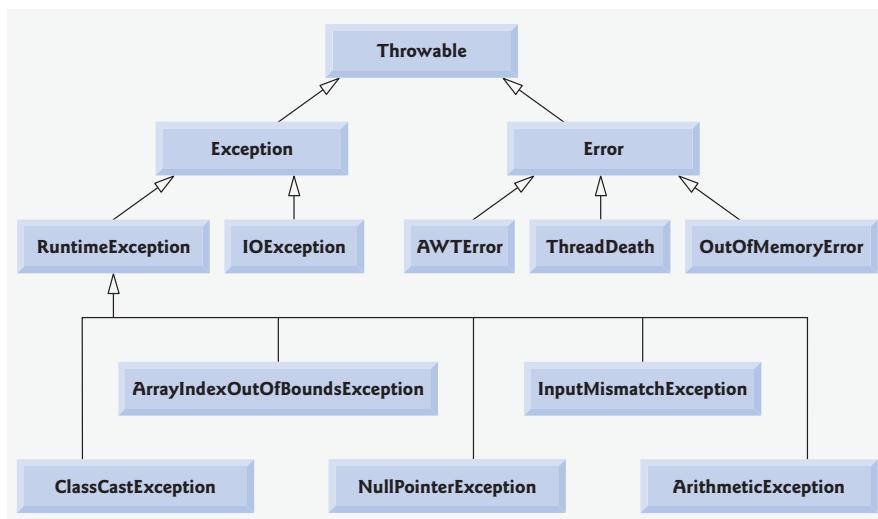

Fig. 13.3 | Portion of class `Throwable`'s inheritance hierarchy.

This includes exceptions you have seen already, such as `ArrayIndexOutOfBoundsException` and `ArithmeticExceptions` (shown in Fig. 13.3). All classes that inherit from class `Exception` but not class `RuntimeException` are considered to be checked exceptions. Classes that inherit from class `Error` are considered to be unchecked. The compiler *checks* each method call and method declaration to determine whether the method throws checked exceptions. If so, the compiler ensures that the checked exception is caught or is declared in a `throws` clause. Recall from Section 13.4 that the `throws` clause specifies the exceptions a method throws. Such exceptions are not caught in the method's body. To satisfy the *catch* part of the catch-or-declare requirement, the code that generates the exception must be wrapped in a `try` block and must provide a `catch` handler for the checked-exception type (or one of its superclass types). To satisfy the *declare* part of the catch-or-declare requirement, the method containing the code that generates the exception must provide a `throws` clause containing the checked-exception type after its parameter list and before its method body. If the catch-or-declare requirement is not satisfied, the compiler will issue an error message indicating that the exception must be caught or declared. This forces programmers to think about the problems that may occur when a method that throws checked exceptions is called. Exception classes are defined to be checked when they are considered important enough to catch or declare.

Software Engineering Observation 13.6

Programmers are forced to deal with checked exceptions. This results in more robust code than would be created if programmers were able to simply ignore the exceptions.

Common Programming Error 13.4

A compilation error occurs if a method explicitly attempts to throw a checked exception (or calls another method that throws a checked exception) and that exception is not listed in that method's `throws` clause.

Common Programming Error 13.5

If a subclass method overrides a superclass method, it is an error for the subclass method to list more exceptions in its throws clause than the overridden superclass method does. However, a subclass's throws clause can contain a subset of a superclass's throws list.

Software Engineering Observation 13.7

If your method calls other methods that explicitly throw checked exceptions, those exceptions must be caught or declared in your method. If an exception can be handled meaningfully in a method, the method should catch the exception rather than declare it.

Unlike checked exceptions, the Java compiler does not check the code to determine whether an unchecked exception is caught or declared. Unchecked exceptions typically can be prevented by proper coding. For example, the unchecked `ArithmaticException` thrown by method `quotient` (lines 9–13) in Fig. 13.2 can be avoided if the method ensures that the denominator is not zero before attempting to perform the division. Unchecked exceptions are not required to be listed in a method's throws clause—even if they are, it is not required that such exceptions be caught by an application.

Software Engineering Observation 13.8

Although the compiler does not enforce the catch-or-declare requirement for unchecked exceptions, provide appropriate exception-handling code when it is known that such exceptions might occur. For example, a program should process the `NumberFormatException` from `Integer` method `parseInt`, even though `NumberFormatException` (a subclass of `RuntimeException`) is an unchecked exception type. This makes your programs more robust.

Exception classes can be derived from a common superclass. If a catch handler is written to catch superclass-type exception objects, it can also catch all objects of that class's subclasses. This enables catch to handle related errors with a concise notation and allows for polymorphic processing of related exceptions. You can certainly catch each subclass type individually if those exceptions require different processing. Catching related exceptions in one catch block makes sense only if the handling behavior is the same for all subclasses.

If there are multiple catch blocks that match a particular exception type, only the first matching catch block executes when an exception of that type occurs. It is a compilation error to catch the exact same type in two different catch blocks associated with a particular try block. However, there may be several catch blocks that match an exception—i.e., several catch blocks whose types are the same as the exception type or a superclass of that type. For instance, we could follow a catch block for type `ArithmaticException` with a catch block for type `Exception`—both would match `ArithmaticExceptions`, but only the first matching catch block would execute.

Error-Prevention Tip 13.6

Catching subclass types individually is subject to error if you forget to test for one or more of the subclass types explicitly; catching the superclass guarantees that objects of all subclasses will be caught. Positioning a catch block for the superclass type after all other subclass catch blocks for subclasses of that superclass ensures that all subclass exceptions are eventually caught.

Common Programming Error 13.6

Placing a catch block for a superclass exception type before other catch blocks that catch subclass exception types prevents those catch blocks from executing, so a compilation error occurs.

666 Chapter 13 Exception Handling

13.7 finally Block

Programs that obtain certain types of resources must return them to the system explicitly to avoid so-called **resource leaks**. In programming languages such as C and C++, the most common kind of resource leak is a memory leak. Java performs automatic garbage collection of memory no longer used by programs, thus avoiding most memory leaks. However, other types of resource leaks can occur. For example, files, database connections and network connections that are not closed properly might not be available for use in other programs.

Error-Prevention Tip 13.7

A subtle issue is that Java does not entirely eliminate memory leaks. Java will not garbage-collect an object until there are no remaining references to it. Thus, if programmers erroneously keep references to unwanted objects, memory leaks can occur.

The **finally** block (which consists of the **finally** keyword, followed by code enclosed in curly braces) is optional, and is sometimes referred to as the **finally clause**. If it is present, it is placed after the last **catch** block, as in Fig. 13.4.

Java guarantees that a **finally** block (if one is present in a **try** statement) will execute whether or not an exception is thrown in the corresponding **try** block or any of its corresponding **catch** blocks. Java also guarantees that a **finally** block (if one is present) will execute if a **try** block exits by using a **return**, **break** or **continue** statement, or simply by reaching the **try** block's closing right brace. The **finally** block will *not* execute if the application exits early from a **try** block by calling method **System.exit**. This method, which we demonstrate in the next chapter, immediately terminates an application.

Because a **finally** block almost always executes, it typically contains resource-release code. Suppose a resource is allocated in a **try** block. If no exception occurs, the **catch**

```

try
{
    statements
    resource-acquisition statements
} // end try
catch ( AKindOfException exception1 )
{
    exception-handling statements
} // end catch
.
.
.
catch ( AnotherKindOfException exception2 )
{
    exception-handling statements
} // end catch
finally
{
    statements
    resource-release statements
} // end finally

```

Fig. 13.4 | A **try** statement with a **finally** block.

13.7 finally Block **667**

blocks are skipped and control proceeds to the `finally` block, which frees the resource. Control then proceeds to the first statement after the `finally` block. If an exception does occur in the `try` block, the program skips the rest of the `try` block. If the program catches the exception in one of the `catch` blocks, the program processes the exception, then the `finally` block releases the resource, and control proceeds to the first statement after the `finally` block.

**Performance Tip 13.2**

Always release each resource explicitly and at the earliest possible moment at which it is no longer needed. This makes resources immediately available to be reused by your program or other programs, thus improving resource utilization.

**Error-Prevention Tip 13.8**

Because the `finally` block is guaranteed to execute whether or not an exception occurs in the corresponding `try` block, this block is an ideal place to release resources acquired in a `try` block. This is also an effective way to eliminate resource leaks. For example, the `finally` block should close any files opened in the `try` block.

If an exception that occurs in a `try` block cannot be caught by one of that `try` block's `catch` handlers, the program skips the rest of the `try` block and control proceeds to the `finally` block. Then the program passes the exception to the next outer `try` block—normally in the calling method—where an associated `catch` block might catch it. This process can occur through many levels of `try` blocks. It is also possible that the exception could go uncaught.

If a `catch` block throws an exception, the `finally` block still executes. Then the exception is passed to the next outer `try` block—again, normally in the calling method.

Figure 13.5 demonstrates that the `finally` block executes even if an exception is not thrown in the corresponding `try` block. The program contains static methods `main` (lines 7–19), `throwException` (lines 22–45) and `doesNotThrowException` (lines 48–65). Methods `throwException` and `doesNotThrowException` are declared `static`, so `main` can call them directly without instantiating a `UsingExceptions` object.

```

1 // Fig. 13.5: UsingExceptions.java
2 // Demonstration of the try...catch...finally exception handling
3 // mechanism.
4
5 public class UsingExceptions
6 {
7     public static void main( String args[] )
8     {
9         try
10        {
11            throwException(); // call method throwException
12        } // end try
13        catch ( Exception exception ) // exception thrown by throwException
14        {

```

Fig. 13.5 | `try...catch...finally` exception-handling mechanism. (Part I of 3.)

668 Chapter 13 Exception Handling

```

15         System.err.println( "Exception handled in main" );
16     } // end catch
17
18     doesNotThrowException();
19 } // end main
20
21 // demonstrate try...catch...finally
22 public static void throwException() throws Exception
23 {
24     try // throw an exception and immediately catch it
25     {
26         System.out.println( "Method throwException" );
27         throw new Exception(); // generate exception
28     } // end try
29     catch ( Exception exception ) // catch exception thrown in try
30     {
31         System.err.println(
32             "Exception handled in method throwException" );
33         throw exception; // rethrow for further processing
34
35         // any code here would not be reached
36
37     } // end catch
38     finally // executes regardless of what occurs in try...catch
39     {
40         System.err.println( "Finally executed in throwException" );
41     } // end finally
42
43     // any code here would not be reached, exception rethrown in catch
44
45 } // end method throwException
46
47 // demonstrate finally when no exception occurs
48 public static void doesNotThrowException()
49 {
50     try // try block does not throw an exception
51     {
52         System.out.println( "Method doesNotThrowException" );
53     } // end try
54     catch ( Exception exception ) // does not execute
55     {
56         System.err.println( exception );
57     } // end catch
58     finally // executes regardless of what occurs in try...catch
59     {
60         System.err.println(
61             "Finally executed in doesNotThrowException" );
62     } // end finally
63
64     System.out.println( "End of method doesNotThrowException" );
65 } // end method doesNotThrowException
66 } // end class UsingExceptions

```

13.7 finally Block **669**

```

Method throwException
Exception handled in method throwException
Finally executed in throwException
Exception handled in main
Method doesNotThrowException
Finally executed in doesNotThrowException
End of method doesNotThrowException

```

Fig. 13.5 | try...catch...finally exception-handling mechanism. (Part 3 of 3.)

Note the use of the `System.err` to output data (lines 15, 31–32, 40, 56 and 60–61). By default, `System.err.println`, like `System.out.println`, displays data to the command prompt.

Both `System.out` and `System.err` are **streams**—a sequence of bytes. While `System.out` (known as the **standard output stream**) is used to display a program's output, `System.err` (known as the **standard error stream**) is used to display a program's errors. Output from these streams can be redirected (i.e., sent somewhere other than the command prompt, such as to a file). Using two different streams enables the programmer to easily separate error messages from other output. For instance, data output from `System.err` could be sent to a log file, while data output from `System.out` can be displayed on the screen. For simplicity, this chapter will not redirect output from `System.err`, but will display such messages to the command prompt. You will learn more about streams in Chapter 14, Files and Streams.

Throwing Exceptions Using the throw Statement

Method `main` (Fig. 13.5) begins executing, enters its `try` block and immediately calls method `throwException` (line 11). Method `throwException` throws an `Exception`. The statement at line 27 is known as a **throw statement**. The `throw` statement is executed to indicate that an exception has occurred. So far, you have only caught exceptions thrown by called methods. Programmers can throw exceptions by using the `throw` statement. Just as with exceptions thrown by the Java API's methods, this indicates to client applications that an error has occurred. A `throw` statement specifies an object to be thrown. The operand of a `throw` can be of any class derived from class `Throwable`.

**Software Engineering Observation 13.9**

When `toString` is invoked on any `Throwable` object, its resulting string includes the descriptive string that was supplied to the constructor, or simply the class name if no string was supplied.

**Software Engineering Observation 13.10**

An object can be thrown without containing information about the problem that occurred. In this case, simple knowledge that an exception of a particular type occurred may provide sufficient information for the handler to process the problem correctly.

**Software Engineering Observation 13.11**

Exceptions can be thrown from constructors. When an error is detected in a constructor, an exception should be thrown rather than creating an improperly formed object.

670 Chapter 13 Exception Handling***Rethrowing Exceptions***

Line 33 of Fig. 13.5 [rethrows the exception](#). Exceptions are rethrown when a catch block, upon receiving an exception, decides either that it cannot process that exception or that it can only partially process it. Rethrowing an exception defers the exception handling (or perhaps a portion of it) to another catch block associated with an outer try statement. An exception is rethrown by using the [throw keyword](#), followed by a reference to the exception object that was just caught. Note that exceptions cannot be rethrown from a finally block, as the exception parameter from the catch block has expired.

When a rethrow occurs, the next enclosing try block detects the rethrown exception, and that try block's catch blocks attempt to handle the exception. In this case, the next enclosing try block is found at lines 9–12 in method main. Before the rethrown exception is handled, however, the finally block (lines 38–41) executes. Then method main detects the rethrown exception in the try block and handles it in the catch block (lines 13–16).

Next, main calls method doesNotThrowException (line 18). No exception is thrown in doesNotThrowException's try block (lines 50–53), so the program skips the catch block (lines 54–57), but the finally block (lines 58–62) nevertheless executes. Control proceeds to the statement after the finally block (line 64). Then control returns to main and the program terminates.

