- After a serialized object has been written into a file, it can be read from the file and deserialized—that is, the type information and bytes that represent the object and its data can be used to recreate the object in memory.
- Classes `ObjectInputStream` and `ObjectOutputStream`, which respectively implement the `ObjectInput` and `ObjectOutput` interfaces, enable entire objects to be read from or written to a stream (possibly a file).

Terminology **729**

- Only classes that implement interface `Serializable` can be serialized and deserialized with `ObjectOutputStream` and `ObjectInputStream`.

Section 14.7 Additional java.io Classes

- The `ObjectOutput` interface contains method `writeObject`, which takes an `Object` that implements interface `Serializable` as an argument and writes its information to an `OutputStream`.
- The `ObjectInput` interface contains method `readObject`, which reads and returns a reference to an `Object` from an `InputStream`. After an object has been read, its reference can be cast to the object's actual type.
- Buffering is an I/O-performance-enhancement technique. With a `BufferedOutputStream`, each output statement does not necessarily result in an actual physical transfer of data to the output device. Rather, each output operation is directed to a region in memory called a buffer that is large enough to hold the data of many output operations. Actual transfer to the output device is then performed in one large physical output operation each time the buffer fills.
- With a `BufferedInputStream`, many “logical” chunks of data from a file are read as one large physical input operation into a memory buffer. As a program requests each new chunk of data, it is taken from the buffer. When the buffer is empty, the next actual physical input operation from the input device is performed to read in the next group of “logical” chunks of data.

Section 14.8 Opening Files with JFileChooser

- Class `JFileChooser` is used to display a dialog that enables users of a program to easily select files from a GUI.

Terminology

absolute path	deserialized object
ASCII (American Standard Code for Information Interchange) character set	direct-access application
batch file	direct-access files
binary file	<code>DIRECTORIES_ONLY</code> constant of class <code>JFileChooser</code>
bit (binary digit)	directory
buffer	directory name
byte-based stream	disk
byte data type	end-of-file marker
<code>CANCEL_OPTION</code> constant of class <code>JFileChooser</code>	<code>EndOfFileException</code>
<code>canRead</code> method of class <code>File</code>	<code>exists</code> method of class <code>File</code>
<code>canWrite</code> method of class <code>File</code>	<code>exit</code> method of class <code>System</code>
capacity	field
character-based stream	file
character set	<code>File</code> class
<code>-classpath</code> command-line argument to <code>java</code>	file-position pointer
<code>-classpath</code> command-line argument to <code>javac</code>	file processing
data hierarchy	<code>FileInputStream</code> class
database	<code> FileOutputStream</code> class
database management system (DBMS)	<code>FileReader</code> class
<code>DataInput</code> interface	<code>FILES_AND_DIRECTORIES</code> constant of class <code>JFileChooser</code>
<code>DataInputStream</code> class	<code>FILES_ONLY</code> constant of class <code>JFileChooser</code>
<code>DataOutput</code> interface	<code>FileWriter</code> class
<code>DataOutputStream</code> class	fixed-length record
decimal digit	

730 Chapter 14 Files and Streams

Formatter class	relative path
getAbsolutePath method of class File	root directory
getName method of class File	secondary storage devices
getParent method of class File	sequential-access file
getPath method of class File	Serializable interface
getSelectedFile method of class JFileChooser	serialized object
InputStream class	setErr method of class System
IOException	setIn method of class System
isAbsolute method of class File	setOut method of class System
isDirectory method of class File	setSelectionMode of class JFileChooser
isFile method of class File	shell script
java.io package	showOpenDialog of class JFileChooser
JFileChooser class	standard error stream object
JFileChooser dialog	stream object
lastModified method of class File	stream of bytes
length method of class File	stream processing
list method of class File	System.err (standard error stream)
logical input operations	tagging interface
logical output operations	text file
memory buffer	transient keyword
NoSuchElementException	truncated
object serialization	Unicode character set
ObjectInputStream class	URI (Uniform Resource Identifier)
ObjectOutputStream class	wrapped byte array
optical disk	wrapping of stream objects
OutputStream class	writeBoolean method of interface DataOutput
parent directory	writeByte method of interface DataOutput
pathSeparator static field of class File	writeBytes method of interface DataOutput
persistent data	writeChar method of interface DataOutput
physical input operation	writeChars method of interface DataOutput
physical output operation	writeDouble method of interface DataOutput
PrintStream class	writeFloat method of interface DataOutput
PrintWriter class	writeInt method of interface DataOutput
read-only file	writeLong method of interface DataOutput
Reader class	writeObject method of class ObjectOutputStream
readLine method of class BufferedReader	writeObject method of interface ObjectOutputStream
readObject method of class ObjectInputStream	Writer class
readObject method of interface ObjectInput	writeShort method of interface DataOutput
record	writeUTF method of interface DataOutput
record key	

Self-Review Exercises

- 14.1** Fill in the blanks in each of the following statements:
- Ultimately, all data items processed by a computer are reduced to combinations of _____ and _____.
 - The smallest data item a computer can process is called a(n) _____.
 - A(n) _____ can sometimes be viewed as a group of related records.
 - Digits, letters and special symbols are referred to as _____.
 - A database is a group of related _____.
 - Object _____ normally enables a program to output error messages to the screen.

Self-Review Exercises **731**

- 14.2** Determine which of the following statements are *true* and which are *false*. If *false*, explain why.
- The programmer must explicitly create the stream objects `System.in`, `System.out` and `System.err`.
 - When reading data from a file using class `Scanner`, if the programmer wishes to read data in the file multiple times, the file must be closed and reopened to read from the beginning of the file. This moves the file-position pointer back to the beginning of the file.
 - Method `exists` of class `File` returns `true` if the name specified as the argument to the `File` constructor is a file or directory in the specified path.
 - Binary files are human readable.
 - An absolute path contains all the directories, starting with the root directory, that lead to a specific file or directory.
 - Class `Formatter` contains method `printf`, which enables formatted data to be output to the screen or to a file.
- 14.3** Complete the following tasks, assuming that each applies to the same program:
- Write a statement that opens file "oldmast.txt" for input—use Scanner variable `inOldMaster`.
 - Write a statement that opens file "trans.txt" for input—use Scanner variable `inTransaction`.
 - Write a statement that opens file "newmast.txt" for output (and creation)—use `Formatter` variable `outNewMaster`.
 - Write the statements needed to read a record from the file "oldmast.txt". The data read should be used to create an object of class `AccountRecord`—use Scanner variable `inOldMaster`. Assume that class `AccountRecord` is the same as the `AccountRecord` class in Fig. 14.6.
 - Write the statements needed to read a record from the file "trans.txt". The record is an object of class `TransactionRecord`—use Scanner variable `inTransaction`. Assume that class `TransactionRecord` contains method `setAccount` (which takes an `int`) to set the account number and method `setAmount` (which takes a `double`) to set the amount of the transaction.
 - Write a statement that outputs a record to the file "newmast.txt". The record is an object of type `AccountRecord`—use `Formatter` variable `outNewMaster`.
- 14.4** Complete the following tasks, assuming that each applies to the same program:
- Write a statement that opens file "oldmast.ser" for input—use `ObjectInputStream` variable `inOldMaster` to wrap a `FileInputStream` object.
 - Write a statement that opens file "trans.ser" for input—use `ObjectInputStream` variable `inTransaction` to wrap a `FileInputStream` object.
 - Write a statement that opens file "newmast.ser" for output (and creation)—use `ObjectOutputStream` variable `outNewMaster` to wrap a `FileOutputStream`.
 - Write a statement that reads a record from the file "oldmast.ser". The record is an object of class `AccountRecordSerializable`—use `ObjectInputStream` variable `inOldMaster`. Assume class `AccountRecordSerializable` is the same as the `AccountRecordSerializable` class in Fig. 14.17
 - Write a statement that reads a record from the file "trans.ser". The record is an object of class `TransactionRecord`—use `ObjectInputStream` variable `inTransaction`.
 - Write a statement that outputs a record to the file "newmast.ser". The record is an object of type `AccountRecordSerializable`—use `ObjectOutputStream` variable `outNewMaster`.

732 Chapter 14 Files and Streams

- 14.5** Find the error in each block of code and show how to correct it.

a) Assume that `account`, `company` and `amount` are declared.

```
ObjectOutputStream outputStream;
outputStream.writeInt( account );
outputStream.writeChars( company );
outputStream.writeDouble( amount );
```

b) The following statements should read a record from the file "payables.txt". The Scanner variable `inPayable` should be used to refer to this file.

```
Scanner inPayable = new Scanner( new File( "payables.txt" ) );
PayablesRecord record = ( PayablesRecord ) inPayable.readObject();
```

Answers to Self-Review Exercises

14.1 a) ones, zeros. b) bit. c) file. d) characters. e) files. f) `System.err`.

14.2 a) False. These three streams are created for the programmer when a Java application begins executing.

b) True.

c) True.

d) False. Text files are human readable.

e) True.

f) False. Class `Formatter` contains method `format`, which enables formatted data to be output to the screen or to a file.

14.3 a) `Scanner inOldMaster = new Scanner(new File("oldmast.txt"));`

b) `Scanner inTransaction = new Scanner(new File("trans.txt"));`

c) `Formatter outNewMaster = new Formatter("newmast.txt");`

d) `AccountRecord account = new AccountRecord();`

```
account.setAccount( inOldMaster.nextInt() );
account.setFirstName( inOldMaster.next() );
account.setLastName( inOldMaster.next() );
account.setBalance( inOldMaster.nextDouble() );
```

e) `TransactionRecord transaction = new Transaction();
transaction.setAccount(inTransaction.nextInt());
transaction.setAmount(inTransaction.nextDouble());`

f) `outNewMaster.format("%d %s %s %.2f\n",
account.getAccount(), account.getFirstName(),
account.getLastName(), account.getBalance());`

14.4 a) `ObjectInputStream inOldMaster = new ObjectInputStream(
new FileInputStream("oldmast.ser"));`

b) `ObjectInputStream inTransaction = new ObjectInputStream(
new FileInputStream("trans.ser"));`

c) `ObjectOutputStream outNewMaster = new ObjectOutputStream(
new FileOutputStream("newmast.ser"));`

d) `accountRecord = (AccountRecordSerializable) inOldMaster.readObject();`

e) `transactionRecord = (TransactionRecord) inTransaction.readObject();`

f) `outNewMaster.writeObject(newAccountRecord);`

14.5 a) Error: The file has not been opened before the attempt is made to output data to the stream.

Correction: Open a file for output by creating a new `ObjectOutputStream` object that wraps a `FileOutputStream` object.

Exercises **733**

- b) Error: This example uses text files with a Scanner, there is no object serialization. As a result, method `readObject` cannot be used to read that data from the file. Each piece of data must be read separately, then used to create a `PayablesRecord` object.
 Correction: Use methods of `InputStream` to read each piece of the `PayablesRecord` object.

Exercises

14.6 Fill in the blanks in each of the following statements:

- Computers store large amounts of data on secondary storage devices as _____.
- A(n) _____ is composed of several fields.
- To facilitate the retrieval of specific records from a file, one field in each record is chosen as a(n) _____.
- Files that are created using byte-based streams are referred to as _____ files, while files created using character-based streams are referred to as _____ files.
- The standard stream objects are _____, _____ and _____.

14.7 Determine which of the following statements are *true* and which are *false*. If *false*, explain why.

- The impressive functions performed by computers essentially involve the manipulation of zeros and ones.
- People specify programs and data items as characters. Computers then manipulate and process these characters as groups of zeros and ones.
- Data items represented in computers form a data hierarchy in which data items become larger and more complex as we progress from fields to characters to bits and so on.
- A record key identifies a record as belonging to a particular field.
- Companies store all their information in a single file to facilitate computer processing of the information. When a program creates a file, the file is retained by the computer for future reference.

14.8 (*File Matching*) Self-Review Exercise 14.3 asks the reader to write a series of single statements. Actually, these statements form the core of an important type of file-processing program, namely, a file-matching program. In commercial data processing, it is common to have several files in each application system. In an accounts receivable system, for example, there is generally a master file containing detailed information about each customer, such as the customer's name, address, telephone number, outstanding balance, credit limit, discount terms, contract arrangements and possibly a condensed history of recent purchases and cash payments.

As transactions occur (i.e., sales are made and payments arrive in the mail), information about them is entered into a file. At the end of each business period (a month for some companies, a week for others, and a day in some cases), the file of transactions (called "trans.txt") is applied to the master file (called "oldmast.txt") to update each account's purchase and payment record. During an update, the master file is rewritten as the file "newmast.txt", which is then used at the end of the next business period to begin the updating process again.

File-matching programs must deal with certain problems that do not arise in single-file programs. For example, a match does not always occur. If a customer on the master file has not made any purchases or cash payments in the current business period, no record for this customer will appear on the transaction file. Similarly, a customer who did make some purchases or cash payments could have just moved to this community, and if so, the company may not have had a chance to create a master record for this customer.

Write a complete file-matching accounts receivable program. Use the account number on each file as the record key for matching purposes. Assume that each file is a sequential text file with records stored in increasing account-number order.

- Define class `TransactionRecord`. Objects of this class contain an account number and amount for the transaction. Provide methods to modify and retrieve these values.

734 Chapter 14 Files and Streams

- b) Modify class `AccountRecord` in Fig. 14.6 to include method `combine`, which takes a `TransactionRecord` object and combines the balance of the `AccountRecord` object and the amount value of the `TransactionRecord` object.
- c) Write a program to create data for testing the program. Use the sample account data in Figs. 14.24 and 14.25. Run the program to create the files `trans.txt` and `oldmast.txt`, to be used by your file-matching program.
- d) Create class `FileMatch` to perform the file-matching functionality. The class should contain methods that read `oldmast.txt` and `trans.txt`. When a match occurs (i.e., records with the same account number appear in both the master file and the transaction file), add the dollar amount in the transaction record to the current balance in the master record, and write the "newmast.txt" record. (Assume that purchases are indicated by positive amounts in the transaction file and payments by negative amounts.) When there is a master record for a particular account, but no corresponding transaction record, merely write the master record to "newmast.txt". When there is a transaction record, but no corresponding master record, print to a log file the message "Unmatched transaction record for account number..." (fill in the account number from the transaction record). The log file should be a text file named "log.txt".

14.9 (*File Matching with Multiple Transactions*) It is possible (and actually common) to have several transaction records with the same record key. This situation occurs, for example, when a customer makes several purchases and cash payments during a business period. Rewrite your accounts receivable file-matching program from Exercise 14.8 to provide for the possibility of handling several transaction records with the same record key. Modify the test data of `CreateData.java` to include the additional transaction records in Fig. 14.26.

Master file account number	Name	Balance
100	Alan Jones	348.17
300	Mary Smith	27.19
500	Sam Sharp	0.00
700	Suzy Green	-14.22

Fig. 14.24 | Sample data for master file.

Transaction file account number	Transaction amount
100	27.14
300	62.11
400	100.56
900	82.17

Fig. 14.25 | Sample data for transaction file.

Exercises **735**

Account number	Dollar amount
300	83.89
700	80.78
700	1.53

Fig. 14.26 | Additional transaction records.

14.10 (*File Matching with Object Serialization*) Recreate your solution for Exercise 14.9 using object serialization. Use the statements from Exercise 14.4 as your basis for this program. You may want to create applications to read the data stored in the .ser files—the code in Section 14.6.2 can be modified for this purpose.

14.11 (*Telephone-Number Word Generator*) Standard telephone keypads contain the digits zero through nine. The numbers two through nine each have three letters associated with them (Fig. 14.27). Many people find it difficult to memorize phone numbers, so they use the correspondence between digits and letters to develop seven-letter words that correspond to their phone numbers. For example, a person whose telephone number is 686-2377 might use the correspondence indicated in Fig. 14.27 to develop the seven-letter word “NUMBERS.” Every seven-letter word corresponds to exactly one seven-digit telephone number. A restaurant wishing to increase its takeout business could surely do so with the number 825-3688 (i.e., “TAKEOUT”).

Digit	Letters
2	A B C
3	D E F
4	G H I
5	J K L
6	M N O
7	P R S
8	T U V
9	W X Y

Fig. 14.27 | Telephone keypad digits and letters.

Every seven-letter phone number corresponds to many different seven-letter words. Unfortunately, most of these words represent unrecognizable juxtapositions of letters. It is possible, however, that the owner of a barbershop would be pleased to know that the shop’s telephone number, 424-7288, corresponds to “HAIRCUT.” The owner of a liquor store would, no doubt, be delighted to find that the store’s number, 233-7226, corresponds to “BEERCAN.” A veterinarian with the phone number 738-2273 would be pleased to know that the number corresponds to the letters “PETCARE.” An automotive dealership would be pleased to know that the dealership number, 639-2277, corresponds to “NEWCARS.”

736 Chapter 14 Files and Streams

Write a program that, given a seven-digit number, uses a `PrintStream` object to write to a file every possible seven-letter word combination corresponding to that number. There are 2,187 (3^7) such combinations. Avoid phone numbers with the digits 0 and 1.

14.12 (*Student Poll*) Figure 7.8 contains an array of survey responses that is hard coded into the program. Suppose we wish to process survey results that are stored in a file. This exercise requires two separate programs. First, create an application that prompts the user for survey responses and outputs each response to a file. Use a `Formatter` to create a file called `numbers.txt`. Each integer should be written using method `format`. Then modify the program in Fig. 7.8 to read the survey responses from `numbers.txt`. The responses should be read from the file by using a `Scanner`. Method `nextInt` should be used to input one integer at a time from the file. The program should continue to read responses until it reaches the end of file. The results should be output to the text file "output.txt".

14.13 Modify Exercise 11.18 to allow the user to save a drawing into a file or load a prior drawing from a file using object serialization. Add buttons **Load** (to read objects from a file), **Save** (to write objects to a file) and **Generate Shapes** (to display a random set of shapes on the screen). Use an `ObjectOutputStream` to write to the file and an `ObjectInputStream` to read from the file. Write the array of `MyShape` objects using method `writeObject` (class `ObjectOutputStream`), and read the array using method `readObject` (`ObjectInputStream`). Note that the object-serialization mechanism can read or write entire arrays—it is not necessary to manipulate each element of the array of `MyShape` objects individually. It is simply required that all the shapes be `Serializable`. For both the **Load** and **Save** buttons, use a `JFileChooser` to allow the user to select the file in which the shapes will be stored or from which they will be read. When the user first runs the program, no shapes should be displayed on the screen. The user can display shapes by opening a previously saved file of shapes or by clicking the **Generate Shapes** button. When the **Generate Shapes** button is clicked, the application should generate a random number of shapes up to a total of 15. Once there are shapes on the screen, users can save them to a file using the **Save** button.

Recursion

We must learn to explore all the options and possibilities that confront us in a complex and rapidly changing world.

—James William Fulbright

O! thou hast damnable iteration, and art indeed able to corrupt a saint.

—William Shakespeare

It's a poor sort of memory that only works backwards.

—Lewis Carroll

Life can only be understood backwards; but it must be lived forwards.

—Soren Kierkegaard

Push on—keep moving.

—Thomas Morton

OBJECTIVES

In this chapter you will learn:

- The concept of recursion.
- How to write and use recursive methods.
- How to determine the base case and recursion step in a recursive algorithm.
- How recursive method calls are handled by the system.
- The differences between recursion and iteration, and when it is appropriate to use each.
- What the geometric shapes called fractals are and how to draw them using recursion.
- What recursive backtracking is and why it is an effective problem-solving technique.

738 Chapter 15 Recursion

Outline

- 15.1** Introduction
- 15.2** Recursion Concepts
- 15.3** Example Using Recursion: Factorials
- 15.4** Example Using Recursion: Fibonacci Series
- 15.5** Recursion and the Method-Call Stack
- 15.6** Recursion vs. Iteration
- 15.7** Towers of Hanoi
- 15.8** Fractals
- 15.9** Recursive Backtracking
- 15.10** Wrap-Up
- 15.11** Internet and Web Resources

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

15.1 Introduction

The programs we have discussed so far are generally structured as methods that call one another in a disciplined, hierarchical manner. For some problems, however, it is useful to have a method call itself. Such a method is known as a **recursive method**. A recursive method can be called either directly or indirectly through another method. Recursion is an important topic discussed at length in upper-level computer science courses. In this chapter, we consider recursion conceptually, then present several programs containing recursive methods. Figure 15.1 summarizes the recursion examples and exercises in the book.

Chapter	Recursion examples and exercises in this book
15	Factorial Method (Figs. 15.3 and 15.4) Fibonacci Method (Figs. 15.5 and 15.6) Towers of Hanoi (Figs. 15.13 and 15.14) Fractals (Figs. 15.21 and 15.22) What Does This Code Do? (Exercise 15.7, Exercise 15.12 and Exercise 15.13) Find the Error in the Following Code (Exercise 15.8) Raising an Integer to an Integer Power (Exercise 15.9) Visualizing Recursion (Exercise 15.10) Greatest Common Divisor (Exercise 15.11) Determine Whether a String Is a Palindrome (Exercise 15.14) Eight Queens (Exercise 15.15) Print an Array (Exercise 15.16) Print an Array Backward (Exercise 15.17) Minimum Value in an Array (Exercise 15.18) Star Fractal (Exercise 15.19) Maze Traversal Using Recursive Backtracking (Exercise 15.20) Generating Mazes Randomly (Exercise 15.21) Mazes of Any Size (Exercise 15.22) Time Needed to Calculate a Fibonacci Number (Exercise 15.23)

Fig. 15.1 | Summary of the recursion examples and exercises in this text. (Part 2 of 2.)

15.2 Recursion Concepts

Recursive problem-solving approaches have a number of elements in common. When a recursive method is called to solve a problem, the method actually is capable of solving only the simplest case(s), or **base case(s)**. If the method is called with a base case, the method returns a result. If the method is called with a more complex problem, the method typically divides the problem into two conceptual pieces—a piece that the method knows how to do and a piece that it does not know how to do. To make recursion feasible, the latter piece must resemble the original problem, but be a slightly simpler or smaller version of it. Because this new problem looks like the original problem, the method calls a fresh copy of itself to work on the smaller problem—this is referred to as a **recursive call** and is also called the **recursion step**. The recursion step normally includes a return statement, because its result will be combined with the portion of the problem the method knew how to solve to form a result that will be passed back to the original caller. This concept of separating the problem into two smaller portions is a form of the divide-and-conquer approach introduced in Chapter 6.

The recursion step executes while the original call to the method is still active (i.e., while it has not finished executing). It can result in many more recursive calls as the method divides each new subproblem into two conceptual pieces. For the recursion to eventually terminate, each time the method calls itself with a simpler version of the original problem, the sequence of smaller and smaller problems must converge on a base case. At that point, the method recognizes the base case and returns a result to the previous copy of the method. A sequence of returns ensues until the original method call returns the final result to the caller.

A recursive method may call another method, which may in turn make a call back to the recursive method. Such a process is known as an **indirect recursive call** or **indirect recursion**. For example, method A calls method B, which makes a call back to method A. This is still considered recursion, because the second call to method A is made while the first call to method A is active—that is, the first call to method A has not yet finished executing (because it is waiting on method B to return a result to it) and has not returned to method A's original caller.

740 Chapter 15 Recursion

To better understand the concept of recursion, let us look at an example of recursion that is quite common to computer users—the recursive definition of a directory on a computer. A computer normally stores related files in a directory. A directory can be empty, can contain files and/or can contain other directories (usually referred to as subdirectories). Each of these subdirectories, in turn, may also contain both files and directories. If we want to list each file in a directory (including all the files in the directory's subdirectories), we need to create a method that first lists the initial directory's files, then makes recursive calls to list the files in each of that directory's subdirectories. The base case occurs when a directory is reached that does not contain any subdirectories. At this point, all the files in the original directory have been listed and no further recursion is necessary.

15.3 Example Using Recursion: Factorials

Let us write a recursive program to perform a popular mathematical calculation. Consider the factorial of a positive integer n , written $n!$ (and pronounced “ n factorial”), which is the product

$$n \cdot (n - 1) \cdot (n - 2) \cdot \dots \cdot 1$$

with $1!$ equal to 1 and $0!$ defined to be 1. For example, $5!$ is the product $5 \cdot 4 \cdot 3 \cdot 2 \cdot 1$, which is equal to 120.

The factorial of integer `number` (where `number` ≥ 0) can be calculated **iteratively** (non-recursively) using a `for` statement as follows:

```
factorial = 1;
for (int counter = number; counter >= 1; counter--)
    factorial *= counter;
```

A recursive declaration of the factorial method is arrived at by observing the following relationship:

$$n! = n \cdot (n - 1)!$$

For example, $5!$ is clearly equal to $5 \cdot 4!$, as is shown by the following equations:

$$\begin{aligned} 5! &= 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 \\ 5! &= 5 \cdot (4 \cdot 3 \cdot 2 \cdot 1) \\ 5! &= 5 \cdot (4!) \end{aligned}$$

The evaluation of $5!$ would proceed as shown in Fig. 15.2. Figure 15.2(a) shows how the succession of recursive calls proceeds until $1!$ (the base case) is evaluated to be 1, which terminates the recursion. Figure 15.2(b) shows the values returned from each recursive call to its caller until the final value is calculated and returned.

Figure 15.3 uses recursion to calculate and print the factorials of the integers from 0–10. The recursive method `factorial` (lines 7–13) first tests to determine whether a terminating condition (line 9) is `true`. If `number` is less than or equal to 1 (the base case), `factorial` returns 1, no further recursion is necessary and the method returns. If `number` is greater than 1, line 12 expresses the problem as the product of `number` and a recursive call

15.3 Example Using Recursion: Factorials 741

to factorial evaluating the factorial of `number - 1`, which is a slightly smaller problem than the original calculation, `factorial(number)`.

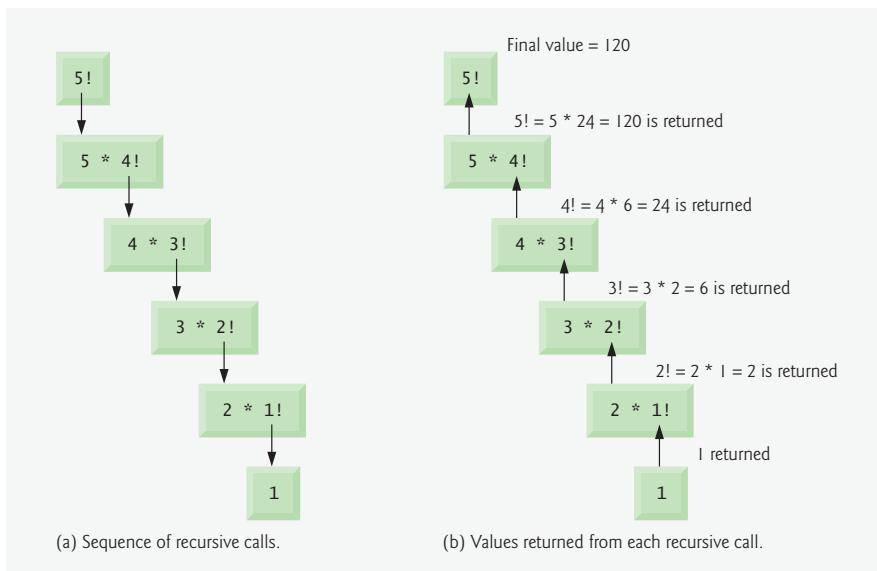

Fig. 15.2 | Recursive evaluation of $5!$.

```

1 // Fig. 15.3: FactorialCalculator.java
2 // Recursive factorial method.
3
4 public class FactorialCalculator
5 {
6     // recursive method factorial
7     public long factorial( long number )
8     {
9         if ( number <= 1 ) // test for base case
10            return 1; // base cases:  $0! = 1$  and  $1! = 1$ 
11        else // recursion step
12            return number * factorial( number - 1 );
13    } // end method factorial
14
15    // output factorials for values 0-10
16    public void displayFactorials()
17    {
18        // calculate the factorials of 0 through 10
19        for ( int counter = 0; counter <= 10; counter++ )
20            System.out.printf( "%d! = %d\n", counter, factorial( counter ) );
21    } // end method displayFactorials
22 } // end class FactorialCalculator
  
```

742 Chapter 15 Recursion

**Common Programming Error 15.1**

*Either omitting the base case or writing the recursion step incorrectly so that it does not converge on the base case can cause a logic error known as **infinite recursion**, where recursive calls are continuously made until memory has been exhausted. This error is analogous to the problem of an infinite loop in an iterative (nonrecursive) solution.*

Method `displayFactorials` (lines 16–21) displays the factorials of 0–10. The call to method `factorial` occurs in line 20. Method `factorial` receives a parameter of type `long` and returns a result of type `long`. Figure 15.4 tests our `factorial` and `displayFactorials` methods by calling `displayFactorials` (line 10). The output of Fig. 15.4 shows that factorial values become large quickly. We use type `long` (which can represent relatively large integers) so the program can calculate factorials greater than $12!$. Unfortunately, the `factorial` method produces large values so quickly that factorial values soon exceed the maximum value that can be stored even in a `long` variable.

Due to the limitations of integral types, `float` or `double` variables may ultimately be needed to calculate factorials of larger numbers. This points to a weakness in most programming languages—namely, that the languages are not easily extended to handle unique application requirements. As we saw in Chapter 9, Java is an extensible language that allows us to create arbitrarily large integers if we wish. In fact, package `java.math` provides classes `BigInteger` and `BigDecimal` explicitly for arbitrary precision mathematical calculations that cannot be performed with primitive types. For more information on these classes visit, java.sun.com/javase/6/docs/api/java/math/BigInteger.html and java.sun.com/javase/6/docs/api/java/math/BigDecimal.html, respectively.

15.4 Example Using Recursion: Fibonacci Series **743**

15.4 Example Using Recursion: Fibonacci Series

The **Fibonacci series**,

0, 1, 1, 2, 3, 5, 8, 13, 21, ...

begins with 0 and 1 and has the property that each subsequent Fibonacci number is the sum of the previous two Fibonacci numbers. This series occurs in nature and describes a form of spiral. The ratio of successive Fibonacci numbers converges on a constant value of 1.618..., a number that has been called the **golden ratio** or the **golden mean**. Humans tend to find the golden mean aesthetically pleasing. Architects often design windows, rooms and buildings whose length and width are in the ratio of the golden mean. Postcards are often designed with a golden-mean length-to-width ratio.

The Fibonacci series may be defined recursively as follows:

```
fibonacci(0) = 0
fibonacci(1) = 1
fibonacci(n) = fibonacci(n - 1) + fibonacci(n - 2)
```

Note that there are two base cases for the Fibonacci calculation: `fibonacci(0)` is defined to be 0, and `fibonacci(1)` is defined to be 1. The program in Fig. 15.5 calculates the *i*th Fibonacci number recursively, using method `fibonacci` (lines 7–13). Method `displayFibonacci` (lines 15–20) tests `fibonacci`, displaying the Fibonacci values of 0–10. The variable counter created in the `for` header in line 17 indicates which Fibonacci number to calculate for each iteration of the `for` statement. Fibonacci numbers tend to become large quickly. Therefore, we use type `long` as the parameter type and the return type of method `fibonacci`. Line 9 of Fig. 15.6 calls method `displayFibonacci` (line 9) to calculate the Fibonacci values.

```
1 // Fig. 15.5: FibonacciCalculator.java
2 // Recursive fibonacci method.
3
4 public class FibonacciCalculator
5 {
6     // recursive declaration of method fibonacci
7     public long fibonacci( long number )
8     {
9         if ( ( number == 0 ) || ( number == 1 ) ) // base cases
10            return number;
11        else // recursion step
12            return fibonacci( number - 1 ) + fibonacci( number - 2 );
13    } // end method fibonacci
14
15    public void displayFibonacci()
16    {
17        for ( int counter = 0; counter <= 10; counter++ )
18            System.out.printf( "Fibonacci of %d is: %d\n", counter,
19                               fibonacci( counter ) );
20    } // end method displayFibonacci
21 } // end class FibonacciCalculator
```

Fig. 15.5 | Fibonacci numbers generated with a recursive method.

744 Chapter 15 Recursion

```

1 // Fig. 15.6: FibonacciTest.java

3
4 public class FibonacciTest
5 {
6     public static void main( String args[] )
7     {
8         FibonacciCalculator fibonacciCalculator = new FibonacciCalculator();
9         fibonacciCalculator.displayFibonacci();
10    } // end main
11 } // end class FibonacciTest

```

Fibonacci of 0 is: 0
 Fibonacci of 1 is: 1
 Fibonacci of 2 is: 1
 Fibonacci of 3 is: 2
 Fibonacci of 4 is: 3
 Fibonacci of 5 is: 5
 Fibonacci of 6 is: 8
 Fibonacci of 7 is: 13
 Fibonacci of 8 is: 21
 Fibonacci of 9 is: 34
 Fibonacci of 10 is: 55

Fig. 15.6 | Testing the fibonacci method.

The call to method `fibonacci` (line 19 of Fig. 15.5) from `displayFibonacci` is not a recursive call, but all subsequent calls to `fibonacci` performed from the body of `fibonacci` (line 12 of Fig. 15.5) are recursive, because at that point the calls are initiated by method `fibonacci` itself. Each time `fibonacci` is called, it immediately tests for the base cases—number equal to 0 or number equal to 1 (line 9). If this condition is true, `fibonacci` simply returns number because `fibonacci(0)` is 0, and `fibonacci(1)` is 1. Interestingly, if number is greater than 1, the recursion step generates *two* recursive calls (line 12), each for a slightly smaller problem than the original call to `fibonacci`.

Figure 15.7 shows how method `fibonacci` evaluates `fibonacci(3)`. Note that at the bottom of the figure, we are left with the values 1, 0 and 1—the results of evaluating the base cases. The first two return values (from left to right), 1 and 0, are returned as the values for the calls `fibonacci(1)` and `fibonacci(0)`. The sum 1 plus 0 is returned as the value of `fibonacci(2)`. This is added to the result (1) of the call to `fibonacci(1)`, producing the value 2. This final value is then returned as the value of `fibonacci(3)`.

Figure 15.7 raises some interesting issues about the order in which Java compilers evaluate the operands of operators. This order is different from the order in which operators are applied to their operands—namely, the order dictated by the rules of operator precedence. From Figure 15.7, it appears that while `fibonacci(3)` is being evaluated, two recursive calls will be made—`fibonacci(2)` and `fibonacci(1)`. But in what order will these calls be made? The Java language specifies that the order of evaluation of the operands is from left to right. Thus, the call `fibonacci(2)` is made first and the call `fibonacci(1)` is made second.

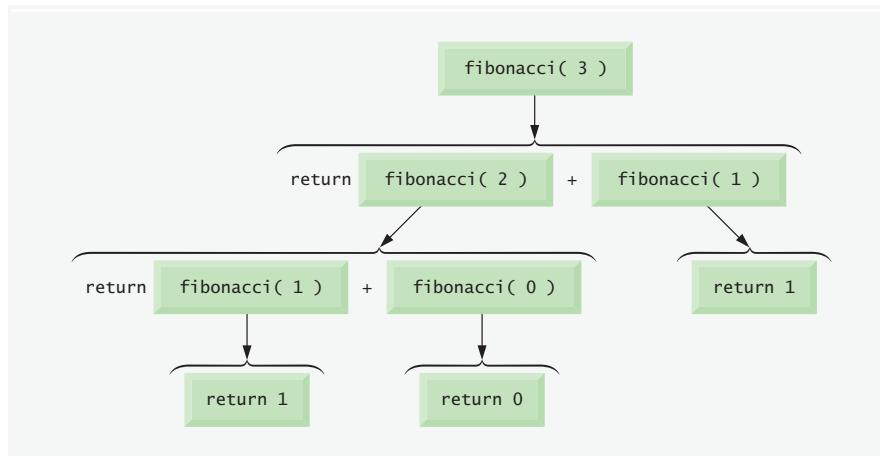

15.4 Example Using Recursion: Fibonacci Series **745**

Fig. 15.7 | Set of recursive calls for `fibonacci(3)`.

A word of caution is in order about recursive programs like the one we use here to generate Fibonacci numbers. Each invocation of the `fibonacci` method that does not match one of the base cases (0 or 1) results in two more recursive calls to the `fibonacci` method. Hence, this set of recursive calls rapidly gets out of hand. Calculating the Fibonacci value of 20 with the program in Fig. 15.5 requires 21,891 calls to the `fibonacci` method; calculating the Fibonacci value of 30 requires 2,692,537 calls! As you try to calculate larger Fibonacci values, you will notice that each consecutive Fibonacci number you use the application to calculate results in a substantial increase in calculation time and in the number of calls to the `fibonacci` method. For example, the Fibonacci value of 31 requires 4,356,617 calls, and the Fibonacci value of 32 requires 7,049,155 calls! As you can see, the number of calls to `fibonacci` increases quickly—1,664,080 additional calls between Fibonacci values of 30 and 31 and 2,692,538 additional calls between Fibonacci values of 31 and 32! The difference in the number of calls made between Fibonacci values of 31 and 32 is more than 1.5 times the difference in the number of calls for Fibonacci values between 30 and 31. Problems of this nature can humble even the world's most powerful computers. [Note: In the field of complexity theory, computer scientists study how hard algorithms work to complete their tasks. Complexity issues are discussed in detail in the upper-level computer science curriculum course generally called "Algorithms." We introduce various complexity issues in Chapter 16, Searching and Sorting.] In the exercises, you will be asked to enhance the Fibonacci program of Fig. 15.5 such that it calculates the approximate amount of time required to perform the calculation. For this purpose, you will call static `System` method `currentTimeMillis`, which takes no arguments and returns the computer's current time in milliseconds.

Performance Tip 15.1

Avoid Fibonacci-style recursive programs, because they result in an exponential “explosion” of method calls.

746 Chapter 15 Recursion

15.5 Recursion and the Method-Call Stack

In Chapter 6, the stack data structure was introduced in the context of understanding how Java performs method calls. We discussed both the method-call stack (also known as the program execution stack) and activation records. In this section, we will use these concepts to demonstrate how the program execution stack handles recursive method calls.

Let's begin by returning to the Fibonacci example—specifically, calling method `fibonacci` with the value 3, as in Fig. 15.7. To show the order in which the method calls' activation records are placed on the stack, we have lettered the method calls in Fig. 15.8.

When the first method call (A) is made, an activation record is pushed onto the program execution stack which contains the value of the local variable `number` (3, in this case). The program execution stack, including the activation record for method call A, is illustrated in part (a) of Fig. 15.9. [Note: We use a simplified stack here. In an actual computer, the program execution stack and its activation records would be more complex than in Fig. 15.9, containing such information as where the method call is to return to when it has completed execution.]

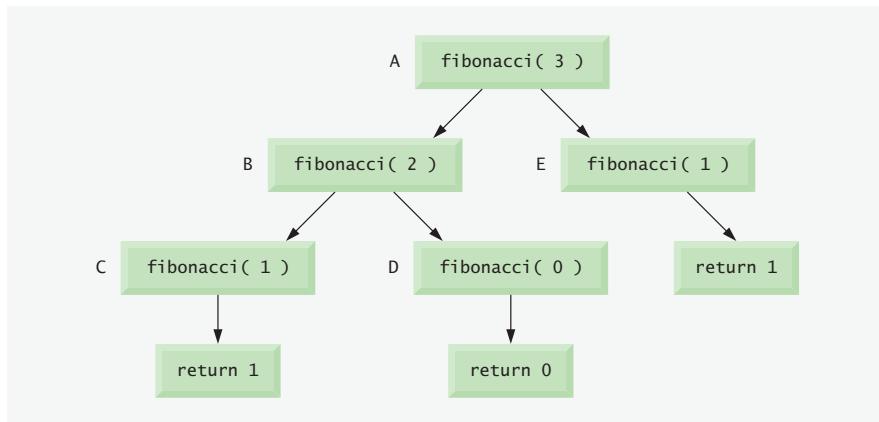

Fig. 15.8 | Method calls made within the call `fibonacci(3)`.

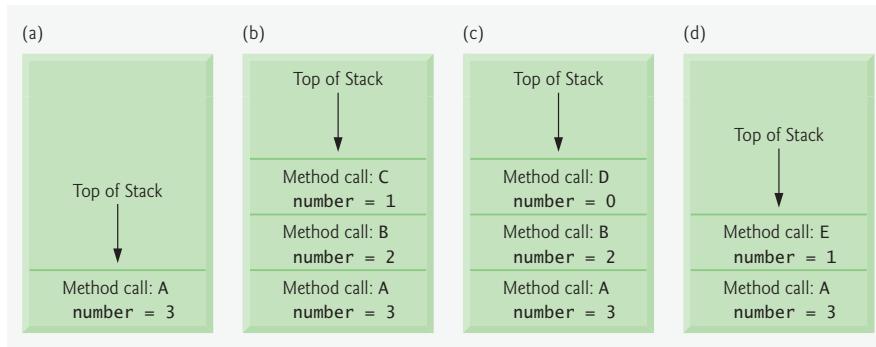

Fig. 15.9 | Method calls on the program execution stack.

15.6 Recursion vs. Iteration **747**

Within method call A, method calls B and E are made. The original method call has not yet completed, so its activation record remains on the stack. The first method call to be made from within A is method call B, so the activation record for method call B is pushed onto the stack on top of the activation record for method call A. Method call B must execute and complete before method call E is made. Within method call B, method calls C and D will be made. Method call C is made first, and its activation record is pushed onto the stack [part (b) of Fig. 15.9]. Method call B has not yet finished, and its activation record is still on the method-call stack. When method call C executes, it does not make any further method calls, but simply returns the value 1. When this method returns, its activation record is popped off the top of the stack. The method call at the top of the stack is now B, which continues to execute by performing method call D. The activation record for method call D is pushed onto the stack [part (c) of Fig. 15.9]. Method call D completes without making any more method calls, and returns the value 0. The activation record for this method call is then popped off the stack. Now, both method calls made from within method call B have returned. Method call B continues to execute, returning the value 1. Method call B completes and its activation record is popped off the stack. At this point, the activation record for method call A is at the top of the stack and the method continues its execution. This method makes method call E, whose activation record is now pushed onto the stack [part (d) of Fig. 15.9]. Method call E completes and returns the value 1. The activation record for this method call is popped off the stack, and once again method call A continues to execute. At this point, method call A will not be making any other method calls and can finish its execution, returning the value 2 to A's caller (`fibonacci(3) = 2`). A's activation record is popped off the stack. Note that the executing method is always the one whose activation record is at the top of the stack, and the activation record for that method contains the values of its local variables.

15.6 Recursion vs. Iteration

In the preceding sections, we studied methods `factorial` and `fibonacci`, which can easily be implemented either recursively or iteratively. In this section, we compare the two approaches and discuss why the programmer might choose one approach over the other in a particular situation.

Both iteration and recursion are based on a control statement: Iteration uses a repetition statement (e.g., `for`, `while` or `do...while`), whereas recursion uses a selection statement (e.g., `if`, `if...else` or `switch`). Both iteration and recursion involve repetition: Iteration explicitly uses a repetition statement, whereas recursion achieves repetition through repeated method calls. Iteration and recursion each involve a termination test: Iteration terminates when the loop-continuation condition fails, whereas recursion terminates when a base case is reached. Iteration with counter-controlled repetition and recursion each gradually approach termination: Iteration keeps modifying a counter until the counter assumes a value that makes the loop-continuation condition fail, whereas recursion keeps producing smaller versions of the original problem until the base case is reached. Both iteration and recursion can occur infinitely: An infinite loop occurs with iteration if the loop-continuation test never becomes false, whereas infinite recursion occurs if the recursion step does not reduce the problem each time in a manner that converges on the base case, or if the base case is not tested.

748 Chapter 15 Recursion

To illustrate the differences between iteration and recursion, let us examine an iterative solution to the factorial problem (Figs. 15.10–15.11). Note that a repetition statement is used (lines 12–13 of Fig. 15.10) rather than the selection statement of the recursive solution (lines 9–12 of Fig. 15.3). Note that both solutions use a termination test. In the recursive solution, line 9 tests for the base case. In the iterative solution, line 12 tests the loop-continuation condition—if the test fails, the loop terminates. Finally, note that instead of producing smaller versions of the original problem, the iterative solution uses a counter that is modified until the loop-continuation condition becomes false.

```

9! = 362880
10! = 3628800

```

Fig. 15.11 | Testing the iterative factorial solution. (Part 2 of 2.)

Recursion has many negatives. It repeatedly invokes the mechanism, and consequently the overhead, of method calls. This repetition can be expensive in terms of both processor time and memory space. Each recursive call causes another copy of the method (actually, only the method's variables, stored in the activation record) to be created—this set of copies can consume considerable memory space. Since iteration occurs within a method, repeated method calls and extra memory assignment are avoided. So why choose recursion?

Software Engineering Observation 15.1

Any problem that can be solved recursively can also be solved iteratively (nonrecursively). A recursive approach is normally preferred over an iterative approach when the recursive approach more naturally mirrors the problem and results in a program that is easier to understand and debug. A recursive approach can often be implemented with fewer lines of code. Another reason to choose a recursive approach is that an iterative one might not be apparent.

Performance Tip 15.2

Avoid using recursion in situations requiring high performance. Recursive calls take time and consume additional memory.

Common Programming Error 15.2

Accidentally having a nonrecursive method call itself either directly or indirectly through another method can cause infinite recursion.

15.7 Towers of Hanoi

In the preceding sections of this chapter, we studied methods that can be easily implemented both recursively and iteratively. In this section, we present a problem whose recursive solution demonstrates the elegance of recursion, and whose iterative solution may not be as apparent.

The **Towers of Hanoi** is one of the classic problems every budding computer scientist must grapple with. Legend has it that in a temple in the Far East, priests are attempting to move a stack of golden disks from one diamond peg to another (Fig. 15.12). The initial stack has 64 disks threaded onto one peg and arranged from bottom to top by decreasing size. The priests are attempting to move the stack from one peg to another under the constraints that exactly one disk is moved at a time and at no time may a larger disk be placed

750 Chapter 15 Recursion

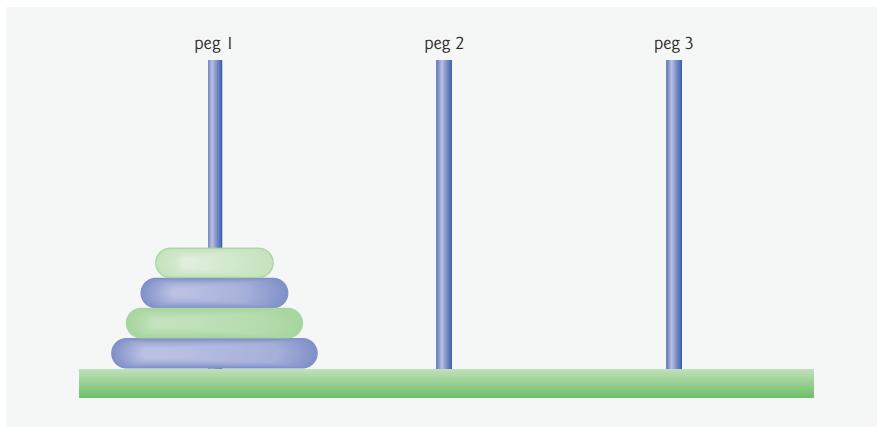

Fig. 15.12 | Towers of Hanoi for the case with four disks.

above a smaller disk. Three pegs are provided, one being used for temporarily holding disks. Supposedly, the world will end when the priests complete their task, so there is little incentive for us to facilitate their efforts.

Let's assume that the priests are attempting to move the disks from peg 1 to peg 3. We wish to develop an algorithm that prints the precise sequence of peg-to-peg disk transfers.

If we try to find an iterative solution, we will likely find ourselves hopelessly "knotted up" in managing the disks. Instead, attacking this problem recursively quickly yields a solution. Moving n disks can be viewed in terms of moving only $n - 1$ disks (hence the recursion) as follows:

1. Move $n - 1$ disks from peg 1 to peg 2, using peg 3 as a temporary holding area.
2. Move the last disk (the largest) from peg 1 to peg 3.
3. Move $n - 1$ disks from peg 2 to peg 3, using peg 1 as a temporary holding area.

The process ends when the last task involves moving $n = 1$ disk (i.e., the base case). This task is accomplished by simply moving the disk, without the need for a temporary holding area.

The program of Figs. 15.13–15.14 solves the Towers of Hanoi. In the constructor (lines 9–12), the number of disks to be moved (`numDisks`) is initialized. Method `solveTowers` (lines 15–34) solves the Towers of Hanoi puzzle, given the total number of disks (in this case 3), the starting peg, the ending peg, and the temporary holding peg as parameters. The base case (lines 19–23) occurs when only one disk needs to be moved from the starting peg to the ending peg. In the recursion step (lines 27–33), line 27 moves $disks - 1$ disks from the first peg (`sourcePeg`) to the temporary holding peg (`tempPeg`). When all but one of the disks have been moved to the temporary peg, line 30 moves the largest disk from the start peg to the destination peg. Line 33 finishes the rest of the moves by calling the method `solveTowers` to recursively move $disks - 1$ disks from the temporary peg (`tempPeg`) to the destination peg (`destinationPeg`), this time using the first peg (`sourcePeg`) as the temporary peg.

15.7 Towers of Hanoi 751

```

1 // Fig. 15.13: TowersOfHanoi.java
2 // Program solves the towers of Hanoi problem, and
3 // demonstrates recursion.
4
5 public class TowersOfHanoi
6 {
7     int numDisks; // number of disks to move
8
9     public TowersOfHanoi( int disks )
10    {
11        numDisks = disks;
12    } // end TowersOfHanoi constructor
13
14    // recursively move disks between towers
15    public void solveTowers( int disks, int sourcePeg, int destinationPeg,
16                           int tempPeg )
17    {
18        // base case -- only one disk to move
19        if ( disks == 1 )
20        {
21            System.out.printf( "\n%d --> %d", sourcePeg, destinationPeg );
22            return;
23        } // end if
24
25        // recursion step -- move (disk - 1) disks from sourcePeg
26        // to tempPeg using destinationPeg
27        solveTowers( disks - 1, sourcePeg, tempPeg, destinationPeg );
28
29        // move last disk from sourcePeg to destinationPeg
30        System.out.printf( "\n%d --> %d", sourcePeg, destinationPeg );
31
32        // move ( disks - 1 ) disks from tempPeg to destinationPeg
33        solveTowers( disks - 1, tempPeg, destinationPeg, sourcePeg );
34    } // end method solveTowers
35 } // end class TowersOfHanoi

```

Fig. 15.13 | Towers of Hanoi solution with a recursive method.

Figure 15.14 tests our Towers of Hanoi solution. Line 12 creates a `TowersOfHanoi` object, passing as a parameter the total number of disks (in this case, 3) to be moved from one peg to another. Line 15 calls the recursive `solveTowers` method, which outputs the steps to the command prompt.

15.8 Fractals

A **fractal** is a geometric figure that can be generated from a pattern repeated recursively (Fig. 15.15). The figure is modified by applying the pattern to each segment of the original figure. We will look at a few such approximations in this section. [Note: We will refer to our geometric figures as fractals, even though they are approximations.] Although these figures had been studied before the 20th century, it was the Polish mathematician Benoit Mandelbrot who introduced the term “fractal” in the 1970s, along with the specifics of how a fractal is created and the practical applications of fractals. Mandelbrot’s fractal geometry provides mathematical models for many complex forms found in nature, such as mountains, clouds and coastlines. Fractals have many uses in mathematics and science. Fractals can be used to better understand systems or patterns that appear in nature (e.g., ecosystems), in the human body (e.g., in the folds of the brain), or in the universe (e.g., galaxy clusters). Not all fractals resemble objects in nature. Drawing fractals has become a popular art form. Fractals have a **self-similar property**—when subdivided into parts, each resembles a reduced-size copy of the whole. Many fractals yield an exact copy of the original when a portion of the original image is magnified—such a fractal is said to be **strictly self-similar**. Links are provided in Section 15.11 for various websites that discuss and demonstrate fractals.