**Common Programming Error 13.7**

If an exception has not been caught when control enters a finally block and the finally block throws an exception that is not caught in the finally block, the first exception will be lost and the exception from the finally block will be returned to the calling method.

**Error-Prevention Tip 13.9**

Avoid placing code that can throw an exception in a finally block. If such code is required, enclose the code in a try...catch within the finally block.

**Common Programming Error 13.8**

Assuming that an exception thrown from a catch block will be processed by that catch block or any other catch block associated with the same try statement can lead to logic errors.

**Good Programming Practice 13.2**

Java's exception-handling mechanism is intended to remove error-processing code from the main line of a program's code to improve program clarity. Do not place try...catch...finally around every statement that may throw an exception. This makes programs difficult to read. Rather, place one try block around a significant portion of your code, follow that try block with catch blocks that handle each possible exception and follow the catch blocks with a single finally block (if one is required).

13.8 Stack Unwinding

When an exception is thrown but not caught in a particular scope, the method-call stack is “unwound,” and an attempt is made to catch the exception in the next outer try block. This process is called [stack unwinding](#). Unwinding the method-call stack means that the method in which the exception was not caught terminates, all local variables in that method are destroyed and control returns to the statement that originally invoked that method. If a try block encloses that statement, an attempt is made to catch the exception. If a try

13.8 Stack Unwinding **671**

block does not enclose that statement, stack unwinding occurs again. If no catch block ever catches this exception and the exception is checked (as in the following example), compiling the program will result in an error. The program of Fig. 13.6 demonstrates stack unwinding.

When method `main` executes, line 10 in the try block calls method `throwException` (lines 19–35). In the try block of method `throwException` (lines 21–25), line 24 throws an `Exception`. This terminates the try block immediately, and control skips the catch block at line 26, because the type being caught (`RuntimeException`) is not an exact match with the thrown type (`Exception`) and is not a superclass of it. Method `throwException`

```

1 // Fig. 13.6: UsingExceptions.java
2 // Demonstration of stack unwinding.
3
4 public class UsingExceptions
5 {
6     public static void main( String args[] )
7     {
8         try // call throwException to demonstrate stack unwinding
9         {
10             throwException();
11         } // end try
12         catch ( Exception exception ) // exception thrown in throwException
13         {
14             System.err.println( "Exception handled in main" );
15         } // end catch
16     } // end main
17
18 // throwException throws exception that is not caught in this method
19 public static void throwException() throws Exception
20 {
21     try // throw an exception and catch it in main
22     {
23         System.out.println( "Method throwException" );
24         throw new Exception(); // generate exception
25     } // end try
26     catch ( RuntimeException runtimeException ) // catch incorrect type
27     {
28         System.err.println(
29             "Exception handled in method throwException" );
30     } // end catch
31     finally // finally block always executes
32     {
33         System.err.println( "Finally is always executed" );
34     } // end finally
35 } // end method throwException
36 } // end class UsingExceptions

```

```

Method throwException
Finally is always executed
Exception handled in main

```

Fig. 13.6 | Stack unwinding.

672 Chapter 13 Exception Handling

terminates (but not until its `finally` block executes) and returns control to line 10—the point from which it was called in the program. Line 10 is in an enclosing `try` block. The exception has not yet been handled, so the `try` block terminates and an attempt is made to catch the exception at line 12. The type being caught (`Exception`) does match the thrown type. Consequently, the `catch` block processes the exception, and the program terminates at the end of `main`. If there were no matching `catch` blocks, a compilation error would occur. Remember that this is not always the case—for unchecked exceptions, the application will compile, but will run with unexpected results.

13.9 `printStackTrace`, `getStackTrace` and `getMessage`

Recall from Section 13.6 that exceptions derive from class `Throwable`. Class `Throwable` offers a `printStackTrace` method that outputs to the standard error stream the stack trace (discussed in Section 13.3). Often, this is helpful in testing and debugging. Class `Throwable` also provides a `getStackTrace` method that retrieves stack-trace information that might be printed by `printStackTrace`. Class `Throwable`'s `getMessage` method returns the descriptive string stored in an exception. The example in this section demonstrates these three methods.

Error-Prevention Tip 13.10

An exception that is not caught in an application causes Java's default exception handler to run. This displays the name of the exception, a descriptive message that indicates the problem that occurred and a complete execution stack trace. In an application with a single thread of execution, the application terminates. In an application with multiple threads, the thread that caused the exception terminates.

Error-Prevention Tip 13.11

Throwable method `toString` (inherited by all `Throwable` subclasses) returns a string containing the name of the exception's class and a descriptive message.

Figure 13.7 demonstrates `getMessage`, `printStackTrace` and `getStackTrace`. If we wanted to output the stack-trace information to streams other than the standard error stream, we could use the information returned from `getStackTrace`, and output this data to another stream. Sending data to other streams is discussed in Chapter 14, Files and Streams.

In `main`, the `try` block (lines 8–11) calls `method1` (declared at lines 35–38). Next, `method1` calls `method2` (declared at lines 41–44), which in turn calls `method3` (declared at lines 47–50). Line 49 of `method3` throws an `Exception` object—this is the throw point. Because the `throw` statement at line 49 is not enclosed in a `try` block, stack unwinding occurs—`method3` terminates at line 49, then returns control to the statement in `method2` that invoked `method3` (i.e., line 43). Because no `try` block encloses line 43, stack unwinding occurs again—`method2` terminates at line 43 and returns control to the statement in `method1` that invoked `method2` (i.e., line 37). Because no `try` block encloses line 37, stack unwinding occurs one more time—`method1` terminates at line 37 and returns control to the statement in `main` that invoked `method1` (i.e., line 10). The `try` block at lines 8–11 encloses this statement. The exception has not been handled, so the `try` block terminates and the first matching `catch` block (lines 12–31) catches and processes the exception.

13.9 printStackTrace, getStackTrace and getMessage 673

```

1 // Fig. 13.7: UsingExceptions.java
2 // Demonstrating getMessage and printStackTrace from class Exception.
3
4 public class UsingExceptions
5 {
6     public static void main( String args[] )
7     {
8         try
9         {
10            method1(); // call method1
11        } // end try
12        catch ( Exception exception ) // catch exception thrown in method1
13        {
14            System.err.printf( "%s\n\n", exception.getMessage() );
15            exception.printStackTrace(); // print exception stack trace
16
17            // obtain the stack-trace information
18            StackTraceElement[] traceElements = exception.getStackTrace();
19
20            System.out.println( "\nStack trace from getStackTrace:" );
21            System.out.println( "Class\t\tFile\t\tLine\tMethod" );
22
23            // loop through traceElements to get exception description
24            for ( StackTraceElement element : traceElements )
25            {
26                System.out.printf( "%s\t", element.getClassName() );
27                System.out.printf( "%s\t", element.getFileName() );
28                System.out.printf( "%s\t", element.getLineNumber() );
29                System.out.printf( "%s\n", element.getMethodName() );
30            } // end for
31        } // end catch
32    } // end main
33
34    // call method2; throw exceptions back to main
35    public static void method1() throws Exception
36    {
37        method2();
38    } // end method method1
39
40    // call method3; throw exceptions back to method1
41    public static void method2() throws Exception
42    {
43        method3();
44    } // end method method2
45
46    // throw Exception back to method2
47    public static void method3() throws Exception
48    {
49        throw new Exception( "Exception thrown in method3" );
50    } // end method method3
51 } // end class UsingExceptions

```

Fig. 13.7 | Throwable methods getMessage, getStackTrace and printStackTrace. (Part 2 of 2.)

Line 14 invokes the exception's `getMessage` method to get the exception description. Line 15 invokes the exception's `printStackTrace` method to output the stack trace that indicates where the exception occurred. Line 18 invokes the exception's `getStackTrace` method to obtain the stack-trace information as an array of `StackTraceElement` objects. Lines 24–30 get each `StackTraceElement` in the array and invoke its methods `getClassName`, `getFileName`, `getLineNumber` and `getMethodName` to get the class name, file name, line number and method name, respectively, for that `StackTraceElement`. Each `StackTraceElement` represents one method call on the method-call stack.

The output in Fig. 13.7 shows that the stack-trace information printed by `printStackTrace` follows the pattern: `className.methodName(fileName:lineNumber)`, where `className`, `methodName` and `fileName` indicate the names of the class, method and file in which the exception occurred, respectively, and the `lineNumber` indicates where in the file the exception occurred. You saw this in the output for Fig. 13.1. Method `getStackTrace` enables custom processing of the exception information. Compare the output of `printStackTrace` with the output created from the `StackTraceElements` to see that both contain the same stack-trace information.

Software Engineering Observation 13.12

Never ignore an exception you catch. At least use printStackTrace to output an error message. This will inform users that a problem exists, so that they can take appropriate actions.

13.10 Chained Exceptions

Sometimes a `catch` block catches one exception type, then throws a new exception of a different type to indicate that a program-specific exception occurred. In earlier Java versions, there was no mechanism to wrap the original exception information with the new exception's information to provide a complete stack trace showing where the original problem occurred in the program. This made debugging such problems particularly difficult. **Chained exceptions** enable an exception object to maintain the complete stack-trace information. Figure 13.8 demonstrates chained exceptions.

The program consists of four methods—`main` (lines 6–16), `method1` (lines 19–29), `method2` (lines 32–42) and `method3` (lines 45–48). Line 10 in method `main`'s `try` block

13.10 Chained Exceptions **675**

calls `method1`. Line 23 in `method1`'s try block calls `method2`. Line 36 in `method2`'s try block calls `method3`. In `method3`, line 47 throws a new Exception. Because this statement

```

1 // Fig. 13.8: UsingChainedExceptions.java
2 // Demonstrating chained exceptions.
3
4 public class UsingChainedExceptions
5 {
6     public static void main( String args[] )
7     {
8         try
9         {
10             method1(); // call method1
11         } // end try
12         catch ( Exception exception ) // exceptions thrown from method1
13         {
14             exception.printStackTrace();
15         } // end catch
16     } // end main
17
18     // call method2; throw exceptions back to main
19     public static void method1() throws Exception
20     {
21         try
22         {
23             method2(); // call method2
24         } // end try
25         catch ( Exception exception ) // exception thrown from method2
26         {
27             throw new Exception( "Exception thrown in method1", exception );
28         } // end try
29     } // end method method1
30
31     // call method3; throw exceptions back to method1
32     public static void method2() throws Exception
33     {
34         try
35         {
36             method3(); // call method3
37         } // end try
38         catch ( Exception exception ) // exception thrown from method3
39         {
40             throw new Exception( "Exception thrown in method2", exception );
41         } // end catch
42     } // end method method2
43
44     // throw Exception back to method2
45     public static void method3() throws Exception
46     {
47         throw new Exception( "Exception thrown in method3" );
48     } // end method method3
49 } // end class UsingChainedExceptions

```

Fig. 13.8 | Chained exceptions. (Part I of 2.)

676 Chapter 13 Exception Handling

```

java.lang.Exception: Exception thrown in method1
    at UsingChainedExceptions.method1(UsingChainedExceptions.java:27)
    at UsingChainedExceptions.main(UsingChainedExceptions.java:10)
Caused by: java.lang.Exception: Exception thrown in method2
    at UsingChainedExceptions.method2(UsingChainedExceptions.java:40)
    at UsingChainedExceptions.method1(UsingChainedExceptions.java:23)
    ... 1 more
Caused by: java.lang.Exception: Exception thrown in method3
    at UsingChainedExceptions.method3(UsingChainedExceptions.java:47)
    at UsingChainedExceptions.method2(UsingChainedExceptions.java:36)
    ... 2 more

```

Fig. 13.8 | Chained exceptions. (Part 2 of 2.)

is not in a `try` block, `method3` terminates, and the exception is returned to the calling method (`method2`) at line 36. This statement *is* in a `try` block; therefore, the `try` block terminates and the exception is caught at lines 38–41. Line 40 in the `catch` block throws a new exception. In this case, the `Exception` constructor with two arguments is called. The second argument represents the exception that was the original cause of the problem. In this program, that exception occurred at line 47. Because an exception is thrown from the `catch` block, `method2` terminates and returns the new exception to the calling method (`method1`) at line 23. Once again, this statement is in a `try` block, so the `try` block terminates and the exception is caught at lines 25–28. Line 27 in the `catch` block throws a new exception and uses the exception that was caught as the second argument to the `Exception` constructor. Because an exception is thrown from the `catch` block, `method1` terminates and returns the new exception to the calling method (`main`) at line 10. The `try` block in `main` terminates, and the exception is caught at lines 12–15. Line 14 prints a stack trace.

Notice in the program output that the first three lines show the most recent exception that was thrown (i.e., the one from `method1` at line 23). The next four lines indicate the exception that was thrown from `method2` at line 40. Finally, the last four lines represent the exception that was thrown from `method3` at line 47. Also notice that, as you read the output in reverse, it shows how many more chained exceptions remain.

13.11 Declaring New Exception Types

Most Java programmers use existing classes from the Java API, third-party vendors and freely available class libraries (usually downloadable from the Internet) to build Java applications. The methods of those classes typically are declared to throw appropriate exceptions when problems occur. Programmers write code that processes these existing exceptions to make programs more robust.

If you build classes that other programmers will use, you might find it useful to declare your own exception classes that are specific to the problems that can occur when another programmer uses your reusable classes.

Software Engineering Observation 13.13

If possible, indicate exceptions from your methods by using existing exception classes, rather than creating new exception classes. The Java API contains many exception classes that might be suitable for the type of problem your method needs to indicate.

13.12 Preconditions and Postconditions **677**

A new exception class must extend an existing exception class to ensure that the class can be used with the exception-handling mechanism. Like any other class, an exception class can contain fields and methods. However, a typical new exception class contains only two constructors—one that takes no arguments and passes a default exception message to the superclass constructor, and one that receives a customized exception message as a string and passes it to the superclass constructor.

**Good Programming Practice 13.3**

Associating each type of serious execution-time malfunction with an appropriately named Exception class improves program clarity.

**Software Engineering Observation 13.14**

When defining your own exception type, study the existing exception classes in the Java API and try to extend a related exception class. For example, if you are creating a new class to represent when a method attempts a division by zero, you might extend class `ArithmaticException` because division by zero occurs during arithmetic. If the existing classes are not appropriate superclasses for your new exception class, decide whether your new class should be a checked or an unchecked exception class. The new exception class should be a checked exception (i.e., extend `Exception` but not `RuntimeException`) if possible clients should be required to handle the exception. The client application should be able to reasonably recover from such an exception. The new exception class should extend `RuntimeException` if the client code should be able to ignore the exception (i.e., the exception is an unchecked exception).