As an example, let us look at a popular strictly self-similar fractal known as the **Koch Curve** (Fig. 15.15). This fractal is formed by removing the middle third of each line in the drawing and replacing it with two lines that form a point, such that if the middle third of the original line remained, an equilateral triangle would be formed. Formulas for creating fractals often involve removing all or part of the previous fractal image. This pattern has already been determined for this fractal—in this section we focus not on how to determine what formulas are needed for a specific fractal, but how to use those formulas in a recursive solution.

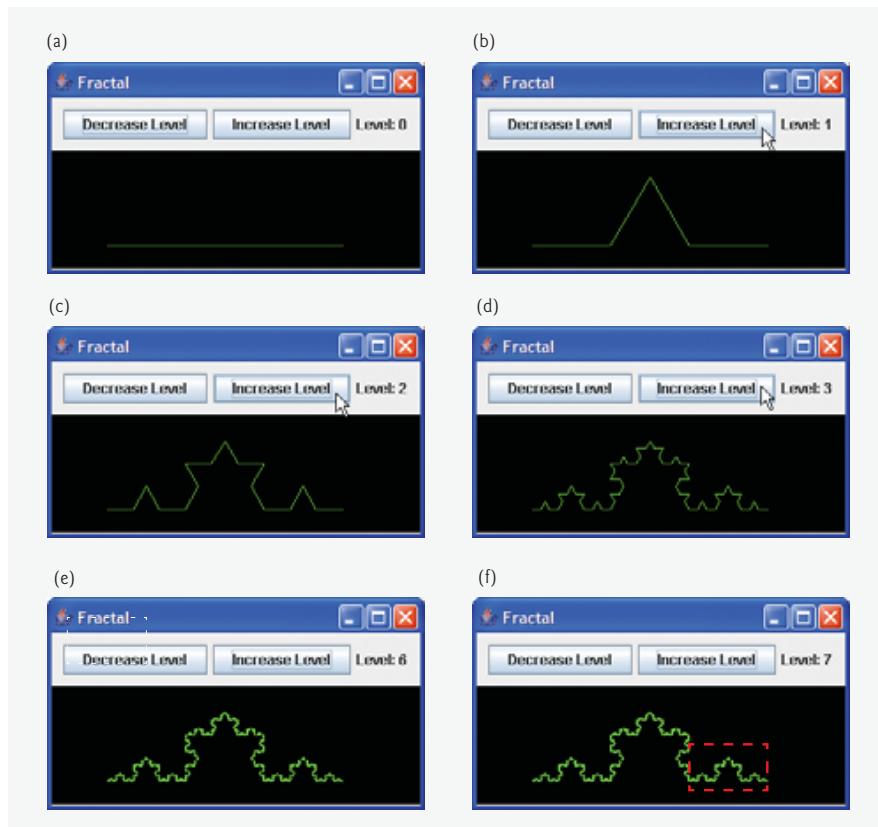

Fig. 15.15 | Koch Curve fractal.

We start with a straight line [Fig. 15.15, part (a)] and apply the pattern, creating a triangle from the middle third [Fig. 15.15, part (b)]. We then apply the pattern again to each straight line, resulting in Fig. 15.15, part (c). Each time the pattern is applied, we say that the fractal is at a new **level**, or **depth** (sometimes the term **order** is also used). Fractals can be displayed at many levels—for instance, a fractal at level 3 has had three iterations of the pattern applied [Fig. 15.15, part (d)]. After only a few iterations, this fractal begins to look like a portion of a snowflake [Fig. 15.15, parts (e and f)]. Since this is a strictly self-similar fractal, each portion of the fractal contains an exact copy of the fractal. In part (f) of Fig. 15.15, for example, we have highlighted a portion of the fractal with a dashed red box. If the image in this box were increased in size, it would look exactly like the entire fractal of part (f).

A similar fractal, the **Koch Snowflake**, is the same as the Koch Curve but begins with a triangle rather than a line. The same pattern is applied to each side of the triangle, resulting in an image that looks like an enclosed snowflake. We have chosen to focus on the Koch Curve for simplicity. To learn more about the Koch Curve and Koch Snowflake, see the links in Section 15.11.

754 Chapter 15 Recursion

We now demonstrate the use of recursion to draw fractals by writing a program to create a strictly self-similar fractal. We call this the “Lo fractal,” named for Sin Han Lo, a Deitel & Associates colleague who created it. The fractal will eventually resemble one-half of a feather (see the outputs in Fig. 15.22). The base case, or fractal level of 0, begins as a line between two points, A and B (Fig. 15.16). To create the next higher level, we find the midpoint (C) of the line. To calculate the location of point C, use the following formula: [Note: The x and y to the left of each letter refer to the x-coordinate and y-coordinate of that point, respectively. For instance, x_A refers to the x-coordinate of point A, while y_C refers to the y-coordinate of point C. In our diagrams we denote the point by its letter, followed by two numbers representing the x- and y-coordinates.]

$$\begin{aligned}x_C &= (x_A + x_B) / 2; \\y_C &= (y_A + y_B) / 2;\end{aligned}$$

To create this fractal, we also must find a point D that lies left of segment AC and creates an isosceles right triangle ADC. To calculate the location of point D, use the following formulas:

$$\begin{aligned}x_D &= x_A + (x_C - x_A) / 2 - (y_C - y_A) / 2; \\y_D &= y_A + (y_C - y_A) / 2 + (x_C - x_A) / 2;\end{aligned}$$

We now move from level 0 to level 1 as follows: First, add points C and D (as in Fig. 15.17). Then, remove the original line and add segments DA, DC and DB. The remaining lines will curve at an angle, causing our fractal to look like a feather. For the next level of the fractal, this algorithm is repeated on each of the three lines in level 1. For each line, the formulas above are applied, where the former point D is now considered to be point A, while the other end of each line is considered to be point B. Figure 15.18 contains the line from level 0 (now a dashed line) and the three added lines from level 1. We have changed point D to be point A, and the original points A, C and B to B1, B2 and B3, respectively. The preceding formulas have been used to find the new points C and D on each line. These points are also numbered 1–3 to keep track of which point is associated with each line. The points C1 and D1, for instance, represent points C and D associated with the line formed

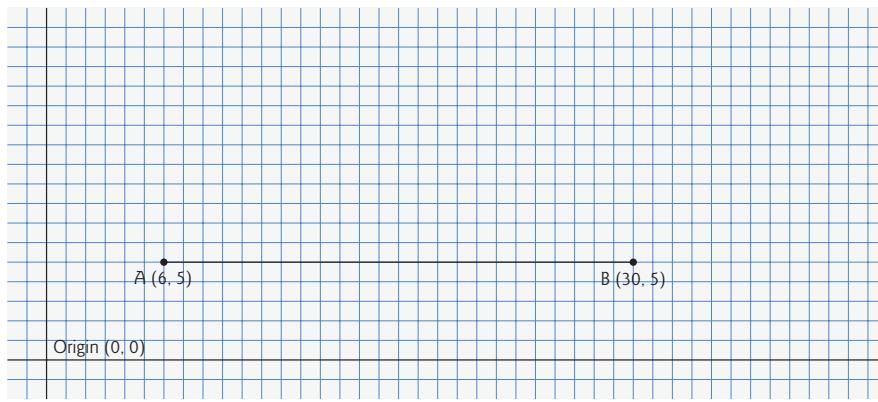

Fig. 15.16 | “Lo fractal” at level 0.

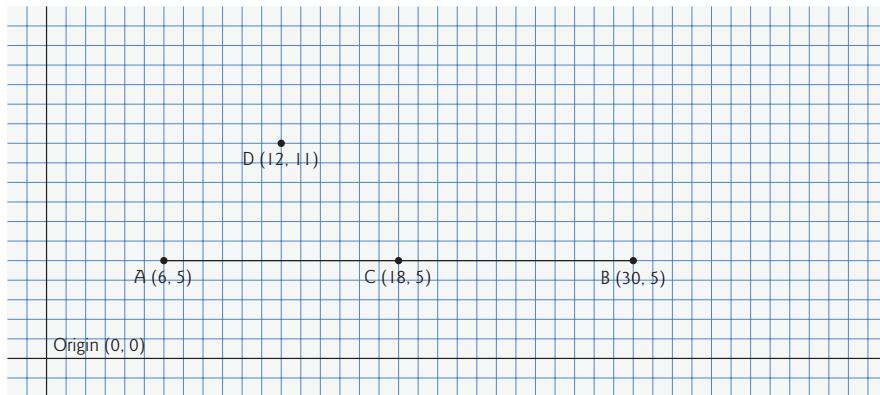

Fig. 15.17 | Determining points C and D for level 1 of the “Lo fractal.”

from points A to B1. To achieve level 2, the three lines in Fig. 15.18 are removed and replaced with new lines from the C and D points just added. Figure 15.19 shows the new lines (the lines from level 2 are shown as dashed lines for your convenience). Figure 15.20 shows level 2 without the dashed lines from level 1. Once this process has been repeated several times, the fractal created will begin to look like one-half of a feather, as shown in the output of Fig. 15.22. We will present the code for this application shortly.

The application in Fig. 15.21 defines the user interface for drawing this fractal (shown at the end of Fig. 15.22). The interface consists of three buttons—one for the user to change the color of the fractal, one to increase the level of recursion and one to decrease the level of recursion. A `JLabel` keeps track of the current level of recursion, which is modified by calling method `setLevel`, to be discussed shortly. Lines 15–16 specify constants `WIDTH` and `HEIGHT` to be 400 and 480 respectively for the size of the `JFrame`. The default

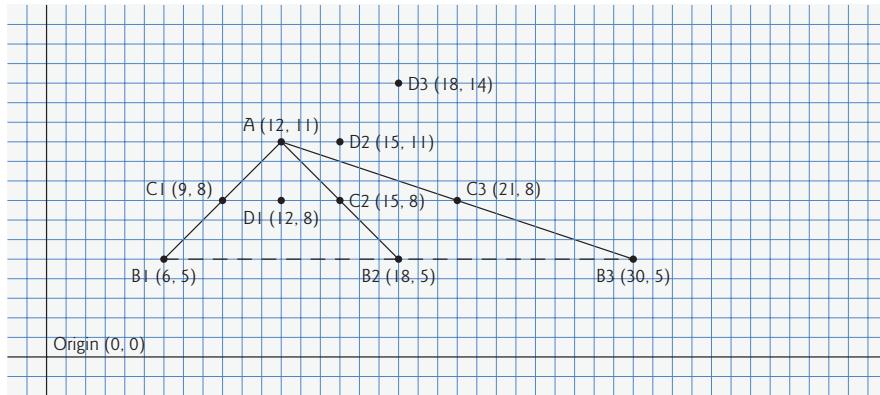

Fig. 15.18 | “Lo fractal” at level 1, with C and D points determined for level 2. [Note: The fractal at level 0 is included as a dashed line as a reminder of where the line was located in relation to the current fractal.]

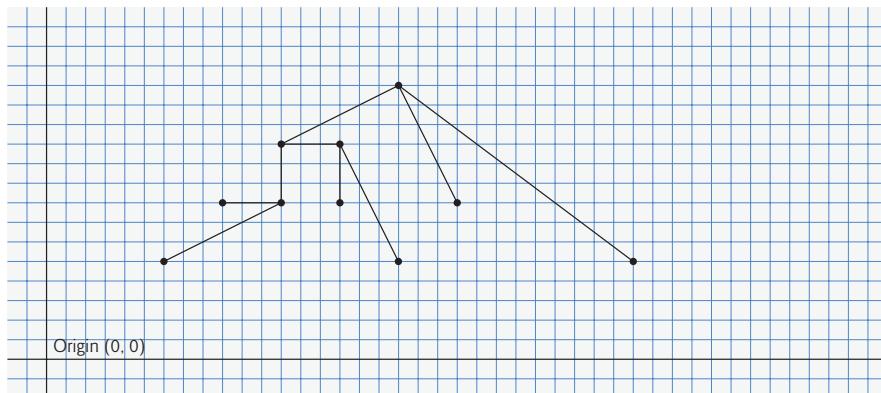

Fig. 15.20 | “Lo fractal” at level 2.

color to draw the fractal will be blue (line 18). The user triggers an `ActionEvent` by clicking the `Color` button. The event handler for this button is registered in lines 38–54. The method `actionPerformed` displays a `JColorChooser`. This dialog returns the selected `Color` object or blue (if the user presses `Cancel` or closes the dialog without pressing `OK`). Line 51 calls the `setColor` method in class `FractalJPanel` to update the color.

125 } // end main
126 } // end class Fractal

```

Fig. 15.21 | Demonstrating the fractal user interface. (Part 4 of 4.)

The event handler for the **Decrease Level** JButton is registered in lines 60–78. In method actionPerformed, lines 66–67 retrieve the current level of recursion and decrement it by 1. Line 70 checks to make sure that the level is greater than or equal to 0 (**MIN_LEVEL**)—the fractal is not defined for any recursion level lower than 0. The program allows the user to go up to any desired level, but at a certain point (level 10 and higher in this example) the rendering of the fractal becomes increasingly slow, as there is a lot of detail to be drawn. Lines 72–74 reset the level label to reflect the change—the new level is set and the repaint method is called to update the image to show the fractal corresponding to the new level.

The **Increase Level** JButton works the same way as the **Decrease Level** JButton, except that the level is incremented rather than decremented to show more details of the fractal (lines 90–91). When the application is first executed, the level will be set to 0, which will display a blue line between two points that were specified in the FractalJPanel class.

The FractalJPanel class in Fig. 15.22 specifies the dimensions of the drawing JPanel to be 400 by 400 (lines 13–14). The FractalJPanel constructor (lines 18–24) takes the current level as a parameter and assigns it to its instance variable **level**. Instance variable **color** is set to the default color blue. Lines 22–23 change the background color of the JPanel to be white (for visibility of the colors used to draw the fractal), and set the new dimensions of the JPanel where the fractal will be drawn.

79 } // end class FractalJPanel
```

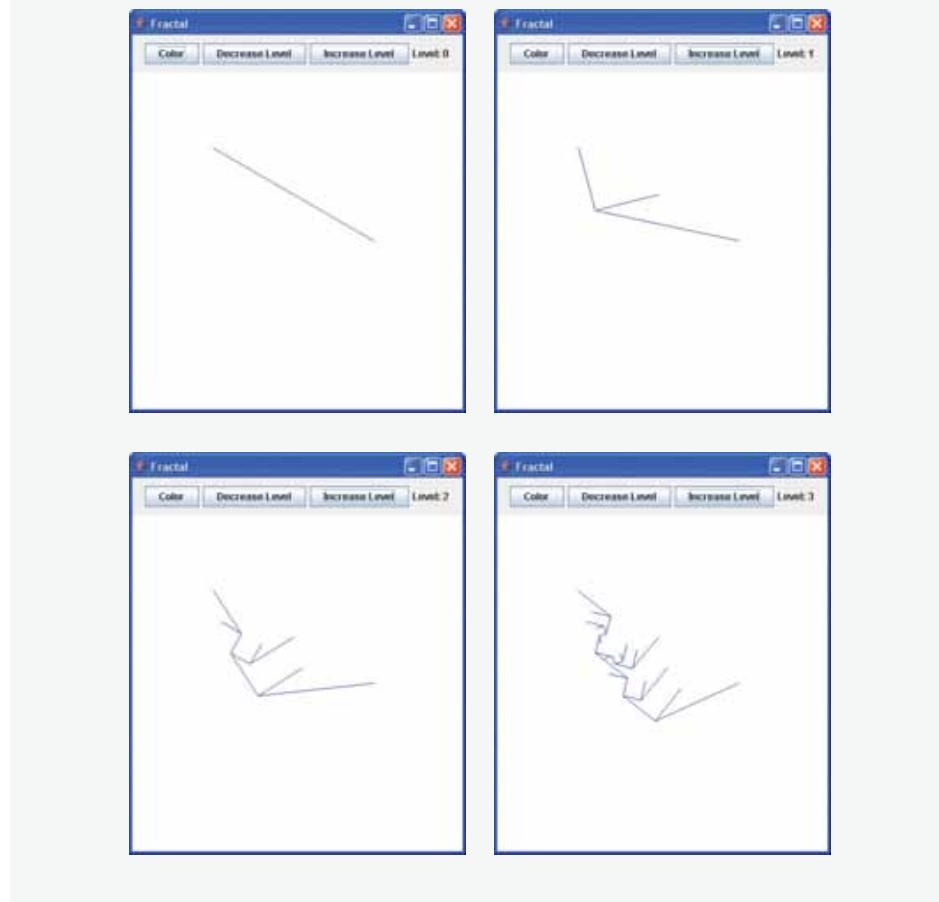

Fig. 15.22 | Drawing the “Lo fractal” using recursion. (Part 3 of 4.)

762 Chapter 15 Recursion

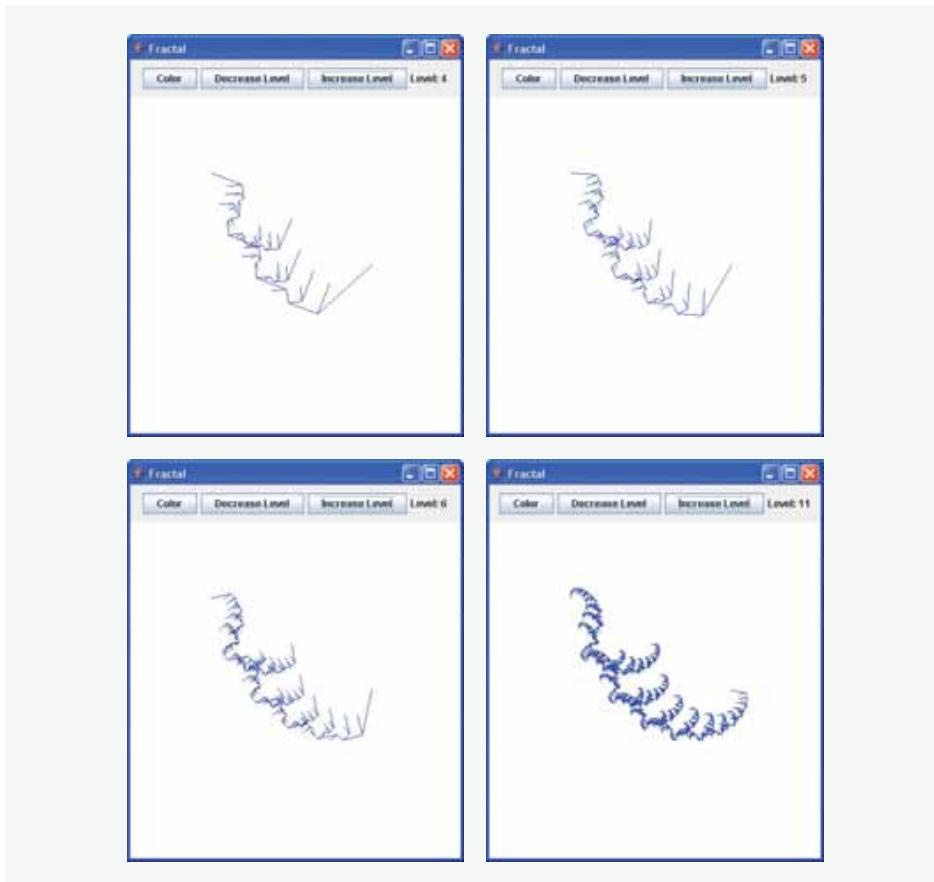

Fig. 15.22 | Drawing the “Lo fractal” using recursion. (Part 4 of 4.)

Lines 27–50 define the recursive method that creates the fractal. This method takes six parameters: the level, four integers that specify the *x*- and *y*-coordinates of two points, and the *Graphics* object *g*. The base case for this method (line 31) occurs when *level* equals 0, at which time a line will be drawn between the two points given as parameters. Lines 36–43 calculate (*xC*, *yC*), the midpoint between (*xA*, *yA*) and (*xB*, *yB*), and (*xD*, *yD*), the point that creates a right isosceles triangle with (*xA*, *yA*) and (*xC*, *yC*). Lines 46–48 make three recursive calls on three different sets of points.

In method *paintComponent*, line 59 makes the first call to method *drawFractal* to start the drawing. This method call is not recursive, but all subsequent calls to *drawFractal* performed from the body of *drawFractal* are. Since the lines will not be drawn until the base case is reached, the distance between two points decreases on each recursive call. As the level of recursion increases, the fractal becomes smoother and more detailed. The shape of this fractal stabilizes as the level approaches 11. Fractals will stabilize at different levels based on the shape and size of the fractal.

15.9 Recursive Backtracking 763

Figure 15.22 shows the development of the fractal from levels 0 to 6. The last image shows the defining shape of the fractal at level 11. If we focus on one of the arms of this fractal, it will be identical to the whole image. This property defines the fractal to be strictly self-similar. See Section 15.11 for further resources on fractals.

15.9 Recursive Backtracking

Our recursive methods all have a similar architecture—if the base case is reached, return a result; if not, make one or more recursive calls. In this section we will explore a more complex recursive method that finds a path through a maze, returning true if there is a possible solution to the maze. The solution involves moving through the maze one step at a time, where moves can be made by going down, right, up or left (diagonal moves are not permitted). From the current location in the maze (starting with the entry point), the following steps are taken: A direction is chosen, the move is made in that direction and a recursive call is made to solve the remainder of the maze from the new location. When a dead end is reached (i.e., we cannot take any more steps forward without hitting a wall), we back up to the previous location and try to go in a different direction. If no other direction can be taken, we back up again. This process continues until we find a point in the maze where a move can be made in another direction. Once such a location is found, we move in the new direction and continue with another recursive call to solve the rest of the maze.

To back up to the previous location in the maze, our recursive method simply returns false, moving up the method-call chain to the previous recursive call (which references the previous location in the maze). This process of using recursion to return to an earlier decision point is known as **recursive backtracking**. If one set of recursive calls does not result in a solution to the problem, the program backs up to the previous decision point and makes a different decision, often resulting in another set of recursive calls. In this example, the previous decision point is the previous location in the maze, and the decision to be made is the direction that the next move should take. One direction has led to a dead end, so the search continues with a different direction. Unlike our other recursive programs, which reached the base case and then returned all the way up the method-call chain to the original method call, the recursive backtracking solution to the maze problem uses recursion to return only partway up the method-call chain, then try a different direction. If the backtracking reaches the entry location of the maze and the paths in all directions have been attempted, the maze does not have a solution.

In the chapter exercises you are asked to implement recursive backtracking solutions to the maze problem (Exercise 15.20, Exercise 15.21 and Exercise 15.22) and the Eight Queens problem (Exercise 15.15), which attempts to find a way to place eight queens on an empty chessboard so that no queen is “attacking” any other (i.e., no two queens are in the same row, in the same column or along the same diagonal). See Section 15.11 for links to further information on recursive backtracking.

15.10 Wrap-Up

In this chapter, you learned how to create recursive methods—i.e., methods that call themselves. You learned that recursive methods typically divide a problem into two conceptual pieces—a piece that the method knows how to do (the base case) and a piece that the method does not know how to do (the recursion step). The recursion step is a slightly

764 Chapter 15 Recursion

smaller version of the original problem and is performed by a recursive method call. You saw some popular recursion examples, including calculating factorials and producing values in the Fibonacci series. You then learned how recursion works “under the hood,” including the order in which recursive method calls are pushed on or popped off the program execution stack. Next, you compared recursive and iterative (non-recursive) approaches. You learned how to solve a more complex problem using recursion—displaying fractals. The chapter concluded with an introduction to recursive backtracking, a technique for solving problems that involves backing up through recursive calls to try different possible solutions. In the next chapter, you will learn numerous techniques for sorting lists of data and searching for an item in a list of data, and under what circumstances each searching and sorting technique should be used.

www.cs.sfu.ca/CourseCentral/201/havens/notes/Lecture14.pdf

Provides a brief introduction to recursive backtracking, including an example on planning a travel route.

www.cs.utexas.edu/users/scottm/cs307/handouts/Slides/Lec11RecursiveBacktracking-4Up.pdf

Demonstrates recursive backtracking and walks through several examples.

math.hws.edu/xJava/PentominoSolver

Provides a program that uses recursive backtracking to solve a problem known as the Pentominoes puzzle (described at the site).

www.cs.rockhurst.edu/~burger/research/scramble/paper.pdf

Demonstrates using recursive backtracking to solve a scrambled squares puzzle.

Summary

Section 15.1 Introduction

- A recursive method calls itself directly or indirectly through another method.
- When a recursive method is called to solve a problem, the method actually is capable of solving only the simplest case(s), or base case(s). If it is called with a base case, the method returns a result.

Section 15.2 Recursion Concepts

- If a recursive method is called with a more complex problem than a base case, it typically divides the problem into two conceptual pieces—a piece that the method knows how to do and a piece that the method does not know how to do.
- To make recursion feasible, the piece that the method does not know how to do must resemble the original problem, but be a slightly simpler or smaller version of it. Because this new problem looks like the original problem, the method calls a fresh copy of itself to work on the smaller problem—this is called the recursion step.
- For recursion to eventually terminate, each time a method calls itself with a simpler version of the original problem, the sequence of smaller and smaller problems must converge on a base case. When, the method recognizes the base case, it returns a result to the previous copy of the method.
- A recursive call may be a call to another method, which in turn makes a call back to the original method. Such a process still results in a recursive call to the original method. This is known as an indirect recursive call or indirect recursion.

Section 15.3 Example Using Recursion: Factorials

- Either omitting the base case or writing the recursion step incorrectly so that it does not converge on the base case can cause infinite recursion, eventually exhausting memory. This error is analogous to the problem of an infinite loop in an iterative (nonrecursive) solution.

Section 15.4 Example Using Recursion: Fibonacci Series

- The Fibonacci series begins with 0 and 1 and has the property that each subsequent Fibonacci number is the sum of the preceding two.
- The ratio of successive Fibonacci numbers converges on a constant value of 1.618..., a number that has been called the golden ratio or the golden mean.
- Some recursive solutions, such as Fibonacci (which makes two calls per recursion step), result in an “explosion” of method calls.

766 Chapter 15 Recursion***Section 15.5 Recursion and the Method-Call Stack***

- A stack is a data structure in which data can be added or removed only at the top.
- A stack is analogous to a pile of dishes. When a dish is placed on the pile, it is always placed at the top (referred to as pushing the dish onto the stack). Similarly, when a dish is removed from the pile, it is always removed from the top (referred to as popping the dish off the stack).
- Stacks are known as last-in, first-out (LIFO) data structures—the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.
- Stacks have many interesting applications. For example, when a program calls a method, the called method must know how to return to its caller, so the return address of the calling method is pushed onto the program execution stack (sometimes referred to as the method-call stack).
- The program execution stack contains the memory for local variables on each invocation of a method during a program’s execution. This data, stored as a portion of the program execution stack, is known as the activation record or stack frame of the method call.
- If there are more recursive or nested method calls than can be stored on the program execution stack, an error known as a stack overflow occurs.

Section 15.6 Recursion vs. Iteration

- Both iteration and recursion are based on a control statement: Iteration uses a repetition statement, recursion a selection statement.
- Both iteration and recursion involve repetition: Iteration explicitly uses a repetition statement, whereas recursion achieves repetition through repeated method calls.
- Iteration and recursion each involve a termination test: Iteration terminates when the loop-continuation condition fails, recursion when a base case is recognized.
- Iteration with counter-controlled repetition and recursion each gradually approach termination: Iteration keeps modifying a counter until the counter assumes a value that makes the loop-continuation condition fail, whereas recursion keeps producing simpler versions of the original problem until the base case is reached.
- Both iteration and recursion can occur infinitely: An infinite loop occurs with iteration if the loop-continuation test never becomes false, whereas infinite recursion occurs if the recursion step does not reduce the problem each time in a manner that converges on the base case.
- Recursion repeatedly invokes the mechanism, and consequently the overhead, of method calls.
- Any problem that can be solved recursively can also be solved iteratively.
- A recursive approach is normally preferred over an iterative approach when it more naturally mirrors the problem and results in a program that is easier to understand and debug.
- A recursive approach can often be implemented with few lines of code, but a corresponding iterative approach might take a large amount of code. Another reason to choose a recursive solution is that an iterative solution might not be apparent.

Section 15.8 Fractals

- A fractal is a geometric figure that is generated from a pattern repeated recursively an infinite number of times.
- Fractals have a self-similar property—subparts are reduced-size copies of the whole.

Section 15.9 Recursive Backtracking

- Using recursion to return to an earlier decision point is known as recursive backtracking. If one set of recursive calls does not result in a solution to the problem, the program backs up to the previous decision point and makes a different decision, often resulting in another set of recursive calls.

Terminology

activation record	last-in, first-out (LIFO) data structures
backtracking	level of a fractal
base case	maze traversal problem
complexity theory	method-call stack
converge on a base case	palindrome
Eight Queens problem	program execution stack
exhaustive recursion	recursion overhead
factorial	recursion step
Fibonacci series	recursive backtracking
fractal	recursive call
fractal depth	recursive evaluation
fractal level	recursive method
fractal order	self-similar fractal
golden mean	stack
golden ratio	stack frame
indirect recursion	stack overflow
infinite recursion	strictly self-similar fractal
Koch Curve fractal	termination test
Koch Snowflake fractal	Towers of Hanoi problem

Self-Review Exercises

- 15.1** State whether each of the following is *true* or *false*. If *false*, explain why.
- A method that calls itself indirectly is not an example of recursion.
 - Recursion can be efficient in computation because of reduced memory-space usage.
 - When a recursive method is called to solve a problem, it actually is capable of solving only the simplest case(s), or base case(s).
 - To make recursion feasible, the recursion step in a recursive solution must resemble the original problem, but be a slightly larger version of it.
- 15.2** A _____ is needed to terminate recursion.
- recursion step
 - break statement
 - void return type
 - base case
- 15.3** The first call to invoke a recursive method is _____.
- not recursive
 - recursive
 - the recursion step
 - none of the above
- 15.4** Each time a fractal's pattern is applied, the fractal is said to be at a new _____.
- width
 - height
 - level
 - volume
- 15.5** Iteration and recursion each involve a _____.
- repetition statement
 - termination test

768 Chapter 15 Recursion

- c) counter variable
- d) none of the above

15.6 Fill in the blanks in each of the following statements:

- a) The ratio of successive Fibonacci numbers converges on a constant value of 1.618..., a number that has been called the _____ or the _____.
- b) Data can be added or removed only from the _____ of the stack.
- c) Stacks are known as _____ data structures—the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.
- d) The program execution stack contains the memory for local variables on each invocation of a method during a program's execution. This data, stored as a portion of the program execution stack, is known as the _____ or _____ of the method call.
- e) If there are more recursive or nested method calls than can be stored on the program execution stack, an error known as a(n) _____ occurs.
- f) Iteration normally uses a repetition statement, whereas recursion normally uses a(n) _____ statement.
- g) Fractals have a(n) _____ property—when subdivided into parts, each is a reduced-size copy of the whole.
- h) The _____ of a string are all the different strings that can be created by rearranging the characters of the original string.
- i) The program execution stack is also referred to as the _____ stack.

Answers to Self-Review Exercises

15.1 a) False. A method that calls itself indirectly is an example of recursion—more specifically, an example of indirect recursion. b) False. Recursion can be inefficient in computation because of multiple method calls and memory-space usage. c) True. d) False. To make recursion feasible, the recursion step in a recursive solution must resemble the original problem, but be a slightly *smaller* version of it.

15.2 d

15.3 a

15.4 c

15.5 b

15.6 a) golden ratio, golden mean. b) top. c) last-in, first-out (LIFO). d) activation record, stack frame. e) stack overflow. f) selection. g) self-similar. h) permutations. i) method-call.

Exercises

15.7 What does the following code do?

```

1 public int mystery( int a, int b )
2 {
3     if ( b == 1 )
4         return a;
5     else
6         return a + mystery( a, b - 1 );
7 } // end method mystery

```

15.8 Find the error(s) in the following recursive method, and explain how to correct it (them). This method should find the sum of the values from 0 to n.

Exercises **769**

```

1 public int sum( int n )
2 {
3     if ( n == 0 )
4         return 0;
5     else
6         return n + sum( n );
7 } // end method sum

```

- 15.9** (*Recursive power Method*) Write a recursive method `power(base, exponent)` that, when called, returns

$$\text{base}^{\text{exponent}}$$

For example, $\text{power}(3, 4) = 3 * 3 * 3 * 3$. Assume that `exponent` is an integer greater than or equal to 1. [Hint: The recursion step should use the relationship

$$\text{base}^{\text{exponent}} = \text{base} \cdot \text{base}^{\text{exponent} - 1}$$

and the terminating condition occurs when `exponent` is equal to 1, because

$$\text{base}^1 = \text{base}$$

Incorporate this method into a program that enables the user to enter the `base` and `exponent`.]

- 15.10** (*Visualizing Recursion*) It is interesting to watch recursion “in action.” Modify the factorial method in Fig. 15.3 to print its local variable and recursive-call parameter. For each recursive call, display the outputs on a separate line and add a level of indentation. Do your utmost to make the outputs clear, interesting and meaningful. Your goal here is to design and implement an output format that makes it easier to understand recursion. You may want to add such display capabilities to other recursion examples and exercises throughout the text.

- 15.11** (*Greatest Common Divisor*) The greatest common divisor of integers `x` and `y` is the largest integer that evenly divides into both `x` and `y`. Write a recursive method `gcd` that returns the greatest common divisor of `x` and `y`. The `gcd` of `x` and `y` is defined recursively as follows: If `y` is equal to 0, then `gcd(x, y)` is `x`; otherwise, `gcd(x, y)` is `gcd(y, x % y)`, where `%` is the remainder operator. Use this method to replace the one you wrote in the application of Exercise 6.27.

- 15.12** What does the following program do?

```

1 // Exercise 15.12 Solution: MysteryClass.java
2
3 public class MysteryClass
4 {
5     public int mystery( int array2[], int size )
6     {
7         if ( size == 1 )
8             return array2[ 0 ];
9         else
10            return array2[ size - 1 ] + mystery( array2, size - 1 );
11    } // end method mystery
12 } // end class MysteryClass

```

770 Chapter 15 Recursion

```

1 // Exercise 15.12 Solution: MysteryTest.java
2
3 public class MysteryTest
4 {
5     public static void main( String args[] )
6     {
7         MysteryClass mysteryObject = new MysteryClass();
8
9         int array[] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
10
11        int result = mysteryObject.mystery( array, array.length );
12
13        System.out.printf( "Result is: %d\n", result );
14    } // end method main
15 } // end class MysteryTest

```

15.13 What does the following program do?

```

1 // Exercise 15.13 Solution: SomeClass.java
2
3 public class SomeClass
4 {
5     public String someMethod(
6         int array2[], int x, String output )
7     {
8         if ( x < array2.length )
9             return String.format(
10                 "%s%d ", someMethod( array2, x + 1 ), array2[ x ] );
11         else
12             return "";
13     } // end method someMethod
14 } // end class SomeClass

```

```

1 // Exercise 15.13 Solution: SomeClassTest.java
2
3 public class SomeClassTest
4 {
5     public static void main( String args[] )
6     {
7         SomeClass someClassObject = new SomeClass();
8
9         int array[] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
10
11        String results =
12            someClassObject.someMethod( array, 0 );
13
14        System.out.println( results );
15    } // end main
16 } // end class SomeClassTest

```

Exercises **771**

15.14 (Palindromes) A palindrome is a string that is spelled the same way forward and backward. Some examples of palindromes are “radar,” “able was i ere i saw elba” and (if spaces are ignored) “a man a plan a canal panama.” Write a recursive method `testPalindrome` that returns boolean value `true` if the string stored in the array is a palindrome and `false` otherwise. The method should ignore spaces and punctuation in the string.

15.15 (Eight Queens) A puzzler for chess buffs is the Eight Queens problem, which asks the following: Is it possible to place eight queens on an empty chessboard so that no queen is “attacking” any other (i.e., no two queens are in the same row, in the same column or along the same diagonal)? For instance, if a queen is placed in the upper-left corner of the board, no other queens could be placed in any of the marked squares shown in Fig. 15.23. Solve the problem recursively. [Hint: Your solution should begin with the first column and look for a location in that column where a queen can be placed—initially, place the queen in the first row. The solution should then recursively search the remaining columns. In the first few columns, there will be several locations where a queen may be placed. Take the first available location. If a column is reached with no possible location for a queen, the program should return to the previous column, and move the queen in that column to a new row. This continuous backtracking up and trying new alternatives is an example of recursive backtracking.]

15.16 (Print an Array) Write a recursive method `printArray` that displays all the elements in an array of integers, separated by spaces.

15.17 (Print an Array Backward) Write a recursive method `stringReverse` that takes a character array containing a string as an argument and prints the string backward. [Hint: Use `String` method `toCharArray`, which takes no arguments, to get a `char` array containing the characters in the `String`.]

15.18 (Find the Minimum Value in an Array) Write a recursive method `recursiveMinimum` that determines the smallest element in an array of integers. The method should return when it receives an array of one element.

15.19 (Fractals) Repeat the fractal pattern in Section 15.8 to form a star. Begin with five lines, instead of one, where each line is a different arm of the star. Apply the “Lo fractal” pattern to each arm of the star.

15.20 (Maze Traversal Using Recursive Backtracking) The grid of #s and dots(.) in Fig. 15.24 is a two-dimensional array representation of a maze. The #s represent the walls of the maze, and the dots represent locations in the possible paths through the maze. Moves can be made only to a location in the array that contains a dot.

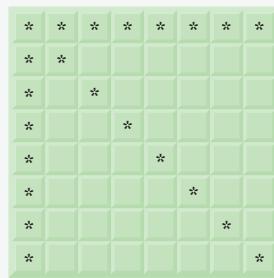

Fig. 15.23 | Squares eliminated by placing a queen in the upper-left corner of a chessboard.

```

Fig. 15.24 | Two-dimensional array representation of a maze.

Write a recursive method (`mazeTraversal`) to walk through mazes like the one in Fig. 15.24. The method should receive as arguments a 12-by-12 character array representing the maze and the current location in the maze (the first time this method is called, the current location should be the entry point of the maze). As `mazeTraversal` attempts to locate the exit, it should place the character `x` in each square in the path. There is a simple algorithm for walking through a maze that guarantees finding the exit (assuming there is an exit). If there is no exit, you will arrive at the starting location again. The algorithm is as follows: From the current location in the maze, try to move one space in any of the possible directions (down, right, up or left). If it is possible to move in at least one direction, call `mazeTraversal` recursively, passing the new spot on the maze as the current spot. If it is not possible to go in any direction, “back up” to a previous location in the maze and try a new direction for that location. Program the method to display the maze after each move so the user can watch as the maze is solved. The final output of the maze should display only the path needed to solve the maze—if going in a particular direction results in a dead end, the `x`’s going in that direction should not be displayed. [Hint: To display only the final path, it may be helpful to mark off spots that result in a dead end with another character (such as ‘0’).]

15.21 (*Generating Mazes Randomly*) Write a method `mazeGenerator` that takes as an argument a two-dimensional 12-by-12 character array and randomly produces a maze. The method should also provide the starting and ending locations of the maze. Test your method `mazeTraversal` from Exercise 15.20, using several randomly generated mazes.

15.22 (*Mazes of Any Size*) Generalize methods `mazeTraversal` and `mazeGenerator` of Exercise 15.20 and Exercise 15.21 to process mazes of any width and height.

15.23 (*Time to Calculate Fibonacci Numbers*) Enhance the Fibonacci program of Fig. 15.5 so that it calculates the approximate amount of time required to perform the calculation and the number of calls made to the recursive method. For this purpose, call static `System` method `currentTimeMillis`, which takes no arguments and returns the computer’s current time in milliseconds. Call this method twice—once before and once after the call to `fibonacci`. Save each value and calculate the difference in the times to determine how many milliseconds were required to perform the calculation. Then, add a variable to the `FibonacciCalculator` class, and use this variable to determine the number of calls made to method `fibonacci`. Display your results.

Searching and Sorting

*With sobs and tears he sorted
out
Those of the largest size ...*
—Lewis Carroll

*Attempt the end, and never
stand to doubt;
Nothing's so hard, but search
will find it out.*
—Robert Herrick

*'Tis in my memory lock'd,
And you yourself shall keep
the key of it.*
—William Shakespeare

*It is an immutable law in
business that words are
words, explanations are
explanations, promises are
promises — but only
performance is reality.*
—Harold S. Green

OBJECTIVES

In this chapter you will learn:

- To search for a given value in an array using linear search and binary search.
- To sort arrays using the iterative selection and insertion sort algorithms.
- To sort arrays using the recursive merge sort algorithm.
- To determine the efficiency of searching and sorting algorithms.
- To use loop invariants to help ensure the correctness of your programs.

774 Chapter 16 Searching and Sorting

Outline

- 16.1** Introduction
- 16.2** Searching Algorithms
 - 16.2.1** Linear Search
 - 16.2.2** Binary Search
- 16.3** Sorting Algorithms
 - 16.3.1** Selection Sort

- 16.5** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

16.1 Introduction

Searching data involves determining whether a value (referred to as the **search key**) is present in the data and, if so, finding its location. Two popular search algorithms are the simple linear search and the faster but more complex binary search. **Sorting** places data in ascending or descending order, based on one or more **sort keys**. A list of names could be sorted alphabetically, bank accounts could be sorted by account number, employee payroll records could be sorted by social security number, and so on. This chapter introduces two simple sorting algorithms, the selection sort and the insertion sort, along with the more efficient but more complex merge sort. Figure 16.1 summarizes the searching and sorting algorithms discussed in the examples and exercises of this book.

16.2 Searching Algorithms

Looking up a phone number, finding a website via a search engine and checking the definition of a word in a dictionary all involve searching large amounts of data. The next two sections discuss two common search algorithms—one that is easy to program yet relatively inefficient and one that is relatively efficient but more complex and difficult to program.

16.2.1 Linear Search

The **linear search algorithm** searches each element in an array sequentially. If the search key does not match an element in the array, the algorithm tests each element, and when the end of the array is reached, informs the user that the search key is not present. If the search key is in the array, the algorithm tests each element until it finds one that matches the search key and returns the index of that element.

As an example, consider an array containing the following values

34 56 2 10 77 51 93 30 5 52

and a program that is searching for 51. Using the linear search algorithm, the program first checks whether 34 matches the search key. It does not, so the algorithm checks whether 56 matches the search key. The program continues moving through the array sequentially, testing 2, then 10, then 77. When the program tests 51, which matches the search key, the program returns the index 5, which is the location of 51 in the array. If, after checking every array element, the program determines that the search key does not match any element in the array, the program returns a sentinel value (e.g., -1).

Figure 16.2 declares the `LinearArray` class. This class has two private instance variables—an array of `ints` named `data`, and a `static Random` object to fill the array with randomly generated `ints`. When an object of class `LinearArray` is instantiated, the constructor (lines 12–19) creates and initializes the array `data` with random `ints` in the

776 Chapter 16 Searching and Sorting

```

1 // Fig. 16.2: LinearArray.java
2 // Class that contains an array of random integers and a method
3 // that will search that array sequentially
4 import java.util.Random;
5
6 public class LinearArray
7 {
8     private int[] data; // array of values
9     private static Random generator = new Random();
10
11    // create array of given size and fill with random numbers
12    public LinearArray( int size )
13    {
14        data = new int[ size ]; // create space for array
15
16        // fill array with random ints in range 10-99
17        for ( int i = 0; i < size; i++ )
18            data[ i ] = 10 + generator.nextInt( 90 );
19    } // end LinearArray constructor
20
21    // perform a linear search on the data
22    public int linearSearch( int searchKey )
23    {
24        // loop through array sequentially
25        for ( int index = 0; index < data.length; index++ )
26            if ( data[ index ] == searchKey )
27                return index; // return index of integer
28
29        return -1; // integer was not found
30    } // end method linearSearch
31
32    // method to output values in array
33    public String toString()
34    {
35        StringBuilder temporary = new StringBuilder();
36
37        // iterate through array
38        for ( int element : data )
39            temporary.append( element + " " );
40
41        temporary.append( "\n" ); // add endline character
42        return temporary.toString();
43    } // end method toString
44 } // end class LinearArray

```

Fig. 16.2 | LinearArray class.

range 10–99. If there are duplicate values in the array, linear search returns the index of the first element in the array that matches the search key.

Lines 22–30 perform the linear search. The search key is passed to parameter `searchKey`. Lines 25–27 loop through the elements in the array. Line 26 compares each element in the array with `searchKey`. If the values are equal, line 27 returns the index of

16.2 Searching Algorithms 777

the element. If the loop ends without finding the value, line 29 returns -1. Lines 33–43 declare method `toString`, which returns a `String` representation of the array for printing.

Figure 16.3 creates a `LinearArray` object containing an array of 10 `ints` (line 16) and allows the user to search the array for specific elements. Lines 20–22 prompt the user for the search key and store it in `searchInt`. Lines 25–41 then loop until the `searchInt` is equal to -1. The array holds `ints` from 10–99 (line 18 of Fig. 16.2). Line 28 calls method `linearSearch` to determine whether `searchInt` is in the array. If it is not, `linearSearch`

```

1 // Fig. 16.3: LinearSearchTest.java
2 // Sequentially search an array for an item.
3 import java.util.Scanner;
4
5 public class LinearSearchTest
6 {
7     public static void main( String args[] )
8     {
9         // create Scanner object to input data
10        Scanner input = new Scanner( System.in );
11
12        int searchInt; // search key
13        int position; // location of search key in array
14
15        // create array and output it
16        LinearArray searchArray = new LinearArray( 10 );
17        System.out.println( searchArray ); // print array
18
19        // get input from user
20        System.out.print(
21            "Please enter an integer value (-1 to quit): " );
22        searchInt = input.nextInt(); // read first int from user
23
24        // repeatedly input an integer; -1 terminates the program
25        while ( searchInt != -1 )
26        {
27            // perform linear search
28            position = searchArray.linearSearch( searchInt );
29
30            if ( position == -1 ) // integer was not found
31                System.out.println( "The integer " + searchInt +
32                    " was not found.\n" );
33            else // integer was found
34                System.out.println( "The integer " + searchInt +
35                    " was found in position " + position + ".\n" );
36
37            // get input from user
38            System.out.print(
39                "Please enter an integer value (-1 to quit): " );
40            searchInt = input.nextInt(); // read next int from user
41        } // end while
42    } // end main
43 } // end class LinearSearchTest

returns `-1` and the program notifies the user (lines 31–32). If `searchInt` is in the array, `linearSearch` returns the position of the element, which the program outputs in lines 34–35. Lines 38–40 retrieve the next integer from the user.

Efficiency of Linear Search

Searching algorithms all accomplish the same goal—finding an element that matches a given search key, if such an element does, in fact, exist. There are, however, a number of things that differentiate search algorithms from one another. The major difference is the amount of effort they require to complete the search. One way to describe this effort is with [Big O notation](#), which indicates the worst-case run time for an algorithm—that is, how hard an algorithm may have to work to solve a problem. For searching and sorting algorithms, this depends particularly on how many data elements there are.

Suppose an algorithm is designed to test whether the first element of an array is equal to the second element. If the array has 10 elements, this algorithm requires one comparison. If the array has 1000 elements, it still requires one comparison. In fact, the algorithm is completely independent of the number of elements in the array. This algorithm is said to have a [constant run time](#), which is represented in Big O notation as $O(1)$. An algorithm that is $O(1)$ does not necessarily require only one comparison. $O(1)$ just means that the number of comparisons is *constant*—it does not grow as the size of the array increases. An algorithm that tests whether the first element of an array is equal to any of the next three elements is still $O(1)$ even though it requires three comparisons.

An algorithm that tests whether the first element of an array is equal to *any* of the other elements of the array will require at most $n - 1$ comparisons, where n is the number of elements in the array. If the array has 10 elements, this algorithm requires up to nine comparisons. If the array has 1000 elements, it requires up to 999 comparisons. As n grows larger, the n part of the expression “dominates,” and subtracting one becomes inconsequential. Big O is designed to highlight these dominant terms and ignore terms that become unimportant as n grows. For this reason, an algorithm that requires a total of $n - 1$ comparisons (such as the one we described earlier) is said to be $O(n)$. An $O(n)$ algorithm is referred to as having a [linear run time](#). $O(n)$ is often pronounced “on the order of n ” or more simply “order n .”

Now suppose you have an algorithm that tests whether *any* element of an array is duplicated elsewhere in the array. The first element must be compared with every other element in the array. The second element must be compared with every other element except the

16.2 Searching Algorithms **779**

first (it was already compared to the first). The third element must be compared with every other element except the first two. In the end, this algorithm will end up making $(n - 1) + (n - 2) + \dots + 2 + 1$ or $n^2/2 - n/2$ comparisons. As n increases, the n^2 term dominates and the n term becomes inconsequential. Again, Big O notation highlights the n^2 term, leaving $n^2/2$. But as we will soon see, constant factors are omitted in Big O notation.

Big O is concerned with how an algorithm's run time grows in relation to the number of items processed. Suppose an algorithm requires n^2 comparisons. With four elements, the algorithm requires 16 comparisons; with eight elements, 64 comparisons. With this algorithm, doubling the number of elements quadruples the number of comparisons. Consider a similar algorithm requiring $n^2/2$ comparisons. With four elements, the algorithm requires eight comparisons; with eight elements, 32 comparisons. Again, doubling the number of elements quadruples the number of comparisons. Both of these algorithms grow as the square of n , so Big O ignores the constant and both algorithms are considered to be $O(n^2)$, which is referred to as **quadratic run time** and pronounced "on the order of n -squared" or more simply "order n -squared."

When n is small, $O(n^2)$ algorithms (running on today's billion-operation-per-second personal computers) will not noticeably affect performance. But as n grows, you will start to notice the performance degradation. An $O(n^2)$ algorithm running on a million-element array would require a trillion "operations" (where each could actually require several machine instructions to execute). This could require several hours to execute. A billion-element array would require a quintillion operations, a number so large that the algorithm could take decades! $O(n^2)$ algorithms, unfortunately, are easy to write, as you'll see in this chapter. You'll also see algorithms with more favorable Big O measures. These efficient algorithms often take a bit more cleverness and work to create, but their superior performance can be well worth the extra effort, especially as n gets large and as algorithms are combined into larger programs.

The linear search algorithm runs in $O(n)$ time. The worst case in this algorithm is that every element must be checked to determine whether the search item exists in the array. If the size of the array is doubled, the number of comparisons that the algorithm must perform is also doubled. Note that linear search can provide outstanding performance if the element matching the search key happens to be at or near the front of the array. But we seek algorithms that perform well, on average, across all searches, including those where the element matching the search key is near the end of the array.

Linear search is the easiest search algorithm to program, but it can be slow compared to other search algorithms. If a program needs to perform many searches on large arrays, it may be better to implement a more efficient algorithm, such as the binary search, which we present in the next section.

**Performance Tip 16.1**

Sometimes the simplest algorithms perform poorly. Their virtue is that they are easy to program, test and debug. Sometimes more complex algorithms are required to realize maximum performance.

16.2.2 Binary Search

The **binary search algorithm** is more efficient than the linear search algorithm, but it requires that the array be sorted. The first iteration of this algorithm tests the middle element

780 Chapter 16 Searching and Sorting

in the array. If this matches the search key, the algorithm ends. Assuming the array is sorted in ascending order, then if the search key is less than the middle element, it cannot match any element in the second half of the array and the algorithm continues with only the first half of the array (i.e., the first element up to, but not including, the middle element). If the search key is greater than the middle element, it cannot match any element in the first half of the array and the algorithm continues with only the second half of the array (i.e., the element after the middle element through the last element). Each iteration tests the middle value of the remaining portion of the array. If the search key does not match the element, the algorithm eliminates half of the remaining elements. The algorithm ends by either finding an element that matches the search key or reducing the subarray to zero size.

As an example consider the sorted 15-element array

2 3 5 10 27 30 34 51 56 65 77 81 82 93 99

and a search key of 65. A program implementing the binary search algorithm would first check whether 51 is the search key (because 51 is the middle element of the array). The search key (65) is larger than 51, so 51 is discarded along with the first half of the array (all elements smaller than 51.) Next, the algorithm checks whether 81 (the middle element of the remainder of the array) matches the search key. The search key (65) is smaller than 81, so 81 is discarded along with the elements larger than 81. After just two tests, the algorithm has narrowed the number of values to check to three (56, 65 and 77). The algorithm then checks 65 (which indeed matches the search key), and returns the index of the array element containing 65. This algorithm required just three comparisons to determine whether the search key matched an element of the array. Using a linear search algorithm would have required 10 comparisons. [Note: In this example, we have chosen to use an array with 15 elements so that there will always be an obvious middle element in the array. With an even number of elements, the middle of the array lies between two elements. We implement the algorithm to choose the lower of those two elements.]

Figure 16.4 declares class `BinaryArray`. This class is similar to `LinearArray`—it has two `private` instance variables, a constructor, a search method (`binarySearch`), a `remainingElements` method and a `toString` method. Lines 13–22 declare the constructor. After the array has been initialized with random ints from 10–99 (lines 18–19), line 21 calls the `Arrays.sort` method on the array `data`. Method `sort` is a `static` method of class `Arrays` that sorts the elements in an array in ascending order by default; an overloaded version of this method allows you to change the sorting order. Recall that the binary search algorithm will work only on a sorted array.

782 Chapter 16 Searching and Sorting

```

62      // output spaces for alignment
63      for ( int i = 0; i < low; i++ )
64          temporary.append( " " );
65
66      // output elements left in array
67      for ( int i = low; i <= high; i++ )
68          temporary.append( data[ i ] + " " );
69
70      temporary.append( "\n" );
71      return temporary.toString();
72  } // end method remainingElements
73
74  // method to output values in array
75  public String toString()
76  {
77      return remainingElements( 0, data.length - 1 );
78  } // end method toString
79 } // end class BinaryArray

```

Fig. 16.4 | BinaryArray class. (Part 3 of 3.)

Lines 25–56 declare method `binarySearch`. The search key is passed into parameter `searchElement` (line 25). Lines 27–29 calculate the `low` end index, `high` end index and `middle` index of the portion of the array that the program is currently searching. At the beginning of the method, the `low` end is 0, the `high` end is the length of the array minus 1 and the `middle` is the average of these two values. Line 30 initializes the `location` of the element to `-1`—the value that will be returned if the element is not found. Lines 32–53 loop until `low` is greater than `high` (this occurs when the element is not found) or `location` does not equal `-1` (indicating that the search key was found). Line 43 tests whether the value in the `middle` element is equal to `searchElement`. If this is `true`, line 44 assigns `middle` to `location`. Then the loop terminates and `location` is returned to the caller. Each iteration of the loop tests a single value (line 43) and eliminates half of the remaining values in the array (line 48 or 50).

Lines 26–44 of Fig. 16.5 loop until the user enters `-1`. For each other number the user enters, the program performs a binary search on the data to determine whether it matches an element in the array. The first line of output from this program is the array of `ints`, in increasing order. When the user instructs the program to search for 23, the program first tests the middle element, which is 42 (as indicated by `*`). The search key is less than 42, so the program eliminates the second half of the array and tests the middle element from the first half. The search key is smaller than 34, so the program eliminates the second half of the array, leaving only three elements. Finally, the program checks 23 (which matches the search key) and returns the index 1.

Efficiency of Binary Search

In the worst-case scenario, searching a sorted array of 1023 elements will take only 10 comparisons when using a binary search. Repeatedly dividing 1023 by 2 (because after each comparison we are able to eliminate half of the array) and rounding down (because we also remove the middle element) yields the values 511, 255, 127, 63, 31, 15, 7, 3, 1 and 0. The

16.2 Searching Algorithms **783**

number $1023 (2^{10} - 1)$ is divided by 2 only 10 times to get the value 0, which indicates that there are no more elements to test. Dividing by 2 is equivalent to one comparison in the binary search algorithm. Thus, an array of 1,048,575 ($2^{20} - 1$) elements takes a maximum of 20 comparisons to find the key, and an array of over one billion elements takes a

```

maximum of 30 comparisons to find the key. This is a tremendous improvement in performance over the linear search. For a one-billion-element array, this is a difference between an average of 500 million comparisons for the linear search and a maximum of only 30 comparisons for the binary search! The maximum number of comparisons needed for the binary search of any sorted array is the exponent of the first power of 2 greater than the number of elements in the array, which is represented as $\log_2 n$. All logarithms grow at roughly the same rate, so in big O notation the base can be omitted. This results in a big O of $O(\log n)$ for a binary search which is also known as **logarithmic run time**.

16.3 Sorting Algorithms

Sorting data (i.e., placing the data into some particular order, such as ascending or descending) is one of the most important computing applications. A bank sorts all checks by account number so that it can prepare individual bank statements at the end of each

16.3 Sorting Algorithms 785

month. Telephone companies sort their lists of accounts by last name and, further, by first name to make it easy to find phone numbers. Virtually every organization must sort some data, and often massive amounts of it. Sorting data is an intriguing, computer-intensive problem that has attracted intense research efforts.

An important item to understand about sorting is that the end result—the sorted array—will be the same no matter which algorithm you use to sort the array. The choice of algorithm affects only the run time and memory use of the program. The rest of the chapter introduces three common sorting algorithms. The first two—selection sort and insertion sort—are simple to program but inefficient. The last algorithm—merge sort—is much faster than selection sort and insertion sort but harder to program. We focus on sorting arrays of primitive-type data, namely `ints`. It is possible to sort arrays of objects of classes as well. We discuss this in Section 19.6.1.

16.3.1 Selection Sort

Selection sort is a simple, but inefficient, sorting algorithm. The first iteration of the algorithm selects the smallest element in the array and swaps it with the first element. The second iteration selects the second-smallest item (which is the smallest item of the remaining elements) and swaps it with the second element. The algorithm continues until the last iteration selects the second-largest element and swaps it with the second-to-last index, leaving the largest element in the last index. After the i th iteration, the smallest i items of the array will be sorted into increasing order in the first i elements of the array.

As an example, consider the array

34 56 4 10 77 51 93 30 5 52

A program that implements selection sort first determines the smallest element (4) of this array which is contained in index 2. The program swaps 4 with 34, resulting in

4 56 34 10 77 51 93 30 5 52

The program then determines the smallest value of the remaining elements (all elements except 4), which is 5, contained in index 8. The program swaps 5 with 56, resulting in

4 5 34 10 77 51 93 30 56 52

On the third iteration, the program determines the next smallest value (10) and swaps it with 34.

4 5 10 34 77 51 93 30 56 52

The process continues until the array is fully sorted.

4 5 10 30 34 51 52 56 77 93

Note that after the first iteration, the smallest element is in the first position. After the second iteration, the two smallest elements are in order in the first two positions. After the third iteration, the three smallest elements are in order in the first three positions.

Figure 16.6 declares the `SelectionSort` class. This class has two `private` instance variables—an array of `ints` named `data`, and a `static Random` object to generate random integers to fill the array. When an object of class `SelectionSort` is instantiated, the constructor (lines 12–19) creates and initializes the array `data` with random `ints` in the range 10–99.

786 Chapter 16 Searching and Sorting

```

1 // Fig 16.6: SelectionSort.java
2 // Class that creates an array filled with random integers.
3 // Provides a method to sort the array with selection sort.
4 import java.util.Random;
5
6 public class SelectionSort
7 {
8     private int[] data; // array of values
9     private static Random generator = new Random();
10
11    // create array of given size and fill with random integers
12    public SelectionSort( int size )
13    {
14        data = new int[ size ]; // create space for array
15
16        // fill array with random ints in range 10-99
17        for ( int i = 0; i < size; i++ )
18            data[ i ] = 10 + generator.nextInt( 90 );
19    } // end SelectionSort constructor
20
21    // sort array using selection sort
22    public void sort()
23    {
24        int smallest; // index of smallest element
25
26        // loop over data.length - 1 elements
27        for ( int i = 0; i < data.length - 1; i++ )
28        {
29            smallest = i; // first index of remaining array
30
31            // loop to find index of smallest element
32            for ( int index = i + 1; index < data.length; index++ )
33                if ( data[ index ] < data[ smallest ] )
34                    smallest = index;
35
36            swap( i, smallest ); // swap smallest element into position
37            printPass( i + 1, smallest ); // output pass of algorithm
38        } // end outer for
39    } // end method sort
40
41    // helper method to swap values in two elements
42    public void swap( int first, int second )
43    {
44        int temporary = data[ first ]; // store first in temporary
45        data[ first ] = data[ second ]; // replace first with second
46        data[ second ] = temporary; // put temporary in second
47    } // end method swap
48
49    // print a pass of the algorithm
50    public void printPass( int pass, int index )
51    {
52        System.out.print( String.format( "after pass %2d: ", pass ) );
53

```

16.3 Sorting Algorithms **787**

```

54     // output elements till selected item
55     for ( int i = 0; i < index; i++ )
56         System.out.print( data[ i ] + " " );
57
58     System.out.print( data[ index ] + "* " ); // indicate swap
59
60     // finish outputting array
61     for ( int i = index + 1; i < data.length; i++ )
62         System.out.print( data[ i ] + " " );
63
64     System.out.print( "\n" ); // for alignment
65
66     // indicate amount of array that is sorted
67     for ( int j = 0; j < pass; j++ )
68         System.out.print( "-- " );
69     System.out.println( "\n" ); // add endline
70 } // end method indicateSelection
71
72 // method to output values in array
73 public String toString()
74 {
75     StringBuilder temporary = new StringBuilder();
76
77     // iterate through array
78     for ( int element : data )
79         temporary.append( element + " " );
80
81     temporary.append( "\n" ); // add endline character
82     return temporary.toString();
83 } // end method toString
84 } // end class SelectionSort

```

Fig. 16.6 | SelectionSort class. (Part 2 of 2.)

Lines 22–39 declare the `sort` method. Line 24 declares the variable `smallest`, which will store the index of the smallest element in the remaining array. Lines 27–38 loop `data.length - 1` times. Line 29 initializes the index of the smallest element to the current item. Lines 32–34 loop over the remaining elements in the array. For each of these elements, line 33 compares its value to the value of the smallest element. If the current element is smaller than the smallest element, line 34 assigns the current element's index to `smallest`. When this loop finishes, `smallest` will contain the index of the smallest element in the remaining array. Line 36 calls method `swap` (lines 42–47) to place the smallest remaining element in the next spot in the array.

Line 9 of Fig. 16.7 creates a `SelectionSort` object with 10 elements. Line 12 implicitly calls method `toString` to output the unsorted object. Line 14 calls method `sort` (lines 22–39 of Fig. 16.6), which sorts the elements using selection sort. Then lines 16–17 output the sorted object. The output of this program uses dashes to indicate the portion of the array that is sorted after each pass. An asterisk is placed next to the position of the element that was swapped with the smallest element on that pass. On each pass, the element next to the asterisk and the element above the rightmost set of dashes were the two values that were swapped.

Fig. 16.7 | SelectionSortTest class.

16.3 Sorting Algorithms 789

Efficiency of Selection Sort

The selection sort algorithm runs in $O(n^2)$ time. The `sort` method in lines 22–39 of Fig. 16.6, which implements the selection sort algorithm, contains two `for` loops. The outer `for` loop (lines 27–38) iterates over the first $n - 1$ elements in the array, swapping the smallest remaining item into its sorted position. The inner `for` loop (lines 32–34) iterates over each item in the remaining array, searching for the smallest element. This loop executes $n - 1$ times during the first iteration of the outer loop, $n - 2$ times during the second iteration, then $n - 3, \dots, 3, 2, 1$. This inner loop will iterate a total of $n(n - 1) / 2$ or $(n^2 - n)/2$. In Big O notation, smaller terms drop out and constants are ignored, leaving a final Big O of $O(n^2)$.

16.3.2 Insertion Sort

Insertion sort is another simple, but inefficient, sorting algorithm. The first iteration of this algorithm takes the second element in the array and, if it is less than the first element, swaps it with the first element. The second iteration looks at the third element and inserts it into the correct position with respect to the first two elements, so all three elements are in order. At the i th iteration of this algorithm, the first i elements in the original array will be sorted.

Consider as an example the following array. [Note: This array is identical to the one used in the discussions of selection sort and merge sort.]

34 56 4 10 77 51 93 30 5 52

A program that implements the insertion sort algorithm will first look at the first two elements of the array, 34 and 56. These two elements are already in order, so the program continues (if they were out of order, the program would swap them).

In the next iteration, the program looks at the third value, 4. This value is less than 56, so the program stores 4 in a temporary variable and moves 56 one element to the right. The program then checks and determines that 4 is less than 34, so it moves 34 one element to the right. The program has now reached the beginning of the array, so it places 4 in the zeroth element. The array now is

4 34 56 10 77 51 93 30 5 52

In the next iteration, the program stores the value 10 in a temporary variable. Then the program compares 10 to 56 and moves 56 one element to the right because it is larger than 10. The program then compares 10 to 34, moving 34 right one element. When the program compares 10 to 4, it observes that 10 is larger than 4 and places 10 in element 1. The array now is

4 10 34 56 77 51 93 30 5 52

Using this algorithm, at the i th iteration, the first i elements of the original array are sorted. They may not be in their final locations, however, because smaller values may be located later in the array.

Figure 16.8 declares the `InsertionSort` class. Lines 22–46 declare the `sort` method. Line 24 declares the variable `insert`, which holds the element you are going to insert while you move the other elements. Lines 27–45 loop over `data.length - 1` items in the array.

790 Chapter 16 Searching and Sorting

```

1 // Fig. 16.8: InsertionSort.java
2 // Class that creates an array filled with random integers.
3 // Provides a method to sort the array with insertion sort.
4 import java.util.Random;
5
6 public class InsertionSort
7 {
8     private int[] data; // array of values
9     private static Random generator = new Random();
10
11    // create array of given size and fill with random integers
12    public InsertionSort( int size )
13    {
14        data = new int[ size ]; // create space for array
15
16        // fill array with random ints in range 10-99
17        for ( int i = 0; i < size; i++ )
18            data[ i ] = 10 + generator.nextInt( 90 );
19    } // end InsertionSort constructor
20
21    // sort array using insertion sort
22    public void sort()
23    {
24        int insert; // temporary variable to hold element to insert
25
26        // loop over data.length - 1 elements
27        for ( int next = 1; next < data.length; next++ )
28        {
29            // store value in current element
30            insert = data[ next ];
31
32            // initialize location to place element
33            int moveItem = next;
34
35            // search for place to put current element
36            while ( moveItem > 0 && data[ moveItem - 1 ] > insert )
37            {
38                // shift element right one slot
39                data[ moveItem ] = data[ moveItem - 1 ];
40                moveItem--;
41            } // end while
42
43            data[ moveItem ] = insert; // place inserted element
44            printPass( next, moveItem ); // output pass of algorithm
45        } // end for
46    } // end method sort
47
48    // print a pass of the algorithm
49    public void printPass( int pass, int index )
50    {
51        System.out.print( String.format( "after pass %2d: ", pass ) );
52

```

Fig. 16.8 | InsertionSort class. (Part I of 2.)

16.3 Sorting Algorithms 791

```

53 // output elements till swapped item
54 for ( int i = 0; i < index; i++ )
55     System.out.print( data[ i ] + " " );
56
57 System.out.print( data[ index ] + "* " ); // indicate swap
58
59 // finish outputting array
60 for ( int i = index + 1; i < data.length; i++ )
61     System.out.print( data[ i ] + " " );
62
63 System.out.print( "\n" ); // for alignment
64
65 // indicate amount of array that is sorted
66 for( int i = 0; i <= pass; i++ )
67     System.out.print( "-- " );
68 System.out.println( "\n" ); // add endline
69 } // end method printPass
70
71 // method to output values in array
72 public String toString()
73 {
74     StringBuilder temporary = new StringBuilder();
75
76     // iterate through array
77     for ( int element : data )
78         temporary.append( element + " " );
79
80     temporary.append( "\n" ); // add endline character
81     return temporary.toString();
82 } // end method toString
83 } // end class InsertionSort

```

Fig. 16.8 | InsertionSort class. (Part 2 of 2.)

In each iteration, line 30 stores in `insert` the value of the element that will be inserted into the sorted portion of the array. Line 33 declares and initializes the variable `moveItem`, which keeps track of where to insert the element. Lines 36–41 loop to locate the correct position where the element should be inserted. The loop will terminate either when the program reaches the front of the array or when it reaches an element that is less than the value to be inserted. Line 39 moves an element to the right, and line 40 decrements the position at which to insert the next element. After the loop ends, line 43 inserts the element into place. Figure 16.9 is the same as Fig. 16.7 except that it creates and uses an `InsertionSort` object. The output of this program uses dashes to indicate the portion of the array that is sorted after each pass. An asterisk is placed next to the element that was inserted into place on that pass.

```

1 // Fig. 16.9: InsertionSortTest.java
2 // Test the insertion sort class.

           -- -- --
after pass 9: 10* 17 30 32 40 44 45 62 82 93
           -- -- --
Sorted array:
10 17 30 32 40 44 45 62 82 93

```

Fig. 16.9 | InsertionSortTest class. (Part 2 of 2.)*Efficiency of Insertion Sort*

The insertion sort algorithm also runs in $O(n^2)$ time. Like selection sort, the implementation of insertion sort (lines 22–46 of Fig. 16.8) contains two loops. The **for** loop (lines 27–45) iterates `data.length - 1` times, inserting an element into the appropriate position in the elements sorted so far. For the purposes of this application, `data.length - 1` is

equivalent to $n - 1$ (as `data.length` is the size of the array). The `while` loop (lines 36–41) iterates over the preceding elements in the array. In the worst case, this `while` loop will require $n - 1$ comparisons. Each individual loop runs in $O(n)$ time. In Big O notation, nested loops mean that you must multiply the number of comparisons. For each iteration of an outer loop, there will be a certain number of iterations of the inner loop. In this algorithm, for each $O(n)$ iterations of the outer loop, there will be $O(n)$ iterations of the inner loop. Multiplying these values results in a Big O of $O(n^2)$.

16.3.3 Merge Sort

Merge sort is an efficient sorting algorithm, but is conceptually more complex than selection sort and insertion sort. The merge sort algorithm sorts an array by splitting it into two equal-sized subarrays, sorting each subarray and then merging them into one larger array. With an odd number of elements, the algorithm creates the two subarrays such that one has one more element than the other.

The implementation of merge sort in this example is recursive. The base case is an array with one element, which is, of course, sorted, so the merge sort immediately returns in this case. The recursion step splits the array into two approximately equal pieces, recursively sorts them, then merges the two sorted arrays into one larger, sorted array.

Suppose the algorithm has already merged smaller arrays to create sorted arrays A:

4 10 34 56 77

and B:

5 30 51 52 93

Merge sort combines these two arrays into one larger, sorted array. The smallest element in A is 4 (located in the zeroth index of A). The smallest element in B is 5 (located in the zeroth index of B). In order to determine the smallest element in the larger array, the algorithm compares 4 and 5. The value from A is smaller, so 4 becomes the first element in the merged array. The algorithm continues by comparing 10 (the second element in A) to 5 (the first element in B). The value from B is smaller, so 5 becomes the second element in the larger array. The algorithm continues by comparing 10 to 30, with 10 becoming the third element in the array, and so on.

Lines 22–25 of Fig. 16.10 declare the `sort` method. Line 24 calls method `sortArray` with 0 and `data.length - 1` as the arguments—corresponding to the beginning and ending indices, respectively, of the array to be sorted. These values tell method `sortArray` to operate on the entire array.

```

1 // Figure 16.10: MergeSort.java
2 // Class that creates an array filled with random integers.
3 // Provides a method to sort the array with merge sort.
4 import java.util.Random;
5
6 public class MergeSort
7 {
8     private int[] data; // array of values

```

794 Chapter 16 Searching and Sorting

```

9     private static Random generator = new Random();
10
11    // create array of given size and fill with random integers
12    public MergeSort( int size )
13    {
14        data = new int[ size ]; // create space for array
15
16        // fill array with random ints in range 10-99
17        for ( int i = 0; i < size; i++ )
18            data[ i ] = 10 + generator.nextInt( 90 );
19    } // end MergeSort constructor
20
21    // calls recursive split method to begin merge sorting
22    public void sort()
23    {
24        sortArray( 0, data.length - 1 ); // split entire array
25    } // end method sort
26
27    // splits array, sorts subarrays and merges subarrays into sorted array
28    private void sortArray( int low, int high )
29    {
30        // test base case; size of array equals 1
31        if ( ( high - low ) >= 1 ) // if not base case
32        {
33            int middle1 = ( low + high ) / 2; // calculate middle of array
34            int middle2 = middle1 + 1; // calculate next element over
35
36            // output split step
37            System.out.println( "split: " + subarray( low, high ) );
38            System.out.println( "      " + subarray( low, middle1 ) );
39            System.out.println( "      " + subarray( middle2, high ) );
40            System.out.println();
41
42            // split array in half; sort each half (recursive calls)
43            sortArray( low, middle1 ); // first half of array
44            sortArray( middle2, high ); // second half of array
45
46            // merge two sorted arrays after split calls return
47            merge( low, middle1, middle2, high );
48        } // end if
49    } // end method sortArray
50
51    // merge two sorted subarrays into one sorted subarray
52    private void merge( int left, int middle1, int middle2, int right )
53    {
54        int leftIndex = left; // index into left subarray
55        int rightIndex = middle2; // index into right subarray
56        int combinedIndex = left; // index into temporary working array
57        int[] combined = new int[ data.length ]; // working array
58
59        // output two subarrays before merging
60        System.out.println( "merge: " + subarray( left, middle1 ) );
61        System.out.println( "      " + subarray( middle2, right ) );

```

Fig. 16.10 | MergeSort class. (Part 2 of 3.)

16.3 Sorting Algorithms **795**

```

62      // merge arrays until reaching end of either
63      while ( leftIndex <= middle1 && rightIndex <= right )
64      {
65          // place smaller of two current elements into result
66          // and move to next space in arrays
67          if ( data[ leftIndex ] <= data[ rightIndex ] )
68              combined[ combinedIndex++ ] = data[ leftIndex++ ];
69          else
70              combined[ combinedIndex++ ] = data[ rightIndex++ ];
71      } // end while
72
73
74      // if left array is empty
75      if ( leftIndex == middle2 )
76          // copy in rest of right array
77          while ( rightIndex <= right )
78              combined[ combinedIndex++ ] = data[ rightIndex++ ];
79      else // right array is empty
80          // copy in rest of left array
81          while ( leftIndex <= middle1 )
82              combined[ combinedIndex++ ] = data[ leftIndex++ ];
83
84      // copy values back into original array
85      for ( int i = left; i <= right; i++ )
86          data[ i ] = combined[ i ];
87
88      // output merged array
89      System.out.println( "        " + subarray( left, right ) );
90      System.out.println();
91  } // end method merge
92
93  // method to output certain values in array
94  public String subarray( int low, int high )
95  {
96      StringBuilder temporary = new StringBuilder();
97
98      // output spaces for alignment
99      for ( int i = 0; i < low; i++ )
100          temporary.append( " " );
101
102      // output elements left in array
103      for ( int i = low; i <= high; i++ )
104          temporary.append( " " + data[ i ] );
105
106      return temporary.toString();
107  } // end method subarray
108
109  // method to output values in array
110  public String toString()
111  {
112      return subarray( 0, data.length - 1 );
113  } // end method toString
114 } // end class MergeSort

```

Fig. 16.10 | MergeSort class. (Part 3 of 3.)

796 Chapter 16 Searching and Sorting

Method `sortArray` is declared in lines 28–49. Line 31 tests the base case. If the size of the array is 1, the array is already sorted, so the method returns immediately. If the size of the array is greater than 1, the method splits the array in two, recursively calls method `sortArray` to sort the two subarrays, then merges them. Line 43 recursively calls method `sortArray` on the first half of the array, and line 44 recursively calls method `sortArray` on the second half of the array. When these two method calls return, each half of the array has been sorted. Line 47 calls method `merge` (lines 52–91) on the two halves of the array to combine the two sorted arrays into one larger sorted array.

Lines 64–72 in method `merge` loop until the program reaches the end of either subarray. Line 68 tests which element at the beginning of the arrays is smaller. If the element in the left array is smaller, line 69 places it in position in the combined array. If the element in the right array is smaller, line 71 places it in position in the combined array. When the `while` loop has completed (line 72), one entire subarray is placed in the combined array, but the other subarray still contains data. Line 75 tests whether the left array has reached the end. If so, lines 77–78 fill the combined array with the elements of the right array. If the left array has not reached the end, then the right array must have reached the end, and lines 81–82 fill the combined array with the elements of the left array. Finally, lines 85–86 copy the combined array into the original array. Figure 16.11 creates and uses a `MergeSort` object. The fascinating output from this program displays the splits and merges performed by merge sort, showing the progress of the sort at each step of the algorithm. It is well worth your time to step through these outputs to fully understand this elegant sorting algorithm.

Fig. 16.11 | MergeSortTest class. (Part 3 of 3.)*Efficiency of Merge Sort*

Merge sort is a far more efficient algorithm than either insertion or selection sort. Consider the first (nonrecursive) call to method `sortArray`. This results in two recursive calls to method `sortArray` with subarrays each approximately half the size of the original array, and a single call to method `merge`. This call to `merge` requires, at worst, $n - 1$ comparisons to fill the original array, which is $O(n)$. (Recall that each element in the array can be chosen by comparing one element from each of the subarrays.) The two calls to method `sortArray` result in four more recursive calls to method `sortArray`, each with a subarray approximately a quarter the size of the original array along with two calls to method `merge`. These two calls to method `merge` each require, at worst, $n/2 - 1$ comparisons for a total number of comparisons of $O(n)$. This process continues, each call to `sortArray` generating two additional calls to `sortArray` and a call to `merge`, until the algorithm has split the array into one-element subarrays. At each level, $O(n)$ comparisons are required to merge the subarrays. Each level splits the size of the arrays in half, so doubling the size of the array requires one more level. Quadrupling the size of the array requires two more levels. This pattern is logarithmic and results in $\log_2 n$ levels. This results in a total efficiency of $O(n \log n)$. Figure 16.12 summarizes many of the searching and sorting algorithms covered in this book and lists the Big O for each of them. Figure 16.13 lists the Big O values we have covered in this chapter along with a number of values for n to highlight the differences in the growth rates.

Algorithm	Location	Big O
<i>Searching Algorithms:</i>		
Linear search	Section 16.2.1	$O(n)$
Binary search	Section 16.2.2	$O(\log n)$
Recursive linear search	Exercise 16.8	$O(n)$
Recursive binary search	Exercise 16.9	$O(\log n)$

16.4 Invariants

After writing an application, a programmer typically tests it thoroughly. Creating an exhaustive set of tests often is quite difficult, and it is always possible that a particular case remains untested. One technique that can help you test your programs thoroughly is to use invariants. An **invariant** is an assertion (see Section 13.13) that is true before and after a portion of your code executes. Invariants are mathematical in nature and their concepts are more applicable to the theoretical side of computer science.

The most common type of invariant is a **loop invariant**, which is an assertion that remains true

- before the execution of the loop,

800 Chapter 16 Searching and Sorting

- after every iteration of the loop body, and
- when the loop terminates.

A properly written loop invariant can help you code a loop correctly. There are four steps to developing a loop from a loop invariant.

1. Set initial values for any loop control variables.
2. Determine the condition that causes the loop to terminate.
3. Modify the control variable(s) so the loop progresses toward termination.
4. Check that the invariant remains true at the end of each iteration.

As an example, we will examine method `linearSearch` from class `LinearArray` in Fig. 16.2. The invariant for the linear search algorithm is:

```
for all k such that 0 <= k and k < index
    data[ k ] != searchKey
```

For example, suppose `index` equals 3. If we pick any non-negative number less than 3, such as 1 for the value of `k`, the element in `data` at location `k` in the array does not equal the `searchKey`. This invariant basically states that the portion of the array, called a **subarray**, from the start of the array up to but not including the element at `index` does not contain the `searchKey`. A subarray can any number of elements.

According to *Step 1*, we must first initialize control variable `index`. From the invariant, we see that if we set `index` to 0, then the subarray contains zero elements. Therefore, the invariant is true because a subarray with no elements cannot contain a value that matches the `searchKey`.

The second step is to determine the condition that causes the loop to terminate. The loop should end after searching the entire array—when `index` equals the length of the array. In this case, no element of array `data` matches the `searchKey`. Once the `index` reaches the end of the array, the invariant remains true—no elements in the subarray (which in this case is the entire array) equal the `searchKey`.

For the loop to proceed to the next element, we increment control variable `index`. The last step is to ensure that the invariant remains true after each iteration. The `if` statement (lines 26–27 of Fig. 16.2) determines whether `data[index]` equals the `searchKey`. If so, the method finishes and returns `index`. Because `index` is the first occurrence of `searchKey` in `data`, the invariant is still true—the subarray up to `index` does not contain the `searchKey`.

16.5 Wrap-Up

This chapter introduced searching and sorting. We discussed two searching algorithms—linear search and binary search—and three sorting algorithms—selection sort, insertion sort and merge sort. We introduced Big O notation, which helps you analyze the efficiency of an algorithm. You also learned about loop invariants, which must remain true before the loop begins executing, while the loop executes and when the loop terminates. In the next chapter, you'll learn about dynamic data structures that can grow or shrink at execution time.

Summary

Section 16.1 Introduction

- Searching data involves determining whether a search key is present in the data and, if so, finding its location.
- Sorting involves arranging data into order.

Section 16.2 Searching Algorithms

- The linear search algorithm searches each element in the array sequentially until it finds the correct element. If the element is not in the array, the algorithm tests each element in the array, and when the end of the array is reached, informs the user that the element is not present. If the element is in the array, linear search tests each item until it finds the correct item.
- A major difference among searching algorithms is the amount of effort they require in order to return a result.
- One way to describe the efficiency of an algorithm is with Big O notation, which indicates how hard an algorithm may have to work to solve a problem.
- For searching and sorting algorithms, Big O is often dependent on how many elements are in the data.
- An algorithm that is $O(1)$ does not necessarily require only one comparison. It just means that the number of comparisons does not grow as the size of the array increases.
- An $O(n)$ algorithm is referred to as having a linear run time.
- Big O is designed to highlight dominant factors and ignore terms that become unimportant with high n values.
- Big O notation is concerned with the growth rate of algorithm run times, so constants are ignored.
- The linear search algorithm runs in $O(n)$ time.
- The worst case in linear search is that every element must be checked to determine whether the search item exists. This occurs if the search key is the last element in the array or is not present.
- The binary search algorithm is more efficient than the linear search algorithm, but it requires that the array be sorted.
- The first iteration of binary search tests the middle element in the array. If this is the search key, the algorithm returns its location. If the search key is less than the middle element, binary search continues with the first half of the array. If the search key is greater than the middle element, binary search continues with the second half of the array. Each iteration of binary search tests the middle value of the remaining array and, if the element is not found, eliminates half of the remaining elements.
- Binary search is a more efficient searching algorithm than linear search because each comparison eliminates from consideration half of the elements in the array.
- Binary search runs in $O(\log n)$ time because each step removes half of the remaining elements.
- If the size of the array is doubled, binary search requires only one extra comparison to complete successfully.

Section 16.3 Sorting Algorithms

- Selection sort is a simple, but inefficient, sorting algorithm.
- The first iteration of selection sort selects the smallest item in the array and swaps it with the first element. The second iteration of selection sort selects the second-smallest item (which is the

802 Chapter 16 Searching and Sorting

smallest remaining item) and swaps it with the second element. Selection sort continues until the last iteration selects the second-largest element and swaps it with the second-to-last element, leaving the largest element in the last index. At the i th iteration of selection sort, the smallest i items of the whole array are sorted into the first i indices.

- The selection sort algorithm runs in $O(n^2)$ time.
- The first iteration of insertion sort takes the second element in the array and, if it is less than the first element, swaps it with the first element. The second iteration of insertion sort looks at the third element and inserts it in the correct position with respect to the first two elements. After the i th iteration of insertion sort, the first i elements in the original array are sorted.
- The insertion sort algorithm runs in $O(n^2)$ time.
- Merge sort is a sorting algorithm that is faster, but more complex to implement, than selection sort and insertion sort.
- The merge sort algorithm sorts an array by splitting the array into two equal-sized subarrays, sorting each subarray recursively and merging the subarrays into one larger array.
- Merge sort's base case is an array with one element. A one-element array is already sorted, so merge sort immediately returns when it is called with a one-element array. The merge part of merge sort takes two sorted arrays (these could be one-element arrays) and combines them into one larger sorted array.
- Merge sort performs the merge by looking at the first element in each array, which is also the smallest element in the array. Merge sort takes the smallest of these and places it in the first element of the larger array. If there are still elements in the subarray, merge sort looks at the second element in that subarray (which is now the smallest element remaining) and compares it to the first element in the other subarray. Merge sort continues this process until the larger array is filled.
- In the worst case, the first call to merge sort has to make $O(n)$ comparisons to fill the n slots in the final array.
- The merging portion of the merge sort algorithm is performed on two subarrays, each of approximately size $n/2$. Creating each of these subarrays requires $n/2 - 1$ comparisons for each subarray, or $O(n)$ comparisons total. This pattern continues as each level works on twice as many arrays, but each is half the size of the previous array.
- Similar to binary search, this halving results in $\log n$ levels for a total efficiency of $O(n \log n)$.

Section 16.4 Invariants

- An invariant is an assertion that is true before and after the execution of a portion of your code.
- A loop invariant is an assertion that is true before you begin executing the loop, during each iteration of the loop and after the loop terminates.

Terminology

Big O notation	$O(1)$
binary search	$O(\log n)$
constant run time	$O(n \log n)$
insertion sort	$O(n)$
invariant	$O(n^2)$
linear run time	search key
linear search	quadratic run time
logarithmic run time	searching
loop invariant	selection sort
merge sort	sorting

Self-Review Exercises

- 16.1** Fill in the blanks in each of the following statements:
- A selection sort application would take approximately _____ times as long to run on a 128-element array as on a 32-element array.
 - The efficiency of merge sort is _____.
- 16.2** What key aspect of both the binary search and the merge sort accounts for the logarithmic portion of their respective Big Os?
- 16.3** In what sense is the insertion sort superior to the merge sort? In what sense is the merge sort superior to the insertion sort?
- 16.4** In the text, we say that after the merge sort splits the array into two subarrays, it then sorts these two subarrays and merges them. Why might someone be puzzled by our statement that “it then sorts these two subarrays”?

Answers to Self-Review Exercises

- 16.1** a) 16, because an $O(n^2)$ algorithm takes 16 times as long to sort four times as much information. b) $O(n \log n)$.
- 16.2** Both of these algorithms incorporate “halving”—somehow reducing something by half. The binary search eliminates from consideration one half of the array after each comparison. The merge sort splits the array in half each time it is called.
- 16.3** The insertion sort is easier to understand and to program than the merge sort. The merge sort is far more efficient [$O(n \log n)$] than the insertion sort [$O(n^2)$].
- 16.4** In a sense, it does not really sort these two subarrays. It simply keeps splitting the original array in half until it provides a one-element subarray, which is, of course, sorted. It then builds up the original two subarrays by merging these one-element arrays to form larger subarrays, which are then merged, and so on.

Exercises

16.5 (*Bubble Sort*) Implement bubble sort—another simple yet inefficient sorting technique. It is called bubble sort or sinking sort because smaller values gradually “bubble” their way to the top of the array (i.e., toward the first element) like air bubbles rising in water, while the larger values sink to the bottom (end) of the array. The technique uses nested loops to make several passes through the array. Each pass compares successive pairs of elements. If a pair is in increasing order (or the values are equal), the bubble sort leaves the values as they are. If a pair is in decreasing order, the bubble sort swaps their values in the array.

The first pass compares the first two elements of the array and swaps their values if necessary. It then compares the second and third elements in the array. The end of this pass compares the last two elements in the array and swaps them if necessary. After one pass, the largest element will be in the last index. After two passes, the largest two elements will be in the last two indices. Explain why bubble sort is an $O(n^2)$ algorithm.

- 16.6** (*Enhanced Bubble Sort*) Make the following simple modifications to improve the performance of the bubble sort you developed in Exercise 16.5:
- After the first pass, the largest number is guaranteed to be in the highest-numbered element of the array; after the second pass, the two highest numbers are “in place”; and so on. Instead of making nine comparisons on every pass, modify the bubble sort to make eight comparisons on the second pass, seven on the third pass, and so on.

804 Chapter 16 Searching and Sorting

- b) The data in the array may already be in proper or near-proper order, so why make nine passes if fewer will suffice? Modify the sort to check at the end of each pass whether any swaps have been made. If none have been made, the data must already be in the proper order, so the program should terminate. If swaps have been made, at least one more pass is needed.

16.7 (*Bucket Sort*) A bucket sort begins with a one-dimensional array of positive integers to be sorted and a two-dimensional array of integers with rows indexed from 0 to 9 and columns indexed from 0 to $n - 1$, where n is the number of values to be sorted. Each row of the two-dimensional array is referred to as a *bucket*. Write a class named `BucketSort` containing a method called `sort` that operates as follows:

- Place each value of the one-dimensional array into a row of the bucket array, based on the value's "ones" (rightmost) digit. For example, 97 is placed in row 7, 3 is placed in row 3 and 100 is placed in row 0. This procedure is called a *distribution pass*.
- Loop through the bucket array row by row, and copy the values back to the original array. This procedure is called a *gathering pass*. The new order of the preceding values in the one-dimensional array is 100, 3 and 97.
- Repeat this process for each subsequent digit position (tens, hundreds, thousands, etc.). On the second (tens digit) pass, 100 is placed in row 0, 3 is placed in row 0 (because 3 has no tens digit) and 97 is placed in row 9. After the gathering pass, the order of the values in the one-dimensional array is 100, 3 and 97. On the third (hundreds digit) pass, 100 is placed in row 1, 3 is placed in row 0 and 97 is placed in row 0 (after the 3). After this last gathering pass, the original array is in sorted order.

Note that the two-dimensional array of buckets is 10 times the length of the integer array being sorted. This sorting technique provides better performance than a bubble sort, but requires much more memory—the bubble sort requires space for only one additional element of data. This comparison is an example of the space–time trade-off: The bucket sort uses more memory than the bubble sort, but performs better. This version of the bucket sort requires copying all the data back to the original array on each pass. Another possibility is to create a second two-dimensional bucket array and repeatedly swap the data between the two bucket arrays.

16.8 (*Recursive Linear Search*) Modify Fig. 16.2 to use recursive method `recursiveLinearSearch` to perform a linear search of the array. The method should receive the search key and starting index as arguments. If the search key is found, return its index in the array; otherwise, return -1. Each call to the recursive method should check one index in the array.

16.9 (*Recursive Binary Search*) Modify Fig. 16.4 to use recursive method `recursiveBinarySearch` to perform a binary search of the array. The method should receive the search key, starting index and ending index as arguments. If the search key is found, return its index in the array. If the search key is not found, return -1.

16.10 (*Quicksort*) The recursive sorting technique called quicksort uses the following basic algorithm for a one-dimensional array of values:

- Partitioning Step:* Take the first element of the unsorted array and determine its final location in the sorted array (i.e., all values to the left of the element in the array are less than the element, and all values to the right of the element in the array are greater than the element—we show how to do this below). We now have one element in its proper location and two unsorted subarrays.
- Recursive Step:* Perform *Step 1* on each unsorted subarray. Each time *Step 1* is performed on a subarray, another element is placed in its final location of the sorted array, and two unsorted subarrays are created. When a subarray consists of one element, that element is in its final location (because a one-element array is already sorted).

Exercises **805**

The basic algorithm seems simple enough, but how do we determine the final position of the first element of each subarray? As an example, consider the following set of values (the element in bold is the partitioning element—it will be placed in its final location in the sorted array):

37 2 6 4 89 8 10 12 68 45

Starting from the rightmost element of the array, compare each element with **37** until an element less than **37** is found; then swap **37** and that element. The first element less than **37** is **12**, so **37** and **12** are swapped. The new array is

12 2 6 4 89 8 10 **37** 68 45

Element **12** is in italics to indicate that it was just swapped with **37**.

Starting from the left of the array, but beginning with the element after **12**, compare each element with **37** until an element greater than **37** is found—then swap **37** and that element. The first element greater than **37** is **89**, so **37** and **89** are swapped. The new array is

12 2 6 4 **37** 8 10 89 68 45

Starting from the right, but beginning with the element before **89**, compare each element with **37** until an element less than **37** is found—then swap **37** and that element. The first element less than **37** is **10**, so **37** and **10** are swapped. The new array is

12 2 6 4 **10** 8 **37** 89 68 45

Starting from the left, but beginning with the element after **10**, compare each element with **37** until an element greater than **37** is found—then swap **37** and that element. There are no more elements greater than **37**, so when we compare **37** with itself, we know that **37** has been placed in its final location in the sorted array. Every value to the left of **37** is smaller than it, and every value to the right of **37** is larger than it.

Once the partition has been applied on the previous array, there are two unsorted subarrays. The subarray with values less than **37** contains 12, 2, 6, 4, 10 and 8. The subarray with values greater than **37** contains 89, 68 and 45. The sort continues recursively with both subarrays being partitioned in the same manner as the original array.

Based on the preceding discussion, write recursive method `quickSortHelper` to sort a one-dimensional integer array. The method should receive as arguments a starting index and an ending index on the original array being sorted.

17

Data Structures

OBJECTIVES

In this chapter you will learn:

- To form linked data structures using references, self-referential classes and recursion.
- The type-wrapper classes that enable programs to process primitive data values as objects.
- To use autoboxing to convert a primitive value to an object of the corresponding type-wrapper class.
- To use auto-unboxing to convert an object of a type-wrapper class to a primitive value.
- To create and manipulate dynamic data structures, such as linked lists, queues, stacks and binary trees.
- Various important applications of linked data structures.
- How to create reusable data structures with classes, inheritance and composition.

Special Section: Building Your Own Compiler

17.1 Introduction

In previous chapters, we studied fixed-size **data structures** such as one-dimensional and multidimensional arrays. This chapter introduces **dynamic data structures** that grow and shrink at execution time. **Linked lists** are collections of data items “linked up in a chain”—insertions and deletions can be made anywhere in a linked list. **Stacks** are important in compilers and operating systems; insertions and deletions are made only at one end of a stack—its **top**. **Queues** represent waiting lines; insertions are made at the back (also referred to as the **tail**) of a queue and deletions are made from the front (also referred to as the **head**). **Binary trees** facilitate high-speed searching and sorting of data, eliminating duplicate data items efficiently, representing file-system directories, compiling expressions into machine language and many other interesting applications.

We discuss each of these major data structure types and implement programs that create and manipulate them. We use classes, inheritance and composition to create and package these data structures for reusability and maintainability. In Chapter 19, Collections, we discuss Java’s predefined classes that implement the data structures discussed in this chapter.

The examples presented here are practical programs that can be used in advanced courses and in industrial applications. The exercises include a rich collection of useful applications.

This chapter’s examples manipulate primitive values for simplicity. However, most of the data-structure implementations in this chapter store only **Objects**. Java has a feature called **boxing** that allows primitive values to be converted to and from objects for use in cases like this. The objects that represent primitive values are instances of Java’s so-called type-wrapper classes in package `java.lang`. We discuss these classes and **boxing** in the next two sections, so that we can use them in this chapter’s examples.

We encourage you to attempt the major project described in the special section entitled Building Your Own Compiler. You have been using a Java compiler to translate your Java programs to bytecodes so that you could execute these programs on your computer. In this project, you will actually build your own compiler. It will read a file of statements written in a simple, yet powerful high-level language similar to early versions of the pop-

808 Chapter 17 Data Structures

ular language BASIC. Your compiler will translate these statements into a file of Simpletron Machine Language (SML) instructions—SML is the language you learned in the Chapter 7 special section, Building Your Own Computer. Your Simpletron Simulator program will then execute the SML program produced by your compiler! Implementing this project by using an object-oriented approach will give you a wonderful opportunity to exercise most of what you have learned in this book. The special section carefully walks you through the specifications of the high-level language and describes the algorithms you will need to convert each high-level language statement into machine-language instructions. If you enjoy being challenged, you might attempt the many enhancements to both the compiler and the Simpletron Simulator suggested in the exercises.

17.2 Type-Wrapper Classes for Primitive Types

Each primitive type (listed in Appendix D, Primitive Types) has a corresponding **type-wrapper class** (in package `java.lang`). These classes are called `Boolean`, `Byte`, `Character`, `Double`, `Float`, `Integer`, `Long` and `Short`. Each type-wrapper class enables you to manipulate primitive-type values as objects. Many of the data structures that we develop or reuse in Chapters 17–19 manipulate and share `Objects`. These classes cannot manipulate variables of primitive types, but they can manipulate objects of the type-wrapper classes, because every class ultimately derives from `Object`.

Each of the numeric type-wrapper classes—`Byte`, `Short`, `Integer`, `Long`, `Float` and `Double`—extends class `Number`. Also, the type-wrapper classes are `final` classes, so you cannot extend them.

Primitive types do not have methods, so the methods related to a primitive type are located in the corresponding type-wrapper class (e.g., method `parseInt`, which converts a `String` to an `int` value, is located in class `Integer`). If you need to manipulate a primitive value in your program, first refer to the documentation for the type-wrapper classes—the method you need might already be declared.

17.3 Autoboxing and Auto-Unboxing

Prior to Java SE 5, if you wanted to insert a primitive value into a data structure that could store only `Objects`, you had to create a new object of the corresponding type-wrapper class, then insert this object in the collection. Similarly, if you wanted to retrieve an object of a type-wrapper class from a collection and manipulate its primitive value, you had to invoke a method on the object to obtain its corresponding primitive-type value. For example, suppose you want to add an `int` to an array that stores only references to `Integer` objects. Prior to Java SE 5, you would be required to “wrap” an `int` value in an `Integer` object before adding the integer to the array and to “unwrap” the `int` value from the `Integer` object to retrieve the value from the array, as in

```
Integer[] integerArray = new Integer[ 5 ]; // create integerArray
// assign Integer 10 to integerArray[ 0 ]
integerArray[ 0 ] = new Integer( 10 );
// get int value of Integer
int value = integerArray[ 0 ].intValue();
```

17.4 Self-Referential Classes **809**

Notice that the `int` primitive value 10 is used to initialize an `Integer` object. This achieves the desired result but requires extra code and is cumbersome. We then need to invoke method `intValue` of class `Integer` to obtain the `int` value in the `Integer` object.

Java SE 5 simplified converting between primitive-type values and type-wrapper objects, requiring no additional code on the part of the programmer. Java SE 5 introduced two new conversions—the boxing conversion and the unboxing conversion. A **boxing conversion** converts a value of a primitive type to an object of the corresponding type-wrapper class. An **unboxing conversion** converts an object of a type-wrapper class to a value of the corresponding primitive type. These conversions can be performed automatically (called **autoboxing** and **auto-unboxing**). For example, the previous statements can be rewritten as

```
Integer[] integerArray = new Integer[ 5 ]; // create integerArray
integerArray[ 0 ] = 10; // assign Integer 10 to integerArray[ 0 ]
int value = integerArray[ 0 ]; // get int value of Integer
```

In this case, autoboxing occurs when assigning an `int` value (10) to `integerArray[0]`, because `integerArray` stores references to `Integer` objects, not `int` primitive values. Auto-unboxing occurs when assigning `integerArray[0]` to `int` variable `value`, because variable `value` stores an `int` value, not a reference to an `Integer` object. Autoboxing and auto-unboxing also occur in control statements—the condition of a control statement can evaluate to a primitive `boolean` type or a `Boolean` reference type. Many of this chapter's examples use these conversions to store primitive values in and to retrieve them from data structures that store only references to `Objects`.

17.4 Self-Referential Classes

A **self-referential class** contains an instance variable that refers to another object of the same class type. For example, the declaration

```
class Node
{
    private int data;
    private Node nextNode; // reference to next linked node

    public Node( int data ) { /* constructor body */ }
    public void setData( int data ) { /* method body */ }
    public int getData() { /* method body */ }
    public void setNext( Node next ) { /* method body */ }
    public Node getNext() { /* method body */ }
} // end class Node
```

declares class `Node`, which has two `private` instance variables—`integer data` and `Node` reference `nextNode`. Field `nextNode` references a `Node` object, an object of the same class being declared here—hence, the term “self-referential class.” Field `nextNode` is a **link**—it “links” an object of type `Node` to another object of the same type. Type `Node` also has five methods: a constructor that receives an integer to initialize `data`, a `setData` method to set the value of `data`, a `getData` method to return the value of `data`, a `setNext` method to set the value of `nextNode` and a `getNext` method to return a reference to the next node.

Programs can link self-referential objects together to form such useful data structures as lists, queues, stacks and trees. Figure 17.1 illustrates two self-referential objects linked together to form a list. A backslash—representing a `null` reference—is placed in the link

810 Chapter 17 Data Structures

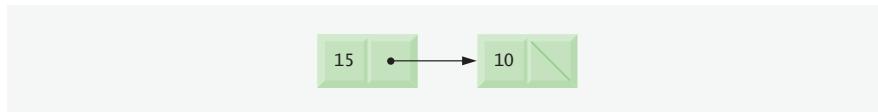

Fig. 17.1 | Self-referential-class objects linked together.

member of the second self-referential object to indicate that the link does not refer to another object. Note that the backslash is illustrative; it does not correspond to the backslash character in Java. We use the `null` to reference indicate the end of a data structure.

17.5 Dynamic Memory Allocation

Creating and maintaining dynamic data structures requires **dynamic memory allocation**—the ability for a program to obtain more memory space at execution time to hold new nodes and to release space no longer needed. Remember that Java programs do not explicitly release dynamically allocated memory. Rather, Java performs automatic garbage collection of objects that are no longer referenced in a program.

The limit for dynamic memory allocation can be as large as the amount of available physical memory in the computer or the amount of available disk space in a virtual-memory system. Often, the limits are much smaller, because the computer's available memory must be shared among many applications.

The declaration and class-instance creation expression

```
Node nodeToAdd = new Node( 10 ); // 10 is nodeToAdd's data
```

allocates the memory to store a `Node` object and returns a reference to the object, which is assigned to `nodeToAdd`. If insufficient memory is available, the expression throws an `OutOfMemoryError`.

The following sections discuss lists, stacks, queues and trees that all use dynamic memory allocation and self-referential classes to create dynamic data structures.

17.6 Linked Lists

A linked list is a linear collection (i.e., a sequence) of self-referential-class objects, called **nodes**, connected by reference links—hence, the term “linked” list. Typically, a program accesses a linked list via a reference to the first node in the list. The program accesses each subsequent node via the link reference stored in the previous node. By convention, the link reference in the last node of the list is set to `null`. Data is stored in a linked list dynamically—the program creates each node as necessary. A node can contain data of any type, including references to objects of other classes. Stacks and queues are also linear data structures and, as we will see, are constrained versions of linked lists. Trees are nonlinear data structures.

Lists of data can be stored in arrays, but linked lists provide several advantages. A linked list is appropriate when the number of data elements to be represented in the data structure is unpredictable. Linked lists are dynamic, so the length of a list can increase or decrease as necessary. The size of a “conventional” Java array, however, cannot be altered—the array size is fixed at the time the program creates the array. “Conventional”

17.6 Linked Lists **811**

arrays can become full. Linked lists become full only when the system has insufficient memory to satisfy dynamic storage allocation requests. Package `java.util` contains class `LinkedList` for implementing and manipulating linked lists that grow and shrink during program execution. We discuss class `LinkedList` in Chapter 19, Collections.

**Performance Tip 17.1**

An array can be declared to contain more elements than the number of items expected, but this wastes memory. Linked lists provide better memory utilization in these situations. Linked lists allow the program to adapt to storage needs at runtime.

**Performance Tip 17.2**

Insertion into a linked list is fast—only two references have to be modified (after locating the insertion point). All existing node objects remain at their current locations in memory.

Linked lists can be maintained in sorted order simply by inserting each new element at the proper point in the list. (It does, of course, take time to locate the proper insertion point.) Existing list elements do not need to be moved.

**Performance Tip 17.3**

Insertion and deletion in a sorted array can be time consuming—all the elements following the inserted or deleted element must be shifted appropriately.

Linked list nodes normally are not stored contiguously in memory. Rather, they are logically contiguous. Figure 17.2 illustrates a linked list with several nodes. This diagram presents a **singly linked list**—each node contains one reference to the next node in the list. Often, linked lists are implemented as doubly linked lists—each node contains a reference to the next node in the list and a reference to the previous node in the list. Java's `LinkedList` class is a doubly linked list implementation.

**Performance Tip 17.4**

Normally, the elements of an array are contiguous in memory. This allows immediate access to any array element, because its address can be calculated directly as its offset from the beginning of the array. Linked lists do not afford such immediate access to their elements—an element can be accessed only by traversing the list from the front (or from the back in a doubly linked list).

The program of Figs. 17.3–17.5 uses an object of our `List` class to manipulate a list of miscellaneous objects. The program consists of four classes—`ListNode` (Fig. 17.3, lines

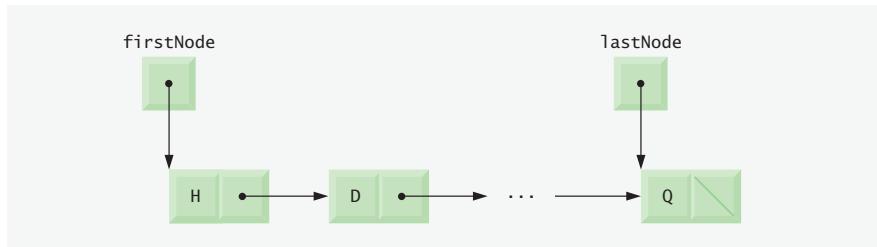

Fig. 17.2 | Linked list graphical representation.

812 Chapter 17 Data Structures

6–37), `List` (Fig. 17.3, lines 40–147), `EmptyListException` (Fig. 17.4) and `ListTest` (Fig. 17.5). The `List`, `ListNode` and `EmptyListException` classes are placed in package `com.deitel.jhtp7.ch17`, so they can be reused throughout this chapter. Encapsulated in each `List` object is a linked list of `ListNode` objects. [Note: Many of the classes in this chapter are declared in the package `com.deitel.jhtp7.ch17`. Each such class should be compiled with the `-d` command-line option to `javac`. When compiling the classes that are not in this package and when running the programs, be sure to use the option `-classpath` to `javac` and `java`, respectively.]

Class `ListNode` (Fig. 17.3, lines 6–37) declares package-access fields `data` and `nextNode`. The `data` field is an `Object` reference, so it can refer to any object. `ListNode` member `nextNode` stores a reference to the next `ListNode` object in the linked list (or `null` if the node is the last one in the list).