In Chapter 17, Data Structures, we provide an example of a custom exception class. We declare a reusable class called `List` that is capable of storing a list of references to objects. Some operations typically performed on a `List` are not allowed if the `List` is empty, such as removing an item from the front or back of the list (i.e., no items can be removed, as the `List` does not currently contain any items). For this reason, some `List` methods throw exceptions of exception class `EmptyListException`.

**Good Programming Practice 13.4**

By convention, all exception-class names should end with the word `Exception`.

13.12 Preconditions and Postconditions

Programmers spend significant portions of their time maintaining and debugging code. To facilitate these tasks and to improve the overall design, they generally specify the expected states before and after a method's execution. These states are called preconditions and postconditions, respectively.

A **precondition** must be true when a method is invoked. Preconditions describe constraints on method parameters and any other expectations the method has about the current state of a program. If the preconditions are not met, then the method's behavior is undefined—it may throw an exception, proceed with an illegal value or attempt to recover from the error. However, you should never rely on or expect consistent behavior if the preconditions are not satisfied.

A **postcondition** is true after the method successfully returns. Postconditions describe constraints on the return value and any other side effects the method may have. When calling a method, you may assume that a method fulfills all of its postconditions. If you

678 Chapter 13 Exception Handling

are writing your own method, you should document all postconditions so others know what to expect when they call your method, and you should make certain that your method honors all its postconditions if its preconditions are indeed met.

When their preconditions or postconditions are not met, methods typically throw exceptions. As an example, examine `String` method `charAt`, which has one `int` parameter—an index in the `String`. For a precondition, method `charAt` assumes that `index` is greater than or equal to zero and less than the length of the `String`. If the precondition is met, the postcondition states the method will return the character at the position in the `String` specified by the parameter `index`. Otherwise, the method throws an `IndexOutOfBoundsException`. We trust that method `charAt` satisfies its postcondition, provided that we meet the precondition. We do not need to be concerned with the details of how the method actually retrieves the character at the index.

Some programmers state the preconditions and postconditions informally as part of the general method specification, while others prefer a more formal approach by explicitly defining them. When designing your own methods, you should state the preconditions and postconditions in a comment before the method declaration in whichever manner you prefer. Stating the preconditions and postconditions before writing a method will also help guide you as you implement the method.

13.13 Assertions

When implementing and debugging a class, it is sometimes useful to state conditions that should be true at a particular point in a method. These conditions, called **assertions**, help ensure a program's validity by catching potential bugs and identifying possible logic errors during development. Preconditions and postconditions are two types of assertions. Preconditions are assertions about a program's state when a method is invoked, and postconditions are assertions about a program's state after a method finishes.

While assertions can be stated as comments to guide the programmer during development, Java includes two versions of the `assert` statement for validating assertions programmatically. The `assert` statement evaluates a `boolean` expression and determines whether it is true or false. The first form of the `assert` statement is

```
assert expression;
```

This statement evaluates `expression` and throws an `AssertionError` if the expression is `false`. The second form is

```
assert expression1 : expression2;
```

This statement evaluates `expression1` and throws an `AssertionError` with `expression2` as the error message if `expression1` is `false`.

You can use assertions to programmatically implement preconditions and postconditions or to verify any other intermediate states that help you ensure your code is working correctly. The example in Fig. 13.9 demonstrates the functionality of the `assert` statement. Line 11 prompts the user to enter a number between 0 and 10, then line 12 reads the number from the command line. The `assert` statement at line 15 determines whether the user entered a number within the valid range. If the number is out of range, then the program reports an error; otherwise, the program proceeds normally.

13.14 Wrap-Up **679**

```

1 // Fig. 13.9: AssertTest.java
2 // Demonstrates the assert statement
3 import java.util.Scanner;
4
5 public class AssertTest
6 {
7     public static void main( String args[] )
8     {
9         Scanner input = new Scanner( System.in );
10
11        System.out.print( "Enter a number between 0 and 10: " );
12        int number = input.nextInt();
13
14        // assert that the absolute value is >= 0
15        assert ( number >= 0 && number <= 10 ) : "bad number: " + number;
16
17        System.out.printf( "You entered %d\n", number );
18    } // end main
19 } // end class AssertTest

```

Enter a number between 0 and 10: 5
You entered 5

Enter a number between 0 and 10: 50
Exception in thread "main" java.lang.AssertionError: bad number: 50
at AssertTest.main(AssertTest.java:15)

Fig. 13.9 | Checking with assert that a value is within range.

Assertions are primarily used by the programmer for debugging and identifying logic errors in an application. By default, assertions are disabled when executing a program because they reduce performance and are unnecessary for the program's user. To enable assertions at runtime, use the `java` command's `-ea` command-line option. To execute the program in Fig. 13.9 with assertions enabled, type

```
java -ea AssertTest
```

You should not encounter any `AssertionErrors` through normal execution of a properly written program. Such errors should only indicate bugs in the implementation. As a result, you should never catch an `AssertionError`. Rather, you should allow the program to terminate when the error occurs, so you can see the error message; then you should locate and fix the source of the problem. Since application users can choose not to enable assertions at runtime, you should not use the `assert` statement to indicate runtime problems in production code. Rather, you should use the exception mechanism for this purpose.

13.14 Wrap-Up

In this chapter, you learned how to use exception handling to deal with errors in an application. You learned that exception handling enables programmers to remove error-handling code from the “main line” of the program’s execution. You saw exception handling

680 Chapter 13 Exception Handling

in the context of a divide-by-zero example. You learned how to use `try` blocks to enclose code that may throw an exception, and how to use `catch` blocks to deal with exceptions that may arise. You learned about the termination model of exception handling, which dictates that after an exception is handled, program control does not return to the throw point. You learned the difference between checked and unchecked exceptions, and how to specify with the `throws` clause that specific exceptions occurring in a method will be thrown by that method to its caller. You learned how to use the `finally` block to release resources whether or not an exception occurs. You also learned how to throw and rethrow exceptions. You then learned how to obtain information about an exception using methods `printStackTrace`, `getStackTrace` and `getMessage`. The chapter continued with a discussion of chained exceptions, which allow programmers to wrap original exception information with new exception information. Next, we overviewed how to create your own exception classes. We then introduced preconditions and postconditions to help programmers using your methods understand conditions that must be true with the method is called and when it returns. When preconditions and postconditions are not met, methods typically throw exceptions. Finally, we discussed the `assert` statement and how it can be used to help you debug your programs. In particular, these can be used to ensure that preconditions and postconditions are met. In the next chapter, you will learn about file processing, including how persistent data is stored and how to manipulate it.

Summary

Section 13.1 Introduction

- An exception is an indication of a problem that occurs during a program's execution.
- Exception handling enables programmers to create applications that can resolve exceptions.

Section 13.2 Exception-Handling Overview

- Exception handling enables programmers to remove error-handling code from the "main line" of the program's execution, improving program clarity and enhancing modifiability.

Section 13.3 Example: Divide by Zero without Exception Handling

- Exceptions are thrown when a method detects a problem and is unable to handle it.
- An exception's stack trace includes the name of the exception in a descriptive message that indicates the problem that occurred and the complete method-call stack (i.e., the call chain) at the time the exception occurred.
- The point in the program at which an exception occurs is called the throw point.

Section 13.4 Example: Handling `ArithmeticException` and `InputMismatchException`

- A `try` block encloses the code that might throw an exception and the code that should not execute if that exception occurs.
- Exceptions may surface through explicitly mentioned code in a `try` block, through calls to other methods or even through deeply nested method calls initiated by code in the `try` block.
- A `catch` block begins with the keyword `catch` and an exception parameter followed by a block of code that catches (i.e., receives) and handles the exception. This code executes when the `try` block detects the exception.

Summary 681

- An uncaught exception is an exception that occurs for which there are no matching `catch` blocks.
- An uncaught exception will cause a program to terminate early if that program contains only one thread. If the program contains more than one thread, only the thread where the exception occurred will terminate. The rest of the program will run but may yield adverse effects.
- At least one `catch` block or a `finally` block must immediately follow the `try` block.
- Each `catch` block specifies in parentheses an exception parameter that identifies the exception type the handler can process. The exception parameter's name enables the `catch` block to interact with a caught exception object.
- If an exception occurs in a `try` block, the `try` block terminates immediately and program control transfers to the first of the following `catch` blocks whose exception parameter type matches the type of the thrown exception.
- After an exception is handled, program control does not return to the throw point, because the `try` block has expired. This is known as the termination model of exception handling.
- If there are multiple matching `catch` blocks when an exception occurs, only the first is executed.
- After executing a `catch` block, the program's flow of control proceeds to the first statement after the last `catch` block.
- A `throws` clause specifies the exceptions the method throws, and appears after the method's parameter list and before the method body.
- The `throws` clause contains a comma-separated list of exceptions that the method will throw if a problem occurs when the method executes.

Section 13.5 When to Use Exception Handling

- Exception handling is designed to process synchronous errors, which occur when a statement executes.
- Exception handling is not designed to process problems associated with asynchronous events, which occur in parallel with, and independent of, the program's flow of control.

Section 13.6 Java Exception Hierarchy

- All Java exception classes inherit, either directly or indirectly, from class `Exception`. Because of this fact, Java's exception classes form a hierarchy. Programmers can extend this hierarchy to create their own exception classes.
- Class `Throwable` is the superclass of class `Exception`, and is therefore also the superclass of all exceptions. Only `Throwable` objects can be used with the exception-handling mechanism.
- Class `Throwable` has two subclasses: `Exception` and `Error`.
- Class `Exception` and its subclasses represent exceptional situations that could occur in a Java program and be caught by the application.
- Class `Error` and its subclasses represent exceptional situations that could happen in the Java runtime system. Errors happen infrequently, and typically should not be caught by an application.
- Java distinguishes between two categories of exceptions: checked and unchecked.
- Unlike checked exceptions, the Java compiler does not check the code to determine whether an unchecked exception is caught or declared. Unchecked exceptions typically can be prevented by proper coding.
- An exception's type determines whether the exception is checked or unchecked. All exception types that are direct or indirect subclasses of class `RuntimeException` are unchecked exceptions. All exception types that inherit from class `Exception` but not from `RuntimeException` are checked.

682 Chapter 13 Exception Handling

- Various exception classes can be derived from a common superclass. If a catch block is written to catch exception objects of a superclass type, it can also catch all objects of that class's subclasses. This allows for polymorphic processing of related exceptions.

Section 13.7 finally block

- Programs that obtain certain types of resources must return them to the system explicitly to avoid so-called resource leaks. Resource-release code typically is placed in a `finally` block.
- The `finally` block is optional. If it is present, it is placed after the last catch block.
- Java guarantees that a provided `finally` block will execute whether or not an exception is thrown in the corresponding try block or any of its corresponding catch blocks. Java also guarantees that a `finally` block executes if a try block exits by using a `return`, `break` or `continue` statement.
- If an exception that occurs in the try block cannot be caught by one of that try block's associated catch handlers, the program skips the rest of the try block and control proceeds to the `finally` block, which releases the resource. Then the program passes to the next outer try block—normally in the calling method.
- If a catch block throws an exception, the `finally` block still executes. Then the exception is passed to the next outer try block—normally in the calling method.
- Programmers can throw exceptions by using the `throw` statement.
- A `throw` statement specifies an object to be thrown. The operand of a `throw` can be of any class derived from class `Throwable`.

Section 13.8 Stack Unwinding

- Exceptions are rethrown when a catch block, upon receiving an exception, decides either that it cannot process that exception or that it can only partially process it. Rethrowing an exception defers the exception handling (or perhaps a portion of it) to another catch block.
- When a rethrow occurs, the next enclosing try block detects the rethrown exception, and that try block's catch blocks attempt to handle the exception.
- When an exception is thrown but not caught in a particular scope, the method-call stack is unwound, and an attempt is made to catch the exception in the next outer try statement. This process is called stack unwinding.

Section 13.9 printStackTrace, getStackTrace and getMessage

- Class `Throwable` offers a `printStackTrace` method that prints the method-call stack. Often, this is helpful in testing and debugging.
- Class `Throwable` also provides a `getStackTrace` method that obtains stack-trace information printed by `printStackTrace`.
- Class `Throwable`'s `getMessage` method returns the descriptive string stored in an exception.
- Method `getStackTrace` obtains the stack-trace information as an array of `StackTraceElement` objects. Each `StackTraceElement` represents one method call on the method-call stack.
- `StackTraceElement` methods `getClassName`, `getFileName`, `getLineNumber` and `getMethodName` get the class name, file name, line number and method name, respectively.

Section 13.10 Chained Exceptions

- Chained exceptions enable an exception object to maintain the complete stack-trace information, including information about previous exceptions that caused the current exception.

Section 13.11 Declaring New Exception Types

- A new exception class must extend an existing exception class to ensure that the class can be used with the exception-handling mechanism.

Section 13.12 Preconditions and Postconditions

- A method's precondition is a condition that must be true when the method is invoked.
- A method's postcondition is a condition that is true after the method successfully returns.
- When designing your own methods, you should state the preconditions and postconditions in a comment before the method declaration.

Section 13.13 Assertions

- Within an application, programmers may state conditions that they assumed to be true at a particular point. These conditions, called assertions, help ensure a program's validity by catching potential bugs and indentifying possible logic errors.
- Java includes two versions of an assert statement for validating assertions programmatically.
- To enable assertions at runtime, use the -ea switch when running the java command.

Terminology

ArithmaticException class	getStackTrace method of class Throwable
assert statement	InputMismatchException class
assertion	postcondition
asynchronous event	precondition
catch an exception	printStackTrace method of class Throwable
catch block	release a resource
catch clause	resource leak
catch-or-declare requirement	resumption model of exception handling
chained exception	rethrowing an exception
checked exception	RuntimeException class
constructor failure	stack trace
enclosing try block	StackTraceElement class
Error class	stack unwinding
exception	standard error stream
Exception class	standard output stream
exception handler	synchronous error
exception handling	System.err stream
exception parameter	termination model of exception handling
fault-tolerant program	throw an exception
finally block	throw keyword
finally clause	throw point
getClassName method of class	throw statement
StackTraceElement	Throwable class
getFileName method of class	throws clause
StackTraceElement	try block
getLineNumber method of class	try statement
StackTraceElement	try...catch...finally exception-handling mechanism
getMessage method of class Throwable	uncaught exception
getMethodName method of class	unchecked exceptions
StackTraceElement	

Self-Review Exercises

- 13.1** List five common examples of exceptions.
- 13.2** Give several reasons why exception-handling techniques should not be used for conventional program control.