```

1 // Fig. 17.3: List.java
2 // ListNode and List class definitions.
3 package com.deitel.jhtp7.ch17;
4
5 // class to represent one node in a list
6 class ListNode
7 {
8     // package access members; List can access these directly
9     Object data; // data for this node
10    ListNode nextNode; // reference to the next node in the list
11
12    // constructor creates a ListNode that refers to object
13    ListNode( Object object )
14    {
15        this( object, null );
16    } // end ListNode one-argument constructor
17
18    // constructor creates ListNode that refers to
19    // Object and to next ListNode
20    ListNode( Object object, ListNode node )
21    {
22        data = object;
23        nextNode = node;
24    } // end ListNode two-argument constructor
25
26    // return reference to data in node
27    Object getObject()
28    {
29        return data; // return Object in this node
30    } // end method getObject
31
32    // return reference to next node in list
33    ListNode getNext()
34    {
35        return nextNode; // get next node
36    } // end method getNext
37 } // end class ListNode

```

Fig. 17.3 | `ListNode` and `List` class declarations. (Part I of 4.)

17.6 Linked Lists **813**

```

38 // class List definition
39 public class List
40 {
41     private ListNode firstNode;
42     private ListNode lastNode;
43     private String name; // string like "list" used in printing
44
45     // constructor creates empty List with "list" as the name
46     public List()
47     {
48         this( "list" );
49     } // end List no-argument constructor
50
51     // constructor creates an empty List with a name
52     public List( String listName )
53     {
54         name = listName;
55         firstNode = lastNode = null;
56     } // end List one-argument constructor
57
58     // insert Object at front of List
59     public void insertAtFront( Object insertItem )
60     {
61         if ( isEmpty() ) // firstNode and lastNode refer to same object
62             firstNode = lastNode = new ListNode( insertItem );
63         else // firstNode refers to new node
64             firstNode = new ListNode( insertItem, firstNode );
65     } // end method insertAtFront
66
67     // insert Object at end of List
68     public void insertAtBack( Object insertItem )
69     {
70         if ( isEmpty() ) // firstNode and lastNode refer to same Object
71             firstNode = lastNode = new ListNode( insertItem );
72         else // lastNode's nextNode refers to new node
73             lastNode = lastNode.nextNode = new ListNode( insertItem );
74     } // end method insertAtBack
75
76     // remove first node from List
77     public Object removeFromFront() throws EmptyListException
78     {
79         if ( isEmpty() ) // throw exception if List is empty
80             throw new EmptyListException( name );
81
82         Object removedItem = firstNode.data; // retrieve data being removed
83
84         // update references firstNode and lastNode
85         if ( firstNode == lastNode )
86             firstNode = lastNode = null;
87         else
88             firstNode = firstNode.nextNode;
89
90

```

Fig. 17.3 | ListNode and List class declarations. (Part 2 of 4.)

814 Chapter 17 Data Structures

```

91     return removedItem; // return removed node data
92 } // end method removeFromFront
93
94 // remove last node from List
95 public Object removeFromBack() throws EmptyListException
96 {
97     if ( isEmpty() ) // throw exception if List is empty
98         throw new EmptyListException( name );
99
100    Object removedItem = lastNode.data; // retrieve data being removed
101
102    // update references firstNode and lastNode
103    if ( firstNode == lastNode )
104        firstNode = lastNode = null;
105    else // locate new last node
106    {
107        ListNode current = firstNode;
108
109        // loop while current node does not refer to lastNode
110        while ( current.nextNode != lastNode )
111            current = current.nextNode;
112
113        lastNode = current; // current is new lastNode
114        current.nextNode = null;
115    } // end else
116
117    return removedItem; // return removed node data
118 } // end method removeFromBack
119
120 // determine whether list is empty
121 public boolean isEmpty()
122 {
123     return firstNode == null; // return true if list is empty
124 } // end method isEmpty
125
126 // output list contents
127 public void print()
128 {
129     if ( isEmpty() )
130     {
131         System.out.printf( "Empty %s\n", name );
132         return;
133     } // end if
134
135     System.out.printf( "The %s is: ", name );
136     ListNode current = firstNode;
137
138     // while not at end of list, output current node's data
139     while ( current != null )
140     {
141         System.out.printf( "%s ", current.data );
142         current = current.nextNode;
143     } // end while

```

Fig. 17.3 | ListNode and List class declarations. (Part 3 of 4.)

17.6 Linked Lists **815**

```

144         System.out.println( "\n" );
145     } // end method print
146 } // end class List

```

Fig. 17.3 | ListNode and List class declarations. (Part 4 of 4.)

Lines 42–43 of class `List` (Fig. 17.3, lines 40–147) declare references to the first and last `ListNode`s in a `List` (`firstNode` and `lastNode`, respectively). The constructors (lines 47–50 and 53–57) initialize both references to `null`. The most important methods of class `List` are `insertAtFront` (lines 60–66), `insertAtBack` (lines 69–75), `removeFromFront` (lines 78–92) and `removeFromBack` (lines 95–118). Method `isEmpty` (lines 121–124) is a *predicate method* that determines whether the list is empty (i.e., the reference to the first node of the list is `null`). Predicate methods typically test a condition and do not modify the object on which they are called. If the list is empty, method `isEmpty` returns `true`; otherwise, it returns `false`. Method `print` (lines 127–146) displays the list's contents. A detailed discussion of `List`'s methods follows Fig. 17.5.

Method `main` of class `ListTest` (Fig. 17.5) inserts objects at the beginning of the list using method `insertAtFront`, inserts objects at the end of the list using method `insertAtBack`, deletes objects from the front of the list using method `removeFromFront` and deletes objects from the end of the list using method `removeFromBack`. After each insert and remove operation, `ListTest` calls `List` method `print` to display the current list contents. If an attempt is made to remove an item from an empty list, an `EmptyListException` (Fig. 17.4) is thrown, so the method calls to `removeFromFront` and `removeFromBack` are placed in a `try` block that is followed by an appropriate exception handler. Notice in lines 13, 15, 17 and 19 that the application passes literal primitive `int`

```

1 // Fig. 17.4: EmptyListException.java
2 // Class EmptyListException definition.
3 package com.deitel.jhtp7.ch17;
4
5 public class EmptyListException extends RuntimeException
6 {
7     // no-argument constructor
8     public EmptyListException()
9     {
10         this( "List" ); // call other EmptyListException constructor
11     } // end EmptyListException no-argument constructor
12
13     // one-argument constructor
14     public EmptyListException( String name )
15     {
16         super( name + " is empty" ); // call superclass constructor
17     } // end EmptyListException one-argument constructor
18 } // end class EmptyListException

```

Fig. 17.4 | `EmptyListException` class declaration.

816 Chapter 17 Data Structures

values to methods `insertAtFront` and `insertAtBack`, even though each of these methods was declared with a parameter of type `Object` (Fig. 17.3, lines 60 and 69). In this case, the JVM autoboxes each literal value in an `Integer` object, and that object is actually inserted into the list. This, of course, is allowed because `Object` is an indirect superclass of `Integer`.

```

5
6 public class ListTest
7 {
8     public static void main( String args[] )
9     {
10         List list = new List(); // create the List container
11
12         // insert integers in list
13         list.insertAtFront( -1 );
14         list.print();
15         list.insertAtFront( 0 );
16         list.print();
17         list.insertAtBack( 1 );
18         list.print();
19         list.insertAtBack( 5 );
20         list.print();
21
22         // remove objects from list; print after each removal
23         try
24         {
25             Object removedObject = list.removeFromFront();
26             System.out.printf( "%s removed\n", removedObject );
27             list.print();
28
29             removedObject = list.removeFromFront();
30             System.out.printf( "%s removed\n", removedObject );
31             list.print();
32
33             removedObject = list.removeFromBack();
34             System.out.printf( "%s removed\n", removedObject );
35             list.print();
36
37             removedObject = list.removeFromBack();
38             System.out.printf( "%s removed\n", removedObject );
39             list.print();
40         } // end try
41         catch ( EmptyListException emptyListException )
42         {
43             emptyListException.printStackTrace();
44         } // end catch
45     } // end main
46 } // end class ListTest

```

17.6 Linked Lists **817**

```
The list is: -1
The list is: 0 -1
The list is: 0 -1 1
The list is: 0 -1 1 5
0 removed
The list is: -1 1 5
-1 removed
The list is: 1 5
5 removed
The list is: 1
1 removed
Empty list
```

Fig. 17.5 | Linked list manipulations. (Part 2 of 2.)

Now we discuss each method of class `List` (Fig. 17.3) in detail and provide diagrams showing the reference manipulations performed by methods `insertAtFront`, `insertAtBack`, `removeFromFront` and `removeFromBack`. Method `insertAtFront` (lines 60–66 of Fig. 17.3) places a new node at the front of the list. The steps are:

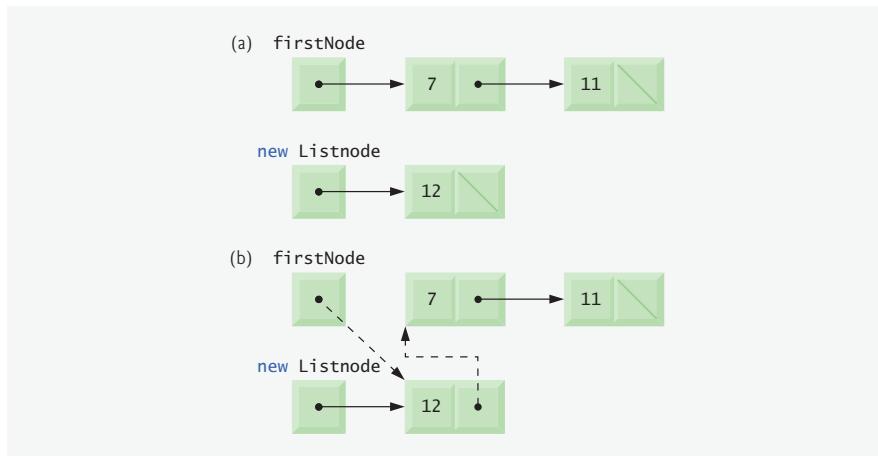

1. Call `isEmpty` to determine whether the list is empty (line 62).
2. If the list is empty, assign `firstNode` and `lastNode` to the new `ListNode` that was initialized with `insertItem` (line 63). The `ListNode` constructor at lines 13–16 calls the `ListNode` constructor at lines 20–24 to set instance variable `data` to refer to the `insertItem` passed as an argument and to set reference `nextNode` to `null`, because this is the first and last node in the list.
3. If the list is not empty, the new node is “linked” into the list by setting `firstNode` to a new `ListNode` object and initializing that object with `insertItem` and `firstNode` (line 65). When the `ListNode` constructor (lines 20–24) executes, it sets instance variable `data` to refer to the `insertItem` passed as an argument and performs the insertion by setting the `nextNode` reference of the new node to the `ListNode` passed as an argument, which previously was the first node.

In Fig. 17.6, part (a) shows a list and a new node during the `insertAtFront` operation and before the program links the new node into the list. The dotted arrows in part (b) illustrate *Step 3* of the `insertAtFront` operation that enables the node containing 12 to become the new first node in the list.

Method `insertAtBack` (lines 69–75 of Fig. 17.3) places a new node at the back of the list. The steps are:

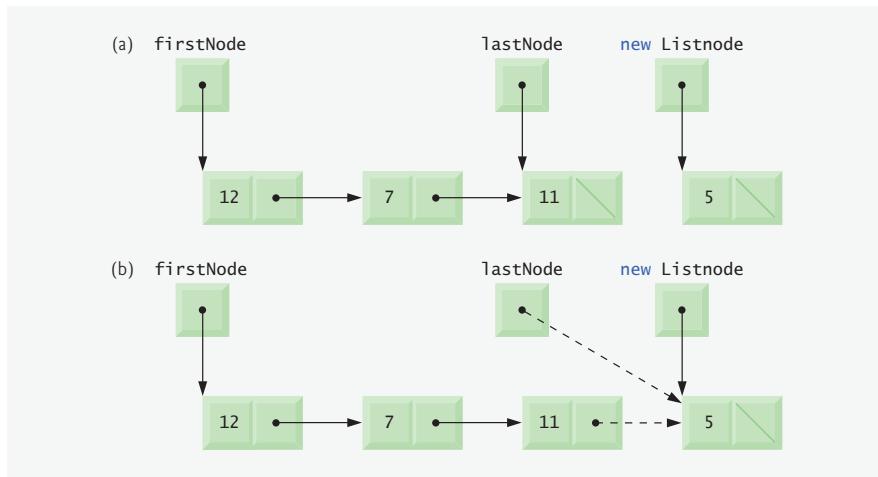

1. Call `isEmpty` to determine whether the list is empty (line 71).
2. If the list is empty, assign `firstNode` and `lastNode` to the new `ListNode` that was initialized with `insertItem` (line 72). The `ListNode` constructor at lines 13–16 calls the constructor at lines 20–24 to set instance variable `data` to refer to the `insertItem` passed as an argument and to set reference `nextNode` to `null`.

818 Chapter 17 Data Structures

**Fig. 17.6** | Graphical representation of operation `insertAtFront`.

- If the list is not empty, line 74 links the new node into the list by assigning to `lastNode` and `lastNode.nextNode` the reference to the new `ListNode` that was initialized with `insertItem`. `ListNode`'s constructor (lines 13–16), sets instance variable `data` to refer to the `insertItem` passed as an argument and sets reference `nextNode` to `null`, because this is the last node in the list.

In Fig. 17.7, part (a) shows a list and a new node during the `insertAtBack` operation and before the program links the new node into the list. The dotted arrows in part (b) illustrate *Step 3* of method `insertAtBack`, which adds the new node to the end of a list that is not empty.

**Fig. 17.7** | Graphical representation of operation `insertAtBack`.

17.6 Linked Lists **819**

Method `removeFromFront` (lines 78–92 of Fig. 17.3) removes the first node of the list and returns a reference to the removed data. The method throws an `EmptyListException` (lines 80–81) if the list is empty when the program calls this method. Otherwise, the method returns a reference to the removed data. The steps are:

1. Assign `firstNode.data` (the data being removed from the list) to reference `removedItem` (line 83).
2. If `firstNode` and `lastNode` refer to the same object (line 86), the list has only one element at this time. So, the method sets `firstNode` and `lastNode` to `null` (line 87) to remove the node from the list (leaving the list empty).
3. If the list has more than one node, then the method leaves reference `lastNode` as is and assigns the value of `firstNode.nextNode` to `firstNode` (line 89). Thus, `firstNode` references the node that was previously the second node in the list.
4. Return the `removedItem` reference (line 91).

In Fig. 17.8, part (a) illustrates the list before the removal operation. The dashed lines and arrows in part (b) show the reference manipulations.

Method `removeFromBack` (lines 95–118 of Fig. 17.3) removes the last node of a list and returns a reference to the removed data. The method throws an `EmptyListException` (lines 97–98) if the list is empty when the program calls this method. The steps are:

1. Assign `lastNode.data` (the data being removed from the list) to `removedItem` (line 100).

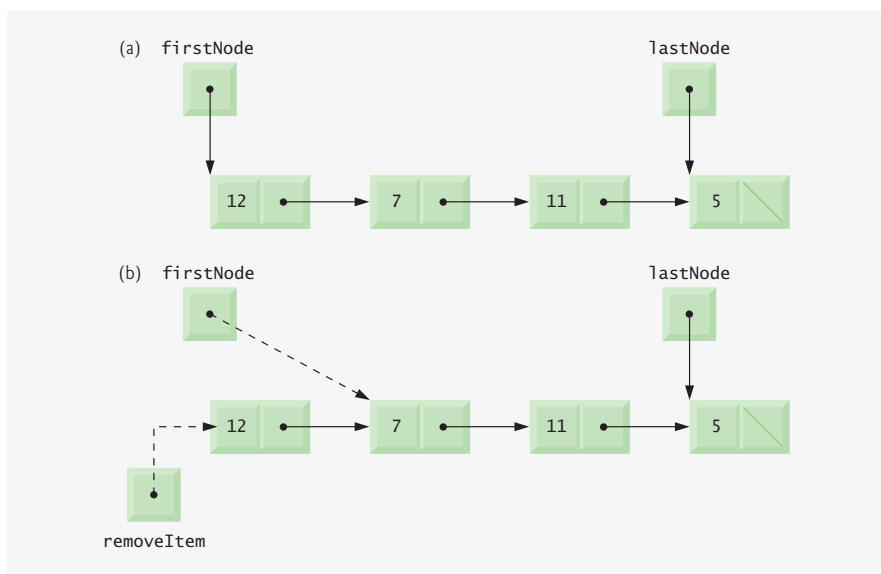

Fig. 17.8 | Graphical representation of operation `removeFromFront`.

820 Chapter 17 Data Structures

2. If the `firstNode` and `lastNode` refer to the same object (line 103), the list has only one element at this time. So, line 104 sets `firstNode` and `lastNode` to `null` to remove that node from the list (leaving the list empty).
3. If the list has more than one node, create the `ListNode` reference `current` and assign it `firstNode` (line 107).
4. Now “walk the list” with `current` until it references the node before the last node. The `while` loop (lines 110–111) assigns `current.nextNode` to `current` as long as `current.nextNode` (the next node in the list) is not `lastNode`.
5. After locating the second-to-last node, assign `current` to `lastNode` (line 113) to update which node is last in the list.
6. Set the `current.nextNode` to `null` (line 114) to remove the last node from the list and terminate the list at the current node.
7. Return the `removedItem` reference (line 117).

In Fig. 17.9, part (a) illustrates the list before the removal operation. The dashed lines and arrows in part (b) show the reference manipulations.

Method `print` (lines 127–146) first determines whether the list is empty (lines 129–133). If so, `print` displays a message indicating that the list is empty and returns control to the calling method. Otherwise, `print` outputs the list’s data. Line 136 creates `ListNode` `current` and initializes it with `firstNode`. While `current` is not `null`, there are more items in the list. Therefore, line 141 outputs a string representation of `current.data`. Line 142 moves to the next node in the list by assigning the value of reference `current.nextNode` to `current`. This printing algorithm is identical for linked lists, stacks and queues.

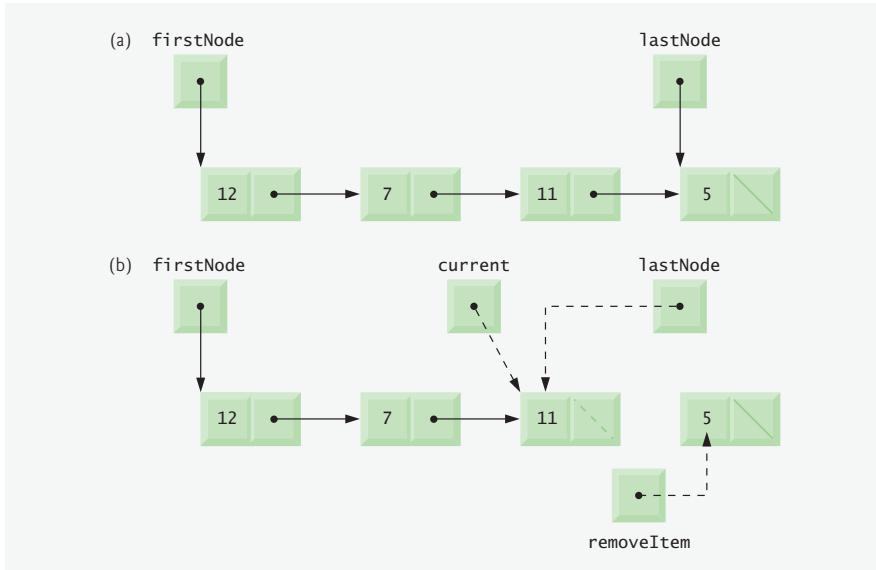

Fig. 17.9 | Graphical representation of operation `removeFromBack`.

17.7 Stacks

A stack is a constrained version of a linked list—new nodes can be added to and removed from a stack only at the top. [Note: A stack does not have to be implemented using a linked list.] For this reason, a stack is referred to as a **last-in, first-out (LIFO)** data structure. The link member in the bottom (i.e., last) node of the stack is set to `null` to indicate the bottom of the stack.

The primary methods for manipulating a stack are `push` and `pop`. Method `push` adds a new node to the top of the stack. Method `pop` removes a node from the top of the stack and returns the data from the popped node.

Stacks have many interesting applications. For example, when a program calls a method, the called method must know how to return to its caller, so the return address of the calling method is pushed onto the **program execution stack**. If a series of method calls occurs, the successive return addresses are pushed onto the stack in last-in, first-out order so that each method can return to its caller. Stacks support recursive method calls in the same manner as they do conventional nonrecursive method calls.

The program execution stack also contains the memory for local variables on each invocation of a method during a program's execution. When the method returns to its caller, the memory for that method's local variables is popped off the stack, and those variables are no longer known to the program. If the local variable is a reference, the reference count for the object to which it referred is decremented by 1. If the reference count becomes zero, the object can be garbage collected.

Compilers use stacks to evaluate arithmetic expressions and generate machine-language code to process the expressions. The exercises in this chapter explore several applications of stacks, including using them to develop a complete working compiler. Also, package `java.util` contains class `Stack` (see Chapter 19, Collections) for implementing and manipulating stacks that can grow and shrink during program execution.

We take advantage of the close relationship between lists and stacks to implement a stack class by reusing a list class. We demonstrate two different forms of reusability. First, we implement the stack class by extending class `List` of Fig. 17.3. Then we implement an identically performing stack class through composition by including a reference to a `List` object as a private instance variable of a stack class. The list, stack and queue data structures in this chapter are implemented to store `Object` references to encourage further reusability. Thus, any object type can be stored in a list, stack or queue.

Stack Class That Inherits from List

The application of Fig. 17.10 and Fig. 17.11 creates a stack class by extending class `List` of Fig. 17.3. We want the stack to have methods `push`, `pop`, `isEmpty` and `print`. Essentially, these are the methods `insertAtFront`, `removeFromFront`, `isEmpty` and `print` of class `List`. Of course, class `List` contains other methods (such as `insertAtBack` and `removeFromBack`) that we would rather not make accessible through the `public` interface to the stack class. It is important to remember that all methods in the `public` interface of class `List` class also are `public` methods of the subclass `StackInheritance` (Fig. 17.10). When we implement the stack's methods, we have each `StackInheritance` method call the appropriate `List` method—method `push` calls `insertAtFront` and method `pop` calls `removeFromFront`. Clients of class `StackInheritance` can call methods `isEmpty` and `print` because they are inherited from `List`. Class `StackInheritance` is declared as part of pack-

822 Chapter 17 Data Structures

```

1 // Fig. 17.10: StackInheritance.java
2 // Derived from class List.
3 package com.deitel.jhtp7.ch17;
4
5 public class StackInheritance extends List
6 {
7     // no-argument constructor
8     public StackInheritance()
9     {
10         super( "stack" );
11     } // end StackInheritance no-argument constructor
12
13     // add object to stack
14     public void push( Object object )
15     {
16         insertAtFront( object );
17     } // end method push
18
19     // remove object from stack
20     public Object pop() throws EmptyListException
21     {
22         return removeFromFront();
23     } // end method pop
24 } // end class StackInheritance

```

Fig. 17.10 | StackInheritance extends class List.

age `com.deitel.jhtp7.ch17` for reuse purposes. Note that `StackInheritance` does not import `List`, because both classes are in the same package.

Class `StackInheritanceTest`'s method `main` (Fig. 17.11) creates an object of class `StackInheritance` called `stack` (line 10). The program pushes integers onto the stack (lines 13, 15, 17 and 19). Once again, note that autoboxing is used here to insert `Integer` objects into the data structure. Lines 27–32 pop the objects from the stack in an infinite while loop. If method `pop` is invoked on an empty stack, the method throws an `EmptyListException`. In this case, the program displays the exception's stack trace, which shows the methods on the program execution stack at the time the exception occurred. Note that the program uses method `print` (inherited from `List`) to output the contents of the stack.

824 Chapter 17 Data Structures*Stack Class That Contains a Reference to a List*

You can also implement a class by reusing a list class through composition. Figure 17.12 uses a `private List` (line 7) in class `StackComposition`'s declaration. Composition enables us to hide the `List` methods that should not be in our stack's public interface. We provide `public` interface methods that use only the required `List` methods. Implementing each stack method as a call to a `List` method is called **delegation**—the stack method invoked **delegates** the call to the appropriate `List` method. In particular, `StackComposition` delegates calls to `List` methods `insertAtFront`, `removeFromFront`, `isEmpty` and `print`. In this example, we do not show class `StackCompositionTest`, because the only difference is that we change the type of the stack from `StackInheritance` to `StackComposition` (lines 3 and 10 of Fig. 17.11). The output is identical using either version of the stack.

```

1 // Fig. 17.12: StackComposition.java
2 // Class StackComposition definition with composed List object.
3 package com.deitel.jhtp7.ch17;
4
5 public class StackComposition
6 {
7     private List stackList;
8
9     // no-argument constructor
10    public StackComposition()
11    {
12        stackList = new List( "stack" );
13    } // end StackComposition no-argument constructor
14
15    // add object to stack
16    public void push( Object object )
17    {
18        stackList.insertAtFront( object );
19    } // end method push
20
21    // remove object from stack
22    public Object pop() throws EmptyListException
23    {
24        return stackList.removeFromFront();
25    } // end method pop
26
27    // determine if stack is empty
28    public boolean isEmpty()
29    {
30        return stackList.isEmpty();
31    } // end method isEmpty
32
33    // output stack contents
34    public void print()
35    {
36        stackList.print();
37    } // end method print
38 } // end class StackComposition

```

Fig. 17.12 | `StackComposition` uses a composed `List` object.

17.8 Queues

Another commonly used data structure is the queue. A queue is similar to a checkout line in a supermarket—the cashier services the person at the beginning of the line first. Other customers enter the line only at the end and wait for service. Queue nodes are removed only from the head (or front) of the queue and are inserted only at the tail (or end). For this reason, a queue is a **first-in, first-out (FIFO)** data structure. The insert and remove operations are known as **enqueue** and **dequeue**.

Queues have many uses in computer systems. Most computers have only a single processor, so only one application at a time can be serviced. Each application requiring processor time is placed in a queue. The application at the front of the queue is the next to receive service. Each application gradually advances to the front as the applications before it receive service.

Queues are also used to support **print spooling**. For example, a single printer might be shared by all users of a network. Many users can send print jobs to the printer, even when the printer is already busy. These print jobs are placed in a queue until the printer becomes available. A program called a **spooler** manages the queue to ensure that, as each print job completes, the next print job is sent to the printer.

Information packets also wait in queues in computer networks. Each time a packet arrives at a network node, it must be routed to the next node along the path to the packet's final destination. The routing node routes one packet at a time, so additional packets are enqueued until the router can route them.

A file server in a computer network handles file-access requests from many clients throughout the network. Servers have a limited capacity to service requests from clients. When that capacity is exceeded, client requests wait in queues.

Figure 17.13 creates a queue class that contains an object of class **List** (Fig. 17.3). Class **Queue** (Fig. 17.13) provides methods **enqueue**, **dequeue**, **isEmpty** and **print**. Class **List** contains other methods (e.g., **insertAtFront** and **removeFromBack**) that we would rather not make accessible through the public interface of class **Queue**. By using composition, these methods in the public interface of class **List** are not accessible to clients of class **Queue**. Each method of class **Queue** calls an appropriate **List** method—method **enqueue** calls **List** method **insertAtBack**, method **dequeue** calls **List** method **removeFromFront**,

```

1 // Fig. 17.13: Queue.java
2 // Class Queue.
3 package com.deitel.jhtp7.ch17;
4
5 public class Queue {
6 {
7     private List queueList;
8
9     // no-argument constructor
10    public Queue()
11    {
12        queueList = new List( "queue" );
13    } // end Queue no-argument constructor
14

```

Fig. 17.13 | Queue uses class List. (Part I of 2.)

826 Chapter 17 Data Structures

```

15 // add object to queue
16 public void enqueue( Object object )
17 {
18     queueList.insertAtBack( object );
19 } // end method enqueue
20
21 // remove object from queue
22 public Object dequeue() throws EmptyListException
23 {
24     return queueList.removeFromFront();
25 } // end method dequeue
26
27 // determine if queue is empty
28 public boolean isEmpty()
29 {
30     return queueList.isEmpty();
31 } // end method isEmpty
32
33 // output queue contents
34 public void print()
35 {
36     queueList.print();
37 } // end method print
38 } // end class Queue

```

Fig. 17.13 | Queue uses class List. (Part 2 of 2.)

method `isEmpty` calls `List` method `isEmpty` and method `print` calls `List` method `print`. For reuse purposes, class `Queue` is declared in package `com.deitel.jhtp7.ch17`.

Class `QueueTest` (Fig. 17.14) method `main` creates an object of class `Queue` called `queue`. Lines 13, 15, 17 and 19 enqueue four integers, taking advantage of autoboxing to insert `Integer` objects into the queue. Lines 27–32 use an infinite `while` loop to dequeue the objects in first-in, first-out order. When the queue is empty, method `dequeue` throws an `EmptyListException`, and the program displays the exception's stack trace.

```

1 // Fig. 17.14: QueueTest.java
2 // Class QueueTest.
3 import com.deitel.jhtp7.ch17.Queue;
4 import com.deitel.jhtp7.ch17.EmptyListException;
5
6 public class QueueTest
7 {
8     public static void main( String args[] )
9     {
10         Queue queue = new Queue();
11
12         // use enqueue method
13         queue.enqueue( -1 );
14         queue.print();
15         queue.enqueue( 0 );

```

17.9 Trees

Linked lists, stacks and queues are **linear data structures** (i.e., **sequences**). A tree is a non-linear, two-dimensional data structure with special properties. Tree nodes contain two or more links. This section discusses binary trees (Fig. 17.15)—trees whose nodes each con-

828 Chapter 17 Data Structures

tain two links (one or both of which may be `null`). The **root node** is the first node in a tree. Each link in the root node refers to a **child**. The **left child** is the first node in the **left subtree** (also known as the root node of the left subtree), and the **right child** is the first node in the **right subtree** (also known as the root node of the right subtree). The children of a specific node are called **siblings**. A node with no children is called a **leaf node**. Computer scientists normally draw trees from the root node down—the opposite of the way most trees grow in nature.

In our example, we create a special binary tree called a **binary search tree**. A binary search tree (with no duplicate node values) has the characteristic that the values in any left subtree are less than the value in that subtree's parent node, and the values in any right subtree are greater than the value in that subtree's parent node. Figure 17.16 illustrates a binary search tree with 12 integer values. Note that the shape of the binary search tree that corresponds to a set of data can vary, depending on the order in which the values are inserted into the tree.

The application of Fig. 17.17 and Fig. 17.18 creates a binary search tree of integers and traverses it (i.e., walks through all its nodes) three ways—using recursive **inorder**, **pre-order** and **postorder traversals**. The program generates 10 random numbers and inserts each into the tree. Class `Tree` is declared in package `com.deitel.jhtp7.ch17` for reuse purposes.

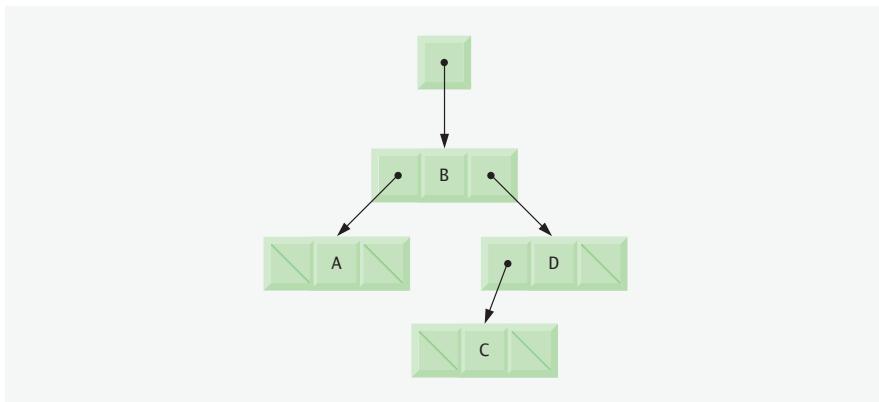

Fig. 17.15 | Binary tree graphical representation.

17.9 Trees **829**

```

1 // Fig. 17.17: Tree.java
2 // Definition of class TreeNode and class Tree.
3 package com.deitel.jhtp7.ch17;
4
5 // class TreeNode definition
6 class TreeNode
7 {
8     // package access members
9     TreeNode leftNode; // Left node
10    int data; // node value
11    TreeNode rightNode; // right node
12
13    // constructor initializes data and makes this a leaf node
14    public TreeNode( int nodeData )
15    {
16        data = nodeData;
17        leftNode = rightNode = null; // node has no children
18    } // end TreeNode constructor
19
20    // locate insertion point and insert new node; ignore duplicate values
21    public void insert( int insertValue )
22    {
23        // insert in left subtree
24        if ( insertValue < data )
25        {
26            // insert new TreeNode
27            if ( leftNode == null )
28                leftNode = new TreeNode( insertValue );
29            else // continue traversing left subtree
30                leftNode.insert( insertValue );
31        } // end if

113 } // end class Tree

```

Fig. 17.17 | TreeNode and Tree class declarations for a binary search tree. (Part 3 of 3.)

Let us walk through the binary tree program. Method `main` of class `TreeTest` (Fig. 17.18) begins by instantiating an empty `Tree` object and assigning its reference to variable `tree` (line 10). Lines 17–22 randomly generate 10 integers, each of which is inserted into the binary tree through a call to method `insertNode` (line 21). The program then performs preorder, inorder and postorder traversals (these will be explained shortly) of `tree` (lines 25, 28 and 31, respectively).

Class `Tree` (Fig. 17.17, lines 44–113) has private field `root` (line 46)—a `TreeNode` reference to the root node of the tree. `Tree`'s constructor (lines 49–52) initializes `root` to `null` to indicate that the tree is empty. The class contains method `insertNode` (lines 55–61) to insert a new node in the tree and methods `preorderTraversal` (lines 64–67), `inorderTraversal` (lines 81–84) and `postorderTraversal` (lines 98–101) to begin traversals of the tree. Each of these methods calls a recursive utility method to perform the traversal operations on the internal representation of the tree. (We discussed recursion in Chapter 15.)

Class `Tree`'s method `insertNode` (lines 55–61) first determines whether the tree is empty. If so, line 58 allocates a new `TreeNode`, initializes the node with the integer being inserted in the tree and assigns the new node to reference `root`. If the tree is not empty, line 60 calls `TreeNode` method `insert` (lines 21–41). This method uses recursion to determine the location for the new node in the tree and inserts the node at that location. A node can be inserted only as a leaf node in a binary search tree.

`TreeNode` method `insert` compares the value to insert with the `data` value in the root node. If the `insert` value is less than the root node `data` (line 24), the program determines if the left subtree is empty (line 27). If so, line 28 allocates a new `TreeNode`, initializes it with the integer being inserted and assigns the new node to reference `leftNode`. Otherwise, line 30 recursively calls `insert` for the left subtree to insert the value into the left subtree. If the `insert` value is greater than the root node `data` (line 32), the program determines if the right subtree is empty (line 35). If so, line 36 allocates a new `TreeNode`, initializes it with the integer being inserted and assigns the new node to reference `rightNode`. Otherwise, line 38 recursively calls `insert` for the right subtree to insert the value in the right subtree. If the `insertValue` is already in the tree, it is simply ignored.

Methods `inorderTraversal`, `preorderTraversal` and `postorderTraversal` call `Tree` helper methods `inorderHelper` (lines 87–95), `preorderHelper` (lines 70–78) and `postorderHelper` (lines 104–112), respectively, to traverse the tree and print the node values. The helper methods in class `Tree` enable the programmer to start a traversal without having

to pass the root node to the method. Reference root is an implementation detail that a programmer should not be able to access. Methods `inorderTraversal`, `preorderTraversal` and `postorderTraversal` simply take the private root reference and pass it to the appropriate helper method to initiate a traversal of the tree. The base case for each helper method determines whether the reference it receives is `null` and, if so, returns immediately.

17.9 Trees **833**

Method `inorderHelper` (lines 87–95) defines the steps for an inorder traversal:

1. Traverse the left subtree with a call to `inorderHelper` (line 92).
2. Process the value in the node (line 93).
3. Traverse the right subtree with a call to `inorderHelper` (line 94).

The inorder traversal does not process the value in a node until the values in that node's left subtree are processed. The inorder traversal of the tree in Fig. 17.19 is

6 13 17 27 33 42 48

Note that the inorder traversal of a binary search tree prints the node values in ascending order. The process of creating a binary search tree actually sorts the data; thus, it is called the **binary tree sort**.

Method `preorderHelper` (lines 70–78) defines the steps for a preorder traversal:

1. Process the value in the node (line 75).
2. Traverse the left subtree with a call to `preorderHelper` (line 76).
3. Traverse the right subtree with a call to `preorderHelper` (line 77).

The preorder traversal processes the value in each node as the node is visited. After processing the value in a given node, the preorder traversal processes the values in the left subtree, then the values in the right subtree. The preorder traversal of the tree in Fig. 17.19 is

27 13 6 17 42 33 48

Method `postorderHelper` (lines 104–112) defines the steps for a postorder traversal:

1. Traverse the left subtree with a call to `postorderHelper` (line 109).
2. Traverse the right subtree with a call to `postorderHelper` (line 110).
3. Process the value in the node (line 111).

The postorder traversal processes the value in each node after the values of all that node's children are processed. The `postorderTraversal` of the tree in Fig. 17.19 is

6 17 13 33 48 42 27

The binary search tree facilitates **duplicate elimination**. While building a tree, the insertion operation recognizes attempts to insert a duplicate value, because a duplicate follows the same “go left” or “go right” decisions on each comparison as the original value did. Thus, the insertion operation eventually compares the duplicate with a node containing the same value. At this point, the insertion operation can decide to discard the duplicate value (as we do in this example).

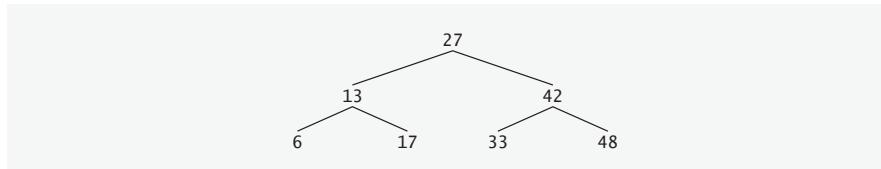

Fig. 17.19 | Binary search tree with seven values.

834 Chapter 17 Data Structures

Searching a binary tree for a value that matches a key value is fast, especially for **tightly packed (or balanced) trees**. In a tightly packed tree, each level contains about twice as many elements as the previous level. Figure 17.19 is a tightly packed binary tree. A tightly packed binary search tree with n elements has $\log_2 n$ levels. Thus, at most $\log_2 n$ comparisons are required either to find a match or to determine that no match exists. Searching a (tightly packed) 1000-element binary search tree requires at most 10 comparisons, because $2^{10} > 1000$. Searching a (tightly packed) 1,000,000-element binary search tree requires at most 20 comparisons, because $2^{20} > 1,000,000$.

The chapter exercises present algorithms for several other binary tree operations, such as deleting an item from a binary tree, printing a binary tree in a two-dimensional tree format and performing a **level-order traversal of a binary tree**. The level-order traversal visits the nodes of the tree row by row, starting at the root node level. On each level of the tree, a level-order traversal visits the nodes from left to right. Other binary tree exercises include allowing a binary search tree to contain duplicate values, inserting string values in a binary tree and determining how many levels are contained in a binary tree. Chapter 19 continues our discussion of data structures by presenting the data structures in the Java API.

17.10 Wrap-Up

In this chapter, you learned about type-wrapper classes, boxing and dynamic data structures that grow and shrink at execution time. You learned that each primitive type has a corresponding type-wrapper class in package `java.lang`. You also saw that Java can convert between primitive values and objects of the type-wrapper classes using boxing.

You learned that linked lists are collections of data items that are “linked up in a chain.” You also saw that an application can perform insertions and deletions anywhere in a linked list. You learned that the stack and queue data structures are constrained versions of lists. For stacks, you saw that insertions and deletions are made only at the top. For queues that represent waiting lines, you saw that insertions are made at the tail and deletions are made from the head. You also learned the binary tree data structure. You saw a binary search tree that facilitated high-speed searching and sorting of data and eliminating duplicate data items efficiently. Throughout the chapter, you learned how to create and package these data structures for reusability and maintainability.

Chapter 18, Generics, presents a mechanism for declaring classes and methods without specific type information so that the classes and methods can be used with many different types. Generics are used extensively in Java’s built-in set of data structures, known as the Collections API, which we discuss in Chapter 19.

Summary

Section 17.1 Introduction

- Dynamic data structures can grow and shrink at execution time.
- Linked lists are collections of data items “linked up in a chain”—insertions and deletions can be made anywhere in a linked list.
- Stacks are important in compilers and operating systems—insertions and deletions are made only at one end of a stack, its top.

- Insertions are made at the tail of a queue and deletions are made from the head.
- Binary trees facilitate high-speed searching and sorting of data, eliminating duplicate data items efficiently, representing file-system directories and compiling expressions into machine language.

Section 17.2 Type-Wrapper Classes for Primitive Types

- Type-wrapper classes (e.g., `Integer`, `Double`, `Boolean`) enable programmers to manipulate primitive-type values as objects. Objects of these classes can be used in collections and data structures that can store only references to objects—not primitive-type values.

Section 17.3 Autoboxing and Auto-Unboxing

- A boxing conversion converts a value of a primitive type to an object of the corresponding type-wrapper class. An unboxing conversion converts an object of a type-wrapper class to a value of the corresponding primitive type.
- Java performs boxing conversions and unboxing conversions automatically (called autoboxing and auto-unboxing).

Section 17.4 Self-Referential Classes

- A self-referential class contains a reference that refers to another object of the same class type. Self-referential objects can be linked together to form dynamic data structures.

Section 17.5 Dynamic Memory Allocation

- The limit for dynamic memory allocation can be as large as the available physical memory in the computer or the amount of available disk space in a virtual-memory system. Often, the limits are much smaller because the computer's available memory must be shared among many users.
- If no memory is available, an `OutOfMemoryError` is thrown.

Section 17.6 Linked Lists

- A linked list is accessed via a reference to the first node of the list. Each subsequent node is accessed via the link-reference member stored in the previous node.
- By convention, the link reference in the last node of a list is set to `null` to mark the end of the list.
- A node can contain data of any type, including objects of other classes.
- A linked list is appropriate when the number of data elements to be stored is unpredictable. Linked lists are dynamic, so the length of a list can increase or decrease as necessary.
- The size of a “conventional” Java array cannot be altered—it is fixed at creation time.
- Linked lists can be maintained in sorted order simply by inserting each new element at the proper point in the list.
- List nodes normally are not stored contiguously in memory. Rather, they are logically contiguous.

Section 17.7 Stacks

- A stack is a last-in, first-out (LIFO) data structure. The primary methods used to manipulate a stack are `push` and `pop`. Method `push` adds a new node to the top of the stack. Method `pop` removes a node from the top of the stack and returns the data object from the popped node.
- Stacks have many interesting applications. When a method call is made, the called method must know how to return to its caller, so the return address is pushed onto the program execution stack. If a series of method calls occurs, the successive return values are pushed onto the stack in last-in, first-out order so that each method can return to its caller. The program execution stack contains the space created for local variables on each invocation of a method. When the method returns to its caller, the space for that method's local variables is popped off the stack, and those variables are no longer available to the program.

836 Chapter 17 Data Structures

- Stacks are used by compilers to evaluate arithmetic expressions and generate machine-language code to process the expressions.
- The technique of implementing each stack method as a call to a `List` method is called delegation—the stack method invoked delegates the call to the appropriate `List` method.

Section 17.8 Queues

- A queue is similar to a checkout line in a supermarket—the first person in line is serviced first, and other customers enter the line only at the end and wait to be serviced.
- Queue nodes are removed only from the head of the queue and are inserted only at the tail. For this reason, a queue is referred to as a first-in, first-out (FIFO) data structure.
- The insert and remove operations for a queue are known as `enqueue` and `dequeue`.
- Queues have many uses in computer systems. Most computers have only a single processor, so only one application at a time can be serviced. Entries for the other applications are placed in a queue. The entry at the front of the queue is the next to receive service. Each entry gradually advances to the front of the queue as applications receive service.

Section 17.9 Trees

- A tree is a nonlinear, two-dimensional data structure. Tree nodes contain two or more links.
- A binary tree is a tree whose nodes all contain two links. The root node is the first node in a tree.
- Each link in the root node refers to a child. The left child is the first node in the left subtree, and the right child is the first node in the right subtree.
- The children of a node are called siblings. A node with no children is called a leaf node.
- In a binary search tree with no duplicate values, the values in any left subtree are less than the value in the subtree's parent node, and the values in any right subtree are greater than the value in the subtree's parent node. A node can be inserted only as a leaf node in a binary search tree.
- An inorder traversal of a binary search tree processes the node values in ascending order.
- In a preorder traversal, the value in each node is processed as the node is visited. Then the values in the left subtree are processed, and then the values in the right subtree.
- In a postorder traversal, the value in each node is processed after the values of its children.
- The binary search tree facilitates duplicate elimination. As the tree is created, attempts to insert a duplicate value are recognized, because a duplicate follows the same “go left” or “go right” decisions on each comparison as the original value did. Thus, the duplicate eventually is compared with a node containing the same value. The duplicate value can be discarded at this point.
- Searching a binary tree for a value that matches a key value is also fast, especially for tightly packed trees. In a tightly packed tree, each level contains about twice as many elements as the previous one. So a tightly packed binary search tree with n elements has $\log_2 n$ levels, and thus at most $\log_2 n$ comparisons would have to be made either to find a match or to determine that no match exists. Searching a (tightly packed) 1000-element binary search tree requires at most 10 comparisons, because $2^{10} > 1000$. Searching a (tightly packed) 1,000,000-element binary search tree requires at most 20 comparisons, because $2^{20} > 1,000,000$.

Terminology

autoboxing	binary tree sort
auto-unboxing	Boolean class
balanced tree	boxing conversion
binary search tree	Byte class
binary tree	Character class

Self-Review Exercises **837**

child node	OutOfMemoryError
children of a node	packed tree
delegate a method call	parent node
delete a node	pop
dequeue	postorder traversal of a binary tree
duplicate elimination	predicate method
dynamic data structure	preorder traversal of a binary tree
enqueue	program execution stack
FIFO (first-in, first-out)	push
Float class	queue
head of a queue	recursive tree traversal algorithms
inorder traversal of a binary tree	right child
insert a node	right subtree
Integer class	root node
leaf node	self-referential class
left child	Short class
left subtree	stack
level-order traversal of a binary tree	subtree
LIFO (last-in, first-out)	tail of a queue
linear data structure	top of a stack
linked list	traversal
Long class	tree
node	type-wrapper classes
nonlinear data structure	unboxing conversion
null reference	visiting a node

Self-Review Exercises

17.1 Fill in the blanks in each of the following statements:

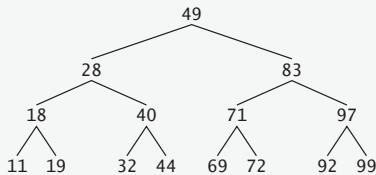

- a) A self-_____ class is used to form dynamic data structures that can grow and shrink at execution time.
- b) A(n) _____ is a constrained version of a linked list in which nodes can be inserted and deleted only from the start of the list.
- c) A method that does not alter a linked list, but simply looks at it to determine whether it is empty, is referred to as a(n) _____ method.
- d) A queue is referred to as a(n) _____ data structure because the first nodes inserted are the first ones removed.
- e) The reference to the next node in a linked list is referred to as a(n) _____.
- f) Automatically reclaiming dynamically allocated memory in Java is called _____.
- g) A(n) _____ is a constrained version of a linked list in which nodes can be inserted only at the end of the list and deleted only from the start of the list.
- h) A(n) _____ is a nonlinear, two-dimensional data structure that contains nodes with two or more links.
- i) A stack is referred to as a(n) _____ data structure because the last node inserted is the first node removed.
- j) The nodes of a(n) _____ tree contain two link members.
- k) The first node of a tree is the _____ node.
- l) Each link in a tree node refers to a(n) _____ or _____ of that node.
- m) A tree node that has no children is called a(n) _____ node.
- n) The three traversal algorithms we mentioned in the text for binary search trees are _____, _____ and _____.

838 Chapter 17 Data Structures

- o)** Assuming that `myArray` contains references to `Double` objects, _____ occurs when the statement "double number = `myArray[0]`;" executes.
- p)** Assuming that `myArray` contains references to `Double` objects, _____ occurs when the statement "`myArray[0] = 1.25;`" executes.

17.2 What are the differences between a linked list and a stack?**17.3** What are the differences between a stack and a queue?**17.4** Perhaps a more appropriate title for this chapter would have been Reusable Data Structures. Comment on how each of the following entities or concepts contributes to the reusability of data structures:

- a)** classes
- b)** inheritance
- c)** composition

17.5 Manually provide the inorder, preorder and postorder traversals of the binary search tree of Fig. 17.20.**Fig. 17.20** | Binary search tree with 15 nodes.**Answers to Self-Review Exercises**

17.1 a) referential. b) stack. c) predicate. d) first-in, first-out (FIFO). e) link. f) garbage collection. g) queue. h) tree i) last-in, first-out (LIFO). j) binary. k) root. l) child or subtree. m) leaf. n) inorder, preorder, postorder. o) auto-unboxing. p) autoboxing.

17.2 It is possible to insert a node anywhere in a linked list and remove a node from anywhere in a linked list. Nodes in a stack may be inserted only at the top of the stack and removed only from the top.

17.3 A queue is a FIFO data structure that has references to both its head and its tail, so that nodes may be inserted at the tail and deleted from the head. A stack is a LIFO data structure that has a single reference to the stack's top, where both insertion and deletion of nodes are performed.

17.4 a) Classes allow us to instantiate as many data structure objects of a certain type (i.e., class) as we wish.
 b) Inheritance enables a subclass to reuse the functionality from a superclass. Public and protected methods of a superclass can be accessed through a subclass to eliminate duplicate logic.
 c) Composition enables a class to reuse code by storing a reference to an instance of another class in a field. Public methods of the instance can be called by methods in the class that contains the reference.

17.5 The inorder traversal is

```
11 18 19 28 32 40 44 49 69 71 72 83 92 97 99
```

Exercises 839

The preorder traversal is

49 28 18 11 19 40 32 44 83 71 69 72 97 92 99

The postorder traversal is

Exercises

17.6 Write a program that concatenates two linked list objects of characters. Class `ListConcatenate` should include a method `concatenate` that takes references to both list objects as arguments and concatenates the second list to the first list.

17.7 Write a program that merges two ordered list objects of integers into a single ordered-list object of integers. Method `merge` of class `ListMerge` should receive references to each of the list objects to be merged and return a reference to the merged list object.

17.8 Write a program that inserts 25 random integers from 0 to 100 in order into a linked-list object. The program should calculate the sum of the elements and the floating-point average of the elements.

17.9 Write a program that creates a linked list object of 10 characters, then creates a second list object containing a copy of the first list, but in reverse order.

17.10 Write a program that inputs a line of text and uses a stack object to print the words of the line in reverse order.

17.11 Write a program that uses a stack to determine whether a string is a palindrome (i.e., the string is spelled identically backward and forward). The program should ignore spaces and punctuation.

17.12 Stacks are used by compilers to help in the process of evaluating expressions and generating machine-language code. In this and the next exercise, we investigate how compilers evaluate arithmetic expressions consisting only of constants, operators and parentheses.

Humans generally write expressions like $3 + 4$ and $7 / 9$ in which the operator (+ or / here) is written between its operands—this is called *infix notation*. Computers “prefer” *postfix notation*, in which the operator is written to the right of its two operands. The preceding infix expressions would appear in postfix notation as $3\ 4\ +$ and $7\ 9\ /$, respectively.

To evaluate a complex infix expression, a compiler would first convert the expression to postfix notation and evaluate the postfix version. Each of these algorithms requires only a single left-to-right pass of the expression. Each algorithm uses a stack object in support of its operation, but each uses the stack for a different purpose.

In this exercise, you will write a Java version of the infix-to-postfix conversion algorithm. In the next exercise, you will write a Java version of the postfix expression evaluation algorithm. In a later exercise, you will discover that code you write in this exercise can help you implement a complete working compiler.

Write class `InfixToPostfixConverter` to convert an ordinary infix arithmetic expression (assume a valid expression is entered) with single-digit integers such as

(6 + 2) * 5 - 8 / 4

to a postfix expression. The postfix version of the preceding infix expression is (note that no parentheses are needed)

6 2 + 5 * 8 4 / -

The program should read the expression into `StringBuffer infix` and use one of the stack classes implemented in this chapter to help create the postfix expression in `StringBuffer postfix`. The algorithm for creating a postfix expression is as follows:

840 Chapter 17 Data Structures

- a) Push a left parenthesis '(' on the stack.
- b) Append a right parenthesis ')' to the end of `infix`.
- c) While the stack is not empty, read `infix` from left to right and do the following:
 - If the current character in `infix` is a digit, append it to `postfix`.
 - If the current character in `infix` is a left parenthesis, push it onto the stack.
 - If the current character in `infix` is an operator:
 - Pop operators (if there are any) at the top of the stack while they have equal or higher precedence than the current operator, and append the popped operators to `postfix`.
 - Push the current character in `infix` onto the stack.
 - If the current character in `infix` is a right parenthesis:
 - Pop operators from the top of the stack and append them to `postfix` until a left parenthesis is at the top of the stack.
 - Pop (and discard) the left parenthesis from the stack.

The following arithmetic operations are allowed in an expression:

- + addition
- subtraction
- * multiplication
- / division
- ^ exponentiation
- % remainder

The stack should be maintained with stack nodes that each contain an instance variable and a reference to the next stack node. Some of the methods you may want to provide are as follows:

- a) Method `convertToPostfix`, which converts the infix expression to postfix notation.
- b) Method `isOperator`, which determines whether `c` is an operator.
- c) Method `precedence`, which determines whether the precedence of `operator1` (from the infix expression) is less than, equal to or greater than the precedence of `operator2` (from the stack). The method returns `true` if `operator1` has lower precedence than `operator2`. Otherwise, `false` is returned.
- d) Method `stackTop` (this should be added to the stack class), which returns the top value of the stack without popping the stack.

17.13 Write class PostfixEvaluator, which evaluates a postfix expression such as

`6 2 + 5 * 8 4 / -`

The program should read a postfix expression consisting of digits and operators into a `StringBuffer`. Using modified versions of the stack methods implemented earlier in this chapter, the program should scan the expression and evaluate it (assume it is valid). The algorithm is as follows:

- a) Append a right parenthesis ')' to the end of the postfix expression. When the right-parenthesis character is encountered, no further processing is necessary.
- b) When the right-parenthesis character has not been encountered, read the expression from left to right.
 - If the current character is a digit, do the following:
 - Push its integer value on the stack (the integer value of a digit character is its value in the computer's character set minus the value of '0' in Unicode).
 - Otherwise, if the current character is an *operator*:
 - Pop the two top elements of the stack into variables `x` and `y`.
 - Calculate `y operator x`.
 - Push the result of the calculation onto the stack.
- c) When the right parenthesis is encountered in the expression, pop the top value of the stack. This is the result of the postfix expression.

Exercises **84I**

[Note: In b) above (based on the sample expression at the beginning of this exercise), if the operator is '/', the top of the stack is 2 and the next element in the stack is 8, then pop 2 into x, pop 8 into y, evaluate $8 / 2$ and push the result, 4, back on the stack. This note also applies to operator '-'.] The arithmetic operations allowed in an expression are:

- + addition
- subtraction
- * multiplication
- / division
- ^ exponentiation
- % remainder

The stack should be maintained with one of the stack classes introduced in this chapter. You may want to provide the following methods:

- a) Method `evaluatePostfixExpression`, which evaluates the postfix expression.
- b) Method `calculate`, which evaluates the expression op1 operator op2.
- c) Method `push`, which pushes a value onto the stack.
- d) Method `pop`, which pops a value off the stack.
- e) Method `isEmpty`, which determines whether the stack is empty.
- f) Method `printStack`, which prints the stack.

17.14 Modify the postfix evaluator program of Exercise 17.13 so that it can process integer operands larger than 9.

17.15 (*Supermarket Simulation*) Write a program that simulates a checkout line at a supermarket. The line is a queue object. Customers (i.e., customer objects) arrive in random integer intervals of from 1 to 4 minutes. Also, each customer is serviced in random integer intervals of from 1 to 4 minutes. Obviously, the rates need to be balanced. If the average arrival rate is larger than the average service rate, the queue will grow infinitely. Even with "balanced" rates, randomness can still cause long lines. Run the supermarket simulation for a 12-hour day (720 minutes), using the following algorithm:

- a) Choose a random integer between 1 and 4 to determine the minute at which the first customer arrives.
- b) At the first customer's arrival time, do the following:
Determine customer's service time (random integer from 1 to 4).
Begin servicing the customer.
Schedule arrival time of next customer (random integer 1 to 4 added to the current time).
- c) For each minute of the day, consider the following:
If the next customer arrives, proceed as follows:
Say so.
Enqueue the customer.
Schedule the arrival time of the next customer.
If service was completed for the last customer, do the following:
Say so.
Dequeue next customer to be serviced.
Determine customer's service completion time (random integer from 1 to 4 added to the current time).

Now run your simulation for 720 minutes and answer each of the following:

- a) What is the maximum number of customers in the queue at any time?
- b) What is the longest wait any one customer experiences?
- c) What happens if the arrival interval is changed from 1 to 4 minutes to 1 to 3 minutes?

17.16 Modify Figs. 17.17 and 17.18 to allow the binary tree to contain duplicates.

842 Chapter 17 Data Structures

17.17 Write a program based on the program of Figs. 17.17 and 17.18 that inputs a line of text, tokenizes the sentence into separate words (you might want to use the `StreamTokenizer` class from the `java.io` package), inserts the words in a binary search tree and prints the inorder, preorder and postorder traversals of the tree.

17.18 In this chapter, we saw that duplicate elimination is straightforward when creating a binary search tree. Describe how you would perform duplicate elimination when using only a one-dimensional array. Compare the performance of array-based duplicate elimination with the performance of binary-search-tree-based duplicate elimination.

17.19 Write a method `depth` that receives a binary tree and determines how many levels it has.

17.20 (*Recursively Print a List Backward*) Write a method `printListBackward` that recursively outputs the items in a linked list object in reverse order. Write a test program that creates a sorted list of integers and prints the list in reverse order.

17.21 (*Recursively Search a List*) Write a method `searchList` that recursively searches a linked list object for a specified value. Method `searchList` should return a reference to the value if it is found; otherwise, `null` should be returned. Use your method in a test program that creates a list of integers. The program should prompt the user for a value to locate in the list.

17.22 (*Binary Tree Delete*) In this exercise, we discuss deleting items from binary search trees. The deletion algorithm is not as straightforward as the insertion algorithm. Three cases are encountered when deleting an item—the item is contained in a leaf node (i.e., it has no children), the item is contained in a node that has one child or the item is contained in a node that has two children.

If the item to be deleted is contained in a leaf node, the node is deleted and the reference in the parent node is set to `null`.

If the item to be deleted is contained in a node with one child, the reference in the parent node is set to reference the child node and the node containing the data item is deleted. This causes the child node to take the place of the deleted node in the tree.

The last case is the most difficult. When a node with two children is deleted, another node in the tree must take its place. However, the reference in the parent node cannot simply be assigned to reference one of the children of the node to be deleted. In most cases, the resulting binary search tree would not embody the following characteristic of binary search trees (with no duplicate values): *The values in any left subtree are less than the value in the parent node, and the values in any right subtree are greater than the value in the parent node.*

Which node is used as a *replacement node* to maintain this characteristic? It is either the node containing the largest value in the tree less than the value in the node being deleted, or the node containing the smallest value in the tree greater than the value in the node being deleted. Let us consider the node with the smaller value. In a binary search tree, the largest value less than a parent's value is located in the left subtree of the parent node and is guaranteed to be contained in the rightmost node of the subtree. This node is located by walking down the left subtree to the right until the reference to the right child of the current node is `null`. We are now referencing the replacement node, which is either a leaf node or a node with one child to its left. If the replacement node is a leaf node, the steps to perform the deletion are as follows:

- a) Store the reference to the node to be deleted in a temporary reference variable.
- b) Set the reference in the parent of the node being deleted to reference the replacement node.
- c) Set the reference in the parent of the replacement node to `null`.
- d) Set the reference to the right subtree in the replacement node to reference the right subtree of the node to be deleted.
- e) Set the reference to the left subtree in the replacement node to reference the left subtree of the node to be deleted.

Exercises **843**

The deletion steps for a replacement node with a left child are similar to those for a replacement node with no children, but the algorithm also must move the child into the replacement node's position in the tree. If the replacement node is a node with a left child, the steps to perform the deletion are as follows:

- a) Store the reference to the node to be deleted in a temporary reference variable.
- b) Set the reference in the parent of the node being deleted to reference the replacement node.
- c) Set the reference in the parent of the replacement node to reference the left child of the replacement node.
- d) Set the reference to the right subtree in the replacement node to reference the right subtree of the node to be deleted.
- e) Set the reference to the left subtree in the replacement node to reference the left subtree of the node to be deleted.

Write method `deleteNode`, which takes as its argument the value to delete. Method `deleteNode` should locate in the tree the node containing the value to delete and use the algorithms discussed here to delete the node. If the value is not found in the tree, the method should print a message that indicates whether the value is deleted. Modify the program of Figs. 17.17 and 17.18 to use this method. After deleting an item, call the methods `inorderTraversal`, `preorderTraversal` and `postorderTraversal` to confirm that the delete operation was performed correctly.

17.23 (Binary Tree Search) Write method `binaryTreeSearch`, which attempts to locate a specified value in a binary-search-tree object. The method should take as an argument a search key to be located. If the node containing the search key is found, the method should return a reference to that node; otherwise, it should return a null reference.

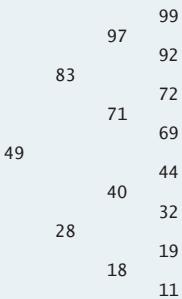

17.24 (Level-Order Binary Tree Traversal) The program of Figs. 17.17 and 17.18 illustrated three recursive methods of traversing a binary tree—inorder, preorder and postorder traversals. This exercise presents the *level-order traversal* of a binary tree, in which the node values are printed level by level, starting at the root node level. The nodes on each level are printed from left to right. The level-order traversal is not a recursive algorithm. It uses a queue object to control the output of the nodes. The algorithm is as follows:

- a) Insert the root node in the queue.
- b) While there are nodes left in the queue, do the following:
 - Get the next node in the queue.
 - Print the node's value.
 - If the reference to the left child of the node is not null:
 - Insert the left child node in the queue.
 - If the reference to the right child of the node is not null:
 - Insert the right child node in the queue.

Write method `levelOrder` to perform a level-order traversal of a binary tree object. Modify the program of Figs. 17.17 and 17.18 to use this method. [Note: You will also need to use queue-processing methods of Fig. 17.13 in this program.]

17.25 (Printing Trees) Write a recursive method `outputTree` to display a binary tree object on the screen. The method should output the tree row by row, with the top of the tree at the left of the screen and the bottom of the tree toward the right of the screen. Each row is output vertically. For example, the binary tree illustrated in Fig. 17.20 is output as shown in Fig. 17.21.

The rightmost leaf node appears at the top of the output in the rightmost column and the root node appears at the left of the output. Each column starts five spaces to the right of the preceding column. Method `outputTree` should receive an argument `totalSpaces` representing the number of spaces preceding the value to be output. (This variable should start at zero so that the root node is output at the left of the screen.) The method uses a modified inorder traversal to output the tree—it starts at the rightmost node in the tree and works back to the left. The algorithm is as follows:

844 Chapter 17 Data Structures**Fig. 17.21** | Sample output of recursive method `outputTree`.

While the reference to the current node is not null, perform the following:

Recursively call `outputTree` with the right subtree of the current node and
`totalSpaces + 5`.

Use a `for` statement to count from 1 to `totalSpaces` and output spaces.

Output the value in the current node.

Set the reference to the current node to refer to the left subtree of the current node.

Increment `totalSpaces` by 5.

Special Section: Building Your Own Compiler

In Exercises 7.34–7.35, we introduced Simpletron Machine Language (SML), and you implemented a Simpletron computer simulator to execute programs written in SML. In this section, we build a compiler that converts programs written in a high-level programming language to SML. This section “ties” together the entire programming process. You will write programs in this new high-level language, compile them on the compiler you build and run them on the simulator you built in Exercise 7.35. You should make every effort to implement your compiler in an object-oriented manner.

17.26 (The Simple Language) Before we begin building the compiler, we discuss a simple, yet powerful high-level language similar to early versions of the popular language BASIC. We call the language *Simple*. Every Simple *statement* consists of a *line number* and a Simple *instruction*. Line numbers must appear in ascending order. Each instruction begins with one of the following Simple *commands*: `rem`, `input`, `let`, `print`, `goto`, `if/goto` or `end` (see Fig. 17.22). All commands except `end` can be used repeatedly. Simple evaluates only integer expressions using the `+`, `-`, `*` and `/` operators. These operators have the same precedence as in Java. Parentheses can be used to change the order of evaluation of an expression.

Our Simple compiler recognizes only lowercase letters. All characters in a Simple file should be lowercase. (Uppercase letters result in a syntax error unless they appear in a `rem` statement, in which case they are ignored.) A *variable name* is a single letter. Simple does not allow descriptive variable names, so variables should be explained in remarks to indicate their use in a program. Simple uses only integer variables. Simple does not have variable declarations—merely mentioning a variable name in a program causes the variable to be declared and initialized to zero. The syntax of Simple does not allow string manipulation (reading a string, writing a string, comparing strings, and so on). If a string is encountered in a Simple program (after a command other than `rem`), the compiler generates a syntax error. The first version of our compiler assumes that Simple programs are entered correctly. Exercise 17.29 asks the reader to modify the compiler to perform syntax error checking.

Special Section: Building Your Own Compiler **845**

Command	Example statement	Description
rem	50 rem this is a remark	Any text following the command rem is for documentation purposes only and is ignored by the compiler.
input	30 input x	Display a question mark to prompt the user to enter an integer. Read that integer from the keyboard and store the integer in x.
let	80 let u = 4 * (j - 56)	Assign u the value of 4 * (j - 56). Note that an arbitrarily complex expression can appear to the right of the equal sign.
print	10 print w	Display the value of w.
goto	70 goto 45	Transfer program control to line 45.
if/goto	35 if i == z goto 80	Compare i and z for equality and transfer program control to line 80 if the condition is true; otherwise, continue execution with the next statement.
end	99 end	Terminate program execution.

Fig. 17.22 | Simple commands.

Simple uses the conditional if/goto and unconditional goto statements to alter the flow of control during program execution. If the condition in the if/goto statement is true, control is transferred to a specific line of the program. The following relational and equality operators are valid in an if/goto statement: <, >, <=, >=, == or !=. The precedence of these operators is the same as in Java.

Let us now consider several programs that demonstrate Simple's features. The first program (Fig. 17.23) reads two integers from the keyboard, stores the values in variables a and b and computes and prints their sum (stored in variable c).

```

1 10 rem determine and print the sum of two integers
2 15 rem
3 20 rem input the two integers
4 30 input a
5 40 input b
6 45 rem
7 50 rem add integers and store result in c
8 60 let c = a + b
9 65 rem
10 70 rem print the result
11 80 print c
12 90 rem terminate program execution
13 99 end

```

Fig. 17.23 | Simple program that determines the sum of two integers.

846 Chapter 17 Data Structures

The program of Fig. 17.24 determines and prints the larger of two integers. The integers are input from the keyboard and stored in *s* and *t*. The if/goto statement tests the condition *s* \geq *t*. If the condition is true, control is transferred to line 90 and *s* is output; otherwise, *t* is output and control is transferred to the end statement in line 99, where the program terminates.

Simple does not provide a repetition statement (such as Java's for, while or do...while). However, Simple can simulate each of Java's repetition statements by using the if/goto and goto statements. Figure 17.25 uses a sentinel-controlled loop to calculate the squares of several integers. Each integer is input from the keyboard and stored in variable *j*. If the value entered is the sentinel value -9999, control is transferred to line 99, where the program terminates. Otherwise, *k* is assigned the square of *j*, *k* is output to the screen and control is passed to line 20, where the next integer is input.

Using the sample programs of Figs. 17.23–17.25 as your guide, write a Simple program to accomplish each of the following:

- Input three integers, determine their average and print the result.
- Use a sentinel-controlled loop to input 10 integers and compute and print their sum.
- Use a counter-controlled loop to input 7 integers, some positive and some negative, and compute and print their average.
- Input a series of integers and determine and print the largest. The first integer input indicates how many numbers should be processed.
- Input 10 integers and print the smallest.
- Calculate and print the sum of the even integers from 2 to 30.
- Calculate and print the product of the odd integers from 1 to 9.

```

1 10 rem  determine and print the larger of two integers
2 20 input s
3 30 input t
4 32 rem
5 35 rem  test if s >= t
6 40 if s >= t goto 90
7 45 rem
8 50 rem  t is greater than s, so print t
9 60 print t
10 70 goto 99
11 75 rem
12 80 rem  s is greater than or equal to t, so print s
13 90 print s
14 99 end

```

Fig. 17.24 | Simple program that finds the larger of two integers.

```

1 10 rem  calculate the squares of several integers
2 20 input j
3 23 rem
4 25 rem  test for sentinel value
5 30 if j == -9999 goto 99
6 33 rem
7 35 rem  calculate square of j and assign result to k
8 40 let k = j * j
9 50 print k

```

Fig. 17.25 | Calculate the squares of several integers. (Part I of 2.)

Special Section: Building Your Own Compiler

17.27 (Building a Compiler. Prerequisites: Complete Exercise 7.34, Exercise 7.35, Exercise 17.12, Exercise 17.13 and Exercise 17.26) Now that the Simple language has been presented (Exercise 17.26), we discuss how to build a Simple compiler. First, we consider the process by which a Simple program is converted to SML and executed by the Simpletron simulator (see Fig. 17.26). A file containing a Simple program is read by the compiler and converted to SML code. The SML code is output to a file on disk, in which SML instructions appear one per line. The SML file is then loaded into the Simpletron simulator, and the results are sent to a file on disk and to the screen. Note that the Simpletron program developed in Exercise 7.35 took its input from the keyboard. It must be modified to read from a file so it can run the programs produced by our compiler.

The Simple compiler performs two *passes* of the Simple program to convert it to SML. The first pass constructs a *symbol table* (object) in which every *line number* (object), *variable name* (object) and *constant* (object) of the Simple program is stored with its type and corresponding location in the final SML code (the symbol table is discussed in detail below). The first pass also produces the corresponding SML instruction object(s) for each of the Simple statements (object, and so on). If the Simple program contains statements that transfer control to a line later in the program, the first pass results in an SML program containing some “unfinished” instructions. The second pass of the compiler locates and completes the unfinished instructions and outputs the SML program to a file.

First Pass

The compiler begins by reading one statement of the Simple program into memory. The line must be separated into its individual *tokens* (i.e., “pieces” of a statement) for processing and compilation. (The `StreamTokenizer` class from the `java.io` package can be used.) Recall that every statement begins with a line number followed by a command. As the compiler breaks a statement into tokens, if the token is a line number, a variable or a constant, it is placed in the symbol table. A line number is placed in the symbol table only if it is the first token in a statement. The `symbolTable` object is an array of `tableEntry` objects representing each symbol in the program. There is no restriction on the number of symbols that can appear in the program. Therefore, the `symbolTable` for a particular program could be large. Make it a 100-element array for now. You can increase or decrease its size once the program is working.

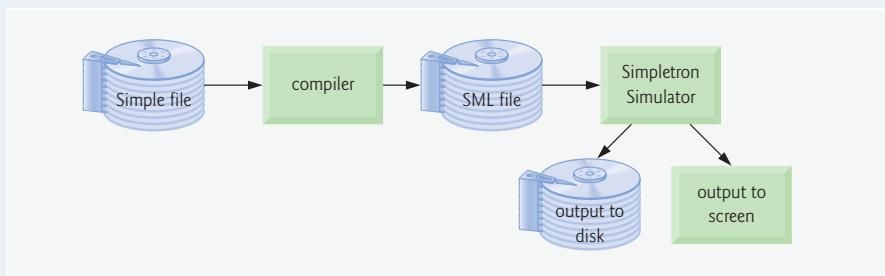

Fig. 17.26 | Writing, compiling and executing a Simple language program.

848 Chapter 17 Data Structures

Each `tableEntry` object contains three fields. Field `symbol` is an integer containing the Unicode representation of a variable (remember that variable names are single characters), a line number or a constant. Field `type` is one of the following characters indicating the symbol's type: 'C' for constant, 'L' for line number or 'V' for variable. Field `location` contains the Simpletron memory location (00 to 99) to which the symbol refers. Simpletron memory is an array of 100 integers in which SML instructions and data are stored. For a line number, the location is the element in the Simpletron memory array at which the SML instructions for the Simple statement begin. For a variable or constant, the location is the element in the Simpletron memory array in which the variable or constant is stored. Variables and constants are allocated from the end of Simpletron's memory backward. The first variable or constant is stored at location 99, the next at location 98, an so on.

The symbol table plays an integral part in converting Simple programs to SML. We learned in Chapter 7 that an SML instruction is a four-digit integer comprised of two parts—the *operation code* and the *operand*. The operation code is determined by commands in Simple. For example, the simple command `input` corresponds to SML operation code 10 (read), and the Simple command `print` corresponds to SML operation code 11 (write). The operand is a memory location containing the data on which the operation code performs its task (e.g., operation code 10 reads a value from the keyboard and stores it in the memory location specified by the operand). The compiler searches `symbolTable` to determine the Simpletron memory location for each symbol, so the corresponding location can be used to complete the SML instructions.

The compilation of each Simple statement is based on its command. For example, after the line number in a `rem` statement is inserted in the symbol table, the remainder of the statement is ignored by the compiler, because a remark is for documentation purposes only. The `input`, `print`, `goto` and `end` statements correspond to the SML *read*, *write*, *branch* (to a specific location) and *halt* instructions. Statements containing these Simple commands are converted directly to SML. [Note: A `goto` statement may contain an unresolved reference if the specified line number refers to a statement further into the Simple program file; this is sometimes called a forward reference.]

When a `goto` statement is compiled with an unresolved reference, the SML instruction must be *flagged* to indicate that the second pass of the compiler must complete the instruction. The flags are stored in a 100-element array `flags` of type `int` in which each element is initialized to -1. If the memory location to which a line number in the Simple program refers is not yet known (i.e., it is not in the symbol table), the line number is stored in array `flags` in the element with the same index as the incomplete instruction. The operand of the incomplete instruction is set to 00 temporarily. For example, an unconditional branch instruction (making a forward reference) is left as +4000 until the second pass of the compiler. The second pass will be described shortly.

Compilation of `if/goto` and `let` statements is more complicated than for other statements—they are the only statements that produce more than one SML instruction. For an `if/goto` statement, the compiler produces code to test the condition and to branch to another line if necessary. The result of the branch could be an unresolved reference. Each of the relational and equality operators can be simulated by using SML's *branch zero* and *branch negative* instructions (or possibly a combination of both).

For a `let` statement, the compiler produces code to evaluate an arbitrarily complex arithmetic expression consisting of integer variables and/or constants. Expressions should separate each operand and operator with spaces. Exercise 17.12 and Exercise 17.13 presented the infix-to-postfix conversion algorithm and the postfix evaluation algorithm used by compilers to evaluate expressions. Before proceeding with your compiler, you should complete each of these exercises. When a compiler encounters an expression, it converts the expression from infix notation to postfix notation, then evaluates the postfix expression.

How is it that the compiler produces the machine language to evaluate an expression containing variables? The postfix evaluation algorithm contains a “hook” where the compiler can generate SML instructions rather than actually evaluating the expression. To enable this “hook” in the

Special Section: Building Your Own Compiler **849**

compiler, the postfix evaluation algorithm must be modified to search the symbol table for each symbol it encounters (and possibly insert it), determine the symbol's corresponding memory location and *push the memory location (instead of the symbol) onto the stack*. When an operator is encountered in the postfix expression, the two memory locations at the top of the stack are popped, and machine language for effecting the operation is produced by using the memory locations as operands. The result of each subexpression is stored in a temporary location in memory and pushed back onto the stack so the evaluation of the postfix expression can continue. When postfix evaluation is complete, the memory location containing the result is the only location left on the stack. This is popped, and SML instructions are generated to assign the result to the variable at the left of the `let` statement.

Second Pass

The second pass of the compiler performs two tasks: Resolve any unresolved references and output the SML code to a file. Resolution of references occurs as follows:

- a) Search the `flags` array for an unresolved reference (i.e., an element with a value other than -1).
- b) Locate the object in array `symbolTable` containing the symbol stored in the `flags` array (be sure that the type of the symbol is 'L' for line number).
- c) Insert the memory location from field `location` into the instruction with the unresolved reference (remember that an instruction containing an unresolved reference has operand 00).
- d) Repeat Steps (a), (b) and (c) until the end of the `flags` array is reached.

After the resolution process is complete, the entire array containing the SML code is output to a disk file with one SML instruction per line. This file can be read by the Simpletron for execution (after the simulator is modified to read its input from a file). Compiling your first Simple program into an SML file and executing that file should give you a real sense of personal accomplishment.

A Complete Example

The following example illustrates the complete conversion of a Simple program to SML as it will be performed by the Simple compiler. Consider a Simple program that inputs an integer and sums the values from 1 to that integer. The program and the SML instructions produced by the first pass of the Simple compiler are illustrated in Fig. 17.27. The symbol table constructed by the first pass is shown in Fig. 17.28.

Simple program	SML location and instruction	Description
5 rem sum 1 to x	none	rem ignored
10 input x	00 +1099	read x into location 99
15 rem check y == x	none	rem ignored
20 if y == x goto 60	01 +2098	load y (98) into accumulator
	02 +3199	sub x (99) from accumulator
	03 +4200	branch zero to unresolved location

Fig. 17.27 | SML instructions produced after the compiler's first pass. (Part 1 of 2.)

850 Chapter 17 Data Structures

Simple program	SML location and instruction	Description
25 rem increment y	none	rem ignored
30 let y = y + 1	04 +2098	load y into accumulator
	05 +3097	add 1 (97) to accumulator
	06 +2196	store in temporary location 96
	07 +2096	load from temporary location 96
	08 +2198	store accumulator in y
35 rem add y to total	none	rem ignored
40 let t = t + y	09 +2095	load t (95) into accumulator
	10 +3098	add y to accumulator
	11 +2194	store in temporary location 94
	12 +2094	load from temporary location 94
	13 +2195	store accumulator in t
45 rem loop y	none	rem ignored
50 goto 20	14 +4001	branch to location 01
55 rem output result	none	rem ignored
60 print t	15 +1195	output t to screen
99 end	16 +4300	terminate execution

Fig. 17.28 | Symbol table for program of Fig. 17.27. (Part 2 of 2.)

Most Simple statements convert directly to single SML instructions. The exceptions in this program are remarks, the if/goto statement in line 20 and the let statements. Remarks do not translate into machine language. However, the line number for a remark is placed in the symbol table in case the line number is referenced in a goto statement or an if/goto statement. Line 20 of the program specifies that, if the condition $y == x$ is true, program control is transferred to line 60. Since line 60 appears later in the program, the first pass of the compiler has not as yet placed 60 in the symbol table. (Statement line numbers are placed in the symbol table only when they appear as the first token in a statement.) Therefore, it is not possible at this time to determine the operand of the SML *branch zero* instruction at location 03 in the array of SML instructions. The compiler places 60 in location 03 of the flags array to indicate that the second pass completes this instruction.

We must keep track of the next instruction location in the SML array because there is not a one-to-one correspondence between Simple statements and SML instructions. For example, the if/goto statement of line 20 compiles into three SML instructions. Each time an instruction is produced, we must increment the *instruction counter* to the next location in the SML array. Note that the size of Simpletron's memory could present a problem for Simple programs with many statements, variables and constants. It is conceivable that the compiler will run out of memory. To test for this case, your program should contain a *data counter* to keep track of the location at which the next variable or constant will be stored in the SML array. If the value of the instruction counter is larger than the value of the data counter, the SML array is full. In this case, the compilation process should terminate, and the compiler should print an error message indicating that it ran out of memory during compilation. This serves to emphasize that, although the programmer is freed from the burdens of managing memory by the compiler, the compiler itself must carefully determine the placement of instructions and data in memory and must check for such errors as memory being exhausted during the compilation process.

A Step-by-Step View of the Compilation Process

Let us now walk through the compilation process for the Simple program in Fig. 17.27. The compiler reads the first line of the program

```
5 rem sum 1 to x
```

852 Chapter 17 Data Structures

into memory. The first token in the statement (the line number) is determined using the `StringTokenizer` class. (See Chapter 30 for a discussion of this class.) The token returned by the `StringTokenizer` is converted to an integer by using static method `Integer.parseInt()`, so the symbol 5 can be located in the symbol table. If the symbol is not found, it is inserted in the symbol table.

We are at the beginning of the program and this is the first line, and no symbols are in the table yet. Therefore, 5 is inserted into the symbol table as type L (line number) and assigned the first location in the SML array (00). Although this line is a remark, a space in the symbol table is still allocated for the line number (in case it is referenced by a `goto` or an `if/goto`). No SML instruction is generated for a `rem` statement, so the instruction counter is not incremented.

```
10 input x
```

is tokenized next. The line number 10 is placed in the symbol table as type L and assigned the first location in the SML array (00 because a remark began the program, so the instruction counter is currently 00). The command `input` indicates that the next token is a variable (only a variable can appear in an `input` statement). `input` corresponds directly to an SML operation code; therefore, the compiler simply has to determine the location of `x` in the SML array. Symbol `x` is not found in the symbol table, so it is inserted into the symbol table as the Unicode representation of `x`, given type V and assigned location 99 in the SML array (data storage begins at 99 and is allocated backward). SML code can now be generated for this statement. Operation code 10 (the SML read operation code) is multiplied by 100, and the location of `x` (as determined in the symbol table) is added to complete the instruction. The instruction is then stored in the SML array at location 00. The instruction counter is incremented by one, because a single SML instruction was produced.

The statement

```
15 rem check y == x
```

is tokenized next. The symbol table is searched for line number 15 (which is not found). The line number is inserted as type L and assigned the next location in the array, 01. (Remember that `rem` statements do not produce code, so the instruction counter is not incremented.)

The statement

```
20 if y == x goto 60
```

is tokenized next. Line number 20 is inserted in the symbol table and given type L at the next location in the SML array 01. The command `if` indicates that a condition is to be evaluated. The variable `y` is not found in the symbol table, so it is inserted and given the type V and the SML location 98. Next, SML instructions are generated to evaluate the condition. There is no direct equivalent in SML for the `if/goto`; it must be simulated by performing a calculation using `x` and `y` and branching according to the result. If `y` is equal to `x`, the result of subtracting `x` from `y` is zero, so the `branch zero` instruction can be used with the result of the calculation to simulate the `if/goto` statement. The first step requires that `y` be loaded (from SML location 98) into the accumulator. This produces the instruction 01 +2098. Next, `x` is subtracted from the accumulator. This produces the instruction 02 +3199. The value in the accumulator may be zero, positive or negative. The operator is `==`, so we want to `branch zero`. First, the symbol table is searched for the branch location (60 in this case), which is not found. So, 60 is placed in the `flags` array at location 03, and the instruction 03 +4200 is generated. (We cannot add the branch location because we have not yet assigned a location to line 60 in the SML array.) The instruction counter is incremented to 04.

The compiler proceeds to the statement

```
25 rem increment y
```

The line number 25 is inserted in the symbol table as type L and assigned SML location 04. The instruction counter is not incremented.

Special Section: Building Your Own Compiler **853**

When the statement

```
30 let y = y + 1
```

is tokenized, the line number 30 is inserted in the symbol table as type L and assigned SML location 04. Command `let` indicates that the line is an assignment statement. First, all the symbols on the line are inserted in the symbol table (if they are not already there). The integer 1 is added to the symbol table as type C and assigned SML location 97. Next, the right side of the assignment is converted from infix to postfix notation. Then the postfix expression ($y + 1$) is evaluated. Symbol `y` is located in the symbol table, and its corresponding memory location is pushed onto the stack. Symbol 1 is also located in the symbol table, and its corresponding memory location is pushed onto the stack. When the operator `+` is encountered, the postfix evaluator pops the stack into the right operand of the operator and pops the stack again into the left operand of the operator, then produces the SML instructions

```
04 +2098 (load y)
05 +3097 (add 1)
```

The result of the expression is stored in a temporary location in memory (96) with the instruction

```
06 +2196 (store temporary)
```

and the temporary location is pushed onto the stack. Now that the expression has been evaluated, the result must be stored in `y` (i.e., the variable on the left side of `=`). So, the temporary location is loaded into the accumulator and the accumulator is stored in `y` with the instructions

```
07 +2096 (load temporary)
08 +2198 (store y)
```

The reader should immediately notice that SML instructions appear to be redundant. We will discuss this issue shortly.

When the statement

```
35 rem add y to total
```

is tokenized, line number 35 is inserted in the symbol table as type L and assigned location 09.

The statement

```
40 let t = t + y
```

is similar to line 30. The variable `t` is inserted in the symbol table as type V and assigned SML location 95. The instructions follow the same logic and format as line 30, and the instructions 09 +2095, 10 +3098, 11 +2194, 12 +2094 and 13 +2195 are generated. Note that the result of $t + y$ is assigned to temporary location 94 before being assigned to `t` (95). Once again, the reader should note that the instructions in memory locations 11 and 12 appear to be redundant. Again, we will discuss this shortly.

The statement

```
45 rem loop y
```

is a remark, so line 45 is added to the symbol table as type L and assigned SML location 14.

The statement

```
50 goto 20
```

transfers control to line 20. Line number 50 is inserted in the symbol table as type L and assigned SML location 14. The equivalent of `goto` in SML is the *unconditional branch* (40) instruction that transfers control to a specific SML location. The compiler searches the symbol table for line 20 and finds that it corresponds to SML location 01. The operation code (40) is multiplied by 100, and location 01 is added to it to produce the instruction 14 +4001.

854 Chapter 17 Data Structures

The statement

```
55 rem    output result
```

is a remark, so line 55 is inserted in the symbol table as type L and assigned SML location 15.

The statement

```
60 print t
```

is an output statement. Line number 60 is inserted in the symbol table as type L and assigned SML location 15. The equivalent of `print` in SML is operation code 11 (*write*). The location of `t` is determined from the symbol table and added to the result of the operation code multiplied by 100.

The statement

```
99 end
```

is the final line of the program. Line number 99 is stored in the symbol table as type L and assigned SML location 16. The `end` command produces the SML instruction +4300 (43 is *halt* in SML), which is written as the final instruction in the SML memory array.

This completes the first pass of the compiler. We now consider the second pass. The `flags` array is searched for values other than -1. Location 03 contains 60, so the compiler knows that instruction 03 is incomplete. The compiler completes the instruction by searching the symbol table for 60, determining its location and adding the location to the incomplete instruction. In this case, the search determines that line 60 corresponds to SML location 15, so the completed instruction 03 +4215 is produced, replacing 03 +4200. The Simple program has now been compiled successfully.

To build the compiler, you will have to perform each of the following tasks:

- a) Modify the Simpletron simulator program you wrote in Exercise 7.35 to take its input from a file specified by the user (see Chapter 14). The simulator should output its results to a disk file in the same format as the screen output. Convert the simulator to be an object-oriented program. In particular, make each part of the hardware an object. Arrange the instruction types into a class hierarchy using inheritance. Then execute the program polymorphically simply by telling each instruction to execute itself with an `executeInstruction` message.
- b) Modify the infix-to-postfix evaluation algorithm of Exercise 17.12 to process multidigit integer operands and single-letter variable-name operands. [Hint: Class `StringTokenizer` can be used to locate each constant and variable in an expression, and constants can be converted from strings to integers by using `Integer` class method `parseInt`.] [Note: The data representation of the postfix expression must be altered to support variable names and integer constants.]
- c) Modify the postfix evaluation algorithm to process multidigit integer operands and variable-name operands. Also, the algorithm should now implement the “hook” discussed earlier so that SML instructions are produced rather than directly evaluating the expression. [Hint: Class `StringTokenizer` can be used to locate each constant and variable in an expression, and constants can be converted from strings to integers by using `Integer` class method `parseInt`.] [Note: The data representation of the postfix expression must be altered to support variable names and integer constants.]
- d) Build the compiler. Incorporate parts b) and c) for evaluating expressions in `let` statements. Your program should contain a method that performs the first pass of the compiler and a method that performs the second pass of the compiler. Both methods can call other methods to accomplish their tasks. Make your compiler as object oriented as possible.

17.28 (Optimizing the Simple Compiler) When a program is compiled and converted into SML, a set of instructions is generated. Certain combinations of instructions often repeat themselves, usu-

Special Section: Building Your Own Compiler **855**

ally in triplets called *productions*. A production normally consists of three instructions, such as *load*, *add* and *store*. For example, Fig. 17.29 illustrates five of the SML instructions that were produced in the compilation of the program in Fig. 17.27. The first three instructions are the production that adds 1 to *y*. Note that instructions 06 and 07 store the accumulator value in temporary location 96, then load the value back into the accumulator so instruction 08 can store the value in location 98. Often a production is followed by a load instruction for the same location that was just stored. This code can be *optimized* by eliminating the store instruction and the subsequent load instruction that operate on the same memory location, thus enabling the Simpletron to execute the program faster. Figure 17.30 illustrates the optimized SML for the program of Fig. 17.27. Note that there are four fewer instructions in the optimized code—a memory-space savings of 25%.

```

1 04  +2098  (load)
2 05  +3097  (add)
3 06  +2196  (store)
4 07  +2096  (load)
5 08  +2198  (store)

```

17.29 (*Modifications to the Simple Compiler*) Perform the following modifications to the Simple compiler. Some of these modifications might also require modifications to the Simpletron simulator program written in Exercise 7.35.

- a) Allow the remainder operator (%) to be used in let statements. Simpletron Machine Language must be modified to include a remainder instruction.
- b) Allow exponentiation in a let statement using ^ as the exponentiation operator. Simpletron Machine Language must be modified to include an exponentiation instruction.
- c) Allow the compiler to recognize uppercase and lowercase letters in Simple statements (e.g., 'A' is equivalent to 'a'). No modifications to the Simpletron simulator are required.
- d) Allow input statements to read values for multiple variables such as input x, y. No modifications to the Simpletron simulator are required to perform this enhancement to the Simple compiler.
- e) Allow the compiler to output multiple values from a single print statement, such as print a, b, c. No modifications to the Simpletron simulator are required to perform this enhancement.
- f) Add syntax-checking capabilities to the compiler so error messages are output when syntax errors are encountered in a Simple program. No modifications to the Simpletron simulator are required.
- g) Allow arrays of integers. No modifications to the Simpletron simulator are required to perform this enhancement.
- h) Allow subroutines specified by the Simple commands gosub and return. Command gosub passes program control to a subroutine and command return passes control back to the statement after the gosub. This is similar to a method call in Java. The same subroutine can be called from many gosub commands distributed throughout a program. No modifications to the Simpletron simulator are required.
- i) Allow repetition statements of the form

```
for x = 2 to 10 step 2
  Simple statements
  next
```

This for statement loops from 2 to 10 with an increment of 2. The next line marks the end of the body of the for line. No modifications to the Simpletron simulator are required.

- j) Allow repetition statements of the form

```
for x = 2 to 10
  Simple statements
  next
```

Special Section: Building Your Own Compiler **857**

This `for` statement loops from 2 to 10 with a default increment of 1. No modifications to the Simpletron simulator are required.

- k) Allow the compiler to process string input and output. This requires the Simpletron simulator to be modified to process and store string values. [Hint: Each Simpletron word (i.e., memory location) can be divided into two groups, each holding a two-digit integer. Each two-digit integer represents the Unicode decimal equivalent of a character. Add a machine-language instruction that will print a string beginning at a certain Simpletron memory location. The first half of the Simpletron word at that location is a count of the number of characters in the string (i.e., the length of the string). Each succeeding half-word contains one Unicode character expressed as two decimal digits. The machine-language instruction checks the length and prints the string by translating each two-digit number into its equivalent character.]
- l) Allow the compiler to process floating-point values in addition to integers. The Simpletron Simulator must also be modified to process floating-point values.

17.30 (*A Simple Interpreter*) An interpreter is a program that reads a high-level language program statement, determines the operation to be performed by the statement and executes the operation immediately. The high-level language program is not converted into machine language first. Interpreters execute more slowly than compilers do, because each statement encountered in the program being interpreted must first be deciphered at execution time. If statements are contained in a loop, the statements are deciphered each time they are encountered in the loop. Early versions of the BASIC programming language were implemented as interpreters. Most Java programs are run interpretively.

Write an interpreter for the Simple language discussed in Exercise 17.26. The program should use the infix-to-postfix converter developed in Exercise 17.12 and the postfix evaluator developed in Exercise 17.13 to evaluate expressions in a `let` statement. The same restrictions placed on the Simple language in Exercise 17.26 should be adhered to in this program. Test the interpreter with the Simple programs written in Exercise 17.26. Compare the results of running these programs in the interpreter with the results of compiling the Simple programs and running them in the Simpletron simulator built in Exercise 7.35.

17.31 (*Insert/Delete Anywhere in a Linked List*) Our linked list class allowed insertions and deletions at only the front and the back of the linked list. These capabilities were convenient for us when we used inheritance or composition to produce a stack class and a queue class with a minimal amount of code simply by reusing the list class. Linked lists are normally more general than those we provided. Modify the linked list class we developed in this chapter to handle insertions and deletions anywhere in the list.

17.32 (*Lists and Queues without Tail References*) Our implementation of a linked list (Fig. 17.3) used both a `firstNode` and a `lastNode`. The `lastNode` was useful for the `insertAtBack` and `removeFromBack` methods of the `List` class. The `insertAtBack` method corresponds to the `enqueue` method of the `Queue` class.

Rewrite the `List` class so that it does not use a `lastNode`. Thus, any operations on the tail of a list must begin searching the list from the front. Does this affect our implementation of the `Queue` class (Fig. 17.13)?

17.33 (*Performance of Binary Tree Sorting and Searching*) One problem with the binary tree sort is that the order in which the data is inserted affects the shape of the tree—for the same collection of data, different orderings can yield binary trees of dramatically different shapes. The performance of the binary tree sorting and searching algorithms is sensitive to the shape of the binary tree. What shape would a binary tree have if its data were inserted in increasing order? in decreasing order? What shape should the tree have to achieve maximal searching performance?

17.34 (*Indexed Lists*) As presented in the text, linked lists must be searched sequentially. For large lists, this can result in poor performance. A common technique for improving list-searching perfor-

858 [Chapter 17 Data Structures](#)

mance is to create and maintain an index to the list. An index is a set of references to key places in the list. For example, an application that searches a large list of names could improve performance by creating an index with 26 entries—one for each letter of the alphabet. A search operation for a last name beginning with ‘Y’ would then first search the index to determine where the ‘Y’ entries begin, then “jump into” the list at that point and search linearly until the desired name was found. This would be much faster than searching the linked list from the beginning. Use the `List` class of Fig. 17.3 as the basis of an `IndexedList` class.

Write a program that demonstrates the operation of indexed lists. Be sure to include methods `insertInIndexedList`, `searchIndexedList` and `deleteFromIndexedList`.

17.35 In Section 17.7, we created a stack class from class `List` with inheritance (Fig. 17.10) and with composition (Fig. 17.12). In Section 17.8 we created a queue class from class `List` with composition (Fig. 17.13). Create a queue class by inheriting from class `List`. What are the differences between this class and the one we created with composition?

18

Generics

Every man of genius sees the world at a different angle from his fellows.

—Havelock Ellis

...our special individuality, as distinguished from our generic humanity.

—Oliver Wendell Holmes, Sr.

Born under one law, to another bound.

—Lord Brooke

You deal in the raw material of opinion, and, if my convictions have any validity, opinion ultimately governs the world.

—Woodrow Wilson

OBJECTIVES

In this chapter you will learn:

- To create generic methods that perform identical tasks on arguments of different types.
- To create a generic `Stack` class that can be used to store objects of any class or interface type.
- To understand how to overload generic methods with non-generic methods or with other generic methods.
- To understand raw types and how they help achieve backward compatibility.
- To use wildcards when precise type information about a parameter is not required in the method body.
- The relationship between generics and inheritance.

860 Chapter 18 Generics**Outline**

- 18.1** Introduction
- 18.2** Motivation for Generic Methods
- 18.3** Generic Methods: Implementation and Compile-Time Translation
- 18.4** Additional Compile-Time Translation Issues
- 18.5** Overloading Generic Methods
- 18.6** Generic Classes
- 18.7** Raw Types
- 18.8** Wildcards in Methods That Accept Type Parameters
- 18.9** Generics and Inheritance: Notes
- 18.10** Wrap-Up
- 18.11** Internet and Web Resources

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

18.1 Introduction

It would be nice if we could write a single `sort` method that could sort the elements in an `Integer` array, a `String` array or an array of any type that supports ordering (i.e., its elements can be compared). It would also be nice if we could write a single `Stack` class that could be used as a `Stack` of integers, a `Stack` of floating-point numbers, a `Stack` of `Strings` or a `Stack` of any other type. It would be even nicer if we could detect type mismatches at compile time—known as **compile-time type safety**. For example, if a `Stack` stores only integers, attempting to push a `String` on to that `Stack` should issue a compile-time error.

This chapter discusses **generics**, which provide the means to create the general models mentioned above. **Generic methods** and **generic classes** enable programmers to specify, with a single method declaration, a set of related methods or, with a single class declaration, a set of related types, respectively. Generics also provide compile-time type safety that allows programmers to catch invalid types at compile time.

We might write a generic method for sorting an array of objects, then invoke the generic method with `Integer` arrays, `Double` arrays, `String` arrays and so on, to sort the array elements. The compiler could perform type checking to ensure that the array passed to the sorting method contains the same type elements. We might write a single generic `Stack` class that manipulates a stack of objects, then instantiate `Stack` objects for a stack of `Integers`, a stack of `Doubles`, a stack of `Strings` and so on. The compiler could perform type checking to ensure that the `Stack` stores elements of the same type.

Software Engineering Observation 18.1

Generic methods and classes are among Java's most powerful capabilities for software reuse with compile-time type safety.

This chapter presents generic method and generic class examples. It also considers the relationships between generics and other Java features, such as overloading and inheritance. Chapter 19, Collections, presents an in-depth treatment of the Java Collections Framework's generic methods and classes. A collection is a data structure that maintains references to many objects. The Java Collections Framework uses generics to allow programmers to specify the exact types of objects that a particular collection will store in a program.

18.2 Motivation for Generic Methods **861**

18.2 Motivation for Generic Methods

Overloaded methods are often used to perform similar operations on different types of data. To motivate generic methods, let's begin with an example (Fig. 18.1) that contains three overloaded `printArray` methods (lines 7–14, lines 17–24 and lines 27–34). These methods print the string representations of the elements of an `Integer` array, a `Double` array and a `Character` array, respectively. Note that we could have used arrays of primitive types `int`, `double` and `char` in this example. We chose to use arrays of type `Integer`, `Double` and `Character` to set up our generic method example, because only reference types can be used with generic methods and classes.