684 Chapter 13 Exception Handling

13.3 Why are exceptions particularly appropriate for dealing with errors produced by methods of classes in the Java API?

13.4 What is a “resource leak”?

13.5 If no exceptions are thrown in a `try` block, where does control proceed to, when the `try` block completes execution?

13.6 Give a key advantage of using `catch(Exception exceptionName)`.

13.7 Should a conventional application catch `Error` objects? Explain.

13.8 What happens if no catch handler matches the type of a thrown object?

13.9 What happens if several catch blocks match the type of the thrown object?

13.10 Why would a programmer specify a superclass type as the type in a catch block?

13.11 What is the key reason for using `finally` blocks?

13.12 What happens when a catch block throws an `Exception`?

13.13 What does the statement `throw exceptionReference` do?

13.14 What happens to a local reference in a `try` block when that block throws an `Exception`?

Answers to Self-Review Exercises

13.1 Memory exhaustion, array index out of bounds, arithmetic overflow, division by zero, invalid method parameters.

13.2 (a) Exception handling is designed to handle infrequently occurring situations that often result in program termination, not situations that arise all the time. (b) Flow of control with conventional control structures is generally clearer and more efficient than with exceptions. (c) The “additional” exceptions can get in the way of genuine error-type exceptions. It becomes more difficult for the programmer to keep track of the larger number of exception cases.

13.3 It is unlikely that methods of classes in the Java API could perform error processing that would meet the unique needs of all users.

13.4 A “resource leak” occurs when an executing program does not properly release a resource when it is no longer needed.

13.5 The catch blocks for that `try` statement are skipped, and the program resumes execution after the last catch block. If there is a `finally` block, it is executed first; then the program resumes execution after the `finally` block.

13.6 The form `catch(Exception exceptionName)` catches any type of exception thrown in a `try` block. An advantage is that no thrown `Exception` can slip by without being caught. The programmer can then decide to handle the exception or possibly rethrow it.

13.7 Errors are usually serious problems with the underlying Java system; most programs will not want to catch `Errors` because the program will not be able to recover from such problems.

13.8 This causes the search for a match to continue in the next enclosing `try` statement. If there is a `finally` block, it will be executed before the exception goes to the next enclosing `try` statement. If there are no enclosing `try` statements for which there are matching catch blocks, and the exception is *checked*, a compilation error occurs. If there are no enclosing `try` statements for which there are matching catch blocks and the exception is *unchecked*, a stack trace is printed and the current thread terminates early.

13.9 The first matching catch block after the `try` block is executed.

Exercises 685

- 13.10** This enables a program to catch related types of exceptions and process them in a uniform manner. However, it is often useful to process the subclass types individually for more precise exception handling.
- 13.11** The `finally` block is the preferred means for releasing resources to prevent resource leaks.
- 13.12** First, control passes to the `finally` block if there is one. Then the exception will be processed by a `catch` block (if one exists) associated with an enclosing `try` block (if one exists).
- 13.13** It rethrows the exception for processing by an exception handler of an enclosing `try` statement, after the `finally` block of the current `try` statement executes.
- 13.14** The reference goes out of scope, and the reference count for the object is decremented. If the reference count becomes zero, the object is marked for garbage collection.

Exercises

- 13.15** List the various exceptional conditions that have occurred in programs throughout this text so far. List as many additional exceptional conditions as you can. For each of these, describe briefly how a program typically would handle the exception by using the exception-handling techniques discussed in this chapter. Some typical exceptions are division by zero, arithmetic overflow, and array index out of bounds.
- 13.16** Until this chapter, we have found dealing with errors detected by constructors to be a bit awkward. Explain why exception handling is an effective means for dealing with constructor failure.
- 13.17** (*Catching Exceptions with Superclasses*) Use inheritance to create an exception superclass (called `ExceptionA`) and exception subclasses `ExceptionB` and `ExceptionC`, where `ExceptionB` inherits from `ExceptionA` and `ExceptionC` inherits from `ExceptionB`. Write a program to demonstrate that the `catch` block for type `ExceptionA` catches exceptions of types `ExceptionB` and `ExceptionC`.
- 13.18** (*Catching Exceptions Using Class Exception*) Write a program that demonstrates how various exceptions are caught with

```
catch (Exception exception)
```

This time, define classes `ExceptionA` (which inherits from class `Exception`) and `ExceptionB` (which inherits from class `ExceptionA`). In your program, create `try` blocks that throw exceptions of types `ExceptionA`, `ExceptionB`, `NullPointerException` and `IOException`. All exceptions should be caught with `catch` blocks specifying type `Exception`.

- 13.19** (*Order of catch Blocks*) Write a program that shows that the order of `catch` blocks is important. If you try to catch a superclass exception type before a subclass type, the compiler should generate errors.

- 13.20** (*Constructor Failure*) Write a program that shows a constructor passing information about constructor failure to an exception handler. Define class `SomeException`, which throws an `Exception` in the constructor. Your program should try to create an object of type `SomeException` and catch the exception that is thrown from the constructor.

- 13.21** (*Rethrowing Exceptions*) Write a program that illustrates rethrowing an exception. Define methods `someMethod` and `someMethod2`. Method `someMethod2` should initially throw an exception. Method `someMethod` should call `someMethod2`, catch the exception and rethrow it. Call `someMethod` from method `main`, and catch the rethrown exception. Print the stack trace of this exception.

- 13.22** (*Catching Exceptions Using Outer Scopes*) Write a program showing that a method with its own `try` block does not have to catch every possible error generated within the `try`. Some exceptions can slip through to, and be handled in, other scopes.

14

Files and Streams

OBJECTIVES

In this chapter you will learn:

- To create, read, write and update files.
- To use class `File` to retrieve information about files and directories.
- The Java input/output stream class hierarchy.
- The differences between text files and binary files.
- Sequential-access file processing.
- To use classes `Scanner` and `Formatter` to process text files.
- To use the `InputStream` and `OutputStream` classes.
- To use a `JFileChooser` dialog.
- To use the `ObjectInputStream` and `ObjectOutputStream` classes.

I can only assume that a “Do Not File” document is filed in a “Do Not File” file.

—Senator Frank Church
Senate Intelligence
Subcommittee Hearing, 1975

Consciousness ... does not appear to itself chopped up in bits. ... A “river” or a “stream” are the metaphors by which it is most naturally described.

—William James

I read part of it all the way through.

—Samuel Goldwyn

A great memory does not make a philosopher; any more than a dictionary can be called grammar.

—John Henry, Cardinal Newman

Outline

- 14.1 Introduction
- 14.2 Data Hierarchy
- 14.3 Files and Streams
- 14.4 Class File
- 14.5 Sequential-Access Text Files
 - 14.5.1 Creating a Sequential-Access Text File
 - 14.5.2 Reading Data from a Sequential-Access Text File
 - 14.5.3 Case Study: A Credit-Inquiry Program
 - 14.5.4 Updating Sequential-Access Files
- 14.6 Object Serialization
 - 14.6.1 Creating a Sequential-Access File Using Object Serialization
 - 14.6.2 Reading and Deserializing Data from a Sequential-Access File
- 14.7 Additional `java.io` Classes
- 14.8 Opening Files with `JFileChooser`
- 14.9 Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

14.1 Introduction

Storage of data in variables and arrays is temporary—the data is lost when a local variable goes out of scope or when the program terminates. Computers use files for long-term retention of large amounts of data, even after the programs that created the data terminate. You use files every day for tasks such as writing an essay or creating a spreadsheet. We refer to data maintained in files as **persistent data** because it exists beyond the duration of program execution. Computers store files on **secondary storage devices** such as hard disks, optical disks and magnetic tapes. In this chapter, we explain how Java programs create, update and process files.

File processing is one of the most important capabilities a language must have to support commercial applications, which typically store and process massive amounts of persistent data. In this chapter, we discuss Java’s powerful file-processing and stream input/output features. The term “stream” refers to ordered data that is read from or written to a file. We discuss streams in more detail in Section 14.3. File processing is a subset of Java’s stream-processing capabilities, which enable a program to read and write data in memory, in files and over network connections. We have two goals in this chapter—to introduce file-processing concepts (making the reader more comfortable with using files programmatically) and to provide the reader with sufficient stream-processing capabilities to support the networking features introduced in Chapter 24, Networking. Java provides substantial stream-processing capabilities—far more than we can cover in one chapter. We discuss two forms of file processing here—text-file processing and object serialization.

We begin by discussing the hierarchy of data contained in files. We then cover Java’s architecture for handling files programmatically by discussing several classes in package `java.io`. Next we explain that data can be stored in two different types of files—text files and binary files—and cover the differences between them. We demonstrate retrieving

688 Chapter 14 Files and Streams

information about a file or directory using class `File` and then devote several sections to the different mechanisms for writing data to and reading data from files. First we demonstrate creating and manipulating sequential-access text files. Working with text files allows the reader to quickly and easily start manipulating files. As you will learn, however, it is difficult to read data from text files back into object form. Fortunately, many object-oriented languages (including Java) provide ways to write objects to and read objects from files (known as object serialization and deserialization). To demonstrate this, we recreate some of the sequential-access programs that used text files, this time by storing objects in binary files.

14.2 Data Hierarchy

Ultimately, a computer processes all data items as combinations of zeros and ones, because it is simple and economical for engineers to build electronic devices that can assume two stable states—one representing 0 and the other representing 1. It is remarkable that the impressive functions performed by computers involve only the most fundamental manipulations of 0s and 1s.

The smallest data item in a computer can assume the value 0 or the value 1. Such a data item is called a **bit** (short for “binary digit”—a digit that can assume one of two values). Computer circuitry performs various simple bit manipulations, such as examining the value of a bit, setting the value of a bit and reversing the value of a bit (from 1 to 0 or from 0 to 1).

It is cumbersome for programmers to work with data in the low-level form of bits. Instead, they prefer to work with data in such forms as **decimal digits** (0–9), **letters** (A–Z and a–z), and **special symbols** (e.g., \$, @, %, &, *, (,), –, +, :, ;, ? and /). Digits, letters and special symbols are known as **characters**. The computer’s **character set** is the set of all the characters used to write programs and represent data items. Computers process only 1s and 0s, so a computer’s character set represents every character as a pattern of 1s and 0s. Characters in Java are **Unicode** characters composed of two **bytes**, each composed of eight bits. Java contains a data type, `byte`, that can be used to represent byte data. The Unicode character set contains characters for many of the world’s languages. See Appendix I for more information on this character set. See Appendix B, ASCII Character Set, for more information on the **ASCII (American Standard Code for Information Interchange)** character set, a subset of the Unicode character set that represents uppercase and lowercase letters, digits and various common special characters.

Just as characters are composed of bits, **fields** are composed of characters or bytes. A field is a group of characters or bytes that conveys meaning. For example, a field consisting of uppercase and lowercase letters can be used to represent a person’s name.

Data items processed by computers form a **data hierarchy** that becomes larger and more complex in structure as we progress from bits to characters to fields, and so on.

Typically, several fields compose a **record** (implemented as a `class` in Java). In a payroll system, for example, the record for an employee might consist of the following fields (possible types for these fields are shown in parentheses):

- Employee identification number (`int`)
- Name (`String`)
- Address (`String`)

14.2 Data Hierarchy **689**

- Hourly pay rate (`double`)
- Number of exemptions claimed (`int`)
- Year-to-date earnings (`int` or `double`)
- Amount of taxes withheld (`int` or `double`)

Thus, a record is a group of related fields. In the preceding example, all the fields belong to the same employee. Of course, a company might have many employees and thus have a payroll record for each employee. A **file** is a group of related records. [Note: More generally, a file contains arbitrary data in arbitrary formats. In some operating systems, a file is viewed as nothing more than a collection of bytes—any organization of the bytes in a file (e.g., organizing the data into records) is a view created by the applications programmer.] A company's payroll file normally contains one record for each employee. Thus, a payroll file for a small company might contain only 22 records, whereas one for a large company might contain 100,000 records. It is not unusual for a company to have many files, some containing billions, or even trillions, of characters of information. Figure 14.1 illustrates a portion of the data hierarchy.

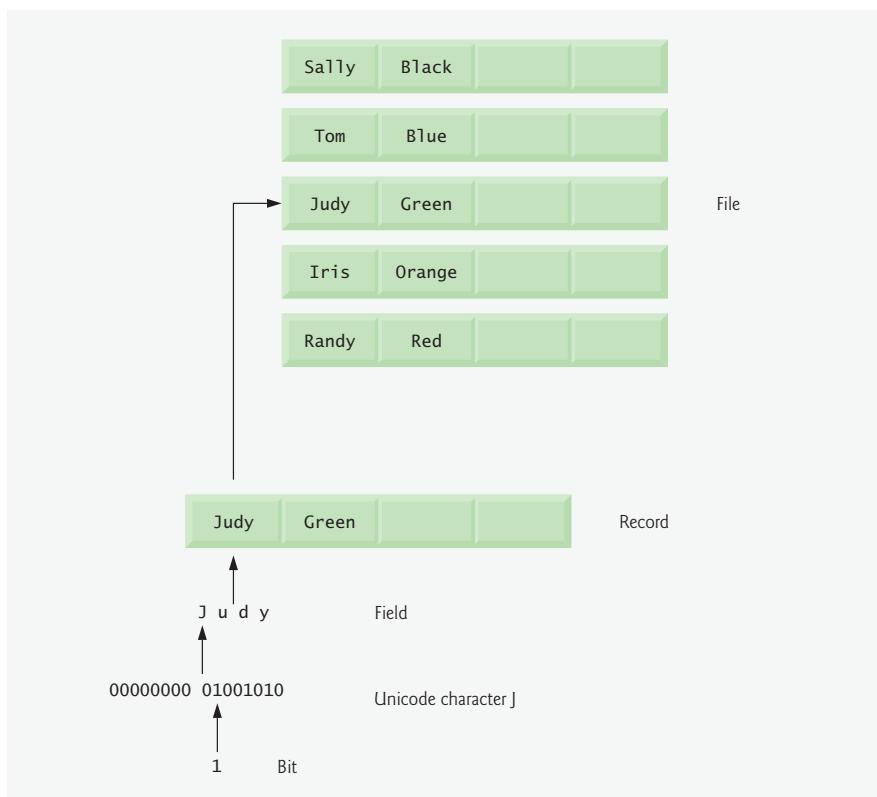

Fig. 14.1 | Data hierarchy.