```

1 // Fig. 18.1: OverloadedMethods.java
2 // Using overloaded methods to print arrays of different types.
3
4 public class OverloadedMethods
5 {
6     // method printArray to print Integer array
7     public static void printArray( Integer[] inputArray )
8     {
9         // display array elements
10        for ( Integer element : inputArray )
11            System.out.printf( "%s ", element );
12
13        System.out.println();
14    } // end method printArray
15
16     // method printArray to print Double array
17     public static void printArray( Double[] inputArray )
18     {
19         // display array elements
20        for ( Double element : inputArray )
21            System.out.printf( "%s ", element );
22
23        System.out.println();
24    } // end method printArray
25
26     // method printArray to print Character array
27     public static void printArray( Character[] inputArray )
28     {
29         // display array elements
30        for ( Character element : inputArray )
31            System.out.printf( "%s ", element );
32
33        System.out.println();
34    } // end method printArray
35
36     public static void main( String args[] )
37     {
38         // create arrays of Integer, Double and Character
39         Integer[] integerArray = { 1, 2, 3, 4, 5, 6 };
40         Double[] doubleArray = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6, 7.7 };

```

Fig. 18.1 | Printing array elements using overloaded methods. (Part I of 2.)

862 Chapter 18 Generics

```

41     Character[] characterArray = { 'H', 'E', 'L', 'L', 'O' };
42
43     System.out.println( "Array integerArray contains:" );
44     printArray( integerArray ); // pass an Integer array
45     System.out.println( "\nArray doubleArray contains:" );
46     printArray( doubleArray ); // pass a Double array
47     System.out.println( "\nArray characterArray contains:" );
48     printArray( characterArray ); // pass a Character array
49 } // end main
50 } // end class OverloadedMethods

```

Array integerArray contains:
1 2 3 4 5 6

Array doubleArray contains:
1.1 2.2 3.3 4.4 5.5 6.6 7.7

Array characterArray contains:
H E L L O

Fig. 18.1 | Printing array elements using overloaded methods. (Part 2 of 2.)

The program begins by declaring and initializing three arrays—six-element `Integer` array `integerArray` (line 39), seven-element `Double` array `doubleArray` (line 40) and five-element `Character` array `characterArray` (line 41). Then, lines 43–48 output the arrays.

When the compiler encounters a method call, it always attempts to locate a method declaration that has the same method name and parameters that match the argument types in the method call. In this example, each `printArray` call exactly matches one of the `printArray` method declarations. For example, line 44 calls `printArray` with `integerArray` as its argument. At compile time, the compiler determines argument `integerArray`'s type (i.e., `Integer[]`) and attempts to locate a method named `printArray` that specifies a single `Integer[]` parameter (lines 7–14) and sets up a call to that method. Similarly, when the compiler encounters the `printArray` call at line 46, it determines argument `doubleArray`'s type (i.e., `Double[]`), then attempts to locate a method named `printArray` that specifies a single `Double[]` parameter (lines 17–24) and sets up a call to that method. Finally, when the compiler encounters the `printArray` call at line 48, it determines argument `characterArray`'s type (i.e., `Character[]`), then attempts to locate a method named `printArray` that specifies a single `Character[]` parameter (lines 27–34) and sets up a call to that method.

Study each `printArray` method. Note that the array element type appears in two locations in each method—the method header (lines 7, 17 and 27) and the `for` statement header (lines 10, 20 and 30). If we were to replace the element types in each method with a generic name—by convention we'll use `E` to represent the “element” type—then all three methods would look like the one in Fig. 18.2. It appears that if we can replace the array element type in each of the three methods with a single generic type, then we should be able to declare one `printArray` method that can display the string representations of the elements of any array that contains objects. Note that the format specifier `%s` can be used to output any object's string representation—the object's `toString` method will be called implicitly. The method in Fig. 18.2 is similar to the generic `printArray` method declaration we discuss in Section 18.3.

18.3 Generic Methods: Implementation and Compile-Time Translation **863**

```

1  public static void printArray( E[] inputArray )
2  {
3      // display array elements
4      for ( E element : inputArray )
5          System.out.printf( "%s ", element );
6
7      System.out.println();
8  } // end method printArray

```

Fig. 18.2 | printArray method in which actual type names are replaced by convention with the generic name E.

18.3 Generic Methods: Implementation and Compile-Time Translation

If the operations performed by several overloaded methods are identical for each argument type, the overloaded methods can be more compactly and conveniently coded using a generic method. You can write a single generic method declaration that can be called with arguments of different types. Based on the types of the arguments passed to the generic method, the compiler handles each method call appropriately.

Figure 18.3 reimplements the application of Fig. 18.1 using a generic printArray method (lines 7–14). Note that the printArray method calls in lines 24, 26 and 28 are identical to those of Fig. 18.1 (lines 44, 46 and 48) and that the outputs of the two applications are identical. This dramatically demonstrates the expressive power of generics.

```

1  // Fig. 18.3: GenericMethodTest.java
2  // Using generic methods to print arrays of different types.
3
4  public class GenericMethodTest
5  {
6      // generic method printArray
7      public static < E > void printArray( E[] inputArray )
8      {
9          // display array elements
10         for ( E element : inputArray )
11             System.out.printf( "%s ", element );
12
13         System.out.println();
14     } // end method printArray
15
16    public static void main( String args[] )
17    {
18        // create arrays of Integer, Double and Character
19        Integer[] intArray = { 1, 2, 3, 4, 5 };
20        Double[] doubleArray = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6, 7.7 };
21        Character[] charArray = { 'H', 'E', 'L', 'L', 'O' };
22
23        System.out.println( "Array integerArray contains:" );
24        printArray( intArray ); // pass an Integer array

```

Fig. 18.3 | Printing array elements using generic method printArray. (Part I of 2.)

864 Chapter 18 Generics

```

25     System.out.println( "\nArray doubleArray contains:" );
26     printArray( doubleArray ); // pass a Double array
27     System.out.println( "\nArray characterArray contains:" );
28     printArray( characterArray ); // pass a Character array
29 } // end main
30 } // end class GenericMethodTest

```

Array integerArray contains:
1 2 3 4 5 6

Array doubleArray contains:
1.1 2.2 3.3 4.4 5.5 6.6 7.7

Array characterArray contains:
H E L L O

Fig. 18.3 | Printing array elements using generic method `printArray`. (Part 2 of 2.)

Line 7 begins method `printArray`'s declaration. All generic method declarations have a **type parameter section** delimited by **angle brackets** (< and >) that precedes the method's return type (< E > in this example). Each type parameter section contains one or more **type parameters** (also called **formal type parameters**), separated by commas. A type parameter, also known as a **type variable**, is an identifier that specifies a generic type name. The type parameters can be used to declare the return type, parameter types and local variable types in a generic method declaration, and act as placeholders for the types of the arguments passed to the generic method, which are known as **actual type arguments**. A generic method's body is declared like that of any other method. Note that type parameters can represent only reference types—not primitive types (like `int`, `double` and `char`). Note, too, that the type parameter names throughout the method declaration must match those declared in the type parameter section. For example, line 10 declares `element` as type `E`, which matches the type parameter (`E`) declared in line 7. Also, a type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list. For example, the type parameter name `E` appears twice in the following method's parameter list:

```
public static < E > void printTwoArrays( E[] array1, E[] array2 )
```

Type-parameter names need not be unique among different generic methods.

Common Programming Error 18.1

When declaring a generic method, failing to place a type parameter section before the return type of a method is a syntax error—the compiler will not understand the type parameter name when it is encountered in the method.

Method `printArray`'s type parameter section declares type parameter, `E`, as the placeholder for the array element type that `printArray` will output. Note that `E` appears in the parameter list as the array element type (line 7). The `for` statement header (line 10) also uses `E` as the element type. These are the same two locations where the overloaded `printArray` methods of Fig. 18.1 specified `Integer`, `Double` or `Character` as the array element type. The remainder of `printArray` is identical to the versions presented in Fig. 18.1.

18.3 Generic Methods: Implementation and Compile-Time Translation 865

Good Programming Practice 18.1

It is recommended that type parameters be specified as individual capital letters. Typically, a type parameter that represents an array element's type (or other collection) is named E for "element."

As in Fig. 18.1, the program begins by declaring and initializing six-element Integer array `integerArray` (line 19), seven-element Double array `doubleArray` (line 20) and five-element Character array `characterArray` (line 21). Then the program outputs each array by calling `printArray` (lines 24, 26 and 28)—once with argument `integerArray`, once with argument `doubleArray` and once with argument `characterArray`.

When the compiler encounters line 24, it first determines argument `integerArray`'s type (i.e., `Integer[]`) and attempts to locate a method named `printArray` that specifies a single `Integer[]` parameter. There is no such method in this example. Next, the compiler determines whether there is a generic method named `printArray` that specifies a single array parameter and uses a type parameter to represent the array element type. The compiler determines that `printArray` (lines 7–14) is a match and sets up a call to the method. The same process is repeated for the calls to method `printArray` at lines 26 and 28.

Common Programming Error 18.2

If the compiler cannot match a method call to a non-generic or a generic method declaration, a compilation error occurs.

Common Programming Error 18.3

If the compiler does not find a method declaration that matches a method call exactly, but does find two or more generic methods that can satisfy the method call, a compilation error occurs.

In addition to setting up the method calls, the compiler also determines whether the operations in the method body can be applied to elements of the type stored in the array argument. The only operation performed on the array elements in this example is to output the string representation of the elements. Line 11 performs an implicit `toString` call on every `element`. To work with generics, every element of the array must be an object of a class or interface type. Since all objects have a `toString` method, the compiler is satisfied that line 11 performs a valid operation for any object in `printArray`'s array argument. The `toString` methods of classes `Integer`, `Double` and `Character` return the string representation of the underlying `int`, `double` or `char` value, respectively.

When the compiler translates generic method `printArray` into Java bytecodes, it removes the type parameter section and replaces the type parameters with actual types. This process is known as **erasure**. By default all generic types are replaced with type `Object`. So the compiled version of method `printArray` appears as shown in Fig. 18.4—there is only one copy of this code which is used for all `printArray` calls in the example. This is quite different from other, similar mechanisms, such as C++'s templates, in which a separate copy of the source code is generated and compiled for every type passed as an argument to the method. As we will discuss in Section 18.4, the translation and compilation of generics is a bit more involved than what we have discussed in this section.

By declaring `printArray` as a generic method in Fig. 18.3, we eliminated the need for the overloaded methods of Fig. 18.1, saving 20 lines of code and creating a reusable method that can output the string representations of the elements in any array that contains objects. However, this particular example could have simply declared the `printArray` method as shown in Fig. 18.4 using an `Object` array as the parameter. This would have

866 Chapter 18 Generics

```

1 public static void printArray( Object[] inputArray )
2 {
3     // display array elements
4     for ( Object element : inputArray )
5         System.out.printf( "%s ", element );
6
7     System.out.println();
8 } // end method printArray

```

Fig. 18.4 | Generic method `printArray` after erasure is performed by the compiler.

yielded the same results, because any `Object` can be output as a `String`. In a generic method, the benefits become apparent when the method also uses a type parameter as the method's return type, as we demonstrate in the next section.

18.4 Additional Compile-Time Translation Issues: Methods That Use a Type Parameter as the Return Type

Let's consider a generic method example in which type parameters are used in the return type and in the parameter list (Fig. 18.5). The application uses a generic method `maximum` to determine and return the largest of its three arguments of the same type. Unfortunately, the relational operator `>` cannot be used with reference types. However, it is possible to compare two objects of the same class if that class implements the generic interface `Comparable< T >` (package `java.lang`). All the type-wrapper classes for primitive types implement this interface. Like generic classes, `generic interfaces` enable programmers to specify, with a single interface declaration, a set of related types. `Comparable< T >` objects have a `compareTo` method. For example, if we have two `Integer` objects, `integer1` and `integer2`, they can be compared with the expression:

```
integer1.compareTo( integer2 )
```

It is the responsibility of the programmer who declares a class that implements `Comparable< T >` to declare method `compareTo` such that it compares the contents of two objects of that class and returns the results of the comparison. The method must return 0 if the objects are equal, -1 if `object1` is less than `object2` or 1 if `object1` is greater than `object2`. For example, class `Integer`'s `compareTo` method compares the `int` values stored in two `Integer` objects. A benefit of implementing interface `Comparable< T >` is that `Comparable< T >` objects can be used with the sorting and searching methods of class `Collections` (package `java.util`). We discuss those methods in Chapter 19, Collections. In this example, we'll use method `compareTo` in method `maximum` to help determine the largest value.

Generic method `maximum` (lines 7–18) uses type parameter `T` as the return type of the method (line 7), as the type of method parameters `x`, `y` and `z` (line 7), and as the type of local variable `max` (line 9). The type parameter section specifies that `T` extends `Comparable< T >`—only objects of classes that implement interface `Comparable< T >` can be used with this method. In this case, `Comparable` is known as the **upper bound** of the type parameter. By default, `Object` is the upper bound. Note that type parameter declarations that **bound** the parameter always use keyword `extends` regardless of whether the type

18.4 Methods That Use a Type Parameter as the Return Type **867**

```

1 // Fig. 18.5: MaximumTest.java
2 // Generic method maximum returns the largest of three objects.
3
4 public class MaximumTest
5 {
6     // determines the largest of three Comparable objects
7     public static < T extends Comparable< T > > T maximum( T x, T y, T z )
8     {
9         T max = x; // assume x is initially the largest
10
11        if ( y.compareTo( max ) > 0 )
12            max = y; // y is the largest so far
13
14        if ( z.compareTo( max ) > 0 )
15            max = z; // z is the largest
16
17        return max; // returns the largest object
18    } // end method maximum
19
20    public static void main( String args[] )
21    {
22        System.out.printf( "Maximum of %d, %d and %d is %d\n\n", 3, 4, 5,
23                           maximum( 3, 4, 5 ) );
24        System.out.printf( "Maximum of %.1f, %.1f and %.1f is %.1f\n\n",
25                           6.6, 8.8, 7.7, maximum( 6.6, 8.8, 7.7 ) );
26        System.out.printf( "Maximum of %s, %s and %s is %s\n", "pear",
27                           "apple", "orange", maximum( "pear", "apple", "orange" ) );
28    } // end main
29 } // end class MaximumTest

```

Maximum of 3, 4 and 5 is 5

Maximum of 6.6, 8.8 and 7.7 is 8.8

Maximum of pear, apple and orange is pear

Fig. 18.5 | Generic method `maximum` with an upper bound on its type parameter.

parameter extends a class or implements an interface. This type parameter is more restrictive than the one specified for `printArray` in Fig. 18.3, which was able to output arrays containing any type of object. The restriction of using `Comparable< T >` objects is important, because not all objects can be compared. However, `Comparable< T >` objects are guaranteed to have a `compareTo` method.

Method `maximum` uses the same algorithm that we used in Section 6.4 to determine the largest of its three arguments. The method assumes that its first argument (`x`) is the largest and assigns it to local variable `max` (line 9). Next, the `if` statement at lines 11–12 determines whether `y` is greater than `max`. The condition invokes `y`'s `compareTo` method with the expression `y.compareTo(max)`, which returns -1, 0 or 1, to determine `y`'s relationship to `max`. If the return value of the `compareTo` is greater than 0, then `y` is greater and is assigned to variable `max`. Similarly, the `if` statement at lines 14–15 determines whether `z` is greater than `max`. If so, line 15 assigns `z` to `max`. Then, line 17 returns `max` to the caller.

868 Chapter 18 Generics

In `main` (lines 20–28), line 23 calls `maximum` with the integers 3, 4 and 5. When the compiler encounters this call, it first looks for a `maximum` method that takes three arguments of type `int`. There is no such method, so the compiler looks for a generic method that can be used and finds generic method `maximum`. However, recall that the arguments to a generic method must be of a reference type. So the compiler autoboxes the three `int` values as `Integer` objects and specifies that the three `Integer` objects will be passed to `maximum`. Note that class `Integer` (package `java.lang`) implements interface `Comparable< Integer >` such that method `compareTo` compares the `int` values in two `Integer` objects. Therefore, `Integers` are valid arguments to method `maximum`. When the `Integer` representing the maximum is returned, we attempt to output it with the `%d` format specifier, which outputs an `int` primitive type value. So `maximum`'s return value is output as an `int` value.

A similar process occurs for the three `double` arguments passed to `maximum` in line 25. Each `double` is autoboxed as a `Double` object and passed to `maximum`. Again, this is allowed because class `Double` (package `java.lang`) implements the `Comparable< Double >` interface. The `Double` returned by `maximum` is output with the format specifier `.1f`, which outputs a `double` primitive-type value. So `maximum`'s return value is auto-unboxed and output as a `double`. The call to `maximum` in line 27 receives three `Strings`, which are also `Comparable< String >` objects. Note that we intentionally placed the largest value in a different position in each method call (lines 23, 25 and 27) to show that the generic method always finds the maximum value, regardless of its position in the argument list.

When the compiler translates generic method `maximum` into Java bytecodes, it uses erasure (introduced in Section 18.3) to replace the type parameters with actual types. In Fig. 18.3, all generic types were replaced with type `Object`. Actually, all type parameters are replaced with the upper bound of the type parameter—unless specified otherwise, `Object` is the default upper bound. The upper bound of a type parameter is specified in the type parameter section. To indicate the upper bound, follow the type parameter's name with the keyword `extends` and the class or interface name that represents the upper bound. In method `maximum`'s type parameter section (Fig. 18.5), we specified the upper bound as type `Comparable< T >`. Thus, only `Comparable< T >` objects can be passed as arguments to `maximum`—anything that is not `Comparable< T >` will result in compilation errors. Figure 18.6 simulates the erasure of method `maximum`'s types by showing the method's source code after the type parameter section is removed and type parameter `T` is

```

1  public static Comparable maximum(Comparable x, Comparable y, Comparable z)
2  {
3      Comparable max = x; // assume x is initially the largest
4
5      if ( y.compareTo( max ) > 0 )
6          max = y; // y is the largest so far
7
8      if ( z.compareTo( max ) > 0 )
9          max = z; // z is the largest
10
11     return max; // returns the largest object
12 } // end method maximum

```

Fig. 18.6 | Generic method `maximum` after erasure is performed by the compiler.

18.5 Overloading Generic Methods 869

replaced with the upper bound, `Comparable`, throughout the method declaration. Note that the erasure of `Comparable< T >` is simply `Comparable`.

After erasure, the compiled version of method `maximum` specifies that it returns type `Comparable`. However, the calling method does not expect to receive a `Comparable`. Rather, the caller expects to receive an object of the same type that was passed to `maximum` as an argument—`Integer`, `Double` or `String` in this example. When the compiler replaces the type parameter information with the upper bound type in the method declaration, it also inserts explicit cast operations in front of each method call to ensure that the returned value is of the type expected by the caller. Thus, the call to `maximum` in line 23 (Fig. 18.5) is preceded by an `Integer` cast, as in

```
(Integer) maximum( 3, 4, 5 )
```

the call to `maximum` in line 25 is preceded by a `Double` cast, as in

```
(Double) maximum( 6.6, 8.8, 7.7 )
```

and the call to `maximum` in line 27 is preceded by a `String` cast, as in

```
(String) maximum( "pear", "apple", "orange" )
```

In each case, the type of the cast for the return value is inferred from the types of the method arguments in the particular method call, because, according to the method declaration, the return type and the argument types match.

In this example, you cannot use a method that accepts `Objects`, because class `Object` provides only an equality comparison. Also, without generics, you would be responsible for implementing the cast operation. Using generics ensures that the inserted cast will never throw a `ClassCastException`, assuming that generics are used throughout your code (i.e., you do not mix old code with new generics code).

18.5 Overloading Generic Methods

A generic method may be overloaded. A class can provide two or more generic methods that specify the same method name but different method parameters. For example, generic method `printArray` of Fig. 18.3 could be overloaded with another `printArray` generic method with the additional parameters `lowSubscript` and `highSubscript` to specify the portion of the array to output (see Exercise 18.5).

A generic method can also be overloaded by non-generic methods that have the same method name and number of parameters. When the compiler encounters a method call, it searches for the method declaration that most precisely matches the method name and the argument types specified in the call. For example, generic method `printArray` of Fig. 18.3 could be overloaded with a version that is specific to `Strings`, which outputs the `Strings` in neat, tabular format (see Exercise 18.6).

When the compiler encounters a method call, it performs a matching process to determine which method to invoke. The compiler tries to find and use a precise match in which the method names and argument types of the method call match those of a specific method declaration. If there is no such method, the compiler determines whether there is an inexact but applicable matching method.

870 Chapter 18 Generics

18.6 Generic Classes

The concept of a data structure, such as a stack, can be understood independently of the element type it manipulates. Generic classes provide a means for describing the concept of a stack (or any other class) in a type-independent manner. We can then instantiate type-specific objects of the generic class. This capability provides a wonderful opportunity for software reusability.

Once you have a generic class, you can use a simple, concise notation to indicate the actual type(s) that should be used in place of the class's type parameter(s). At compilation time, the Java compiler ensures the type safety of your code and uses the erasure techniques described in Sections 18.3–18.4 to enable your client code to interact with the generic class.

One generic Stack class, for example, could be the basis for creating many Stack classes (e.g., “Stack of Double,” “Stack of Integer,” “Stack of Character,” “Stack of Employee”). These classes are known as **parameterized classes** or **parameterized types** because they accept one or more parameters. Recall that type parameters represent only reference types, which means the Stack generic class cannot be instantiated with primitive types. However, we can instantiate a Stack that stores objects of Java's type-wrapper classes and allow Java to use autoboxing to convert the primitive values into objects. Autoboxing occurs when a value of a primitive type (e.g., int) is pushed onto a Stack that contains wrapper-class objects (e.g., Integer). Auto-unboxing occurs when an object of the wrapper class is popped off the Stack and assigned to a primitive-type variable.

Figure 18.7 presents a generic Stack class declaration. A generic class declaration looks like a non-generic class declaration, except that the class name is followed by a type parameter section (line 4). In this case, type parameter E represents the element type the Stack will manipulate. As with generic methods, the type parameter section of a generic class can have one or more type parameters separated by commas. (You will create a generic class with two type parameters in Exercise 18.8.) Type parameter E is used throughout the Stack class declaration to represent the element type. [Note: This example implements a Stack as an array.]

```

1 // Fig. 18.7: Stack.java
2 // Generic class Stack.
3
4 public class Stack< E >
5 {
6     private final int size; // number of elements in the stack
7     private int top; // location of the top element
8     private E[] elements; // array that stores stack elements
9
10    // no-argument constructor creates a stack of the default size
11    public Stack()
12    {
13        this( 10 ); // default stack size
14    } // end no-argument Stack constructor
15

```

Fig. 18.7 | Generic class Stack declaration. (Part I of 2.)

18.6 Generic Classes **871**

```

16  // constructor creates a stack of the specified number of elements
17  public Stack( int s )
18  {
19      size = s > 0 ? s : 10; // set size of Stack
20      top = -1; // Stack initially empty
21
22      elements = ( E[] ) new Object[ size ]; // create array
23 } // end Stack constructor
24
25 // push element onto stack; if successful, return true;
26 // otherwise, throw FullStackException
27 public void push( E pushValue )
28 {
29     if ( top == size - 1 ) // if stack is full
30         throw new FullStackException( String.format(
31             "Stack is full, cannot push %s", pushValue ) );
32
33     elements[ ++top ] = pushValue; // place pushValue on Stack
34 } // end method push
35
36 // return the top element if not empty; else throw EmptyStackException
37 public E pop()
38 {
39     if ( top == -1 ) // if stack is empty
40         throw new EmptyStackException( "Stack is empty, cannot pop" );
41
42     return elements[ top-- ]; // remove and return top element of Stack
43 } // end method pop
44 } // end class Stack< E >

```

Fig. 18.7 | Generic class Stack declaration. (Part 2 of 2.)

Class Stack declares variable `elements` as an array of type `E` (line 8). This array will store the Stack's elements. We would like to create an array of type `E` to store the elements. However, the generics mechanism does not allow type parameters in array-creation expressions because the type parameter (in this case, `E`) is not available at runtime. To create an array with the appropriate type, line 22 in the one-argument constructor creates the array as an array of type `Object` and casts the reference returned by `new` to type `E[]`. Any object could be stored in an `Object` array, but the compiler's type-checking mechanism ensures that only objects of the array variable's declared type can be assigned to the array via any array-access expression that uses variable `elements`. Yet when this class is compiled using the `-Xlint:unchecked` option, e.g.,

```
javac -Xlint:unchecked Stack.java
```

the compiler issues the following warning message about line 22:

```
Stack.java:22: warning: [unchecked] unchecked cast
found   : java.lang.Object[]
required: E[]
        elements = ( E[] ) new Object[ size ]; // create array
```

872 Chapter 18 Generics

The reason for this message is that the compiler cannot ensure with 100% certainty that an array of type `Object` will never contain objects of types other than `E`. Assume that `E` represents type `Integer`, so that array elements should store `Integer` objects. It is possible to assign variable `elements` to a variable of type `Object[]`, as in

```
Object[] objectArray = elements;
```

Then any object can be placed into the array with an assignment statement like

```
objectArray[ 0 ] = "hello";
```

This places a `String` in an array that should contain only `Integers`, which would lead to runtime problems when manipulating the `Stack`. As long as you do not perform statements like those shown here, your `Stack` will contain objects of only the correct element type.

Method `push` (lines 27–34) first determines whether an attempt is being made to push an element onto a full `Stack`. If so, lines 30–31 throw a `FullStackException`. Class `FullStackException` is declared in Fig. 18.8. If the `Stack` is not full, line 33 increments the `top` counter and places the argument in that location of array `elements`.

Method `pop` (lines 37–43) first determines whether an attempt is being made to pop an element from an empty `Stack`. If so, line 40 throws an `EmptyStackException`. Class `EmptyStackException` is declared in Fig. 18.9. Otherwise, line 42 returns the top element of the `Stack`, then postdecrements the `top` counter to indicate the position of the next top element.

Classes `FullStackException` (Fig. 18.8) and `EmptyStackException` (Fig. 18.9) each provide the conventional no-argument constructor and one-argument constructor of exception classes (as discussed in Section 13.11). The no-argument constructor sets the default error message, and the one-argument constructor sets a custom exception message.

As with generic methods, when a generic class is compiled, the compiler performs erasure on the class's type parameters and replaces them with their upper bounds. For class `Stack` (Fig. 18.7), no upper bound is specified, so the default upper bound, `Object`, is used. The scope of a generic class's type parameter is the entire class. However, type parameters cannot be used in a class's `static` declarations.

```

1 // Fig. 18.8: FullStackException.java
2 // Indicates a stack is full.
3 public class FullStackException extends RuntimeException
4 {
5     // no-argument constructor
6     public FullStackException()
7     {
8         this( "Stack is full" );
9     } // end no-argument FullStackException constructor
10
11    // one-argument constructor
12    public FullStackException( String exception )
13    {
14        super( exception );
15    } // end one-argument FullStackException constructor
16 } // end class FullStackException

```

Fig. 18.8 | `FullStackException` class declaration.

18.6 Generic Classes **873**

```

1 // Fig. 18.9: EmptyStackException.java
2 // Indicates a stack is full.
3 public class EmptyStackException extends RuntimeException
4 {
5     // no-argument constructor
6     public EmptyStackException()
7     {
8         this( "Stack is empty" );
9     } // end no-argument EmptyStackException constructor
10
11    // one-argument constructor
12    public EmptyStackException( String exception )
13    {
14        super( exception );
15    } // end one-argument EmptyStackException constructor
16 } // end class EmptyStackException

```

Fig. 18.9 | EmptyStackException class declaration.

Now, let's consider the test application (Fig. 18.10) that uses the Stack generic class. Lines 9–10 declare variables of type Stack< Double > (pronounced “Stack of Double”) and Stack< Integer > (pronounced “Stack of Integer”). The types Double and Integer are known as the Stack’s **type arguments**. They are used by the compiler to replace the type parameters so that the compiler can perform type checking and insert cast operations as necessary. We’ll discuss the cast operations in more detail shortly. Method testStack (called from main) instantiates objects doubleStack of size 5 (line 15) and integerStack of size 10 (line 16), then calls methods testPushDouble (lines 25–44), testPopDouble (lines 47–67), testPushInteger (lines 70–89) and testPopInteger (lines 92–112) to demonstrate the two Stacks in this example.

Method testPushDouble (lines 25–44) invokes method push to place the double values 1.1, 2.2, 3.3, 4.4 and 5.5 stored in array doubleElements onto doubleStack. The for loop terminates when the test program attempts to push a sixth value onto doubleStack (which is full, because doubleStack can store only five elements). In this case,

```

1 // Fig. 18.10: StackTest.java
2 // Stack generic class test program.
3
4 public class StackTest
5 {
6     private double[] doubleElements = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6 };
7     private int[] integerElements = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 };
8
9     private Stack< Double > doubleStack; // stack stores Double objects
10    private Stack< Integer > integerStack; // stack stores Integer objects
11
12    // test Stack objects
13    public void testStacks()
14    {
15        doubleStack = new Stack< Double >( 5 ); // Stack of Doubles

```

Fig. 18.10 | Generic class Stack test program. (Part I of 4.)

874 Chapter 18 Generics

```

16     integerStack = new Stack< Integer >( 10 ); // Stack of Integers
17
18     testPushDouble(); // push double onto doubleStack
19     testPopDouble(); // pop from doubleStack
20     testPushInteger(); // push int onto intStack
21     testPopInteger(); // pop from intStack
22 } // end method testStacks
23
24 // test push method with double stack
25 public void testPushDouble()
26 {
27     // push elements onto stack
28     try
29     {
30         System.out.println( "\nPushing elements onto doubleStack" );
31
32         // push elements to Stack
33         for ( double element : doubleElements )
34         {
35             System.out.printf( "% .1f ", element );
36             doubleStack.push( element ); // push onto doubleStack
37         } // end for
38     } // end try
39     catch ( FullStackException fullStackException )
40     {
41         System.err.println();
42         fullStackException.printStackTrace();
43     } // end catch FullStackException
44 } // end method testPushDouble
45
46 // test pop method with double stack
47 public void testPopDouble()
48 {
49     // pop elements from stack
50     try
51     {
52         System.out.println( "\nPopping elements from doubleStack" );
53         double popValue; // store element removed from stack
54
55         // remove all elements from Stack
56         while ( true )
57         {
58             popValue = doubleStack.pop(); // pop from doubleStack
59             System.out.printf( "% .1f ", popValue );
60         } // end while
61     } // end try
62     catch( EmptyStackException emptyStackException )
63     {
64         System.err.println();
65         emptyStackException.printStackTrace();
66     } // end catch EmptyStackException
67 } // end method testPopDouble

```

Fig. 18.10 | Generic class Stack test program. (Part 2 of 4.)

18.6 Generic Classes **875**

```

68 // test push method with integer stack
69 public void testPushInteger()
70 {
71     // push elements to stack
72     try
73     {
74         System.out.println( "\nPushing elements onto intStack" );
75
76         // push elements to Stack
77         for ( int element : integerElements )
78         {
79             System.out.printf( "%d ", element );
80             integerStack.push( element ); // push onto integerStack
81         } // end for
82     } // end try
83     catch ( FullStackException fullStackException )
84     {
85         System.err.println();
86         fullStackException.printStackTrace();
87     } // end catch FullStackException
88 } // end method testPushInteger
89
90 // test pop method with integer stack
91 public void testPopInteger()
92 {
93     // pop elements from stack
94     try
95     {
96         System.out.println( "\nPopping elements from intStack" );
97         int popValue; // store element removed from stack
98
99         // remove all elements from Stack
100        while ( true )
101        {
102            popValue = integerStack.pop(); // pop from intStack
103            System.out.printf( "%d ", popValue );
104        } // end while
105    } // end try
106    catch( EmptyStackException emptyStackException )
107    {
108        System.err.println();
109        emptyStackException.printStackTrace();
110    } // end catch EmptyStackException
111 } // end method testPopInteger
112
113
114 public static void main( String args[] )

Fig. 18.10 | Generic class Stack test program. (Part 4 of 4.)

the method throws a `FullStackException` (Fig. 18.8) to indicate that the Stack is full. Lines 39–43 catch this exception and print the stack trace information. The stack trace indicates the exception that occurred and shows that `Stack` method `push` generated the exception at lines 30–31 of the file `Stack.java` (Fig. 18.7). The trace also shows that method `push` was called by `StackTest` method `testPushDouble` at line 36 of `StackTest.java`, that method `testPushDouble` was called from method `testStacks` at line 18 of `StackTest.java` and that method `testStacks` was called from method `main` at line 117 of `StackTest.java`. This information enables you to determine the methods that were on the method-call stack at the time that the exception occurred. Because the program catches the exception, the Java runtime environment considers the exception to have been handled and the program can continue executing. Note that autoboxing occurs in line 36 when the program tries to push a primitive `double` value onto the `doubleStack`, which stores only `Double` objects.

Method `testPopDouble` (lines 47–67) invokes `Stack` method `pop` in an infinite `while` loop to remove all the values from the stack. Note in the output that the values indeed pop off in last-in, first-out order (this, of course, is the defining characteristic of stacks). The `while` loop (lines 57–61) continues until the stack is empty (i.e., until an `EmptyStackException` occurs), which causes the program to proceed to the catch block (lines

18.6 Generic Classes **877**

62–66) and handle the exception, so the program can continue executing. When the test program attempts to pop a sixth value, the `doubleStack` is empty, so the `pop` throws an `EmptyStackException`. Auto-unboxing occurs in line 58 when the program assigns the `Double` object popped from the stack to a `double` primitive variable. Recall from Section 18.4 that the compiler inserts cast operations to ensure that the proper types are returned from generic methods. After erasure, `Stack` method `pop` returns type `Object`. However, the client code in method `testPopDouble` expects to receive a `double` when method `pop` returns. So the compiler inserts a `Double` cast, as in

```
popValue = ( Double ) doubleStack.pop();
```

to ensure that a reference of the appropriate type is returned, auto-unboxed and assigned to `popValue`.

Method `testPushInteger` (lines 70–89) invokes `Stack` method `push` to place values onto `integerStack` until it is full. Method `testPopInteger` (lines 92–112) invokes `Stack` method `pop` to remove values from `integerStack` until it is empty. Once again, note that the values pop off in last-in, first-out order. During the erasure process, the compiler recognizes that the client code in method `testPopInteger` expects to receive an `int` when method `pop` returns. So the compiler inserts an `Integer` cast, as in

```
popValue = ( Integer ) integerStack.pop();
```

to ensure that a reference of the appropriate type is returned, auto-unboxed and assigned to `popValue`.

Creating Generic Methods to Test Class `Stack< E >`

Note that the code in methods `testPushDouble` and `testPushInteger` is almost identical for pushing values onto a `Stack< Double >` or a `Stack< Integer >`, respectively, and the code in methods `testPopDouble` and `testPopInteger` is almost identical for popping values from a `Stack< Double >` or a `Stack< Integer >`, respectively. This presents another opportunity to use generic methods. Figure 18.11 declares generic method `testPush` (lines 26–46) to perform the same tasks as `testPushDouble` and `testPushInteger` in Fig. 18.10—that is, push values onto a `Stack< T >`. Similarly, generic method `testPop` (lines 49–69) performs the same tasks as `testPopDouble` and `testPopInteger` in Fig. 18.10—that is, pop values off a `Stack< T >`. Note that the output of Fig. 18.11 precisely matches the output of Fig. 18.10.

```

1 // Fig. 18.11: StackTest2.java
2 // Stack generic class test program.
3
4 public class StackTest2
5 {
6     private Double[] doubleElements = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6 };
7     private Integer[] integerElements =
8         { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 };
9
10    private Stack< Double > doubleStack; // stack stores Double objects
11    private Stack< Integer > integerStack; // stack stores Integer objects

```

Fig. 18.11 | Passing a generic type Stack to a generic method. (Part 3 of 3.)

The `testStacks` method (lines 14–23) creates the `Stack<Double>` (line 16) and `Stack<Integer>` (line 17) objects. Lines 19–22 invoke generic methods `testPush` and `testPop` to test the `Stack` objects. Recall that type parameters can represent only reference types. Therefore, to be able to pass arrays `doubleElements` and `integerElements` to generic method `testPush`, the arrays declared in lines 6–8 must be declared with the wrapper types `Double` and `Integer`. When these arrays are initialized with primitive values, the compiler autoboxes each primitive value.

880 Chapter 18 Generics

Generic method `testPush` (lines 26–46) uses type parameter `T` (specified at line 26) to represent the data type stored in the `Stack< T >`. The generic method takes three arguments—a `String` that represents the name of the `Stack< T >` object for output purposes, a reference to an object of type `Stack< T >` and an array of type `T`—the type of elements that will be pushed onto `Stack< T >`. Note that the compiler enforces consistency between the type of the Stack and the elements that will be pushed onto the Stack when `push` is invoked, which is the real value of the generic method call. Generic method `testPop` (lines 49–69) takes two arguments—a `String` that represents the name of the `Stack< T >` object for output purposes and a reference to an object of type `Stack< T >`.

18.7 Raw Types

The test programs for generic class `Stack` in Section 18.6 instantiate `Stacks` with type arguments `Double` and `Integer`. It is also possible to instantiate generic class `Stack` without specifying a type argument, as follows:

```
Stack objectStack = new Stack( 5 ); // no type argument specified
```

In this case, the `objectStack` is said to have a **raw type**, which means that the compiler implicitly uses type `Object` throughout the generic class for each type argument. Thus the preceding statement creates a `Stack` that can store objects of any type. This is important for backward compatibility with prior versions of Java. For example, the data structures of the Java Collections Framework (see Chapter 19, Collections) all stored references to `Objects`, but are now implemented as generic types.

A raw type `Stack` variable can be assigned a `Stack` that specifies a type argument, such as a `Stack< Double >` object, as follows:

```
Stack rawTypeStack2 = new Stack< Double >( 5 );
```

because type `Double` is a subclass of `Object`. This assignment is allowed because the elements in a `Stack< Double >` (i.e., `Double` objects) are certainly objects—class `Double` is an indirect subclass of `Object`.

Similarly, a `Stack` variable that specifies a type argument in its declaration can be assigned a raw type `Stack` object, as in:

```
Stack< Integer > integerStack = new Stack( 10 );
```

Although this assignment is permitted, it is unsafe because a `Stack` of raw type might store types other than `Integer`. In this case, the compiler issues a warning message which indicates the unsafe assignment.

The test program of Fig. 18.12 uses the notion of raw type. Line 14 instantiates generic class `Stack` with raw type, which indicates that `rawTypeStack1` can hold objects of any type. Line 17 assigns a `Stack< Double >` to variable `rawTypeStack2`, which is declared as a `Stack` of raw type. Line 20 assigns a `Stack` of raw type to `Stack< Integer >` variable, which is legal but causes the compiler to issue a warning message (Fig. 18.13) indicating a potentially unsafe assignment—again, this occurs because a `Stack` of raw type might store types other than `Integer`. Also, each of the calls to generic method `testPush` and `testPop` in lines 22–25 results in a compiler warning message (Fig. 18.13). These warnings occur because variables `rawTypeStack1` and `rawTypeStack2` are declared as `Stacks` of

18.7 Raw Types 881

raw type, but methods `testPush` and `testPop` each expect a second argument that is a `Stack` with a specific type argument. The warnings indicate that the compiler cannot guarantee that the types manipulated by the stacks are the correct types, because we did not supply a variable declared with a type argument. Methods `testPush` (lines 31–51) and `testPop` (lines 54–74) are the same as in Fig. 18.11.

```

Fig. 18.12 | Raw type test program. (Part 3 of 3.)

Figure 18.13 shows the warning messages generated by the compiler (compiled with the `-Xlint:unchecked` option) when the file `RawTypeTest.java` (Fig. 18.12) is compiled. The first warning is generated for line 20, which assigned a raw type `Stack` to a `Stack< Integer >` variable—the compiler cannot ensure that all objects in the `Stack` will be `Integer` objects. The second warning is generated for line 22. Because the second method argument is a raw type `Stack` variable, the compiler determines the type argument for method `testPush` from the `Double` array passed as the third argument. In this case, `Double` is the type argument, so the compiler expects a `Stack< Double >` to be passed as the second argument. The warning occurs because the compiler cannot ensure that a raw type `Stack` contains only `Double` objects. The warning at line 24 occurs for the same reason, even though the actual `Stack` that `rawTypeStack2` references is a `Stack< Double >`. The compiler cannot guarantee that the variable will always refer to the same `Stack` object, so it must use the variable's declared type to perform all type checking. Lines 23 and 25 each generate warnings because method `testPop` expects as an argument a `Stack` for which a type argument has been specified. However, in each call to `testPop`, we pass a raw type `Stack` variable. Thus, the compiler indicates a warning because it cannot check the types used in the body of the method.

18.8 Wildcards in Methods That Accept Type Parameters

In this section, we introduce a powerful generics concept known as **wildcards**. For this purpose, we will also introduce a new data structure from package `java.util`. Chapter 19, Collections, discusses the Java Collections Framework, which provides many generic data structures and algorithms that manipulate the elements of those data structures. Perhaps the simplest of these data structures is class `ArrayList`—a dynamically resizable, array-like data structure. As part of this discussion, you will learn how to create an `ArrayList`, add elements to it and traverse those elements using an enhanced `for` statement.

Before we introduce wildcards, let's consider an example that helps us motivate their use. Suppose that you would like to implement a generic method `sum` that totals the numbers in a collection, such as an `ArrayList`. You would begin by inserting the numbers in the collection. As you know, generic classes can be used only with class or interface types. So the numbers would be autoboxed as objects of the type-wrapper classes. For example, any `int` value would be autoboxed as an `Integer` object, and any `double` value would be autoboxed as a `Double` object. We'd like to be able to total all the numbers in the `ArrayList` regardless of their type. For this reason, we'll declare the `ArrayList` with the type argument `Number`, which is the superclass of both `Integer` and `Double`. In addition, method `sum` will receive a parameter of type `ArrayList<Number>` and total its elements. Figure 18.14 demonstrates totaling the elements of an `ArrayList` of `Numbers`.

18.8 Wildcards in Methods That Accept Type Parameters **885**

```

1 // Fig. 18.14: TotalNumbers.java
2 // Summing the elements of an ArrayList.
3 import java.util.ArrayList;
4
5 public class TotalNumbers
6 {
7     public static void main( String args[] )
8     {
9         // create, initialize and output ArrayList of Numbers containing
10        // both Integers and Doubles, then display total of the elements
11        Number[] numbers = { 1, 2.4, 3, 4.1 }; // Integers and Doubles
12        ArrayList< Number > numberList = new ArrayList< Number >();
13
14        for ( Number element : numbers )
15            numberList.add( element ); // place each number in numberList
16
17        System.out.printf( "numberList contains: %s\n", numberList );
18        System.out.printf( "Total of the elements in numberList: %.1f\n",
19                          sum( numberList ) );
20    } // end main
21
22    // calculate total of ArrayList elements
23    public static double sum( ArrayList< Number > list )
24    {
25        double total = 0; // initialize total
26
27        // calculate sum
28        for ( Number element : list )
29            total += element.doubleValue();
30
31        return total;
32    } // end method sum
33 } // end class TotalNumbers

```

```

numberList contains: [1, 2.4, 3, 4.1]
Total of the elements in numberList: 10.5

```

Fig. 18.14 | Totaling the numbers in an `ArrayList< Number >`.

Line 11 declares and initializes an array of `Number`s. Because the initializers are primitive values, Java autoboxes each primitive value as an object of its corresponding wrapper type. The `int` values 1 and 3 are autoboxed as `Integer` objects, and the `double` values 2.4 and 4.1 are autoboxed as `Double` objects. Line 12 declares and creates an `ArrayList` object that stores `Number`s and assigns it to variable `numberList`. Note that we do not have to specify the size of the `ArrayList` because it will grow automatically as we insert objects.

Lines 14–15 traverse array `numbers` and place each element in `numberList`. Method `add` of class `ArrayList` appends an element to the end of the collection. Line 17 outputs the contents of the `ArrayList` as a `String`. This statement implicitly invokes the `ArrayList`'s `toString` method, which returns a string of the form "[*elements*]" in which *elements* is a comma-separated list of the elements' string representations. Lines 18–19 display the sum of the elements that is returned by the call to method `sum` at line 19.

886 Chapter 18 Generics

Method `sum` (lines 23–32) receives an `ArrayList` of `Numbers` and calculates the total of the `Numbers` in the collection. The method uses `double` values to perform the calculations and returns the result as a `double`. Line 25 declares local variable `total` and initializes it to 0. Lines 28–29 use the enhanced for statement, which is designed to work with both arrays and the collections of the Collections Framework, to total the elements of the `ArrayList`. The for statement assigns each `Number` in the `ArrayList` to variable `element`, then uses method `doubleValue` of class `Number` to obtain the `Number`'s underlying primitive value as a `double` value. The result is added to `total`. When the loop terminates, the method returns the `total`.

Implementing Method `sum` With a Wildcard Type Argument in Its Parameter

Recall that the purpose of method `sum` in Fig. 18.14 was to total any type of `Numbers` stored in an `ArrayList`. We created an `ArrayList` of `Numbers` that contained both `Integer` and `Double` objects. The output of Fig. 18.14 demonstrates that method `sum` worked properly. Given that method `sum` can total the elements of an `ArrayList` of `Numbers`, you might expect that the method would also work for `ArrayLists` that contain elements of only one numeric type, such as `ArrayList< Integer >`. So we modified class `TotalNumbers` to create an `ArrayList` of `Integers` and pass it to method `sum`. When we compile the program, the compiler issues the following error message:

```
sum(java.util.ArrayList<java.lang.Number>) in TotalNumbersErrors
cannot be applied to (java.util.ArrayList<java.lang.Integer>)
```

Although `Number` is the superclass of `Integer`, the compiler does not consider the parameterized type `ArrayList< Number >` to be a supertype of `ArrayList< Integer >`. If it were, then every operation we could perform on `ArrayList< Number >` would also work on an `ArrayList< Integer >`. Consider the fact that you can add a `Double` object to an `ArrayList< Number >` because a `Double` is a `Number`, but you cannot add a `Double` object to an `ArrayList< Integer >` because a `Double` is not an `Integer`. Thus, the subtype relationship does not hold.

How do we create a more flexible version of method `sum` that can total the elements of any `ArrayList` that contains elements of any subclass of `Number`? This is where **wildcard type arguments** are important. Wildcards enable you to specify method parameters, return values, variables or fields, etc. that act as supertypes of parameterized types. In Fig. 18.15, method `sum`'s parameter is declared in line 50 with the type:

```
ArrayList< ? extends Number >
```

A wildcard type argument is denoted by a question mark (?), which by itself represents an “unknown type.” In this case, the wildcard extends class `Number`, which means that the wildcard has an upper bound of `Number`. Thus, the unknown type argument must be either `Number` or a subclass of `Number`. With the parameter type shown here, method `sum` can receive an `ArrayList` argument that contains any type of `Number`, such as `ArrayList< Integer >` (line 20), `ArrayList< Double >` (line 33) or `ArrayList< Number >` (line 46).

Lines 11–20 create and initialize an `ArrayList< Integer >` called `integerList`, output its elements and total its elements by calling method `sum` (line 20). Lines 24–33 perform the same operations for an `ArrayList< Double >` called `doubleList`. Lines 37–46 perform the same operations for an `ArrayList< Number >` called `numberList` that contains both `Integers` and `Doubles`.

18.8 Wildcards in Methods That Accept Type Parameters **887**

```

1 // Fig. 18.15: WildcardTest.java
2 // Wildcard test program.
3 import java.util.ArrayList;
4
5 public class WildcardTest
6 {
7     public static void main( String args[] )
8     {
9         // create, initialize and output ArrayList of Integers, then
10        // display total of the elements
11        Integer[] integers = { 1, 2, 3, 4, 5 };
12        ArrayList< Integer > integerList = new ArrayList< Integer >();
13
14        // insert elements in integerList
15        for ( Integer element : integers )
16            integerList.add( element );
17
18        System.out.printf( "integerList contains: %s\n", integerList );
19        System.out.printf( "Total of the elements in integerList: %.0f\n\n",
20                           sum( integerList ) );
21
22        // create, initialize and output ArrayList of Doubles, then
23        // display total of the elements
24        Double[] doubles = { 1.1, 3.3, 5.5 };
25        ArrayList< Double > doubleList = new ArrayList< Double >();
26
27        // insert elements in doubleList
28        for ( Double element : doubles )
29            doubleList.add( element );
30
31        System.out.printf( "doubleList contains: %s\n", doubleList );
32        System.out.printf( "Total of the elements in doubleList: %.1f\n\n",
33                           sum( doubleList ) );
34
35        // create, initialize and output ArrayList of Numbers containing
36        // both Integers and Doubles, then display total of the elements
37        Number[] numbers = { 1, 2.4, 3, 4.1 }; // Integers and Doubles
38        ArrayList< Number > numberList = new ArrayList< Number >();
39
40        // insert elements in numberList
41        for ( Number element : numbers )
42            numberList.add( element );
43
44        System.out.printf( "numberList contains: %s\n", numberList );
45        System.out.printf( "Total of the elements in numberList: %.1f\n",
46                           sum( numberList ) );
47    } // end main
48
49    // calculate total of stack elements
50    public static double sum( ArrayList< ? extends Number > list )
51    {
52        double total = 0; // initialize total
53

```

Fig. 18.15 | Wildcard test program. (Part I of 2.)

888 Chapter 18 Generics

```

54     // calculate sum
55     for ( Number element : list )
56         total += element.doubleValue();
57
58     return total;
59 } // end method sum
60 } // end class WildcardTest

```

```

integerList contains: [1, 2, 3, 4, 5]
Total of the elements in integerList: 15

doubleList contains: [1.1, 3.3, 5.5]
Total of the elements in doubleList: 9.9

numberList contains: [1, 2.4, 3, 4.1]
Total of the elements in numberList: 10.5

```

Fig. 18.15 | Wildcard test program. (Part 2 of 2.)

In method `sum` (lines 50–59), although the `ArrayList` argument's element types are not directly known by the method, they are known to be at least of type `Number`, because the wildcard was specified with the upper bound `Number`. For this reason line 56 is allowed, because all `Number` objects have a `doubleValue` method.

Although wildcards provide flexibility when passing parameterized types to a method, they also have some disadvantages. Because the wildcard (?) in the method's header (line 50) does not specify a type-parameter name, you cannot use it as a type name throughout the method's body (i.e., you cannot replace `Number` with ? in line 55). You could, however, declare method `sum` as follows:

```
public static <T extends Number> double sum( ArrayList< T > list )
```

which allows the method to receive an `ArrayList` that contains elements of any `Number` subclass. You could then use the type parameter `T` throughout the method body.

If the wildcard is specified without an upper bound, then only the methods of type `Object` can be invoked on values of the wildcard type. Also, methods that use wildcards in their parameter's type arguments cannot be used to add elements to a collection referenced by the parameter.

**Common Programming Error 18.4**

Using a wildcard in a method's type parameter section or using a wildcard as an explicit type of a variable in the method body is a syntax error.

18.9 Generics and Inheritance: Notes

Generics can be used with inheritance in several ways:

- A generic class can be derived from a non-generic class. For example, the `Object` class is a direct or indirect superclass of every generic class.
- A generic class can be derived from another generic class. For example, generic class `Stack` (in package `java.util`) is a subclass of generic class `Vector` (in package `java.util`). We discuss these classes in Chapter 19, Collections.

18.10 Wrap-Up **889**

- A non-generic class can be derived from a generic class. For example, non-generic class `Properties` (in package `java.util`) is a subclass of generic class `Hashtable` (in package `java.util`). We also discuss these classes in Chapter 19.
- Finally, a generic method in a subclass can override a generic method in a superclass if both methods have the same signatures.

18.10 Wrap-Up

This chapter introduced generics. You learned how to declare generic methods and classes. You learned how backward compatibility is achieved via raw types. You also learned how to use wildcards in a generic method or a generic class. In the next chapter, we demonstrate the interfaces, classes and algorithms of the Java collections framework. As you will see, the collections presented all use the generics capabilities you learned here.

The articles *Explorations: Generics, Erasure, and Bridging* and *Explorations: Wildcards in the Generics Specification*, each by William Grosso, overview generics features and how to use wildcards.

Summary**Section 18.1 Introduction**

- Generic methods enable programmers to specify, with a single method declaration, a set of related methods.
- Generic classes enable programmers to specify, with a single class declaration, a set of related types.
- Generic methods and classes are among Java's most powerful capabilities for software reuse with compile-time type safety.

Section 18.2 Motivation for Generic Methods

- Overloaded methods are often used to perform similar operations on different types of data.
- When the compiler encounters a method call, it attempts to locate a method declaration that has the same method name and parameters that match the argument types in the method call.

Section 18.3 Generic Methods: Implementation and Compile-Time Translation

- If the operations performed by several overloaded methods are identical for each argument type, the overloaded methods can be more compactly and conveniently coded using a generic method. You can write a single generic method declaration, which can be called with arguments of differ-

890 [Chapter 18 Generics](#)

ent data types. Based on the types of the arguments passed to the generic method, the compiler handles each method call appropriately.

- All generic method declarations have a type parameter section delimited by angle brackets (< and >) that precedes the method's return type.
- Each type parameter section contains one or more type parameters (also called formal type parameters) separated by commas.
- A type parameter is an identifier that specifies a generic type name. The type parameters can be used as the return type, parameter types and local variable types in a generic method declaration, and they act as placeholders for the types of the arguments passed to the generic method, which are known as actual type arguments. Type parameters can represent only reference types.
- The names used for type parameters throughout the method declaration must match those declared in the type parameter section. The name of a type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list. Type-parameter names need not be unique among different generic methods.
- When the compiler encounters a method call, it determines the argument types and attempts to locate a method with the same name and parameters that match the argument types. If there is no such method, the compiler determines whether there is an inexact but applicable match.
- The relational operator > cannot be used with reference types. However, it is possible to compare two objects of the same class if that class implements the generic interface `Comparable` (package `java.lang`).
- `Comparable` objects have a `compareTo` method that must return 0 if the objects are equal, -1 if the first object is less than the second or 1 if the first object is greater than the second.
- All the type-wrapper classes for primitive types implement `Comparable`.
- A benefit of implementing interface `Comparable` is that `Comparable` objects can be used with the sorting and searching methods of class `Collections` (package `java.util`).
- When the compiler translates a generic method into Java bytecodes, it removes the type parameter section and replaces the type parameters with actual types. This process is known as erasure. By default each type parameter is replaced with its upper bound. By default, the upper bound is type `Object` unless specified otherwise in the type parameter section.

Section 18.4 Additional Compile-Time Translation Issues: Methods That Use a Type Parameter as the Return Type

- When the compiler performs erasure on a method that returns a type variable, it also inserts explicit cast operations in front of each method call to ensure that the returned value is of the type expected by the caller.

Section 18.5 Overloading Generic Methods

- A generic method may be overloaded. A class can provide two or more generic methods that specify the same method name but different method parameters. A generic method can also be overloaded by non-generic methods that have the same method name and number of parameters. When the compiler encounters a method call, it searches for the method declaration that most precisely matches the method name and the argument types specified in the call.
- When the compiler encounters a method call, it performs a matching process to determine which method to call. The compiler tries to find and use a precise match in which the method names and argument types of the method call match those of a specific method declaration. If this fails, the compiler determines whether a generic method is available that provides a precise match of the method name and argument types, and if so, uses that generic method.

Summary 891***Section 18.6 Generic Classes***

- Generic classes provide a means for describing a class in a type-independent manner. We can then instantiate type-specific objects of the generic class.
- A generic class declaration looks like a non-generic class declaration, except that the class name is followed by a type parameter section. As with generic methods, the type parameter section of a generic class can have one or more type parameters separated by commas.
- When a generic class is compiled, the compiler performs erasure on the class's type parameters and replaces them with their upper bounds.
- Type parameters cannot be used in a class's `static` declarations.
- When instantiating an object of a generic class, the types specified in angle brackets after the class name are known as type arguments. The compiler uses them to replace the type parameters so that it can perform type checking and insert cast operations as necessary.

Section 18.7 Raw Types

- It is possible to instantiate a generic class without specifying a type argument. In this case, the new object of the class is said to have a raw type, which means that the compiler implicitly uses type `Object` (or the type parameter's upper bound) throughout the generic class for each type argument.

Section 18.8 Wildcards in Methods That Accept Type Parameters

- The Java Collections Framework provides many generic data structures and algorithms that manipulate the elements of those data structures. Perhaps the simplest of the data structures is class `ArrayList`—a dynamically resizable, array-like data structure.
- Class `Number` is the superclass of both `Integer` and `Double`.
- Method `add` of class `ArrayList` appends an element to the end of the collection.
- Method `toString` of class `ArrayList` returns a string of the form "[*elements*]" in which *elements* is a comma-separated list of the elements' string representations.
- Method `doubleValue` of class `Number` obtains the `Number`'s underlying primitive value as a `double` value.
- Wildcard type arguments enable you to specify method parameters, return values, variables, etc. that act as supertypes of parameterized types. A wildcard type argument is denoted by the question mark (?), which represents an "unknown type." A wildcard can also have an upper bound.
- Because a wildcard (?) is not a type parameter name, you cannot use it as a type name throughout a method's body.
- If a wildcard is specified without an upper bound, then only the methods of type `Object` can be invoked on values of the wildcard type.
- Methods that use wildcards as type arguments cannot be used to add elements to a collection referenced by the parameter.

Section 18.9 Generics and Inheritance: Notes

- A generic class can be derived from a non-generic class. For example, `Object` is a direct or indirect superclass of every generic class.
- A generic class can be derived from another generic class.
- A non-generic class can be derived from a generic class.
- A generic method in a subclass can override a generic method in a superclass if both methods have the same signatures.

892 Chapter 18 Generics**Terminology**

? (wildcard type argument)	Number class
actual type arguments	overloaded a generic method
add method of ArrayList	parameterized class
angle brackets (< and >)	parameterized type
ArrayList class	raw type
Comparable<T> interface	scope of a type parameter
compareTo method of Comparable<T>	toString method of ArrayList
default upper bound of a type parameter	type argument
Double class	type parameter
doubleValue method of Number	type parameter scope
erasure	type parameter section
formal type parameter	type variable
generics	upper bound of a type parameter
generic class	upper bound of a wildcard
generic interface	wildcard (?)
generic method	wildcard as a type argument
Integer class	wildcard without an upper bound

Self-Review Exercises

- 18.1** State whether each of the following is *true* or *false*. If *false*, explain why.
- A generic method cannot have the same method name as a non-generic method.
 - All generic method declarations have a type parameter section that immediately precedes the method name.
 - A generic method can be overloaded by another generic method with the same method name but different method parameters.
 - A type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list.
 - Type parameter names among different generic methods must be unique.
 - The scope of a generic class's type parameter is the entire class except its `static` members.
- 18.2** Fill in the blanks in each of the following:
- _____ and _____ enable you to specify, with a single method declaration, a set of related methods, or with a single class declaration, a set of related types, respectively.
 - A type parameter section is delimited by _____.
 - A generic method's _____ can be used to specify the method's argument types, to specify the method's return type and to declare variables within the method.
 - The statement "Stack objectStack = new Stack();" indicates that `objectStack` stores _____.
 - In a generic class declaration, the class name is followed by a(n) _____.
 - The syntax _____ specifies that the upper bound of a wildcard is type E.

Answers to Self-Review Exercises

- 18.1** a) False. Generic and non-generic methods can have the same method name. A generic method can overload another generic method with the same method name but different method parameters. A generic method also can be overloaded by providing non-generic methods with the same method name and number of arguments. b) False. All generic method declarations have a type parameter section that immediately precedes the method's return type. c) True. d) True. e) False. Type parameter names among different generic methods need not be unique. f) True.

Exercises **893**

- 18.2** a) Generic methods, generic classes. b) angle brackets (< and >). c) type parameters. d) a raw type. e) type parameter section. f) ? extends E.

Exercises

- 18.3** Explain the use of the following notation in a Java program:

```
public class Array< T > { }
```

- 18.4** Write a generic method `selectionSort` based on the sort program of Figs. 16.6–16.7. Write a test program that inputs, sorts and outputs an `Integer` array and a `Float` array. [Hint: Use `< T extends Comparable< T >` in the type parameter section for method `selectionSort`, so that you can use method `compareTo` to compare the objects of two generic types `T`.]

- 18.5** Overload generic method `printArray` of Fig. 18.3 so that it takes two additional integer arguments, `lowSubscript` and `highSubscript`. A call to this method prints only the designated portion of the array. Validate `lowSubscript` and `highSubscript`. If either is out of range, or if `highSubscript` is less than or equal to `lowSubscript`, the overloaded `printArray` method should throw an `InvalidSubscriptException`; otherwise, `printArray` should return the number of elements printed. Then modify `main` to exercise both versions of `printArray` on arrays `integerArray`, `doubleArray` and `characterArray`. Test all capabilities of both versions of `printArray`.

- 18.6** Overload generic method `printArray` of Fig. 18.3 with a non-generic version that specifically prints an array of strings in neat, tabular format, as shown in the sample output that follows:

```
Array stringArray contains:
one    two    three    four
five   six    seven   eight
```

- 18.7** Write a simple generic version of method `isEqualTo` that compares its two arguments with the `equals` method and returns `true` if they are equal and `false` otherwise. Use this generic method in a program that calls `isEqualTo` with a variety of built-in types, such as `Object` or `Integer`. What result do you get when you attempt to run this program?

- 18.8** Write a generic class `Pair` which has two type parameters—`F` and `S`, each representing the type of the first and second element of the pair, respectively. Add `get` and `set` methods for the first and second elements of the pair. [Hint: The class header should be `public class Pair< F, S >`.]

- 18.9** Convert classes `TreeNode` and `Tree` from Fig. 17.17 into generic classes. To insert an object in a `Tree`, the object must be compared to the objects in existing `TreeNode`s. For this reason, classes `TreeNode` and `Tree` should specify `Comparable< E >` as the upper bound of each class's type parameter. After modifying classes `TreeNode` and `Tree`, write a test application that creates three `Tree` objects—one that stores `Integers`, one that stores `Doubles` and one that stores `Strings`. Insert 10 values into each tree. Then output the preorder, inorder and postorder traversals for each `Tree`.

- 18.10** Modify your test program from Exercise 18.9 to use a generic method named `testTree` to test the three `Tree` objects. The method should be called three times—once for each `Tree` object.

- 18.11** How can generic methods be overloaded?

- 18.12** The compiler performs a matching process to determine which method to call when a method is invoked. Under what circumstances does an attempt to make a match result in a compile-time error?

- 18.13** Explain why a Java program might use the statement

```
ArrayList< Employee > workerList = new ArrayList< Employee >();
```

19

Collections

OBJECTIVES

In this chapter you will learn:

- What collections are.
- To use class `Arrays` for array manipulations.
- To use the collections framework (prepackaged data structure) implementations.
- To use collections framework algorithms to manipulate (such as `search`, `sort` and `fill`) collections.
- To use the collections framework interfaces to program with collections polymorphically.
- To use iterators to “walk through” a collection.
- To use persistent hash tables manipulated with objects of class `Properties`.
- To use synchronization and modifiability wrappers.

I think this is the most extraordinary collection of talent, of human knowledge, that has ever been gathered together at the White House—with the possible exception of when Thomas Jefferson dined alone.

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

19.1 Introduction

In Chapter 17, we discussed how to create and manipulate data structures. The discussion was “low level” in the sense that we painstakingly created each element of each data structure dynamically and modified the data structures by directly manipulating their elements and the references to their elements. In this chapter, we consider the Java **collections framework**, which contains prepackaged data structures, interfaces and algorithms for manipulating those data structures. Some examples of collections are the cards you hold in a card game, your favorite songs stored in your computer, the members of a sports team and the real-estate records in your local registry of deeds (which map book numbers and page numbers to property owners). In this chapter, we also discuss how generics (see Chapter 18) are used in the Java collections framework.

With collections, programmers use existing data structures, without concern for how they are implemented. This is a marvelous example of code reuse. Programmers can code faster and can expect excellent performance, maximizing execution speed and minimizing memory consumption. In this chapter, we discuss the collections framework interfaces that list the capabilities of each collection type, the implementation classes, the algorithms that

896 Chapter 19 Collections

process the collections, and the so-called [iterators](#) and enhanced `for` statement syntax that “walk through” collections. This chapter provides an introduction to the collections framework. For complete details, visit java.sun.com/javase/6/docs/guide/collections.

The Java collections framework provides ready-to-go, reusable componentry—you do not need to write your own collection classes, but you can if you wish to. The collections are standardized so that applications can share them easily without concern with the details of their implementation. The collections framework encourages further reusability. As new data structures and algorithms are developed that fit this framework, a large base of programmers will already be familiar with the interfaces and algorithms implemented by those data structures.

19.2 Collections Overview

A [collection](#) is a data structure—actually, an object—that can hold references to other objects. Usually, collections contain references to objects that are all of the same type. The collections framework interfaces declare the operations to be performed generically on various types of collections. Figure 19.1 lists some of the interfaces of the collections framework. Several implementations of these interfaces are provided within the framework. Programmers may also provide implementations specific to their own requirements.

The collections framework provides high-performance, high-quality implementations of common data structures and enables software reuse. These features minimize the amount of coding programmers need to do to create and manipulate collections. The classes and interfaces of the collections framework are members of package `java.util`. In the next section, we begin our discussion by examining the collections framework capabilities for array manipulation.

In earlier versions of Java, the classes in the collections framework stored and manipulated `Object` references. Thus, you could store any object in a collection. One inconvenient aspect of storing `Object` references occurs when retrieving them from a collection. A program normally has the need to process specific types of objects. As a result, the `Object` references obtained from a collection typically need to be cast to an appropriate type to allow the program to process the objects correctly.

Interface	Description
<code>Collection</code>	The root interface in the collections hierarchy from which interfaces <code>Set</code> , <code>Queue</code> and <code>List</code> are derived.
<code>Set</code>	A collection that does not contain duplicates.
<code>List</code>	An ordered collection that can contain duplicate elements.
<code>Map</code>	Associates keys to values and cannot contain duplicate keys.
<code>Queue</code>	Typically a first-in, first-out collection that models a waiting line; other orders can be specified.

Fig. 19.1 | Some collection framework interfaces.

19.3 Class Arrays **897**

In Java SE 5, the collections framework was enhanced with the generics capabilities we introduced in Chapter 18. This means that you can specify the exact type that will be stored in a collection. You also receive the benefits of compile-time type checking—the compiler ensures that you are using appropriate types with your collection and, if not, issues compile-time error messages. Also, once you specify the type stored in a collection, any reference you retrieve from the collection will have the specified type. This eliminates the need for explicit type casts that can throw `ClassCastException`s if the referenced object is not of the appropriate type. Programs that were implemented with prior Java versions and that use collections can compile properly because the compiler automatically uses raw types when it encounters collections for which type arguments were not specified.

19.3 Class Arrays

Class `Arrays` provides static methods for manipulating arrays. In Chapter 7, our discussion of array manipulation was low level in the sense that we wrote the actual code to sort and search arrays. Class `Arrays` provides high-level methods, such as `sort` for sorting an array, `binarySearch` for searching a sorted array, `equals` for comparing arrays and `fill` for placing values into an array. These methods are overloaded for primitive-type arrays and `Object` arrays. In addition, methods `sort` and `binarySearch` are overloaded with generic versions that allow programmers to sort and search arrays containing objects of any type. Figure 19.2 demonstrates methods `fill`, `sort`, `binarySearch` and `equals`. Method `main` (lines 65–85) creates a `UsingArrays` object and invokes its methods.

Line 17 calls static method `fill` of class `Arrays` to populate all 10 elements of `filledIntArray` with 7s. Overloaded versions of `fill` allow the programmer to populate a specific range of elements with the same value.

Line 18 sorts the elements of array `doubleArray`. The static method `sort` of class `Arrays` orders the array's elements in ascending order by default. We discuss how to sort in descending order later in the chapter. Overloaded versions of `sort` allow the programmer to sort a specific range of elements.

Lines 21–22 copy array `intArray` into array `intArrayCopy`. The first argument (`intArray`) passed to `System` method `arraycopy` is the array from which elements are to be copied. The second argument (0) is the index that specifies the starting point in the range of elements to copy from the array. This value can be any valid array index. The third argument (`intArrayCopy`) specifies the destination array that will store the copy. The fourth argument (0) specifies the index in the destination array where the first copied element should be stored. The last argument specifies the number of elements to copy from the array in the first argument. In this case, we copy all the elements in the array.

Line 50 calls static method `binarySearch` of class `Arrays` to perform a binary search on `intArray`, using `value` as the key. If `value` is found, `binarySearch` returns the index of the element; otherwise, `binarySearch` returns a negative value. The negative value returned is based on the search key's **insertion point**—the index where the key would be inserted in the array if we were performing an insert operation. After `binarySearch` determines the insertion point, it changes its sign to negative and subtracts 1 to obtain the return value. For example, in Fig. 19.2, the insertion point for the value 8763 is the element with index 6 in the array. Method `binarySearch` changes the insertion point to -6, subtracts 1 from it and returns the value -7. Subtracting 1 from the insertion point guarantees that method `binarySearch` returns positive values (≥ 0) if and only if the key is

898 Chapter 19 Collections

found. This return value is useful for inserting elements in a sorted array. Chapter 16, Searching and Sorting, discusses binary searching in detail.

```

1 // Fig. 19.2: UsingArrays.java
2 // Using Java arrays.
3 import java.util.Arrays;
4
5 public class UsingArrays
6 {
7     private int intArray[] = { 1, 2, 3, 4, 5, 6 };
8     private double doubleArray[] = { 8.4, 9.3, 0.2, 7.9, 3.4 };
9     private int filledIntArray[], intArrayCopy[];
10
11    // constructor initializes arrays
12    public UsingArrays()
13    {
14        filledIntArray = new int[ 10 ]; // create int array with 10 elements
15        intArrayCopy = new int[ intArray.length ];
16
17        Arrays.fill( filledIntArray, 7 ); // fill with 7s
18        Arrays.sort( doubleArray ); // sort doubleArray ascending
19
20        // copy array intArray into array intArrayCopy
21        System.arraycopy( intArray, 0, intArrayCopy,
22                         0, intArray.length );
23    } // end UsingArrays constructor
24
25    // output values in each array
26    public void printArrays()
27    {
28        System.out.print( "doubleArray: " );
29        for ( double doubleValue : doubleArray )
30            System.out.printf( "%1f ", doubleValue );
31
32        System.out.print( "\nintArray: " );
33        for ( int intValue : intArray )
34            System.out.printf( "%d ", intValue );
35
36        System.out.print( "\nfilledIntArray: " );

intArray != filledIntArray
Found 5 at element 4 in intArray
8763 not found in intArray

```

Fig. 19.2 | Arrays class methods. (Part 2 of 2.)**Common Programming Error 19.1**

Passing an unsorted array to binarySearch is a logic error—the value returned is undefined.

900 Chapter 19 Collections

Lines 56 and 60 call static method `equals` of class `Arrays` to determine whether the elements of two arrays are equivalent. If the arrays contain the same elements in the same order, the method returns `true`; otherwise, it returns `false`. The equality of each element is compared using `Object` method `equals`. Many classes override method `equals` to perform the comparisons in a manner specific to those classes. For example, class `String` declares `equals` to compare the individual characters in the two `Strings` being compared. If method `equals` is not overridden, the original version of method `equals` inherited from class `Object` is used.

19.4 Interface Collection and Class Collections

Interface `Collection` is the root interface in the collection hierarchy from which interfaces `Set`, `Queue` and `List` are derived. Interface `Set` defines a collection that does not contain duplicates. Interface `Queue` defines a collection that represents a waiting line—typically, insertions are made at the back of a queue and deletions are made from the front, though other orders can be specified. We discuss `Queue` and `Set` in Section 19.8 and Section 19.9, respectively. Interface `Collection` contains **bulk operations** (i.e., operations performed on an entire collection) for adding, clearing, comparing and retaining objects (or elements) in a collection. A `Collection` can also be converted to an array. In addition, interface `Collection` provides a method that returns an `Iterator` object, which allows a program to walk through the collection and remove elements from the collection during the iteration. We discuss class `Iterator` in Section 19.5.1. Other methods of interface `Collection` enable a program to determine a collection's size and whether a collection is empty.

Software Engineering Observation 19.1

Collection is used commonly as a method parameter type to allow polymorphic processing of all objects that implement interface Collection.

Software Engineering Observation 19.2

Most collection implementations provide a constructor that takes a Collection argument, thereby allowing a new collection to be constructed containing the elements of the specified collection.

Class `Collections` provides static methods that manipulate collections polymorphically. These methods implement algorithms for searching, sorting and so on. Chapter 16, Searching and Sorting, discussed and implemented various searching and sorting algorithms. Section 19.6 discusses more about the algorithms that are available in class `Collections`. We also cover the **wrapper methods** of class `Collections` that enable you to treat a collection as a **synchronized collection** (Section 19.12) or an **unmodifiable collection** (Section 19.13). Unmodifiable collections are useful when a client of a class needs to view the elements of a collection, but should not be allowed to modify the collection by adding and removing elements. Synchronized collections are for use with a powerful capability called multithreading (discussed in Chapter 23). Multithreading enables programs to perform operations in parallel. When two or more threads of a program share a collection, there is the potential for problems to occur. As a brief analogy, consider a traffic intersection. We cannot allow all cars access to one intersection at the same time—if we did, accidents would occur. For this reason, traffic lights are provided at intersections to control access to the intersection. Similarly, we can synchronize access to a collection to

ensure that only one thread manipulates the collection at a time. The synchronization wrapper methods of class `Collections` return synchronized versions of collections that can be shared among threads in a program.

19.5 Lists

A `List` (sometimes called a `sequence`) is an ordered `Collection` that can contain duplicate elements. Like array indices, `List` indices are zero based (i.e., the first element's index is zero). In addition to the methods inherited from `Collection`, `List` provides methods for manipulating elements via their indices, manipulating a specified range of elements, searching for elements and getting a `ListIterator` to access the elements.

Interface `List` is implemented by several classes, including classes `ArrayList`, `LinkedList` and `Vector`. Autoboxing occurs when you add primitive-type values to objects of these classes, because they store only references to objects. Class `ArrayList` and `Vector` are resizable-array implementations of `List`. Class `LinkedList` is a linked list implementation of interface `List`.

Class `ArrayList`'s behavior and capabilities are similar to those of class `Vector`. The primary difference between `Vector` and `ArrayList` is that objects of class `Vector` are synchronized by default, whereas objects of class `ArrayList` are not. Also, class `Vector` is from Java 1.0, before the collections framework was added to Java. As such, `Vector` has several methods that are not part of interface `List` and are not implemented in class `ArrayList`, but perform identical tasks. For example, `Vector` methods `addElement` and `add` both append an element to a `Vector`, but only method `add` is specified in interface `List` and implemented by `ArrayList`. Unsynchronized collections provide better performance than synchronized ones. For this reason, `ArrayList` is typically preferred over `Vector` in programs that do not share a collection among threads.

Performance Tip 19.1

ArrayLists behave like Vectors without synchronization and therefore execute faster than Vectors because ArrayLists do not have the overhead of thread synchronization.

Software Engineering Observation 19.3

LinkedLists can be used to create stacks, queues, trees and deques (double-ended queues, pronounced “decks”). The collections framework provides implementations of some of these data structures.

The following three subsections demonstrate the `List` and `Collection` capabilities with several examples. Section 19.5.1 focuses on removing elements from an `ArrayList` with an `Iterator`. Section 19.5.2 focuses on `ListIterator` and several `List`- and `LinkedList`-specific methods. Section 19.5.3 introduces more `List` methods and several `Vector`-specific methods.

19.5.1 ArrayList and Iterator

Figure 19.3 uses an `ArrayList` to demonstrate several `Collection` interface capabilities. The program places two `Color` arrays in `ArrayLists` and uses an `Iterator` to remove elements in the second `ArrayList` collection from the first `ArrayList` collection.

Lines 10–13 declare and initialize two `String` array variables, which are declared `final`, so they always refer to these arrays. Recall that it is good programming practice to

902 Chapter 19 Collections

declare constants with keywords `static` and `final`. Lines 18–19 create `ArrayList` objects and assign their references to variables `list` and `removeList`, respectively. These two lists store `String` objects. Note that `ArrayList` is a generic class as of Java SE 5, so we are able to specify a type argument (`String` in this case) to indicate the type of the elements in each list. Both `list` and `removeList` are collections of `Strings`. Lines 22–23 populate `list` with `Strings` stored in array `colors`, and lines 26–27 populate `removeList` with `Strings` stored in array `removeColors` using `List` method `add`. Lines 32–33 output each element of `list`. Line 32 calls `List` method `size` to get the number of `ArrayList` elements. Line 33 uses `List` method `get` to retrieve individual element values. Lines 32–33 could have used the enhanced `for` statement. Line 36 calls method `removeColors` (lines 46–57), passing `list` and `removeList` as arguments. Method `removeColors` deletes `Strings` specified in `removeList` from the `list` collection. Lines 41–42 print `list`'s elements after `removeColors` removes the `String` objects specified in `removeList` from the `list`.

```

48 {
49     // get iterator
50     Iterator< String > iterator = collection1.iterator();
51
52     // loop while collection has items
53     while ( iterator.hasNext() )
54
55         if ( collection2.contains( iterator.next() ) )
56             iterator.remove(); // remove current Color
57 } // end method removeColors
58
59 public static void main( String args[] )
60 {
61     new CollectionTest();
62 } // end main
63 } // end class CollectionTest

```

ArrayList:
MAGENTA RED WHITE BLUE CYAN

ArrayList after calling removeColors:
MAGENTA CYAN

Fig. 19.3 | Collection interface demonstrated via an ArrayList object. (Part 2 of 2.)

Method `removeColors` declares two `Collection` parameters (line 47) that allow any `Collections` containing strings to be passed as arguments to this method. The method accesses the elements of the first `Collection` (`collection1`) via an `Iterator`. Line 50 calls `Collection` method `iterator` to get an `Iterator` for the `Collection`. Note that interfaces `Collection` and `Iterator` are generic types. The loop-continuation condition (line 53) calls `Iterator` method `hasNext` to determine whether the `Collection` contains more elements. Method `hasNext` returns `true` if another element exists and `false` otherwise.

The `if` condition in line 55 calls `Iterator` method `next` to obtain a reference to the next element, then uses method `contains` of the second `Collection` (`collection2`) to determine whether `collection2` contains the element returned by `next`. If so, line 56 calls `Iterator` method `remove` to remove the element from the `Collection` `collection1`.

Common Programming Error 19.2

If a collection is modified by one of its methods after an iterator is created for that collection, the iterator immediately becomes invalid—any operations performed with the iterator after this point throw ConcurrentModificationExceptions. For this reason, iterators are said to be “fail fast.”

904 Chapter 19 Collections

19.5.2 LinkedList

Figure 19.4 demonstrates operations on `LinkedLists`. The program creates two `LinkedLists` that contain `Strings`. The elements of one `List` are added to the other. Then all the `Strings` are converted to uppercase, and a range of elements is deleted.

```

1 // Fig. 19.4: ListTest.java

Fig. 19.4 | Lists and ListIterators. (Part 2 of 2.)

906 Chapter 19 Collections

Lines 17–18 create `LinkedLists` `list1` and `list2` of type `String`. Note that `LinkedList` is a generic class that has one type parameter for which we specify the type argument `String` in this example. Lines 21–26 call `List` method `add` to append elements from arrays `colors` and `colors2` to the end of `list1` and `list2`, respectively.

Line 28 calls `List` method `addAll` to append all elements of `list2` to the end of `list1`. Line 29 sets `list2` to `null`, so the `LinkedList` to which `list2` referred can be garbage collected. Line 30 calls method `printList` (lines 42–50) to output list `list1`'s contents. Line 32 calls method `convertToUppercaseStrings` (lines 53–62) to convert each `String` element to uppercase, then line 33 calls `printList` again to display the modified `Strings`. Line 36 calls method `removeItems` (lines 65–68) to remove the elements starting at index 4 up to, but not including, index 7 of the list. Line 38 calls method `printReversedList` (lines 71–80) to print the list in reverse order.

Method `convertToUppercaseStrings` (lines 53–62) changes lowercase `String` elements in its `List` argument to uppercase `Strings`. Line 55 calls `List` method `listIterator` to get a **bidirectional iterator** (i.e., an iterator that can traverse a `List` backward or forward) for the `List`. Note that `ListIterator` is a generic class. In this example, the `ListIterator` contains `String` objects, because method `listIterator` is called on a `List` of `Strings`. The `while` condition (line 57) calls method `hasNext` to determine whether the `List` contains another element. Line 59 gets the next `String` in the `List`. Line 60 calls `String` method `toUpperCase` to get an uppercase version of the `String` and calls `ListIterator` method `set` to replace the current `String` to which `iterator` refers with the `String` returned by method `toUpperCase`. Like method `toUpperCase`, `String` method `toLowerCase` returns a lowercase version of the `String`.

Method `removeItems` (lines 65–68) removes a range of items from the list. Line 67 calls `List` method `subList` to obtain a portion of the `List` (called a `sublist`). The `sublist` is simply another view into the `List` on which `subList` is called. Method `subList` takes two arguments—the beginning and the ending index for the sublist. The ending index is not part of the range of the sublist. In this example, we pass (in line 36) 4 for the beginning index and 7 for the ending index to `subList`. The `sublist` returned is the set of elements with indices 4 through 6. Next, the program calls `List` method `clear` on the `sublist` to remove the elements of the `sublist` from the `List`. Any changes made to a `sublist` are also made to the original `List`.

Method `printReversedList` (lines 71–80) prints the list backward. Line 73 calls `List` method `listIterator` with the starting position as an argument (in our case, the last element in the list) to get a bidirectional iterator for the list. `List` method `size` returns the number of items in the `List`. The `while` condition (line 78) calls method `hasPrevious` to determine whether there are more elements while traversing the list backward. Line 79 gets the previous element from the list and outputs it to the standard output stream.

An important feature of the collections framework is the ability to manipulate the elements of one collection type (such as a set) through a different collection type (such as a list), regardless of the collection's internal implementation. The set of `public` methods through which collections are manipulated is called a `view`.

Class `Arrays` provides static method `asList` to view an array as a `List` collection (which encapsulates behavior similar to that of the linked lists created in Chapter 17). A `List` view allows the programmer to manipulate the array as if it were a list. This is useful for adding the elements in an array to a collection (e.g., a `LinkedList`) and for sorting array

elements. The next example demonstrates how to create a `LinkedList` with a `List` view of an array, because we cannot pass the array to a `LinkedList` constructor. Sorting array elements with a `List` view is demonstrated in Fig. 19.9. Any modifications made through the `List` view change the array, and any modifications made to the array change the `List` view. The only operation permitted on the view returned by `asList` is `set`, which changes the value of the view and the backing array. Any other attempts to change the view (such as adding or removing elements) result in an `UnsupportedOperationException`.

Figure 19.5 uses method `asList` to view an array as a `List` collection and uses method `toArray` of a `List` to get an array from a `LinkedList` collection. The program calls method `asList` to create a `List` view of an array, which is then used for creating a `LinkedList` object, adds a series of strings to a `LinkedList` and calls method `toArray` to obtain an array containing references to the strings. Notice that the instantiation of `LinkedList` (line 13) indicates that `LinkedList` is a generic class that accepts one type argument—`String`, in this example.

```

1 // Fig. 19.5: UsingToArray.java
2 // Using method toArray.
3 import java.util.LinkedList;
4 import java.util.Arrays;
5
6 public class UsingToArray
7 {
8     // constructor creates LinkedList, adds elements and converts to array
9     public UsingToArray()
10    {
11        String colors[] = { "black", "blue", "yellow" };
12
13        LinkedList< String > links =
14            new LinkedList< String >( Arrays.asList( colors ) );
15
16        links.addLast( "red" );    // add as last item
17        links.add( "pink" );      // add to the end
18        links.add( 3, "green" );  // add at 3rd index
19        links.addFirst( "cyan" ); // add as first item
20
21        // get LinkedList elements as an array
22        colors = links.toArray( new String[ links.size() ] );
23
24        System.out.println( "colors: " );
25
26        for ( String color : colors )
27            System.out.println( color );
28    } // end UsingToArray constructor
29
30    public static void main( String args[] )
31    {
32        new UsingToArray();
33    } // end main
34 } // end class UsingToArray

```

Fig. 19.5 | List method `toArray`. (Part I of 2.)

908 Chapter 19 Collections

```
colors:
cyan
black
blue
yellow
green
red
pink
```

Fig. 19.5 | List method toArray. (Part 2 of 2.)

Lines 13–14 construct a `LinkedList` of `Strings` containing the elements of array `colors` and assigns the `LinkedList` reference to `links`. Note the use of `Arrays` method `asList` to return a view of the array as a `List`, then initialize the `LinkedList` with the `List`. Line 16 calls `LinkedList` method `addLast` to add "red" to the end of `links`. Lines 17–18 call `LinkedList` method `add` to add "pink" as the last element and "green" as the element at index 3 (i.e., the fourth element). Note that method `addLast` (line 16) is identical in function to method `add` (line 17). Line 19 calls `LinkedList` method `addFirst` to add "cyan" as the new first item in the `LinkedList`. The add operations are permitted because they operate on the `LinkedList` object, not the view returned by `asList`. [Note: When "cyan" is added as the first element, "green" becomes the fifth element in the `LinkedList`.]

Line 22 calls `List` method `toArray` to get a `String` array from `links`. The array is a copy of the list's elements—modifying the array's contents does not modify the list. The array passed to method `toArray` is of the same type that you would like method `toArray` to return. If the number of elements in the array is greater than or equal to the number of elements in the `LinkedList`, `toArray` copies the list's elements into its array argument and returns that array. If the `LinkedList` has more elements than the number of elements in the array passed to `toArray`, `toArray` allocates a new array of the same type it receives as an argument, copies the list's elements into the new array and returns the new array.

**Common Programming Error 19.3**

Passing an array that contains data to `toArray` can cause logic errors. If the number of elements in the array is smaller than the number of elements in the list on which `toArray` is called, a new array is allocated to store the list's elements—without preserving the array argument's elements. If the number of elements in the array is greater than the number of elements in the list, the elements of the array (starting at index zero) are overwritten with the list's elements. Array elements that are not overwritten retain their values.

19.5.3 Vector

Like `ArrayList`, class `Vector` provides the capabilities of array-like data structures that can resize themselves dynamically. Recall that class `ArrayList`'s behavior and capabilities are similar to those of class `Vector`, except that `ArrayLists` do not provide synchronization by default. We cover class `Vector` here primarily because it is the superclass of class `Stack`, which is presented in Section 19.7.

At any time, a `Vector` contains a number of elements that is less than or equal to its **capacity**. The capacity is the space that has been reserved for the `Vector`'s elements. If a

Vector requires additional capacity, it grows by a **capacity increment** that you specify or by a default capacity increment. If you do not specify a capacity increment or specify one that is less than or equal to zero, the system will double the size of a Vector each time additional capacity is needed.

Performance Tip 19.2

Inserting an element into a Vector whose current size is less than its capacity is a relatively fast operation.

Performance Tip 19.3

Inserting an element into a Vector that needs to grow larger to accommodate the new element is a relatively slow operation.

Performance Tip 19.4

The default capacity increment doubles the size of the Vector. This may seem a waste of storage, but it is actually an efficient way for many Vectors to grow quickly to be “about the right size.” This operation is much more efficient than growing the Vector each time by only as much space as it takes to hold a single element. The disadvantage is that the Vector might occupy more space than it requires. This is a classic example of the space–time trade-off.

Performance Tip 19.5

If storage is at a premium, use Vector method trimToSize to trim a Vector’s capacity to the Vector’s exact size. This operation optimizes a Vector’s use of storage. However, adding another element to the Vector will force the Vector to grow dynamically (again, a relatively slow operation)—trimming leaves no room for growth.

Figure 19.6 demonstrates class Vector and several of its methods. For complete information on class Vector, please visit java.sun.com/javase/6/docs/api/java/util/Vector.html.

```

```

Fig. 19.6 | Vector class of package `java.util`. (Part 3 of 3.)

The application’s constructor creates a `Vector` (line 13) of type `String` with an initial capacity of 10 elements and capacity increment of zero (the defaults for a `Vector`). Note that `Vector` is a generic class, which takes one argument that specifies the type of the elements stored in the `Vector`. A capacity increment of zero indicates that this `Vector` will double in size each time it needs to grow to accommodate more elements. Class `Vector` provides three other constructors. The constructor that takes one integer argument creates an empty `Vector` with the `initial capacity` specified by that argument. The constructor that takes two arguments creates a `Vector` with the initial capacity specified by the first argument and the `capacity increment` specified by the second argument. Each time the `Vector` needs to grow, it will add space for the specified number of elements in the capacity increment. The constructor that takes a `Collection` creates a copy of a collection’s elements and stores them in the `Vector`.

Line 18 calls `Vector` method `add` to add objects (`Strings` in this program) to the end of the `Vector`. If necessary, the `Vector` increases its capacity to accommodate the new element. Class `Vector` also provides a method `add` that takes two arguments. This method takes an object and an integer and inserts the object at the specified index in the `Vector`. Method `set` will replace the element at a specified position in the `Vector` with a specified element. Method `insertElementAt` provides the same functionality as the method `add` that takes two arguments, except that the order of the parameters is reversed.

Line 25 calls `Vector` method `firstElement` to return a reference to the first element in the `Vector`. Line 26 calls `Vector` method `lastElement` to return a reference to the last element in the `Vector`. Each of these methods throws a `NoSuchElementException` if there are no elements in the `Vector` when the method is called.

Line 35 calls `Vector` method `contains` to determine whether the `Vector` contains "red". The method returns `true` if its argument is in the `Vector`—otherwise, the method

912 Chapter 19 Collections

returns `false`. Method `contains` uses `Object` method `equals` to determine whether the search key is equal to one of the `Vector`'s elements. Many classes override method `equals` to perform the comparisons in a manner specific to those classes. For example, class `String` declares `equals` to compare the individual characters in the two `Strings` being compared. If method `equals` is not overridden, the original version of method `equals` inherited from class `Object` is used.

**Common Programming Error 19.4**

Without overriding method `equals`, the program performs comparisons using operator `==` to determine whether two references refer to the same object in memory.

Line 37 calls `Vector` method `indexOf` to determine the index of the first location in the `Vector` that contains the argument. The method returns `-1` if the argument is not found in the `Vector`. An overloaded version of this method takes a second argument specifying the index in the `Vector` at which the search should begin.

**Performance Tip 19.6**

Vector methods `contains` and `indexOf` perform linear searches of a `Vector`'s contents. These searches are inefficient for large `Vectors`. If a program frequently searches for elements in a collection, consider using one of the Java Collection API's Map implementations (Section 19.10), which provide high-speed searching capabilities.

Line 41 calls `Vector` method `remove` to remove the first occurrence of its argument from the `Vector`. The method returns `true` if it finds the element in the `Vector`; otherwise, the method returns `false`. If the element is removed, all elements after that element in the `Vector` shift one position toward the beginning of the `Vector` to fill in the position of the removed element. Class `Vector` also provides method `removeAllElements` to remove every element from a `Vector` and method `removeElementAt` to remove the element at a specified index.

Lines 53–54 use `Vector` methods `size` and `capacity` to determine the number of elements currently in the `Vector` and the number of elements that can be stored in the `Vector` without allocating more memory, respectively.

Line 59 calls `Vector` method `isEmpty` to determine whether the `Vector` is empty. The method returns `true` if there are no elements in the `Vector`; otherwise, the method returns `false`. Lines 66–67 use the enhanced `for` statement to print out all elements in the vector.

Among the methods introduced in Fig. 19.6, `firstElement`, `lastElement` and `capacity` can be used only with `Vector`. Other methods (e.g., `add`, `contains`, `indexOf`, `remove`, `size` and `isEmpty`) are declared by `List`, which means that they can be used by any class that implements `List`, such as `Vector`.

19.6 Collections Algorithms

The collections framework provides several high-performance algorithms for manipulating collection elements. These algorithms are implemented as `static` methods of class `Collections` (Fig. 19.7). Algorithms `sort`, `binarySearch`, `reverse`, `shuffle`, `fill` and `copy` operate on `Lists`. Algorithms `min`, `max`, `addAll`, `frequency` and `disjoint` operate on `Collections`.

19.6 Collections Algorithms **913**

Algorithm	Description
<code>sort</code>	Sorts the elements of a <code>List</code> .
<code>binarySearch</code>	Locates an object in a <code>List</code> .
<code>reverse</code>	Reverses the elements of a <code>List</code> .
<code>shuffle</code>	Randomly orders a <code>List</code> 's elements.
<code>fill</code>	Sets every <code>List</code> element to refer to a specified object.
<code>copy</code>	Copies references from one <code>List</code> into another.
<code>min</code>	Returns the smallest element in a <code>Collection</code> .
<code>max</code>	Returns the largest element in a <code>Collection</code> .
<code>addAll</code>	Appends all elements in an array to a collection.
<code>frequency</code>	Calculates how many elements in the collection are equal to the specified element.
<code>disjoint</code>	Determines whether two collections have no elements in common.

Fig. 19.7 | Collections algorithms.

Software Engineering Observation 19.4

The collections framework algorithms are polymorphic. That is, each algorithm can operate on objects that implement specific interfaces, regardless of the underlying implementations.

19.6.1 Algorithm sort

Algorithm `sort` sorts the elements of a `List`, which must implement the `Comparable` interface. The order is determined by the natural order of the elements' type as implemented by a `compareTo` method. Method `compareTo` is declared in interface `Comparable` and is sometimes called the `natural comparison method`. The `sort` call may specify as a second argument a `Comparator` object that determines an alternative ordering of the elements.

Sorting in Ascending Order

Figure 19.8 uses algorithm `sort` to order the elements of a `List` in ascending order (line 20). Recall that `List` is a generic type and accepts one type argument that specifies the list element type—line 15 declares `list` as a `List` of `String`. Note that lines 18 and 23 each use an implicit call to the `list`'s `toString` method to output the list contents in the format shown on the second and fourth lines of the output.

Sorting in Descending Order

Figure 19.9 sorts the same list of strings used in Fig. 19.8 in descending order. The example introduces the `Comparator` interface, which is used for sorting a `Collection`'s elements in a different order. Line 21 calls `Collections`'s method `sort` to order the `List` in de-

914 Chapter 19 Collections

scending order. The static `Collections` method `reverseOrder` returns a `Comparator` object that orders the collection's elements in reverse order.

Fig. 19.9 | Collections method `sort` with a Comparator object. (Part 2 of 2.)

Sorting with a Comparator

Figure 19.10 creates a custom Comparator class, named `TimeComparator`, that implements interface `Comparator` to compare two `Time2` objects. Class `Time2`, declared in Fig. 8.5, represents times with hours, minutes and seconds.

Class `TimeComparator` implements interface `Comparator`, a generic type that takes one argument (in this case `Time2`). Method `compare` (lines 7–26) performs comparisons between `Time2` objects. Line 9 compares the two hours of the `Time2` objects. If the hours are different (line 12), then we return this value. If this value is positive, then the first hour is greater than the second and the first time is greater than the second. If this value is negative, then the first hour is less than the second and the first time is less than the second. If this value is zero, the hours are the same and we must test the minutes (and maybe the seconds) to determine which time is greater.

Figure 19.11 sorts a list using the custom Comparator class `TimeComparator`. Line 11 creates an `ArrayList` of `Time2` objects. Recall that both `ArrayList` and `List` are generic types and accept a type argument that specifies the element type of the collection. Lines 13–17 create five `Time2` objects and add them to this list. Line 23 calls method `sort`, passing it an object of our `TimeComparator` class (Fig. 19.10).

2 // Custom Comparator class that compares two Time2 objects.
3 import java.util.Comparator;
4
5 public class TimeComparator implements Comparator< Time2 >
6 {
7     public int compare( Time2 time1, Time2 time2 )
8     {
9         int hourCompare = time1.getHour() - time2.getHour(); // compare hour
10
11        // test the hour first
12        if ( hourCompare != 0 )
13            return hourCompare;
14
15        int minuteCompare =
16            time1.getMinute() - time2.getMinute(); // compare minute
17
18        // then test the minute
19        if ( minuteCompare != 0 )
20            return minuteCompare;
21
22        int secondCompare =
23            time1.getSecond() - time2.getSecond(); // compare second
24
25        return secondCompare; // return result of comparing seconds
26    } // end method compare
27 } // end class TimeComparator

```

[6:05:34 AM, 6:24:22 AM, 6:24:34 AM, 12:14:58 PM, 6:14:58 PM]

```

Fig. 19.11 | Collections method `sort` with a custom Comparator object. (Part 2 of 2.)

19.6.2 Algorithm shuffle

Algorithm `shuffle` randomly orders a `List`'s elements. In Chapter 7, we presented a card shuffling and dealing simulation that used a loop to shuffle a deck of cards. In Fig. 19.12, we use algorithm `shuffle` to shuffle a deck of `Card` objects that might be used in a card game simulator.

Class `Card` (lines 8–41) represents a card in a deck of cards. Each `Card` has a face and a suit. Lines 10–12 declare two `enum` types—`Face` and `Suit`—which represent the face and the suit of the card, respectively. Method `toString` (lines 37–40) returns a `String` containing the face and suit of the `Card` separated by the string " of ". When an `enum` constant is converted to a string, the constant's identifier is used as the string representation. Normally we would use all uppercase letters for `enum` constants. In this example, we chose to use capital letters for only the first letter of each `enum` constant because we want the card to be displayed with initial capital letters for the face and the suit (e.g., "Ace of Spades").

```

918 Chapter 19 Collections

```

14     private final Face face; // face of card
15     private final Suit suit; // suit of card
16
17     // two-argument constructor
18     public Card( Face cardFace, Suit cardSuit )
19     {
20         face = cardFace; // initialize face of card
21         suit = cardSuit; // initialize suit of card
22     } // end two-argument Card constructor
23
24     // return face of the card
25     public Face getFace()
26     {
27         return face;
28     } // end method getFace
29
30     // return suit of Card
31     public Suit getSuit()
32     {
33         return suit;
34     } // end method getSuit
35
36     // return String representation of Card
37     public String toString()
38     {
39         return String.format( "%s of %s", face, suit );
40     } // end method toString
41 } // end class Card
42
43 // class DeckOfCards declaration
44 public class DeckOfCards
45 {
46     private List< Card > list; // declare List that will store Cards
47
48     // set up deck of Cards and shuffle
49     public DeckOfCards()
50     {
51         Card[] deck = new Card[ 52 ];
52         int count = 0; // number of cards
53
54         // populate deck with Card objects
55         for ( Card.Suit suit : Card.Suit.values() )
56         {
57             for ( Card.Face face : Card.Face.values() )
58             {
59                 deck[ count ] = new Card( face, suit );
60                 count++;
61             } // end for
62         } // end for
63
64         list = Arrays.asList( deck ); // get List
65         Collections.shuffle( list ); // shuffle deck
66     } // end DeckOfCards constructor

```

Eight of Spades	Five of Spades
Jack of Hearts	Deuce of Diamonds

Fig. 19.12 | Card shuffling and dealing with Collections method shuffle. (Part 3 of 3.)

Lines 55–62 populate the deck array with cards that have unique face and suit combinations. Both Face and Suit are `public static enum` types of class `Card`. To use these enum types outside of class `Card`, you must qualify each enum's type name with the name of the class in which it resides (i.e., `Card`) and a dot (.) separator. Hence, lines 55 and 57 use `Card.Suit` and `Card.Face` to declare the control variables of the `for` statements. Recall that method `values` of an enum type returns an array that contains all the constants of the enum type. Lines 55–62 use enhanced `for` statements to construct 52 new `Cards`.

920 Chapter 19 Collections

The shuffling occurs in line 65, which calls static method `shuffle` of class `Collections` to shuffle the elements of the array. Method `shuffle` requires a `List` argument, so we must obtain a `List` view of the array before we can shuffle it. Line 64 invokes static method `asList` of class `Arrays` to get a `List` view of the `deck` array.

Method `printCards` (lines 69–75) displays the deck of cards in two columns. In each iteration of the loop, lines 73–74 output a card left justified in a 20-character field followed by either a newline or an empty string based on the number of cards output so far. If the number of cards is even, a newline is output; otherwise, a tab is output.

19.6.3 Algorithms `reverse`, `fill`, `copy`, `max` and `min`

Class `Collections` provides algorithms for reversing, filling and copying `Lists`. Algorithm `reverse` reverses the order of the elements in a `List`, and algorithm `fill` overwrites elements in a `List` with a specified value. The `fill` operation is useful for reinitializing a `List`. Algorithm `copy` takes two arguments—a destination `List` and a source `List`. Each source `List` element is copied to the destination `List`. The destination `List` must be at least as long as the source `List`; otherwise, an `IndexOutOfBoundsException` occurs. If the destination `List` is longer, the elements not overwritten are unchanged.

Each algorithm we have seen so far operates on `Lists`. Algorithms `min` and `max` each operate on any `Collection`. Algorithm `min` returns the smallest element in a `Collection`, and algorithm `max` returns the largest element in a `Collection`. Both of these algorithms can be called with a `Comparator` object as a second argument to perform custom comparisons of objects, such as the `TimeComparator` in Fig. 19.11. Figure 19.13 demonstrates the use of algorithms `reverse`, `fill`, `copy`, `min` and `max`. Note that the generic type `List` is declared to store `Characters`.