690 Chapter 14 Files and Streams

To facilitate the retrieval of specific records from a file, at least one field in each record is chosen as a **record key**. A record key identifies a record as belonging to a particular person or entity and is unique to each record. This field typically is used to search and sort records. In the payroll record described previously, the employee identification number normally would be chosen as the record key.

There are many ways to organize records in a file. The most common is called a **sequential file**, in which records are stored in order by the record-key field. In a payroll file, records are placed in ascending order by employee identification number.

Most businesses store data in many different files. For example, companies might have payroll files, accounts receivable files (listing money due from clients), accounts payable files (listing money due to suppliers), inventory files (listing facts about all the items handled by the business) and many others. Often, a group of related files is called a **database**. A collection of programs designed to create and manage databases is called a **database management system** (DBMS). We discuss this topic in Chapter 25, Accessing Databases with JDBC.

14.3 Files and Streams

Java views each file as a sequential **stream** of bytes (Fig. 14.2). Every operating system provides a mechanism to determine the end of a file, such as an **end-of-file marker** or a count of the total bytes in the file that is recorded in a system-maintained administrative data structure. A Java program processing a stream of bytes simply receives an indication from the operating system when it reaches the end of the stream—the program does not need to know how the underlying platform represents files or streams. In some cases, the end-of-file indication occurs as an exception. In other cases, the indication is a return value from a method invoked on a stream-processing object.

File streams can be used to input and output data as either characters or bytes. Streams that input and output bytes to files are known as **byte-based streams**, storing data in its binary format. Streams that input and output characters to files are known as **character-based streams**, storing data as a sequence of characters. For instance, if the value 5 were being stored using a byte-based stream, it would be stored in the binary format of the numeric value 5, or 101. If the value 5 were being stored using a character-based stream, it would be stored in the binary format of the character 5, or 00000000 00110101 (this is the binary for the numeric value 53, which indicates the character 5 in the Unicode character set). The difference between the numeric value 5 and the character 5 is that the numeric value can be used as an integer in calculations, whereas the character 5 is simply a character that can be used in a string of text, as in "Sarah Miller is 15 years old". Files that are created using byte-based streams are referred to as **binary files**, while files created using character-based streams are referred to as **text files**. Text files can be read by text editors, while binary files are read by a program that converts the data to a human-readable format.

Fig. 14.2 | Java's view of a file of n bytes.

14.3 Files and Streams **691**

A Java program **opens** a file by creating an object and associating a stream of bytes or characters with it. The classes used to create these objects are discussed shortly. Java can also associate streams with different devices. In fact, Java creates three stream objects that are associated with devices when a Java program begins executing—`System.in`, `System.out` and `System.err`. Object `System.in` (the standard input stream object) normally enables a program to input bytes from the keyboard; object `System.out` (the standard output stream object) normally enables a program to output data to the screen; and object `System.err` (the standard error stream object) normally enables a program to output error messages to the screen. Each of these streams can be **redirected**. For `System.in`, this capability enables the program to read bytes from a different source. For `System.out` and `System.err`, this capability enables the output to be sent to a different location, such as a file on disk. Class `System` provides methods `setIn`, `setOut` and `setErr` to redirect the standard input, output and error streams, respectively.

Java programs perform file processing by using classes from package `java.io`. This package includes definitions for stream classes, such as `FileInputStream` (for byte-based input from a file), `FileOutputStream` (for byte-based output to a file), `FileReader` (for character-based input from a file) and `FileWriter` (for character-based output to a file). Files are opened by creating objects of these stream classes, which inherit from classes `InputStream`, `OutputStream`, `Reader` and `Writer`, respectively (these classes will be discussed later in this chapter). Thus, the methods of these stream classes can all be applied to file streams as well.

Java contains classes that enable the programmer to perform input and output of objects or variables of primitive data types. The data will still be stored as bytes or characters behind the scenes, allowing the programmer to read or write data in the form of integers, strings, or other data types without having to worry about the details of converting such values to byte format. To perform such input and output, objects of classes `ObjectInputStream` and `ObjectOutputStream` can be used together with the byte-based file stream classes `FileInputStream` and `FileOutputStream` (these classes will be discussed in more detail shortly). The complete hierarchy of classes in package `java.io` can be viewed in the online documentation at

java.sun.com/javase/6/docs/api/java/io/package-tree.html

Each indentation level in the hierarchy indicates that the indented class extends the class under which it is indented. For example, class `InputStream` is a subclass of `Object`. Click a class's name in the hierarchy to view the details of the class.

As you can see in the hierarchy, Java offers many classes for performing input/output operations. We use several of these classes in this chapter to implement file-processing programs that create and manipulate sequential-access files. We also include a detailed example on class `File`, which is useful for obtaining information about files and directories. In Chapter 24, Networking, we use stream classes extensively to implement networking applications. Several other classes in the `java.io` package that we do not use in this chapter are discussed briefly in Section 14.7.

In addition to the classes in this package, character-based input and output can be performed with classes `Scanner` and `Formatter`. Class `Scanner` is used extensively to input data from the keyboard. As we will see, this class can also read data from a file. Class `Formatter` enables formatted data to be output to the screen or to a file in a manner similar

692 Chapter 14 Files and Streams

to `System.out.printf`. Chapter 29, Formatted Output, presents the details of formatted output with `System.out.printf`. All these features can be used to format text files as well.

14.4 Class File

This section presents class `File`, which is particularly useful for retrieving information about files or directories from disk. Objects of class `File` do not open files or provide any file-processing capabilities. However, `File` objects are used frequently with objects of other `java.io` classes to specify files or directories to manipulate.

Creating File Objects

Class `File` provides four constructors. The constructor

```
public File( String name )
```

specifies the name of a file or directory to associate with the `File` object. The name can contain **path information** as well as a file or directory name. A file or directory's path specifies its location on disk. The path includes some or all of the directories leading to the file or directory. An **absolute path** contains all the directories, starting with the **root directory**, that lead to a specific file or directory. Every file or directory on a particular disk drive has the same root directory in its path. A **relative path** normally starts from the directory in which the application began executing, and is therefore a path that is "relative" to the current directory.

The constructor

```
public File( String pathToName, String name )
```

uses argument `pathToName` (an absolute or relative path) to locate the file or directory specified by `name`.

The constructor

```
public File( File directory, String name )
```

uses an existing `File` object `directory` (an absolute or relative path) to locate the file or directory specified by `name`. Figure 14.3 lists some common `File` methods. The complete list can be viewed at java.sun.com/javase/6/docs/api/java/io/File.html.

Method	Description
<code>boolean canRead()</code>	Returns <code>true</code> if a file is readable by the current application; <code>false</code> otherwise.
<code>boolean canWrite()</code>	Returns <code>true</code> if a file is writable by the current application; <code>false</code> otherwise.
<code>boolean exists()</code>	Returns <code>true</code> if the name specified as the argument to the <code>File</code> constructor is a file or directory in the specified path; <code>false</code> otherwise.

Fig. 14.3 | `File` methods. (Part I of 2.)

14.4 Class File 693

Method	Description
<code>boolean isFile()</code>	Returns <code>true</code> if the name specified as the argument to the <code>File</code> constructor is a file; <code>false</code> otherwise.
<code>boolean isDirectory()</code>	Returns <code>true</code> if the name specified as the argument to the <code>File</code> constructor is a directory; <code>false</code> otherwise.
<code>boolean isAbsolute()</code>	Returns <code>true</code> if the arguments specified to the <code>File</code> constructor indicate an absolute path to a file or directory; <code>false</code> otherwise.
<code>String getAbsolutePath()</code>	Returns a string with the absolute path of the file or directory.
<code>String getName()</code>	Returns a string with the name of the file or directory.
<code>String getPath()</code>	Returns a string with the path of the file or directory.
<code>String getParent()</code>	Returns a string with the parent directory of the file or directory (i.e., the directory in which the file or directory can be found).
<code>long length()</code>	Returns the length of the file, in bytes. If the <code>File</code> object represents a directory, 0 is returned.
<code>long lastModified()</code>	Returns a platform-dependent representation of the time at which the file or directory was last modified. The value returned is useful only for comparison with other values returned by this method.
<code>String[] list()</code>	Returns an array of strings representing the contents of a directory. Returns <code>null</code> if the <code>File</code> object does not represent a directory.

Fig. 14.3 | `File` methods. (Part 2 of 2.)

The constructor

```
public File( URI uri )
```

uses the given `URI` object to locate the file. A **Uniform Resource Identifier (URI)** is a more general form of the **Uniform Resource Locators (URLs)** that are used to locate websites. For example, `http://www.deitel.com/` is the URL for the Deitel & Associates' website. URIs for locating files vary across operating systems. On Windows platforms, the URI

```
file:/C:/data.txt
```

identifies the file `data.txt` stored in the root directory of the C: drive. On UNIX/Linux platforms, the URI

```
file:/home/student/data.txt
```

identifies the file `data.txt` stored in the `home` directory of the user `student`.

694 Chapter 14 Files and Streams

**Error-Prevention Tip 14.1**

Use `File` method `isFile` to determine whether a `File` object represents a file (not a directory) before attempting to open the file.

Demonstrating Class `File`

Figures 14.4–14.5 demonstrate class `File`. The application prompts the user to enter a file name or directory name, then outputs information about the file name or directory name input.

```

1 // Fig. 14.4: FileDemonstration.java
2 // Demonstrating the File class.
3 import java.io.File;
4
5 public class FileDemonstration
6 {
7     // display information about file user specifies
8     public void analyzePath( String path )
9     {
10        // create File object based on user input
11        File name = new File( path );
12
13        if ( name.exists() ) // if name exists, output information about it
14        {
15            // display file (or directory) information
16            System.out.printf(
17                "%s%n%s%n%s%n%s%n%s%n%s%n%s%n%s%n%s",
18                name.getName(), " exists",
19                ( name.isFile() ? "is a file" : "is not a file" ),
20                ( name.isDirectory() ? "is a directory" :
21                  "is not a directory" ),
22                ( name.isAbsolute() ? "is absolute path" :
23                  "is not absolute path" ), "Last modified: ",
24                name.lastModified(), "Length: ", name.length(),
25                "Path: ", name.getPath(), "Absolute path: ",
26                name.getAbsolutePath(), "Parent: ", name.getParent() );
27
28        if ( name.isDirectory() ) // output directory listing
29        {
30            String directory[] = name.list();
31            System.out.println( "\n\nDirectory contents:\n" );
32
33            for ( String directoryName : directory )
34                System.out.printf( "%s\n", directoryName );
35            } // end if
36        } // end outer if
37        else // not file or directory, output error message
38        {
39            System.out.printf( "%s %s", path, "does not exist." );
40        } // end else
41    } // end method analyzePath
42 } // end class FileDemonstration

```

Fig. 14.5 | Testing class `FileDemonstration`.

696 Chapter 14 Files and Streams

The program begins by prompting the user for a file or directory (line 12 of Fig. 14.5). Line 13 inputs the file name or directory name and passes it to method `analyzePath` (lines 8–41 of Fig. 14.4). The method creates a new `File` object (line 11) and assigns its reference to `name`. Line 13 invokes `File` method `exists` to determine whether the name input by the user exists (either as a file or as a directory) on the disk. If the name input by the user does not exist, control proceeds to lines 37–40 and displays a message to the screen containing the name the user typed, followed by “does not exist.” Otherwise, the body of the `if` statement (lines 13–36) executes. The program outputs the name of the file or directory (line 18), followed by the results of testing the `File` object with `isFile` (line 19), `isDirectory` (line 20) and `isAbsolute` (line 22). Next, the program displays the values returned by `lastModified` (line 24), `length` (line 24), `getPath` (line 25), `getAbsolutePath` (line 26) and `getParent` (line 26). If the `File` object represents a directory (line 28), the program obtains a list of the directory’s contents as an array of `Strings` by using `File` method `list` (line 30) and displays the list on the screen.

The first output of this program demonstrates a `File` object associated with the `jfc` directory from the Java 2 Software Development Kit. The second output demonstrates a `File` object associated with the `readme.txt` file from the Java 2D example that comes with the Java 2 Software Development Kit. In both cases, we specified an absolute path on our personal computer.

A **separator character** is used to separate directories and files in the path. On a Windows computer, the separator character is a backslash (\) character. On a UNIX workstation, it is a forward slash (/) character. Java processes both characters identically in a path name. For example, if we were to use the path

```
c:\Program Files\Java\jdk1.6.0\demo\jfc
```

which employs each separator character, Java would still process the path properly. When building strings that represent path information, use `File.separator` to obtain the local computer’s proper separator character rather than explicitly using / or \. This constant returns a `String` consisting of one character—the proper separator for the system.

Common Programming Error 14.1

Using \ as a directory separator rather than \\ in a string literal is a logic error. A single \ indicates that the \ followed by the next character represents an escape sequence. Use \\ to insert a \ in a string literal.

14.5 Sequential-Access Text Files

In this section, we create and manipulate sequential-access files. As mentioned earlier, these are files in which records are stored in order by the record-key field. We first demonstrate sequential-access files using text files, allowing the reader to quickly create and edit human-readable files. In the subsections of this chapter we discuss creating, writing data to, reading data from and updating sequential-access text files. We also include a credit-inquiry program that retrieves specific data from a file.

14.5.1 Creating a Sequential-Access Text File

Java imposes no structure on a file—notions such as a record do not exist as part of the Java language. Therefore, the programmer must structure files to meet the requirements

14.5 Sequential-Access Text Files **697**

of the intended application. In the following example, we see how to impose a record structure on a file.

The program in Figs. 14.6–14.7 and Fig. 14.9 creates a simple sequential-access file that might be used in an accounts receivable system to help keep track of the amounts owed to a company by its credit clients. For each client, the program obtains from the user an account number, the client's name and the client's balance (i.e., the amount the client owes the company for goods and services received). The data obtained for each client constitutes a “record” for that client. The account number is used as the record key in this application—the file will be created and maintained in account-number order. The program assumes that the user enters the records in account-number order. In a comprehensive accounts receivable system (based on sequential-access files), a sorting capability would be provided so that the user could enter the records in any order. The records would then be sorted and written to the file.

Class `AccountRecord` (Fig. 14.6) encapsulates the client record information (i.e., account, first name, and so on) used by the examples in this chapter. The class `AccountRecord` is declared in package `com.deitel.jhtp7.ch14` (line 3), so that it can be imported into several examples. Class `AccountRecord` contains private data members `account`, `firstName`, `lastName` and `balance` (lines 7–10). This class also provides public `set` and `get` methods for accessing the private fields.

```

1 // Fig. 14.6: AccountRecord.java
2 // A class that represents one record of information.
3 package com.deitel.jhtp7.ch14; // packaged for reuse
4
5 public class AccountRecord
6 {
7     private int account;
8     private String firstName;
9     private String lastName;
10    private double balance;
11
12    // no-argument constructor calls other constructor with default values
13    public AccountRecord()
14    {
15        this( 0, "", "" , 0.0 ); // call four-argument constructor
16    } // end no-argument AccountRecord constructor
17
18    // initialize a record
19    public AccountRecord( int acct, String first, String last, double bal )
20    {
21        setAccount( acct );
22        setFirstName( first );
23        setLastName( last );
24        setBalance( bal );
25    } // end four-argument AccountRecord constructor
26
27    // set account number
28    public void setAccount( int acct )
29    {

```

Fig. 14.6 | `AccountRecord` maintains information for one account. (Part I of 2.)

698 Chapter 14 Files and Streams

```

30     account = acct;
31 } // end method setAccount
32
33 // get account number
34 public int getAccount()
35 {
36     return account;
37 } // end method getAccount
38
39 // set first name
40 public void setFirstName( String first )
41 {
42     firstName = first;
43 } // end method setFirstName
44
45 // get first name
46 public String getFirstName()
47 {
48     return firstName;
49 } // end method getFirstName
50
51 // set last name
52 public void setLastName( String last )
53 {
54     lastName = last;
55 } // end method setLastName
56
57 // get last name
58 public String getLastname()
59 {
60     return lastName;
61 } // end method getLastname
62
63 // set balance
64 public void setBalance( double bal )
65 {
66     balance = bal;
67 } // end method setBalance
68
69 // get balance
70 public double getBalance()
71 {
72     return balance;
73 } // end method getBalance
74 } // end class AccountRecord

```

Fig. 14.6 | AccountRecord maintains information for one account. (Part 2 of 2.)

Compile class AccountRecord as follows:

```
javac -d c:\examples\ch14 com\deitel\jhtp7\ch14\AccountRecord.java
```

This places `AccountRecord.class` in its package directory structure and places the package in `c:\examples\ch14`. When you compile class `AccountRecord` (or any other classes

14.5 Sequential-Access Text Files **699**

that will be reused in this chapter), you should place them in a common directory (e.g., `c:\examples\ch14`). When you compile or execute classes that use `AccountRecord` (e.g., `CreateTextFile` in Fig. 14.7), you must specify the command-line argument `-classpath` to both `javac` and `java`, as in

```
javac -classpath .;c:\examples\ch14 CreateTextFile.java
java -classpath .;c:\examples\ch14 CreateTextFile
```

Note that the current directory (specified with `.`) is included in the classpath. This ensures that the compiler can locate other classes in the same directory as the class being compiled. The path separator used in the preceding commands should be the one that is appropriate for your platform—for example, a semicolon (`;`) on Windows and a colon (`:`) on UNIX/Linux/Mac OS X.

Now let us examine class `CreateTextFile` (Fig. 14.7). Line 14 declares `Formatter` variable `output`. As discussed in Section 14.3, a `Formatter` object outputs formatted strings, using the same formatting capabilities as method `System.out.printf`. A `Formatter` object can output to various locations, such as the screen or a file, as is done here. The `Formatter` object is instantiated in line 21 in method `openFile` (lines 17–34). The constructor used in line 21 takes one argument—a `String` containing the name of the file, including its path. If a path is not specified, as is the case here, the JVM assumes that the file is in the directory from which the program was executed. For text files, we use the `.txt` file extension. If the file does not exist, it will be created. If an existing file is opened, its contents are `truncated`—all the data in the file is discarded. At this point the file is open for writing, and the resulting `Formatter` object can be used to write data to the file. Lines 23–28 handle the `SecurityException`, which occurs if the user does not have permission to write data to the file. Lines 29–33 handle the `FileNotFoundException`, which occurs if the file does not exist and a new file cannot be created. This exception may also occur if there is an error opening the file. Note that in both exception handlers, we call static method `System.exit`, and pass the value 1. This method terminates the application. An argument of 0 to method `exit` indicates successful program termination. A nonzero value, such as 1 in this example, normally indicates that an error has occurred. This value is passed to the command window that executed the program. The argument is useful if the program is executed from a `batch file` on Windows systems or a `shell script` on UNIX/Linux/Mac OS X systems. Batch files and shell scripts offer a convenient way of executing several programs in sequence. When the first program ends, the next program begins execution. It is possible to use the argument to method `exit` in a batch file or shell script to determine whether other programs should execute. For more information on batch files or shell scripts, see your operating system's documentation.

98 } // end method closeFile
99 } // end class CreateTextFile

```

Fig. 14.7 | Creating a sequential text file. (Part 3 of 3.)

Method `addRecords` (lines 37–91) prompts the user to enter the various fields for each record or to enter the end-of-file key sequence when data entry is complete. Figure 14.8 lists the key combinations for entering end-of-file for various computer systems.

Line 40 creates an `AccountRecord` object, which will be used to store the values of the current record entered by the user. Line 42 creates a `Scanner` object to read input from the user at the keyboard. Lines 44–48 and 50–52 prompt the user for input.

Line 54 uses `Scanner` method `hasNext` to determine whether the end-of-file key combination has been entered. The loop executes until `hasNext` encounters the end-of-file indicators.

Lines 59–62 read data from the user, storing the record information in the `AccountRecord` object. Each statement throws a `NoSuchElementException` (handled in

702 Chapter 14 Files and Streams

Fig. 14.8 | End-of-file key combinations for various popular operating systems.

lines 82–86) if the data is in the wrong format (e.g., a string when an `int` is expected) or if there is no more data to input. If the account number is greater than 0 (line 64), the record's information is written to `clients.txt` (lines 67–69) using method `format`. This method can perform identical formatting to the `System.out.printf` method used extensively in earlier chapters. This method outputs a formatted string to the output destination of the `Formatter` object, in this case the file `clients.txt`. The format string `"%d %s %s %.2\n"` indicates that the current record will be stored as an integer (the account number) followed by a string (the first name), another string (the last name) and a floating-point value (the balance). Each piece of information is separated from the next by a space, and the double value (the balance) is output with two digits to the right of the decimal point. The data in the text file can be viewed with a text editor, or retrieved later by a program designed to read the file (14.5.2). When lines 67–69 execute, if the `Formatter` object is closed, a `FormatterClosedException` will be thrown (handled in lines 77–81). [Note: You can also output data to a text file using class `java.io.PrintWriter`, which also provides method `format` for outputting formatted data.]

Lines 94–98 declare method `closeFile`, which closes the `Formatter` and the underlying output file. Line 97 closes the object by simply calling method `close`. If method `close` is not called explicitly, the operating system normally will close the file when program execution terminates—this is an example of operating system “housekeeping.”

Figure 14.9 runs the program. Line 8 creates a `CreateTextFile` object, which is then used to open, add records to and close the file (lines 10–12). The sample data for this application is shown in Fig. 14.10. In the sample execution for this program, the user enters information for five accounts, then enters end-of-file to signal that data entry is complete. The sample execution does not show how the data records actually appear in the file. In the next section, to verify that the file has been created successfully, we present a program that reads the file and prints its contents. Because this is a text file, you can also verify the information by opening the file in a text editor.

14.5.2 Reading Data from a Sequential-Access Text File

Data is stored in files so that it may be retrieved for processing when needed. Section 14.5.1 demonstrated how to create a file for sequential access. This section shows how to read data sequentially from a text file. In this section, we demonstrate how class Scanner can be used to input data from a file rather than the keyboard.

The application in Figs. 14.11 and 14.12 reads records from the file "clients.txt" created by the application of Section 14.5.1 and displays the record contents. Line 13 of Fig. 14.11 declares a Scanner that will be used to retrieve input from the file.

Method openFile (lines 16–27) opens the file for reading by instantiating a Scanner object in line 20. We pass a File object to the constructor, which specifies that the

Fig. 14.12 | Testing the ReadTextFile class.

Scanner object will read from the file "clients.txt" located in the directory from which the application executes. If the file cannot be found, a `FileNotFoundException` occurs. The exception is handled in lines 22–26.

Method `readRecords` (lines 30–64) reads and displays records from the file. Line 33 creates `AccountRecord` object `record` to store the current record's information. Lines 35–

706 Chapter 14 Files and Streams

36 display headers for the columns in the application's output. Lines 40–51 read data from the file until the end-of-file marker is reached (in which case, method `hasNext` will return `false` at line 40). Lines 42–45 use Scanner methods `nextInt`, `next` and `nextDouble` to input an integer (the account number), two strings (the first and last names) and a double value (the balance). Each record is one line of data in the file. The values are stored in object `record`. If the information in the file is not properly formed (e.g., there is a last name where there should be a balance), a `NoSuchElementException` occurs when the record is input. This exception is handled in lines 53–58. If the Scanner was closed before the data was input, an `IllegalStateException` occurs (handled in lines 59–63). If no exceptions occur, the record's information is displayed on the screen (lines 48–50). Note in the format string in line 48 that the account number, first name and last name are left justified, while the balance is right justified and output with two digits of precision. Each iteration of the loop inputs one line of text from the text file, which represents one record.

Lines 67–71 define method `closeFile`, which closes the Scanner. Method `main` is defined in Fig. 14.12, in lines 6–13. Line 8 creates a `ReadTextFile` object, which is then used to open, add records to and close the file (lines 10–12).

14.5.3 Case Study: A Credit-Inquiry Program

To retrieve data sequentially from a file, programs normally start reading from the beginning of the file and read all the data consecutively until the desired information is found. It might be necessary to process the file sequentially several times (from the beginning of the file) during the execution of a program. Class `Scanner` does not provide the ability to reposition to the beginning of the file. If it is necessary to read the file again, the program must close the file and reopen it.

The program in Figs. 14.13–14.15 allows a credit manager to obtain lists of customers with zero balances (i.e., customers who do not owe any money), customers with credit balances (i.e., customers to whom the company owes money) and customers with debit balances (i.e., customers who owe the company money for goods and services received). A credit balance is a negative amount, and a debit balance is a positive amount.

We begin by creating an `enum` type (Fig. 14.13) to define the different menu options the user will have. The options and their values are listed in lines 7–10. Method `getValue` (lines 19–22) retrieves the value of a specific `enum` constant.

```

1 // Fig. 14.13: MenuOption.java
2 // Defines an enum type for the credit-inquiry program's options.
3
4 public enum MenuOption
5 {
6     // declare contents of enum type
7     ZERO_BALANCE( 1 ),
8     CREDIT_BALANCE( 2 ),
9     DEBIT_BALANCE( 3 ),
10    END( 4 );
11
12    private final int value; // current menu option

```

9         application.processRequests();
10    } // end main
11 } // end class CreditInquiryTest

```

Fig. 14.15 | Testing the CreditInquiry class.

Figure 14.14 contains the functionality for the credit-inquiry program, and Fig. 14.15 contains the `main` method that executes the program. The program displays a text menu and allows the credit manager to enter one of three options to obtain credit information. Option 1 (`ZERO_BALANCE`) produces a list of accounts with zero balances. Option 2 (`CREDIT_BALANCE`) produces a list of accounts with credit balances. Option 3 (`DEBIT_BALANCE`) produces a list of accounts with debit balances. Option 4 (`END`) terminates program execution. A sample output is shown in Fig. 14.16.

The record information is collected by reading through the entire file and determining whether each record satisfies the criteria for the account type selected by the credit manager. Method `processRequests` (lines 116–139 of Fig. 14.14) calls method `getRequest` to display the menu options (line 119) and stores the result in `MenuOption` variable `accountType`. Note that `getRequest` translates the number typed by the user into a `Menu-Option` by using the number to select a `MenuOption` from array `choices`. Lines 121–138 loop until the user specifies that the program should terminate. The `switch` statement in lines 123–134 displays a header for the current set of records to be output to the screen. Line 136 calls method `readRecords` (lines 22–67), which loops through the file and reads every record.

Line 30 of method `readRecords` opens the file for reading with a `Scanner`. Note that the file will be opened for reading with a new `Scanner` object each time this method is called, so that we can again read from the beginning of the file. Lines 34–37 read a record. Line 40 calls method `shouldDisplay` (lines 70–85) to determine whether the current record satisfies the account type requested. If `shouldDisplay` returns `true`, the program displays the account information. When the end-of-file marker is reached, the loop terminates and line 65 calls the `Scanner`'s `close` method to close the `Scanner` and the file. Notice that this occurs in a `finally` block, which will execute whether or not the file was successfully read. Once all the records have been read, control returns to method `processRequests` and `getRequest` is again called (line 137) to retrieve the user's next menu option. Figure 14.15 contains method `main`, and calls method `processRequests` in line 9.

14.5.4 Updating Sequential-Access Files

The data in many sequential files cannot be modified without the risk of destroying other data in the file. For example, if the name “White” needed to be changed to “Worthington,” the old name cannot simply be overwritten because the new name requires more space. The record for `White` was written to the file as

```

Fig. 14.16 | Sample output of the credit-inquiry program in Fig. 14.15.

300 Pam White 0.00

If the record is rewritten beginning at the same location in the file using the new name, the record will be

300 Pam Worthington 0.00

The new record is larger (has more characters) than the original record. The characters beyond the second “o” in “Worthington” will overwrite the beginning of the next sequential record in the file. The problem here is that fields in a text file—and hence records—can vary in size. For example, 7, 14, -117, 2074 and 27383 are all `ints` stored in the same number of bytes (4) internally, but they are different-sized fields when displayed on the screen or written to a file as text.

712 Chapter 14 Files and Streams

Therefore, records in a sequential-access file are not usually updated in place. Instead, the entire file is usually rewritten. To make the preceding name change, the records before 300 Pam White 0.00 would be copied to a new file, the new record (which can be of a different size than the one it replaces) would be written and the records after 300 Pam White 0.00 would be copied to the new file. It is uneconomical to update just one record, but reasonable if a substantial portion of the records needs to be updated.

14.6 Object Serialization

In Section 14.5, we demonstrated how to write the individual fields of an `AccountRecord` object into a file as text, and how to read those fields from a file and place their values into an `AccountRecord` object in memory. In the examples, `AccountRecord` was used to aggregate the information for one record. When the instance variables for an `AccountRecord` were output to a disk file, certain information was lost, such as the type of each value. For instance, if the value "3" were read from a file, there is no way to tell whether the value came from an `int`, a `String` or a `double`. We have only data, not type information, on a disk. If the program that is going to read this data "knows" what object type the data corresponds to, then the data is simply read into objects of that type. For example, in Section 14.5.2, we know that we are inputting an `int` (the account number), followed by two `Strings` (the first and last name) and a `double` (the balance). We also know that these values are separated by spaces, with only one record on each line. Sometimes we will not know exactly how the data is stored in a file. In such cases, we would like to read or write an entire object from a file. Java provides such a mechanism, called **object serialization**. A so-called **serialized object** is an object represented as a sequence of bytes that includes the object's data as well as information about the object's type and the types of data stored in the object. After a serialized object has been written into a file, it can be read from the file and **deserialized**—that is, the type information and bytes that represent the object and its data can be used to recreate the object in memory.

Classes `ObjectInputStream` and `ObjectOutputStream`, which respectively implement the `ObjectInput` and `ObjectOutput` interfaces, enable entire objects to be read from or written to a stream (possibly a file). To use serialization with files, we initialize `ObjectInputStream` and `ObjectOutputStream` objects with stream objects that read from and write to files—objects of classes `FileInputStream` and `FileOutputStream`, respectively. Initializing stream objects with other stream objects in this manner is sometimes called **wrapping**—the new stream object being created wraps the stream object specified as a constructor argument. To wrap a `FileInputStream` in an `ObjectInputStream`, for instance, we pass the `FileInputStream` object to the `ObjectInputStream`'s constructor.

The `ObjectOutput` interface contains method `writeObject`, which takes an `Object` that implements interface `Serializable` (discussed shortly) as an argument and writes its information to an `OutputStream`. Correspondingly, the `ObjectInput` interface contains method `readObject`, which reads and returns a reference to an `Object` from an `InputStream`. After an object has been read, its reference can be cast to the object's actual type. As you will see in Chapter 24, Networking, applications that communicate via a network, such as the Internet, can also transmit entire objects across the network.

In this section, we create and manipulate sequential-access files using object serialization. Object serialization is performed with byte-based streams, so the sequential files cre-

ated and manipulated will be binary files. Recall that binary files cannot be viewed in standard text editors. For this reason, we write a separate application that knows how to read and display serialized objects.

14.6.1 Creating a Sequential-Access File Using Object Serialization

We begin by creating and writing serialized objects to a sequential-access file. In this section, we reuse much of the code from Section 14.5, so we focus only on the new features.

Defining the AccountRecordSerializable Class

Let us begin by modifying our `AccountRecord` class so that objects of this class can be serialized. Class `AccountRecordSerializable` (Fig. 14.17) implements interface `Serializable` (line 7), which allows objects of `AccountRecordSerializable` to be serialized and deserialized with `ObjectOutputStreams` and `ObjectInputStreams`. Interface `Serializable` is a [tagging interface](#). Such an interface does not contain methods. A class that implements `Serializable` is [tagged](#) as being a `Serializable` object. This is important because an `ObjectOutputStream` will not output an object unless it is a `Serializable` object, which is the case for any object of a class that implements `Serializable`.

In a class that implements `Serializable`, the programmer must ensure that every instance variable of the class is a `Serializable` type. Any instance variable that is not seri-

```

4
5 import java.io.Serializable;
6
7 public class AccountRecordSerializable implements Serializable
8 {
9     private int account;
10    private String firstName;
11    private String lastName;
12    private double balance;
13
14    // no-argument constructor calls other constructor with default values
15    public AccountRecordSerializable()
16    {
17        this( 0, "", "", 0.0 );
18    } // end no-argument AccountRecordSerializable constructor
19
20    // four-argument constructor initializes a record
21    public AccountRecordSerializable(
22        int acct, String first, String last, double bal )
23    {
24        setAccount( acct );
25        setFirstName( first );
26        setLastName( last );
27        setBalance( bal );
28    } // end four-argument AccountRecordSerializable constructor
29

```

```

30  // set account number
31  public void setAccount( int acct )
32  {
33      account = acct;
34  } // end method setAccount
35
36  // get account number
37  public int getAccount()
38  {
39      return account;
40  } // end method getAccount
41
42  // set first name
43  public void setFirstName( String first )
44  {
45      firstName = first;
46  } // end method setFirstName
47
48  // get first name
49  public String getFirstName()
50  {
51      return firstName;
52  } // end method getFirstName
53
54  // set last name
55  public void setLastName( String last )
56  {
57      lastName = last;
58  } // end method setLastName
59
60  // get last name
61  public String getLastName()
62  {
63      return lastName;
64  } // end method getLastName
65
66  // set balance
67  public void setBalance( double bal )
68  {
69      balance = bal;
70  } // end method setBalance
71
72  // get balance
73  public double getBalance()
74  {
75      return balance;
76  } // end method getBalance
77 } // end class AccountRecordSerializable

```

Fig. 14.17 | AccountRecordSerializable class for serializable objects. (Part 2 of 2.)

alizable must be declared **transient** to indicate that it is not **Serializable** and should be ignored during the serialization process. By default, all primitive-type variables are serializable. For variables of reference types, you must check the definition of the class (and pos-

14.6 Object Serialization 715

sibly its superclasses) to ensure that the type is `Serializable`. By default, array objects are serializable. However, if the array contains references to other objects, those objects may or may not be serializable.

Class `AccountRecordSerializable` contains private data members `account`, `firstName`, `lastName` and `balance`. This class also provides public `get` and `set` methods for accessing the private fields.

Now let us discuss the code that creates the sequential-access file (Figs. 14.18–14.19). We concentrate only on new concepts here. As stated in Section 14.3, a program can open a file by creating an object of stream class `FileInputStream` or `FileOutputStream`. In this example, the file is to be opened for output, so the program creates a `FileOutputStream` (line 21 of Fig. 14.18). The string argument that is passed to the `FileOutputStream`'s constructor represents the name and path of the file to be opened. Existing files that are opened for output in this manner are truncated. Note that the `.ser` file extension is used—we use this file extension for binary files that contain serialized objects.

```

718 Chapter 14 Files and Streams

**Common Programming Error 14.2**

It is a logic error to open an existing file for output when, in fact, the user wishes to preserve the file.

Class `FileOutputStream` provides methods for writing byte arrays and individual bytes to a file. In this program we wish to write objects to a file—a capability not provided by `FileOutputStream`. For this reason, we wrap a `FileOutputStream` in an `ObjectOutputStream` by passing the new `FileOutputStream` object to the `ObjectOutputStream`'s constructor (lines 20–21). The `ObjectOutputStream` object uses the `FileOutputStream` object to write objects into the file. Lines 20–21 might throw an `IOException` if a problem occurs while opening the file (e.g., when a file is opened for writing on a drive with insufficient space or when a read-only file is opened for writing). If so, the program displays an error message (lines 23–26). If no exception occurs, the file is open and variable `output` can be used to write objects to the file.

This program assumes that data is input correctly and in the proper record-number order. Method `addRecords` (lines 30–86) performs the write operation. Lines 62–63 create an `AccountRecordSerializable` object from the data entered by the user. Line 64 calls `ObjectOutputStream` method `writeObject` to write the `record` object to the output file. Note that only one statement is required to write the entire object.

Method `closeFile` (lines 89–101) closes the file. Method `closeFile` calls `ObjectOutputStream` method `close` on `output` to close both the `ObjectOutputStream` and its underlying `FileOutputStream` (line 94). Note that the call to method `close` is contained in a try block. Method `close` throws an `IOException` if the file cannot be closed properly. In this case, it is important to notify the user that the information in the file might be corrupted. When using wrapped streams, closing the outermost stream also closes the underlying file.

In the sample execution for the program in Fig. 14.19, we entered information for five accounts—the same information shown in Fig. 14.10. The program does not show how the data records actually appear in the file. Remember that now we are using binary files, which are not humanly readable. To verify that the file has been created successfully, the next section presents a program to read the file's contents.

14.6.2 Reading and Deserializing Data from a Sequential-Access File

As discussed in Section 14.5.2, data is stored in files so that it may be retrieved for processing when needed. The preceding section showed how to create a file for sequential access using object serialization. In this section, we discuss how to read serialized data sequentially from a file.

The program in Figs. 14.20–14.21 reads records from a file created by the program in Section 14.6.1 and displays the contents. The program opens the file for input by creating a `FileInputStream` object (line 21). The name of the file to open is specified as an argument to the `FileInputStream` constructor. In Fig. 14.18, we wrote objects to the file, using an `ObjectOutputStream` object. Data must be read from the file in the same format in which it was written. Therefore, we use an `ObjectInputStream` wrapped around a `FileInputStream` in this program (lines 20–21). If no exceptions occur when opening the file, variable `input` can be used to read objects from the file.

14.6 Object Serialization 719

```

400	Sam	Stone	-42.16
500	Sue	Rich	224.62

Fig. 14.21 | Testing class `ReadSequentialFile`.

The program reads records from the file in method `readRecords` (lines 30–60). Line 40 calls `ObjectInputStream` method `readObject` to read an `Object` from the file. To use `AccountRecordSerializable`-specific methods, we downcast the returned `Object` to type

14.7 Additional `java.io` Classes 721

`AccountRecordSerializable`. Method `readObject` throws an `EOFException` (processed at lines 48–51) if an attempt is made to read beyond the end of the file. Method `readObject` throws a `ClassNotFoundException` if the class for the object being read cannot be located. This might occur if the file is accessed on a computer that does not have the class. Figure 14.21 contains method `main` (lines 6–13), which opens the file, calls method `readRecords` and closes the file.

14.7 Additional `java.io` Classes

We now introduce you to other useful classes in the `java.io` package. We overview additional interfaces and classes for byte-based input and output streams and character-based input and output streams.

Interfaces and Classes for Byte-Based Input and Output

`InputStream` and `OutputStream` (subclasses of `Object`) are abstract classes that declare methods for performing byte-based input and output, respectively. We used concrete classes `FileInputStream` (a subclass of `InputStream`) and `FileOutputStream` (a subclass of `OutputStream`) to manipulate files in this chapter.

Pipes are synchronized communication channels between threads. We discuss threads in Chapter 23, Multithreading. Java provides `PipedOutputStream` (a subclass of `OutputStream`) and `PipedInputStream` (a subclass of `InputStream`) to establish pipes between two threads in a program. One thread sends data to another by writing to a `PipedOutputStream`. The target thread reads information from the pipe via a `PipedInputStream`.

A `FilterInputStream` filters an `InputStream`, and a `FilterOutputStream` filters an `OutputStream`. Filtering means simply that the filter stream provides additional functionality, such as aggregating data bytes into meaningful primitive-type units. `FilterInputStream` and `FilterOutputStream` are abstract classes, so some of their filtering capabilities are provided by their concrete subclasses.

A `PrintStream` (a subclass of `FilterOutputStream`) performs text output to the specified stream. Actually, we have been using `PrintStream` output throughout the text to this point—`System.out` and `System.err` are `PrintStream` objects.

Reading data as raw bytes is fast, but crude. Usually, programs read data as aggregates of bytes that form `ints`, `floats`, `doubles` and so on. Java programs can use several classes to input and output data in aggregate form.

Interface `DataInput` describes methods for reading primitive types from an input stream. Classes `DataInputStream` and `RandomAccessFile` each implement this interface to read sets of bytes and view them as primitive-type values. Interface `DataInput` includes methods `readLine` (for byte arrays), `readBoolean`, `readByte`, `readChar`, `readDouble`, `readFloat`, `readFully` (for byte arrays), `readInt`, `readLong`, `readShort`, `readUnsignedByte`, `readUnsignedShort`, `readUTF` (for reading Unicode characters encoded by Java—we discuss UTF encoding in Appendix I, Unicode®) and `skipBytes`.

Interface `DataOutput` describes a set of methods for writing primitive types to an output stream. Classes `DataOutputStream` (a subclass of `FilterOutputStream`) and `RandomAccessFile` each implement this interface to write primitive-type values as bytes. Interface `DataOutput` includes overloaded versions of method `write` (for a byte or for a

722 Chapter 14 Files and Streams

byte array) and methods `writeBoolean`, `writeByte`, `writeBytes`, `writeChar`, `writeChars` (for Unicode Strings), `writeDouble`, `writeFloat`, `writeInt`, `writeLong`, `writeShort` and `writeUTF` (to output text modified for Unicode).

Buffering is an I/O-performance-enhancement technique. With a `BufferedOutputStream` (a subclass of class `FilterOutputStream`), each output statement does not necessarily result in an actual physical transfer of data to the output device (which is a slow operation compared to processor and main memory speeds). Rather, each output operation is directed to a region in memory called a **buffer** that is large enough to hold the data of many output operations. Then, actual transfer to the output device is performed in one large **physical output operation** each time the buffer fills. The output operations directed to the output buffer in memory are often called **logical output operations**. With a `BufferedOutputStream`, a partially filled buffer can be forced out to the device at any time by invoking the stream object's `flush` method.

Using buffering can greatly increase the efficiency of an application. Typical I/O operations are extremely slow compared with the speed of accessing computer memory. Buffering reduces the number of I/O operations by first combining smaller outputs together in memory. The number of actual physical I/O operations is small compared with the number of I/O requests issued by the program. Thus, the program that is using buffering is more efficient.

Performance Tip 14.1

Buffered I/O can yield significant performance improvements over unbuffered I/O.

With a `BufferedInputStream` (a subclass of class `FilterInputStream`), many “logical” chunks of data from a file are read as one large **physical input operation** into a memory buffer. As a program requests each new chunk of data, it is taken from the buffer. (This procedure is sometimes referred to as a **logical input operation**.) When the buffer is empty, the next actual physical input operation from the input device is performed to read in the next group of “logical” chunks of data. Thus, the number of actual physical input operations is small compared with the number of read requests issued by the program.

Java stream I/O includes capabilities for inputting from byte arrays in memory and outputting to byte arrays in memory. A `ByteArrayInputStream` (a subclass of `InputStream`) reads from a byte array in memory. A `ByteArrayOutputStream` (a subclass of `OutputStream`) outputs to a byte array in memory. One use of byte-array I/O is data validation. A program can input an entire line at a time from the input stream into a byte array. Then a validation routine can scrutinize the contents of the byte array and correct the data if necessary. Finally, the program can proceed to input from the byte array, “knowing” that the input data is in the proper format. Outputting to a byte array is a nice way to take advantage of the powerful output-formatting capabilities of Java streams. For example, data can be stored in a byte array, using the same formatting that will be displayed at a later time, and the byte array can then be output to a disk file to preserve the screen image.

A `SequenceInputStream` (a subclass of `InputStream`) enables concatenation of several `InputStreams`, which means that the program sees the group as one continuous `InputStream`. When the program reaches the end of an input stream, that stream closes, and the next stream in the sequence opens.

14.8 Opening Files with JFileChooser 723

Interfaces and Classes for Character-Based Input and Output

In addition to the byte-based streams, Java provides the `Reader` and `Writer` abstract classes, which are Unicode two-byte, character-based streams. Most of the byte-based streams have corresponding character-based concrete `Reader` or `Writer` classes.

Classes `BufferedReader` (a subclass of abstract class `Reader`) and `BufferedWriter` (a subclass of abstract class `Writer`) enable buffering for character-based streams. Remember that character-based streams use Unicode characters—such streams can process data in any language that the Unicode character set represents.

Classes `CharArrayReader` and `CharArrayWriter` read and write, respectively, a stream of characters to a character array. A `LineNumberReader` (a subclass of `BufferedReader`) is a buffered character stream that keeps track of the number of lines read (i.e., a newline, a return or a carriage-return–line-feed combination). Keeping track of line numbers can be useful if the program needs to inform the reader of an error on a specific line.

Class `FileReader` (a subclass of `InputStreamReader`) and class `FileWriter` (a subclass of `OutputStreamWriter`) read characters from and write characters to a file, respectively. Class `PipedReader` and class `PipedWriter` implement piped-character streams that can be used to transfer information between threads. Class `StringReader` and `StringWriter` read characters from and write characters to `Strings`, respectively. A `PrintWriter` writes characters to a stream.

14.8 Opening Files with JFileChooser

Class `JFileChooser` displays a dialog (known as the `JFileChooser` dialog) that enables the user to easily select files or directories. To demonstrate the `JFileChooser` dialog, we enhance the example in Section 14.4, as shown in Figs. 14.22–14.23. The example now contains a graphical user interface, but still displays the same data as before. The constructor calls method `analyzePath` in line 34. This method then calls method `getFile` in line 68 to retrieve the `File` object.

```

1 // Fig. 14.22: FileDemonstration.java
2 // Demonstrating the File class.

724 Chapter 14 Files and Streams

```

19 // set up GUI
20 public FileDemonstration()
21 {
22     super( "Testing class File" );
23
24     outputArea = new JTextArea();
25
26     // add outputArea to scrollPane
27     scrollPane = new JScrollPane( outputArea );
28
29     add( scrollPane, BorderLayout.CENTER ); // add scrollPane to GUI
30
31     setSize( 400, 400 ); // set GUI size
32     setVisible( true ); // display GUI
33
34     analyzePath(); // create and analyze File object
35 } // end FileDemonstration constructor
36
37 // allow user to specify file name
38 private File getFile()
39 {
40     // display file dialog, so user can choose file to open
41     JFileChooser fileChooser = new JFileChooser();
42     fileChooser.setFileSelectionMode(
43         JFileChooser.FILES_AND_DIRECTORIES );
44
45     int result = fileChooser.showOpenDialog( this );
46
47     // if user clicked Cancel button on dialog, return
48     if ( result == JFileChooser.CANCEL_OPTION )
49         System.exit( 1 );
50
51     File fileName = fileChooser.getSelectedFile(); // get selected file
52
53     // display error if invalid
54     if ( ( fileName == null ) || ( fileName.getName().equals( "" ) ) )
55     {
56         JOptionPane.showMessageDialog( this, "Invalid File Name",
57             "Invalid File Name", JOptionPane.ERROR_MESSAGE );
58         System.exit( 1 );
59     } // end if
60
61     return fileName;
62 } // end method getFile
63
64 // display information about file user specifies
65 public void analyzePath()
66 {
67     // create File object based on user input
68     File name = getFile();
69
70     if ( name.exists() ) // if name exists, output information about it
71     {

```

Fig. 14.22 | Demonstrating JFileChooser. (Part 2 of 3.)

14.8 Opening Files with JFileChooser 725

```

72     // display file (or directory) information
73     outputArea.setText( String.format(
74         "%s%s\n%s\n%s\n%s\n%s\n%s\n%s\n%s\n%s\n%s\n",
75         name.getName(), " exists",
76         ( name.isFile() ? "is a file" : "is not a file" ),
77         ( name.isDirectory() ? "is a directory" :
78             "is not a directory" ),
79         ( name.isAbsolute() ? "is absolute path" :
80             "is not absolute path" ), "Last modified: ",
81         name.lastModified(), "Length: ", name.length(),
82         "Path: ", name.getPath(), "Absolute path: ",
83         name.getAbsolutePath(), "Parent: ", name.getParent() ) );
84
85     if ( name.isDirectory() ) // output directory listing
86     {
87         String directory[] = name.list();
88         outputArea.append( "\n\nDirectory contents:\n" );
89
90         for ( String directoryName : directory )
91             outputArea.append( directoryName + "\n" );
92     } // end else
93 } // end outer if
94 else // not file or directory, output error message
95 {
96     JOptionPane.showMessageDialog( this, name +
97         " does not exist.", "ERROR", JOptionPane.ERROR_MESSAGE );
98 } // end else
99 } // end method analyzePath
100 } // end class FileDemonstration

```

Fig. 14.22 | Demonstrating JFileChooser. (Part 3 of 3.)

Method `getFile` is defined in lines 38–62 of Fig. 14.22. Line 41 creates a `JFileChooser` and assigns its reference to `fileChooser`. Lines 42–43 call method `setFileSelectionMode` to specify what the user can select from the `fileChooser`. For this program, we use `JFileChooser` static constant `FILES_AND_DIRECTORIES` to indicate that files and directories can be selected. Other static constants include `FILES_ONLY` and `DIRECTORIES_ONLY`.

```

1 // Fig. 14.23: FileDemonstrationTest.java
2 // Testing the FileDmonstration class.
3 import javax.swing.JFrame;
4
5 public class FileDemonstrationTest
6 {
7     public static void main( String args[] )
8     {
9         FileDemonstration application = new FileDemonstration();
10        application.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11    } // end main
12 } // end class FileDemonstrationTest

```

Fig. 14.23 | Testing class FileDemonstration. (Part 1 of 2.)

726 Chapter 14 Files and Streams

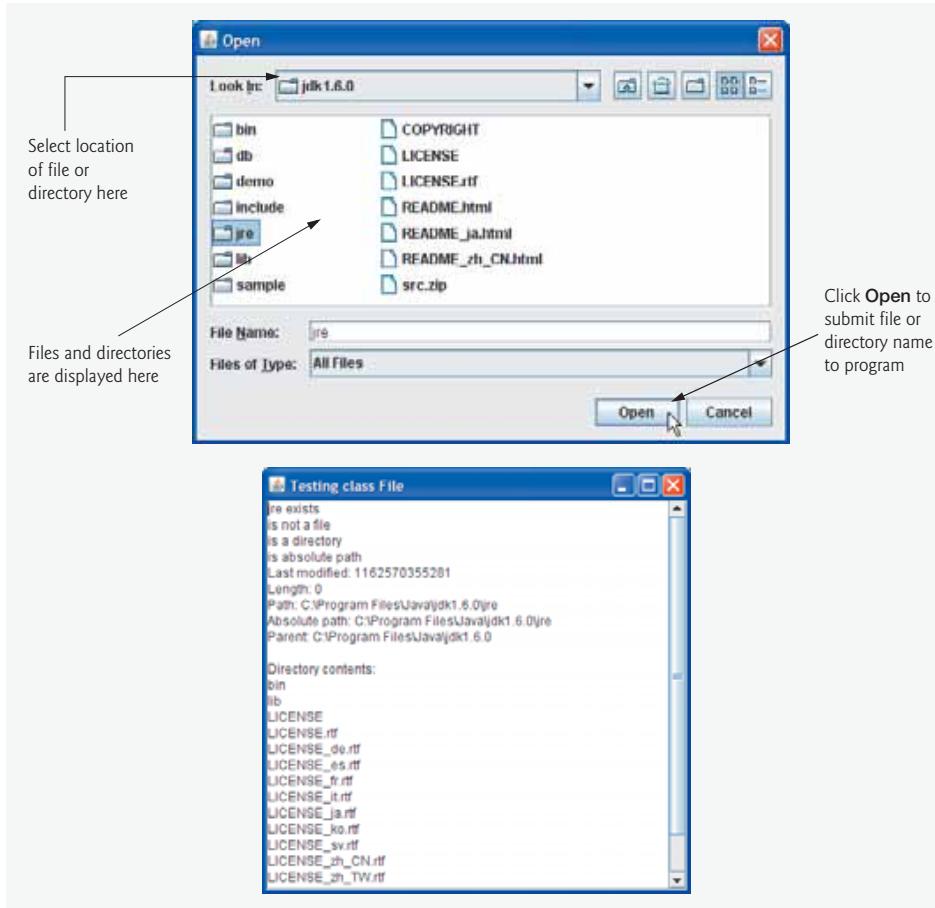

Fig. 14.23 | Testing class `FileDemonstration`. (Part 2 of 2.)

Line 45 calls method `showOpenDialog` to display the `JFileChooser` dialog titled `Open`. Argument `this` specifies the `JFileChooser` dialog's parent window, which determines the position of the dialog on the screen. If `null` is passed, the dialog is displayed in the center of the screen—otherwise, the dialog is centered over the application window (specified by the argument `this`). A `JFileChooser` dialog is a modal dialog that does not allow the user to interact with any other window in the program until the user closes the `JFileChooser` by clicking the `Open` or `Cancel` button. The user selects the drive, directory or file name, then clicks `Open`. Method `showOpenDialog` returns an integer specifying which button (`Open` or `Cancel`) the user clicked to close the dialog. Line 48 tests whether the user clicked `Cancel` by comparing the result with static constant `CANCEL_OPTION`. If they are equal, the program terminates. Line 51 retrieves the file the user selected by calling `JFileChooser` method `getSelectedFile`. The program then displays information about the selected file or directory.

14.9 Wrap-Up

In this chapter, you learned how to use file processing to manipulate persistent data. You learned that data is stored in computers as 0s and 1s, and that combinations of these values are used to form bytes, fields, records and eventually files. We compared character-based and byte-based streams, and introduced several file-processing classes provided by the `java.io` package. You used class `File` to retrieve information about a file or directory. You used sequential-access file processing to manipulate records that are stored in order by the record-key field. You learned the differences between text-file processing and object serialization, and used serialization to store and retrieve entire objects. The chapter concluded with an overview of other classes provided by the `java.io` package, and a small example of using a `JFileChooser` dialog to allow users to easily select files from a GUI. In the next chapter, you will learn the concept of recursion—methods that call themselves. Defining methods in this manner can lead to more intuitive programs.

Summary

Section 14.1 Introduction

- Data stored in variables and arrays is temporary—the data is lost when a local variable goes out of scope or when the program terminates. Computers use files for long-term retention of large amounts of data, even after the programs that created the data terminate.
- Persistent data maintained in files exists beyond the duration of program execution.
- Computers store files on secondary storage devices such as hard disks.

Section 14.2 Data Hierarchy

- The smallest data item in a computer can assume the value 0 or the value 1 and is called a bit. Ultimately, a computer processes all data items as combinations of zeros and ones.
- The computer's character set is the set of all characters used to write programs and represent data.
- Characters in Java are Unicode characters composed of two bytes, each composed of eight bits.
- Just as characters are composed of bits, fields are composed of characters or bytes. A field is a group of characters or bytes that conveys meaning.
- Data items processed by computers form a data hierarchy that becomes larger and more complex in structure as we progress from bits to characters to fields, and so on.
- Typically, several fields compose a record (implemented as a `class` in Java).
- A record is a group of related fields.
- A file is a group of related records.
- To facilitate the retrieval of specific records from a file, at least one field in each record is chosen as a record key. A record key identifies a record as belonging to a particular person or entity and is unique to each record.
- There are many ways to organize records in a file. The most common is called a sequential file, in which records are stored in order by the record-key field.
- A group of related files is often called a database. A collection of programs designed to create and manage databases is called a database management system (DBMS).

Section 14.3 Files and Streams

- Java views each file as a sequential stream of bytes.

728 Chapter 14 Files and Streams

- Every operating system provides a mechanism to determine the end of a file, such as an end-of-file marker or a count of the total bytes in the file that is recorded in a system-maintained administrative data structure.
- Byte-based streams represent data in binary format.
- Character-based streams represent data as sequences of characters.
- Files that are created using byte-based streams are binary files. Files created using character-based streams are text files. Text files can be read by text editors, whereas binary files are read by a program that converts the data to a human-readable format.
- Java also can associate streams with different devices. Three stream objects are associated with devices when a Java program begins executing—`System.in`, `System.out` and `System.err`.
- The `java.io` package includes definitions for stream classes, such as `FileInputStream` (for byte-based input from a file), `FileOutputStream` (for byte-based output to a file), `FileReader` (for character-based input from a file) and `FileWriter` (for character-based output to a file). Files are opened by creating objects of these stream classes.

Section 14.4 Class File

- Class `File` is used to obtain information about files and directories.
- Character-based input and output can be performed with classes `Scanner` and `Formatter`.
- Class `Formatter` enables formatted data to be output to the screen or to a file in a manner similar to `System.out.printf`.
- A file or directory's path specifies its location on disk.
- An absolute path contains all the directories, starting with the root directory, that lead to a specific file or directory. Every file or directory on a disk drive has the same root directory in its path.
- A relative path normally starts from the directory in which the application began executing.
- A separator character is used to separate directories and files in the path.

Section 14.5 Sequential-Access Text Files

- Java imposes no structure on a file—notions such as a record do not exist as part of the Java language. The programmer must structure files to meet an application's requirements.
- To retrieve data sequentially from a file, programs normally start reading from the beginning of the file and read all the data consecutively until the desired information is found.
- Data in many sequential files cannot be modified without the risk of destroying other data in the file. Therefore, records in a sequential-access file are not usually updated in place. Instead, the entire file is usually rewritten.

Section 14.6 Object Serialization

- Java provides a mechanism called object serialization that enables entire objects to be written to or read from a stream.
- A serialized object is an object represented as a sequence of bytes that includes the object's data as well as information about the object's type and the types of data stored in the object.