```

1 // Fig. 19.13: Algorithms1.java
2 // Using algorithms reverse, fill, copy, min and max.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.Collections;
6
7 public class Algorithms1
8 {
9     private Character[] letters = { 'P', 'C', 'M' };
10    private Character[] lettersCopy;
11    private List< Character > list;
12    private List< Character > copyList;
13
14    // create a List and manipulate it with methods from Collections
15    public Algorithms1()
16    {
17        list = Arrays.asList( letters ); // get List
18        lettersCopy = new Character[ 3 ];
19        copyList = Arrays.asList( lettersCopy ); // List view of lettersCopy
20
21        System.out.println( "Initial list: " );
22        output( list );

```

Fig. 19.13 | Collections methods `reverse`, `fill`, `copy`, `max` and `min`. (Part I of 2.)

19.6 Collections Algorithms **921**

```

23     Collections.reverse( list ); // reverse order
24     System.out.println( "\nAfter calling reverse: " );
25     output( list );
26
27     Collections.copy( copyList, list ); // copy List
28     System.out.println( "\nAfter copying: " );
29     output( copyList );
30
31     Collections.fill( list, 'R' ); // fill list with Rs
32     System.out.println( "\nAfter calling fill: " );
33     output( list );
34 } // end Algorithms1 constructor
35
36 // output List information
37 private void output( List< Character > listRef )
38 {
39     System.out.print( "The list is: " );
40
41     for ( Character element : listRef )
42         System.out.printf( "%s ", element );
43
44     System.out.printf( "\nMax: %s", Collections.max( listRef ) );
45     System.out.printf( " Min: %s\n", Collections.min( listRef ) );
46 } // end method output
47
48 public static void main( String args[] )
49 {
50     new Algorithms1();
51 } // end main
52 } // end class Algorithms1

```

Initial list:
 The list is: P C M
 Max: P Min: C

After calling reverse:
 The list is: M C P
 Max: P Min: C

After copying:
 The list is: M C P
 Max: P Min: C

After calling fill:
 The list is: R R R
 Max: R Min: R

Fig. 19.13 | Collections methods reverse, fill, copy, max and min. (Part 2 of 2.)

Line 24 calls `Collections` method `reverse` to reverse the order of `list`. Method `reverse` takes one `List` argument. In this case, `list` is a `List` view of array `letters`. Array `letters` now has its elements in reverse order. Line 28 copies the elements of `list` into `copyList`, using `Collections` method `copy`. Changes to `copyList` do not change `let-`

922 Chapter 19 Collections

ters, because `copyList` is a separate `List` that is not a `List` view for `letters`. Method `copy` requires two `List` arguments. Line 32 calls `Collections` method `fill` to place the string "R" in each element of `list`. Because `list` is a `List` view of `letters`, this operation changes each element in `letters` to "R". Method `fill` requires a `List` for the first argument and an `Object` for the second argument. Lines 45–46 call `Collections` methods `max` and `min` to find the largest and the smallest element of the collection, respectively. Recall that a `List` is a `Collection`, so lines 45–46 can pass a `List` to methods `max` and `min`.

19.6.4 Algorithm `binarySearch`

In Section 16.2.2, we studied the high-speed binary search algorithm. This algorithm is built into the Java collections framework as a `static` method of class `Collections`. The `binarySearch` algorithm locates an object in a `List` (i.e., a `LinkedList`, a `Vector` or an `ArrayList`). If the object is found, its index is returned. If the object is not found, `binarySearch` returns a negative value. Algorithm `binarySearch` determines this negative value by first calculating the insertion point and making its sign negative. Then, `binarySearch` subtracts 1 from the insertion point to obtain the return value, which guarantees that method `binarySearch` returns positive numbers (≥ 0) if and only if the object is found. If multiple elements in the list match the search key, there is no guarantee which one will be located first. Figure 19.14 uses the `binarySearch` algorithm to search for a series of strings in an `ArrayList`.

```

1 // Fig. 19.14: BinarySearchTest.java
2 // Using algorithm binarySearch.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.Collections;
6 import java.util.ArrayList;
7
8 public class BinarySearchTest
9 {
10     private static final String colors[] = { "red", "white",
11         "blue", "black", "yellow", "purple", "tan", "pink" };
12     private List< String > list; // ArrayList reference
13
14     // create, sort and output list
15     public BinarySearchTest()
16     {
17         list = new ArrayList< String >( Arrays.asList( colors ) );
18         Collections.sort( list ); // sort the ArrayList
19         System.out.printf( "Sorted ArrayList: %s\n", list );
20     } // end BinarySearchTest constructor
21
22     // search list for various values
23     private void search()
24     {
25         printSearchResults( colors[ 3 ] ); // first item
26         printSearchResults( colors[ 0 ] ); // middle item
27         printSearchResults( colors[ 7 ] ); // last item

```

19.6 Collections Algorithms **923**

```

28     printSearchResults( "aqua" ); // below lowest
29     printSearchResults( "gray" ); // does not exist
30     printSearchResults( "teal" ); // does not exist
31 } // end method search
32
33 // perform searches and display search result
34 private void printSearchResults( String key )
35 {
36     int result = 0;
37
38     System.out.printf( "\nSearching for: %s\n", key );
39     result = Collections.binarySearch( list, key );
40
41     if ( result >= 0 )
42         System.out.printf( "Found at index %d\n", result );
43     else
44         System.out.printf( "Not Found (%d)\n", result );
45 } // end method printSearchResults
46
47 public static void main( String args[] )
48 {
49     BinarySearchTest binarySearchTest = new BinarySearchTest();
50     binarySearchTest.search();
51 } // end main
52 } // end class BinarySearchTest

```

```

Sorted ArrayList: [black, blue, pink, purple, red, tan, white, yellow]

Searching for: black
Found at index 0

Searching for: red
Found at index 4

Searching for: pink
Found at index 2

Searching for: aqua
Not Found (-1)

Searching for: gray
Not Found (-3)

Searching for: teal
Not Found (-7)

```

Fig. 19.14 | Collections method `binarySearch`. (Part 2 of 2.)

Recall that both `List` and `ArrayList` are generic types (lines 12 and 17). `Collections` method `binarySearch` expects the list's elements to be sorted in ascending order, so line 18 in the constructor sorts the list with `Collections` method `sort`. If the list's elements are not sorted, the result is undefined. Line 19 outputs the sorted list. Method `search` (lines 23–31) is called from `main` to perform the searches. Each search calls method `printSearchResults` (lines 34–45) to perform the search and output the results. Line 39 calls

924 Chapter 19 Collections

Collections method `binarySearch` to search `list` for the specified key. Method `binarySearch` takes a `List` as the first argument and an `Object` as the second argument. Lines 41–44 output the results of the search. An overloaded version of `binarySearch` takes a `Comparator` object as its third argument, which specifies how `binarySearch` should compare elements.

19.6.5 Algorithms `addAll`, `frequency` and `disjoint`

Class `Collections` also provides the algorithms `addAll`, `frequency` and `disjoint`. Algorithm `addAll` takes two arguments—a `Collection` into which to insert the new element(s) and an array that provides elements to be inserted. Algorithm `frequency` takes two arguments—a `Collection` to be searched and an `Object` to be searched for in the collection. Method `frequency` returns the number of times that the second argument appears in the collection. Algorithm `disjoint` takes two `Collections` and returns `true` if they have no elements in common. Figure 19.15 demonstrates the use of algorithms `addAll`, `frequency` and `disjoint`.

```

1 // Fig. 19.15: Algorithms2.java
2 // Using algorithms addAll, frequency and disjoint.
3 import java.util.List;
4 import java.util.Vector;
5 import java.util.Arrays;
6 import java.util.Collections;
7
8 public class Algorithms2
9 {
10     private String[] colors = { "red", "white", "yellow", "blue" };
11     private List< String > list;
12     private Vector< String > vector = new Vector< String >();
13
14     // create List and Vector
15     // and manipulate them with methods from Collections
16     public Algorithms2()
17     {
18         // initialize list and vector
19         list = Arrays.asList( colors );
20         vector.add( "black" );
21         vector.add( "red" );
22         vector.add( "green" );
23
24         System.out.println( "Before addAll, vector contains: " );
25
26         // display elements in vector
27         for ( String s : vector )
28             System.out.printf( "%s ", s );
29
30         // add elements in colors to list
31         Collections.addAll( vector, colors );
32
33         System.out.println( "\n\nAfter addAll, vector contains: " );

```

Fig. 19.15 | Collections method `addAll`, `frequency` and `disjoint`. (Part I of 2.)

19.7 Stack Class of Package `java.util` **925**

```

34     // display elements in vector
35     for ( String s : vector )
36         System.out.printf( "%s ", s );
37
38     // get frequency of "red"
39     int frequency = Collections.frequency( vector, "red" );
40     System.out.printf(
41         "\n\nFrequency of red in vector: %d\n", frequency );
42
43     // check whether list and vector have elements in common
44     boolean disjoint = Collections.disjoint( list, vector );
45
46     System.out.printf( "\nlist and vector %s elements in common\n",
47         ( disjoint ? "do not have" : "have" ) );
48 } // end Algorithms2 constructor
49
50 public static void main( String args[] )
51 {
52     new Algorithms2();
53 } // end main
54 } // end class Algorithms2

```

Before addAll, vector contains:
black red green

After addAll, vector contains:
black red green red white yellow blue

Frequency of red in vector: 2

list and vector have elements in common

Fig. 19.15 | Collections method addAll, frequency and disjoint. (Part 2 of 2.)

Line 19 initializes `list` with elements in array `colors`, and lines 20–22 add Strings "black", "red" and "green" to `vector`. Line 31 invokes method `addAll` to add elements in array `colors` to `vector`. Line 40 gets the frequency of String "red" in Collection `vector` using method `frequency`. Note that lines 41–42 use the new `printf` method to print the frequency. Line 45 invokes method `disjoint` to test whether Collections `list` and `vector` have elements in common.

19.7 Stack Class of Package `java.util`

In Chapter 17, Data Structures, we learned how to build fundamental data structures, including linked lists, stacks, queues and trees. In a world of software reuse, rather than building data structures as we need them, we can often take advantage of existing data structures. In this section, we investigate class `Stack` in the Java utilities package (`java.util`).

Section 19.5.3 discussed class `Vector`, which implements a dynamically resizable array. Class `Stack` extends class `Vector` to implement a stack data structure. Autoboxing

926 Chapter 19 Collections

occurs when you add a primitive type to a Stack, because class Stack stores only references to objects. Figure 19.16 demonstrates several Stack methods. For the details of class Stack, visit java.sun.com/javase/6/docs/api/java/util/Stack.html.

```

1 // Fig. 19.16: StackTest.java
2 // Program to test java.util.Stack.
3 import java.util.Stack;
4 import java.util.EmptyStackException;
5
6 public class StackTest
7 {
8     public StackTest()
9     {
10         Stack< Number > stack = new Stack< Number >();
11
12         // create numbers to store in the stack
13         Long longNumber = 12L;
14         Integer intNumber = 34567;
15         Float floatNumber = 1.0F;
16         Double doubleNumber = 1234.5678;
17
18         // use push method
19         stack.push( longNumber ); // push a long
20         printStack( stack );
21         stack.push( intNumber ); // push an int
22         printStack( stack );
23         stack.push( floatNumber ); // push a float
24         printStack( stack );
25         stack.push( doubleNumber ); // push a double
26         printStack( stack );
27
28         // remove items from stack
29         try
30         {
31             Number removedObject = null;
32
33             // pop elements from stack
34             while ( true )
35             {
36                 removedObject = stack.pop(); // use pop method
37                 System.out.printf( "%s popped\n", removedObject );
38                 printStack( stack );
39             } // end while
40         } // end try
41         catch ( EmptyStackException emptyStackException )
42         {
43             emptyStackException.printStackTrace();
44         } // end catch
45     } // end StackTest constructor
46
47     private void printStack( Stack< Number > stack )

```

Fig. 19.16 | Stack class of package `java.util`. (Part 2 of 2.)

Line 10 of the constructor creates an empty Stack of type Number. Class Number (in package `java.lang`) is the superclass of most wrapper classes (e.g., `Integer`, `Double`) for the primitive types. By creating a Stack of Number, objects of any class that extends the Number class can be pushed onto the stack. Lines 19, 21, 23 and 25 each call Stack method `push` to add objects to the top of the stack. Note the literals `12L` (line 13) and `1.0F` (line 15). Any integer literal that has the `suffix L` is a long value. An integer literal without a

928 Chapter 19 Collections

suffix is an `int` value. Similarly, any floating-point literal that has the `suffix F` is a `float` value. A floating-point literal without a suffix is a `double` value. You can learn more about numeric literals in the *Java Language Specification* at java.sun.com/docs/books/jls/second_edition/html/expressions.doc.html#224125.

An infinite loop (lines 34–39) calls `Stack` method `pop` to remove the top element of the stack. The method returns a `Number` reference to the removed element. If there are no elements in the `Stack`, method `pop` throws an `EmptyStackException`, which terminates the loop. Class `Stack` also declares method `peek`. This method returns the top element of the stack without popping the element off the stack.

Line 49 calls `Stack` method `isEmpty` (inherited by `Stack` from class `Vector`) to determine whether the stack is empty. If it is empty, the method returns `true`; otherwise, the method returns `false`.

Method `printStack` (lines 47–61) uses the enhanced `for` statement to iterate through the elements in the stack. The current top of the stack (the last value pushed onto the stack) is the first value printed. Because class `Stack` extends class `Vector`, the entire public interface of class `Vector` is available to clients of class `Stack`.

Error-Prevention Tip 19.1

Because `Stack` extends `Vector`, all public `Vector` methods can be called on `Stack` objects, even if the methods do not represent conventional stack operations. For example, `Vector` method `add` can be used to insert an element anywhere in a stack—an operation that could “corrupt” the stack. When manipulating a `Stack`, only methods `push` and `pop` should be used to add elements to and remove elements from the `Stack`, respectively.

19.8 Class PriorityQueue and Interface Queue

In Section 17.8, we introduced the queue data structure and created our own implementation of it. In this section we investigate interface `Queue` and class `PriorityQueue` in the Java utilities package (`java.util`). `Queue`, a new collection interface introduced in Java SE 5, extends interface `Collection` and provides additional operations for inserting, removing and inspecting elements in a queue. `PriorityQueue`, one of the classes that implements the `Queue` interface, orders elements by their natural ordering as specified by `Comparable` elements' `compareTo` method or by a `Comparator` object that is supplied through the constructor.

Class `PriorityQueue` provides functionality that enables insertions in sorted order into the underlying data structure and deletions from the front of the underlying data structure. When adding elements to a `PriorityQueue`, the elements are inserted in priority order such that the highest-priority element (i.e., the largest value) will be the first element removed from the `PriorityQueue`.

The common `PriorityQueue` operations are `offer` to insert an element at the appropriate location based on priority order, `poll` to remove the highest-priority element of the priority queue (i.e., the head of the queue), `peek` to get a reference to the highest-priority element of the priority queue (without removing that element), `clear` to remove all elements in the priority queue and `size` to get the number of elements in the priority queue. Figure 19.17 demonstrates the `PriorityQueue` class.

Line 10 creates a `PriorityQueue` that stores `Doubles` with an initial capacity of 11 elements and orders the elements according to the object's natural ordering (the defaults for

```

1 // Fig. 19.17: PriorityQueueTest.java
2 // Standard library class PriorityQueue test program.
3 import java.util.PriorityQueue;
4
5 public class PriorityQueueTest
6 {
7     public static void main( String args[] )
8     {
9         // queue of capacity 11
10        PriorityQueue< Double > queue = new PriorityQueue< Double >();
11
12        // insert elements to queue
13        queue.offer( 3.2 );
14        queue.offer( 9.8 );
15        queue.offer( 5.4 );
16
17        System.out.print( "Polling from queue: " );
18
19        // display elements in queue
20        while ( queue.size() > 0 )
21        {
22            System.out.printf( "%1f ", queue.peek() ); // view top element
23            queue.poll(); // remove top element
24        } // end while
25    } // end main
26 } // end class PriorityQueueTest

```

Polling from queue: 3.2 5.4 9.8

Fig. 19.17 | PriorityQueue test program.

a PriorityQueue). Note that PriorityQueue is a generic class and that line 10 instantiates a PriorityQueue with a type argument Double. Class PriorityQueue provides five additional constructors. One of these takes an int and a Comparator object to create a PriorityQueue with the initial capacity specified by the int and the ordering by the Comparator. Lines 13–15 use method offer to add elements to the priority queue. Method offer throws a NullPointerException if the program attempts to add a null object to the queue. The loop in lines 20–24 uses method size to determine whether the priority queue is empty (line 20). While there are more elements, line 22 uses PriorityQueue method peek to retrieve the highest-priority element in the queue for output (without actually removing the element from the queue). Line 23 removes the highest-priority element in the queue with method poll.

19.9 Sets

A **Set** is a Collection that contains unique elements (i.e., no duplicate elements). The collections framework contains several Set implementations, including **HashSet** and **TreeSet**. HashSet stores its elements in a hash table, and TreeSet stores its elements in a tree. The concept of hash tables is presented in Section 19.10. Figure 19.18 uses a HashSet to remove duplicate strings from a List. Recall that both List and Collection are generic

930 Chapter 19 Collections

```

1 // Fig. 19.18: SetTest.java
2 // Using a HashSet to remove duplicates.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.HashSet;
6 import java.util.Set;
7 import java.util.Collection;
8
9 public class SetTest
10 {
11     private static final String colors[] = { "red", "white", "blue",
12         "green", "gray", "orange", "tan", "white", "cyan",
13         "peach", "gray", "orange" };
14
15     // create and output ArrayList
16     public SetTest()
17     {
18         List< String > list = Arrays.asList( colors );
19         System.out.printf( "ArrayList: %s\n", list );
20         printNonDuplicates( list );
21     } // end SetTest constructor
22
23     // create set from array to eliminate duplicates
24     private void printNonDuplicates( Collection< String > collection )
25     {
26         // create a HashSet
27         Set< String > set = new HashSet< String >( collection );
28
29         System.out.println( "\nNonduplicates are: " );
30
31         for ( String s : set )
32             System.out.printf( "%s ", s );
33
34         System.out.println();
35     } // end method printNonDuplicates
36
37     public static void main( String args[] )
38     {
39         new SetTest();
40     } // end main
41 } // end class SetTest

```

ArrayList: [red, white, blue, green, gray, orange, tan, white, cyan, peach, gray, orange]

Nonduplicates are:
red cyan white tan gray green orange blue peach

Fig. 19.18 | HashSet used to remove duplicate values from array of strings.

types, so line 18 creates a List that contains String objects, and line 24 passes a Collection of Strings to method printNonDuplicates.

Method `printNonDuplicates` (lines 24–35), which is called from the constructor, takes a `Collection` argument. Line 27 constructs a `HashSet` from the `Collection` argument. Note that both `Set` and `HashSet` are generic types. By definition, `Sets` do not contain any duplicates, so when the `HashSet` is constructed, it removes any duplicates in the `Collection`. Lines 31–32 output elements in the `Set`.

Sorted Sets

The collections framework also includes interface `SortedSet` (which extends `Set`) for sets that maintain their elements in sorted order—either the elements' natural order (e.g., numbers are in ascending order) or an order specified by a `Comparator`. Class `TreeSet` implements `SortedSet`. The program in Fig. 19.19 places strings into a `TreeSet`. The strings are sorted as they are added to the `TreeSet`. This example also demonstrates [range-view methods](#), which enable a program to view a portion of a collection.

Lines 16–17 of the constructor create a `TreeSet` of `Strings` that contains the elements of array `names` and assigns the `SortedSet` to variable `tree`. Both `SortedSet` and `TreeSet`

```

1 // Fig. 19.19: SortedSetTest.java
2 // Using TreeSet and SortedSet.
3 import java.util.Arrays;
4 import java.util.SortedSet;
5 import java.util.TreeSet;
6
7 public class SortedSetTest
8 {
9     private static final String names[] = { "yellow", "green",
10         "black", "tan", "grey", "white", "orange", "red", "green" };
11
12     // create a sorted set with TreeSet, then manipulate it
13     public SortedSetTest()
14     {
15         // create TreeSet
16         SortedSet< String > tree =
17             new TreeSet< String >( Arrays.asList( names ) );
18
19         System.out.println( "sorted set: " );
20         printSet( tree ); // output contents of tree
21
22         // get headSet based on "orange"
23         System.out.print( "\nheadSet (\"orange\"): " );
24         printSet( tree.headSet( "orange" ) );
25
26         // get tailSet based upon "orange"
27         System.out.print( "tailSet (\"orange\"): " );
28         printSet( tree.tailSet( "orange" ) );
29
30         // get first and last elements
31         System.out.printf( "first: %s\n", tree.first() );
32         System.out.printf( "last : %s\n", tree.last() );
33     } // end SortedSetTest constructor
34

```

Fig. 19.19 | Using `SortedSets` and `TreeSets`. (Part I of 2.)

932 Chapter 19 Collections

```

35  // output set
36  private void printSet( SortedSet< String > set )
37  {
38      for ( String s : set )
39          System.out.printf( "%s ", s );
40

last : yellow

```

Fig. 19.19 | Using SortedSets and TreeSetes. (Part 2 of 2.)

are generic types. Line 20 outputs the initial set of strings using method `printSet` (lines 36–42), which we discuss momentarily. Line 24 calls `TreeSet` method `headSet` to get a subset of the `TreeSet` in which every element is less than "orange". The view returned from `headSet` is then output with `printSet`. If any changes are made to the subset, they will also be made to the original `TreeSet`, because the subset returned by `headSet` is a view of the `TreeSet`.

Line 28 calls `TreeSet` method `tailSet` to get a subset in which each element is greater than or equal to "orange", then outputs the result. Any changes made through the `tailSet` view are made to the original `TreeSet`. Lines 31–32 call `SortedSet` methods `first` and `last` to get the smallest and largest elements of the set, respectively.

Method `printSet` (lines 36–42) accepts a `SortedSet` as an argument and prints it. Lines 38–39 print each element of the `SortedSet` using the enhanced `for` statement.

19.10 Maps

Maps associate keys to values and cannot contain duplicate keys (i.e., each key can map to only one value; this is called [one-to-one mapping](#)). Maps differ from Sets in that Maps contain keys and values, whereas Sets contain only values. Three of the several classes that implement interface `Map` are `Hashtable`, `HashMap` and `TreeMap`. `Hashtables` and `HashMaps` store elements in hash tables, and `TreeMaps` store elements in trees. This section discusses hash tables and provides an example that uses a `HashMap` to store key/value pairs. Interface `SortedMap` extends `Map` and maintains its keys in sorted order—either the elements' natural order or an order specified by a `Comparator`. Class `TreeMap` implements `SortedMap`.

Map Implementation with Hash Tables

Object-oriented programming languages facilitate creating new types. When a program creates objects of new or existing types, it may need to store and retrieve them efficiently. Storing and retrieving information with arrays is efficient if some aspect of your data directly matches a numerical key value and if the keys are unique and tightly packed. If you have 100 employees with nine-digit social security numbers and you want to store and retrieve employee data by using the social security number as a key, the task would require an array with one billion elements, because there are one billion unique nine-digit numbers (000,000,000–999,999,999). This is impractical for virtually all applications that use social security numbers as keys. A program that had an array that large could achieve high performance for both storing and retrieving employee records by simply using the social security number as the array index.

Numerous applications have this problem—namely, that either the keys are of the wrong type (e.g., not positive integers that correspond to array subscripts) or they are of the right type, but sparsely spread over a huge range. What is needed is a high-speed scheme for converting keys such as social security numbers, inventory part numbers and the like into unique array indices. Then, when an application needs to store something, the scheme could convert the application’s key rapidly into an index, and the record could be stored at that slot in the array. Retrieval is accomplished the same way: Once the application has a key for which it wants to retrieve a data record, the application simply applies the conversion to the key—this produces the array index where the data is stored and retrieved.

The scheme we describe here is the basis of a technique called **hashing**. Why the name? When we convert a key into an array index, we literally scramble the bits, forming a kind of “mishmashed,” or hashed, number. The number actually has no real significance beyond its usefulness in storing and retrieving a particular data record.

A glitch in the scheme is called a **collision**—this occurs when two different keys “hash into” the same cell (or element) in the array. We cannot store two values in the same space, so we need to find an alternative home for all values beyond the first that hash to a particular array index. There are many schemes for doing this. One is to “hash again” (i.e., to apply another hashing transformation to the key to provide a next candidate cell in the array). The hashing process is designed to distribute the values throughout the table, so the assumption is that an available cell will be found with just a few hashes.

Another scheme uses one hash to locate the first candidate cell. If that cell is occupied, successive cells are searched in order until an available cell is found. Retrieval works the same way: The key is hashed once to determine the initial location and check whether it contains the desired data. If it does, the search is finished. If it does not, successive cells are searched linearly until the desired data is found.

The most popular solution to hash-table collisions is to have each cell of the table be a hash “bucket,” typically a linked list of all the key/value pairs that hash to that cell. This is the solution that Java’s `Hashtable` and `HashMap` classes (from package `java.util`) implement. Both `Hashtable` and `HashMap` implement the `Map` interface. The primary differences between them are that `HashMap` is unsynchronized (multiple threads should not modify a `HashMap` concurrently), and allows `null` keys and `null` values.

A hash table’s **load factor** affects the performance of hashing schemes. The load factor is the ratio of the number of occupied cells in the hash table to the total number of cells in the hash table. The closer this ratio gets to 1.0, the greater the chance of collisions.

934 Chapter 19 Collections

**Performance Tip 19.7**

The load factor in a hash table is a classic example of a memory-space/execution-time trade-off: By increasing the load factor, we get better memory utilization, but the program runs slower, due to increased hashing collisions. By decreasing the load factor, we get better program speed, because of reduced hashing collisions, but we get poorer memory utilization, because a larger portion of the hash table remains empty.

Hash tables are complex to program. Computer science students study hashing schemes in courses called “Data Structures” and “Algorithms.” Java provides classes `HashTable` and `HashMap` to enable programmers to use hashing without having to implement hash table mechanisms. This concept is profoundly important in our study of object-oriented programming. As discussed in earlier chapters, classes encapsulate and hide complexity (i.e., implementation details) and offer user-friendly interfaces. Properly crafting classes to exhibit such behavior is one of the most valued skills in the field of object-oriented programming. Figure 19.20 uses a `HashMap` to count the number of occurrences of each word in a string.

Line 17 creates an empty `HashMap` with a default initial capacity (16 elements) and a default load factor (0.75)—these defaults are built into the implementation of `HashMap`. When the number of occupied slots in the `HashMap` becomes greater than the capacity times the load factor, the capacity is doubled automatically. Note that `HashMap` is a generic class that takes two type arguments. The first specifies the type of key (i.e., `String`), and the second the type of value (i.e., `Integer`). Recall that the type arguments passed to a generic class must be reference types, hence the second type argument is `Integer`, not `int`. Line 18 creates a `Scanner` that reads user input from the standard input stream. Line 19 calls method `createMap` (lines 24–46), which uses a `map` to store the number of occurrences of each word in the sentence. Line 27 invokes method `nextLine` of `scanner` to obtain the user input, and line 30 creates a `StringTokenizer` to break the input string into

```

isEmpty:false

```

Fig. 19.20 | HashMaps and Maps. (Part 3 of 3.)

its component individual words. This `StringTokenizer` constructor takes a string argument and creates a `StringTokenizer` for that string and will use the white space to separate the string. The condition in the `while` statement in lines 33–45 uses `StringTokenizer` method `hasMoreTokens` to determine whether there are more tokens in the string being tokenized. If so, line 35 converts the next token to lowercase letters. The next token is obtained with a call to `StringTokenizer` method `nextToken` that returns a `String`. [Note: Section 30.6 discusses class `StringTokenizer` in detail.] Then line 38 calls `Map` method `containsKey` to determine whether the word is in the map (and thus has occurred previously in the string). If the `Map` does not contain a mapping for the word, line 44 uses `Map` method `put` to create a new entry in the map, with the word as the key and an `Integer` object containing 1 as the value. Note that autoboxing occurs when the program passes integer 1 to method `put`, because the map stores the number of occurrences of the word as `Integer`. If the word does exist in the map, line 40 uses `Map` method `get` to obtain the key's associated value (the count) in the map. Line 41 increments that value and uses `put` to replace the key's associated value in the map. Method `put` returns the prior value associated with the key, or `null` if the key was not in the map.

Method `displayMap` (lines 49–64) displays all the entries in the map. It uses `HashMap` method `keySet` (line 51) to get a set of the keys. The keys have type `String` in the `map`, so method `keySet` returns a generic type `Set` with type parameter specified to be `String`. Line 54 creates a `TreeSet` of the keys, in which the keys are sorted. The loop in lines 59–60 accesses each key and its value in the map. Line 60 displays each key and its value using format specifier `%-10s` to left justify each key and format specifier `%10s` to right justify each value. Note that the keys are displayed in ascending order. Line 63 calls `Map` method `size` to get the number of key–value pairs in the `Map`. Line 64 calls `isEmpty`, which returns a `boolean` indicating whether the `Map` is empty.

19.11 Properties Class **937**

19.11 Properties Class

A **Properties** object is a persistent Hashtable that normally stores key–value pairs of strings—assuming that you use methods **setProperty** and **getProperty** to manipulate the table rather than inherited Hashtable methods **put** and **get**. By “persistent,” we mean that the Properties object can be written to an output stream (possibly a file) and read back in through an input stream. A common use of Properties objects in prior versions of Java was to maintain application-configuration data or user preferences for applications. [Note: The **Preferences API** (package **java.util.prefs**) is meant to replace this particular use of class **Properties** but is beyond the scope of this book. To learn more, visit java.sun.com/javase/6/docs/technotes/guides/preferences/index.html.]

Class **Properties** extends class **Hashtable**. Figure 19.21 demonstrates several methods of class **Properties**.

Line 16 uses the no-argument constructor to create an empty **Properties** table with no default properties. Class **Properties** also provides an overloaded constructor that receives a reference to a **Properties** object containing default property values. Lines 19 and 20 each call **Properties** method **setProperty** to store a value for the specified key. If the key does not exist in the table, **setProperty** returns **null**; otherwise, it returns the previous value for that key.

Line 41 calls **Properties** method **getProperty** to locate the value associated with the specified key. If the key is not found in this **Properties** object, **getProperty** returns **null**. An overloaded version of this method receives a second argument that specifies the default value to return if **getProperty** cannot locate the key.

Line 57 calls **Properties** method **store** to save the contents of the **Properties** object to the **OutputStream** object specified as the first argument (in this case, **FileOutputStream**)

```

940 Chapter 19 Collections

`output`). The second argument, a `String`, is a description of the `Properties` object. Class `Properties` also provides method `list`, which takes a `PrintStream` argument. This method is useful for displaying the list of properties.

Line 75 calls `Properties` method `load` to restore the contents of the `Properties` object from the `InputStream` specified as the first argument (in this case, a `FileInputStream`). Line 89 calls `Properties` method `keySet` to obtain a `Set` of the property names. Line 94 obtains the value of a property by passing a key to method `getProperty`.

19.12 Synchronized Collections

In Chapter 23, we discuss multithreading. Except for `Vector` and `Hashtable`, the collections in the collections framework are unsynchronized by default, so they can operate efficiently when multithreading is not required. Because they are unsynchronized, however, concurrent access to a `Collection` by multiple threads could cause indeterminate results or fatal errors. To prevent potential threading problems, synchronization wrappers are used for collections that might be accessed by multiple threads. A `wrapper` object receives method calls, adds thread synchronization (to prevent concurrent access to the collection) and delegates the calls to the wrapped collection object. The `Collections` API provides a set of static methods for wrapping collections as synchronized versions. Method headers for the synchronization wrappers are listed in Fig. 19.22. Details about these methods are available at java.sun.com/javase/6/docs/api/java/util/Collections.html. All these methods take a generic type and return a synchronized view of the generic type. For example, the following code creates a synchronized `List` (`list2`) that stores `String` objects:

```
List< String > list1 = new ArrayList< String >();
List< String > list2 = Collections.synchronizedList( list1 );
```

public static method headers
<pre>< T > Collection< T > synchronizedCollection(Collection< T > c) < T > List< T > synchronizedList(List< T > aList) < T > Set< T > synchronizedSet(Set< T > s) < T > SortedSet< T > synchronizedSortedSet(SortedSet< T > s) < K, V > Map< K, V > synchronizedMap(Map< K, V > m) < K, V > SortedMap< K, V > synchronizedSortedMap(SortedMap< K, V > m)</pre>

Fig. 19.22 | Synchronization wrapper methods.

19.13 Unmodifiable Collections

The `Collections` API provides a set of static methods that create `unmodifiable wrappers` for collections. Unmodifiable wrappers throw `UnsupportedOperationExceptions` if attempts are made to modify the collection. Headers for these methods are listed in Fig. 19.23. Details about these methods are available at java.sun.com/javase/6/docs/

19.14 Abstract Implementations **941**

```
public static method headers

< T > Collection< T > unmodifiableCollection( Collection< T > c )
< T > List< T > unmodifiableList( List< T > aList )
< T > Set< T > unmodifiableSet( Set< T > s )
< T > SortedSet< T > unmodifiableSortedSet( SortedSet< T > s )
< K, V > Map< K, V > unmodifiableMap( Map< K, V > m )
< K, V > SortedMap< K, V > unmodifiableSortedMap( SortedMap< K, V > m )
```

Fig. 19.23 | Unmodifiable wrapper methods.

[api/java/util/Collections.html](#). All these methods take a generic type and return an unmodifiable view of the generic type. For example, the following code creates an unmodifiable `List` (`list2`) that stores `String` objects:

```
List< String > list1 = new ArrayList< String >();
List< String > list2 = Collections.unmodifiableList( list1 );
```

**Software Engineering Observation 19.5**

You can use an unmodifiable wrapper to create a collection that offers read-only access to others, while allowing read-write access to yourself. You do this simply by giving others a reference to the unmodifiable wrapper while retaining for yourself a reference to the original collection.

19.14 Abstract Implementations

The collections framework provides various abstract implementations of `Collection` interfaces from which the programmer can quickly “flesh out” complete customized implementations. These abstract implementations include a thin `Collection` implementation called an `AbstractCollection`, a thin `List` implementation that allows random access to its elements called an `AbstractList`, a thin `Map` implementation called an `AbstractMap`, a thin `List` implementation that allows sequential access to its elements called an `AbstractSequentialList`, a thin `Set` implementation called an `AbstractSet` and a thin `Queue` implementation called `AbstractQueue`. You can learn more about these classes at [java.sun.com/javase/6/docs/api/java/util/package-summary.html](#).

To write a custom implementation, you can extend the abstract implementation that best meets your needs, and implement each of the class’s `abstract` methods. Then, if your collection is to be modifiable, override any concrete methods that prevent modification.

19.15 Wrap-Up

This chapter introduced the Java collections framework. You learned how to use class `Arrays` to perform array manipulations. You learned the collection hierarchy and how to use the collections framework interfaces to program with collections polymorphically. You also learned several predefined algorithms for manipulating collections. In the next chapter, we introduce Java applets, which are Java programs that typically execute in a web

942 Chapter 19 Collections

browser. We start with sample applets that come with the JDK, then show you how to write and execute your own applets.

Summary

Section 19.1 Introduction

- The Java collections framework gives the programmer access to prepackaged data structures as well as to algorithms for manipulating them.

Section 19.2 Collections Overview

- A collection is an object that can hold references to other objects. The collection interfaces declare the operations that can be performed on each type of collection.
- The classes and interfaces of the collections framework are in package `java.util`.

Section 19.3 Class Arrays

- Class `Arrays` provides static methods for manipulating arrays, including `sort` for sorting an array, `binarySearch` for searching a sorted array, `equals` for comparing arrays and `fill` for placing items in an array.
- `Arrays` method `asList` returns a `List` view of an array, which enables a program to manipulate the array as if it were a `List`. Any modifications made through the `List` view change the array, and any modifications to the array change the `List` view.
- Method `size` gets the number of items in a `List`, and method `get` returns a `List` element.

Section 19.4 Interface Collection and Class Collections

- Interface `Collection` is the root interface in the collection hierarchy from which interfaces `Set` and `List` are derived. Interface `Collection` contains bulk operations for adding, clearing, comparing and retaining objects in a collection. Interface `Collection` provides a method `iterator` for getting an `Iterator`.
- Class `Collections` provides static methods for manipulating collections. Many of the methods are implementations of polymorphic algorithms for searching, sorting and so on.

Section 19.5 Lists

- A `List` is an ordered `Collection` that can contain duplicate elements.
- Interface `List` is implemented by classes `ArrayList`, `LinkedList` and `Vector`. Class `ArrayList` is a resizable-array implementation of a `List`. A `LinkedList` is a linked list implementation of a `List`.
- `Iterator` method `hasNext` determines whether a `Collection` contains another element. Method `next` returns a reference to the next object in the `Collection` and advances the `Iterator`.
- Method `subList` returns a view of a portion of a `List`. Any changes made to this view are also made to the `List`.
- Method `clear` removes elements from a `List`.
- Method `toArray` returns the contents of a collection as an array.
- Class `Vector` manages dynamically resizable arrays. At any time, a `Vector` contains a number of elements that is less than or equal to its capacity. If a `Vector` needs to grow, it grows by its capacity increment. If no capacity increment is specified, Java doubles the size of the `Vector` each time additional capacity is required. The default capacity is 10 elements.

Summary 943

- Vector method `add` adds its argument to the end of the Vector. Method `insertElementAt` inserts an element at the specified position. Method `set` sets the element at a specific position.
- Vector method `remove` removes the first occurrence of its argument from the Vector. Method `removeAllElements` removes every element from the Vector. Method `removeElementAt` removes the element at the specified index.
- Vector method `firstElement` returns a reference to the first element. Method `lastElement` returns a reference to the last element.
- Vector method `contains` determines whether the Vector contains the `searchKey` specified as an argument. Vector method `indexOf` gets the index of the first location of its argument. The method returns `-1` if the argument is not found in the Vector.
- Vector method `isEmpty` determines whether the Vector is empty. Methods `size` and `capacity` determine the number of elements currently in the Vector and the number of elements that can be stored in the Vector without allocating more memory, respectively.

Section 19.6 Collections Algorithms

- Algorithms `sort`, `binarySearch`, `reverse`, `shuffle`, `fill` and `copy` operate on Lists. Algorithms `min` and `max` operate on Collections. Algorithm `reverse` reverses the elements of a List, `fill` sets every List element to a specified Object, and `copy` copies elements from one List into another List. Algorithm `sort` sorts the elements of a List.
- Algorithms `addAll` appends all the elements in an array to a collection, `frequency` calculates how many elements in the collection are equal to the specified element, and `disjoint` determines whether two collections have elements in common.
- Algorithms `min` and `max` find the smallest and largest items in a collection.
- The `Comparator` interface provides a means of sorting a Collection's elements in an order other than their natural order.
- Collections method `reverseOrder` returns a `Comparator` object that can be used with `sort` to sort elements of a collection in reverse order.
- Algorithm `shuffle` randomly orders the elements of a List.
- Algorithm `binarySearch` locates an Object in a sorted List.

Section 19.7 Stack Class of Package `java.util`

- Class `Stack` extends `Vector`. `Stack` method `push` adds its argument to the top of the stack. Method `pop` removes the top element of the stack. Method `peek` returns a reference to the top element without removing it. `Stack` method `empty` determines whether the stack is empty.

Section 19.8 Class `PriorityQueue` and Interface `Queue`

- `Queue`, a new collection interface introduced in Java SE 5, extends interface `Collection` and provides additional operations for inserting, removing and inspecting elements in a queue.
- `PriorityQueue`, one of the `Queue` implementations, orders elements by their natural ordering (i.e., the implementation of the `compareTo` method) or by a `Comparator` object that is supplied through the constructor.
- The common `PriorityQueue` operations are `offer` to insert an element at the appropriate location based on priority order, `poll` to remove the highest-priority element of the priority queue (i.e., the head of the queue), `peek` to get a reference to the highest-priority element of the priority queue, `clear` to remove all elements in the priority queue and `size` to get the number of elements in the priority queue.

944 [Chapter 19](#) [Collections](#)***Section 19.9 Sets***

- A Set is a Collection that contains no duplicate elements. HashSet stores its elements in a hash table. TreeSet stores its elements in a tree.
- Interface SortedSet extends Set and represents a set that maintains its elements in sorted order. Class TreeSet implements SortedSet.
- TreeSet method headSet gets a view of a TreeSet that is less than a specified element. Method tailSet gets a view that is greater than or equal to a specified element. Any changes made to the view are made to the TreeSet.

Section 19.10 Maps

- Maps map keys to values and cannot contain duplicate keys. Maps differ from Sets in that Maps contain both keys and values, whereas Sets contain only values. HashMaps store elements in a hash table, and TreeMap store elements in a tree.
- Hashtables and HashMaps store elements in hash tables, and TreeMap store elements in trees.
- HashMap is a generic class that takes two type arguments. The first type argument specifies the type of key, and the second the type of value.
- HashMap method put adds a key and a value into a HashMap. Method get locates the value associated with the specified key. Method isEmpty determines whether the map is empty.
- HashMap method keySet returns a set of the keys. Map methods size and isEmpty return the number of key-value pairs in the Map and a boolean indicating whether the Map is empty, respectively.
- Interface SortedMap extends Map and represents a map that maintains its keys in sorted order. Class TreeMap implements SortedMap.

Section 19.11 Properties Class

- A Properties object is a persistent Hashtable object. Class Properties extends Hashtable.
- The Properties no-argument constructor creates an empty Properties table with no default properties. There is also an overloaded constructor that is passed a reference to a default Properties object containing default property values.
- Properties method setProperty specifies the value associated with the key argument. Properties method getProperty locates the value of the key specified as an argument. Method store saves the contents of the Properties object to the OutputStream object specified as the first argument. Method load restores the contents of the Properties object from the InputStream object specified as the argument.

Section 19.12 Synchronized Collections

- Collections from the collections framework are unsynchronized. Synchronization wrappers are provided for collections that can be accessed by multiple threads simultaneously.

Section 19.13 Unmodifiable Collections

- The Collections API provides a set of public static methods for converting collections to unmodifiable versions. Unmodifiable wrappers throw UnsupportedOperationExceptions if attempts are made to modify the collection.

Section 19.14 Abstract Implementations

- The collections framework provides various abstract implementations of collection interfaces from which the programmer can quickly flesh out complete customized implementations.

Self-Review Exercises

19.1 Fill in the blanks in each of the following statements:

- A(n) _____ is used to walk through a collection and can remove elements from the collection during the iteration.
- An element in a List can be accessed by using the element's _____.
- Lists are sometimes called _____.
- Java classes _____ and _____ provide the capabilities of array-like data structures that can resize themselves dynamically.
- If you do not specify a capacity increment, the system will _____ the size of the Vector each time additional capacity is needed.
- You can use a(n) _____ to create a collection that offers only read-only access to others while allowing read-write access to yourself.
- _____ can be used to create stacks, queues, trees and dequeues (double-ended queues).
- Algorithm _____ of Collections determines whether two collections have elements in common.

19.2 Determine whether each statement is *true* or *false*. If *false*, explain why.

- Values of primitive types may be stored directly in a Vector.
- A Set can contain duplicate values.
- A Map can contain duplicate keys.
- A LinkedList can contain duplicate values.
- Collections is an interface.
- Iterators can remove elements.
- With hashing, as the load factor increases, the chance of collisions decreases.
- A PriorityQueue permits null elements.

Answers to Self-Review Exercises

19.1 a) Iterator. b) index. c) sequences. d) ArrayList, Vector. e) double. f) unmodifiable wrapper. g) LinkedLists. h) disjoint.

19.2 a) False; a Vector stores only objects. Autoboxing occurs when adding a primitive type to the Vector, which means the primitive type is converted to its corresponding type-wrapper class.
 b) False. A Set cannot contain duplicate values.
 c) False. A Map cannot contain duplicate keys.
 d) True.
 e) False. Collections is a class; Collection is an interface.
 f) True.
 g) False. With hashing, as the load factor increases, fewer slots are available relative to the total number of slots, so the chance of selecting an occupied slot (a collision) with a hashing operation increases.

Exercises **947**

- h) False. A `NullPointerException` is thrown if the program attempts to add `null` to a `PriorityQueue`.

Exercises

19.3 Define each of the following terms:

- a) `Collection`
- b) `Collections`
- c) `Comparator`
- d) `List`
- e) load factor
- f) collision
- g) space-time trade-off in hashing
- h) `HashMap`

19.4 Explain briefly the operation of each of the following methods of class `Vector`:

- a) `add`
- b) `insertElementAt`
- c) `set`
- d) `remove`
- e) `removeAllElements`
- f) `removeElementAt`
- g) `firstElement`
- h) `lastElement`
- i) `isEmpty`
- j) `contains`
- k) `indexOf`
- l) `size`
- m) `capacity`

19.5 Explain why inserting additional elements into a `Vector` object whose current size is less than its capacity is a relatively fast operation and why inserting additional elements into a `Vector` object whose current size is at capacity is a relatively slow operation.

19.6 By extending class `Vector`, Java's designers were able to create class `Stack` quickly. What are the negative aspects of this use of inheritance, particularly for class `Stack`?

19.7 Briefly answer the following questions:

- a) What is the primary difference between a `Set` and a `Map`?
- b) Can a two-dimensional array be passed to `Arrays` method `asList`? If yes, how would an individual element be accessed?
- c) What happens when you add a primitive type (e.g., `double`) value to a collection?
- d) Can you print all the elements in a collection without using an `Iterator`? If yes, how?

19.8 Explain briefly the operation of each of the following `Iterator`-related methods:

- a) `iterator`
- b) `hasNext`
- c) `next`

19.9 Explain briefly the operation of each of the following methods of class `HashMap`:

- a) `put`
- b) `get`
- c) `isEmpty`
- d) `containsKey`
- e) `keySet`

948 Chapter 19 Collections

- 19.10** Determine whether each of the following statements is *true* or *false*. If *false*, explain why.
- Elements in a `Collection` must be sorted in ascending order before a `binarySearch` may be performed.
 - Method `first` gets the first element in a `TreeSet`.
 - A `List` created with `Arrays` method `asList` is resizable.
 - Class `Arrays` provides static method `sort` for sorting array elements.
- 19.11** Explain the operation of each of the following methods of the `Properties` class:
- `load`
 - `store`
 - `getProperty`
 - `list`
- 19.12** Rewrite lines 17–26 in Fig. 19.4 to be more concise by using the `asList` method and the `LinkedList` constructor that takes a `Collection` argument.
- 19.13** Write a program that reads in a series of first names and stores them in a `LinkedList`. Do not store duplicate names. Allow the user to search for a first name.
- 19.14** Modify the program of Fig. 19.20 to count the number of occurrences of each letter rather than of each word. For example, the string "HELLO THERE" contains two Hs, three Es, two Ls, one O, one T and one R. Display the results.
- 19.15** Use a `HashMap` to create a reusable class for choosing one of the 13 predefined colors in class `Color`. The names of the colors should be used as keys, and the predefined `Color` objects should be used as values. Place this class in a package that can be imported into any Java program. Use your new class in an application that allows the user to select a color and draw a shape in that color.
- 19.16** Write a program that determines and prints the number of duplicate words in a sentence. Treat uppercase and lowercase letters the same. Ignore punctuation.
- 19.17** Rewrite your solution to Exercise 17.8 to use a `LinkedList` collection.
- 19.18** Rewrite your solution to Exercise 17.9 to use a `LinkedList` collection.
- 19.19** Write a program that takes a whole number input from a user and determines whether it is prime. If the number is not prime, display its unique prime factors. Remember that a prime number's factors are only 1 and the prime number itself. Every number that is not prime has a unique prime factorization. For example, consider the number 54. The prime factors of 54 are 2, 3, 3 and 3. When the values are multiplied together, the result is 54. For the number 54, the prime factors output should be 2 and 3. Use Sets as part of your solution.
- 19.20** Write a program that uses a `StringTokenizer` to tokenize a line of text input by the user and places each token in a `TreeSet`. Print the elements of the `TreeSet`. [Note: This should cause the elements to be printed in ascending sorted order.]
- 19.21** The output of Fig. 19.17 (`PriorityQueueTest`) shows that `PriorityQueue` orders `Double` elements in ascending order. Rewrite Fig. 19.17 so that it orders `Double` elements in descending order (i.e., 9.8 should be the highest-priority element rather than 3.2).

Introduction to Java Applets

OBJECTIVES

In this chapter you will learn:

- To differentiate between applets and applications.
- To observe some of Java's exciting capabilities through the JDK's demonstration applets.
- To write simple applets.
- To write a simple HyperText Markup Language (HTML) document to load an applet into an applet container and execute the applet.
- Five methods that are called automatically by an applet container during an applet's life cycle.

950 Chapter 20 Introduction to Java Applets**Outline**

- 20.1** Introduction
- 20.2** Sample Applets Provided with the JDK
- 20.3** Simple Java Applet: Drawing a String
 - 20.3.1** Executing an Applet in the `appletviewer`
 - 20.3.2** Executing an Applet in a Web Browser
- 20.4** Applet Life-Cycle Methods
- 20.5** Initializing an Instance Variable with Method `init`
- 20.6** Sandbox Security Model
- 20.7** Internet and Web Resources
- 20.8** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercise](#) | [Answers to Self-Review Exercise](#) | [Exercises](#)

20.1 Introduction

[*Note:* This chapter and its exercises are intentionally small and simple for readers who wish to learn about applets after reading only the first few chapters of the book—possibly just Chapters 2 and 3. We present more complex applets in Chapter 21, Multimedia: Applets and Applications, Chapter 23, Multithreading and Chapter 24, Networking.]

This chapter introduces **applets**—Java programs that can be embedded in **HyperText Markup Language (HTML) documents** (i.e., web pages). When a browser loads a web page containing an applet, the applet downloads into the web browser and executes.

The browser that executes an applet is known as the **applet container**. The JDK includes the **appletviewer** applet container for testing applets as you develop them and before you embed them in web pages. We typically demonstrate applets using the **appletviewer**. If you would like to execute your applets in a web browser, be aware that some web browsers do not support Java by default. You can visit java.com and click the **Download Now** button to install Java for your browser. Several popular browsers are supported.

20.2 Sample Applets Provided with the JDK

Let's consider several demonstration applets provided with the JDK. Each sample applet comes with its source code. Some programmers find it interesting to read this source code to learn new and exciting Java features.

The demonstration programs provided with the JDK are located in a directory called `demo`. For Windows, the default location of the JDK 6.0's `demo` directory is

```
C:\Program Files\Java\jdk1.6.0\demo
```

On UNIX/Linux/Mac OS X, the default location is the directory in which you install the JDK followed by `jdk1.6.0/demo`—for example,

```
/usr/local/jdk1.6.0/demo
```

For other platforms, there will be a similar directory (or folder) structure. This chapter assumes that the JDK is installed in `C:\Program Files\Java\jdk1.6.0\demo` on Windows or in your home directory in `~/jdk1.6.0` on UNIX/Linux/Mac OS X. You may need to

20.2 Sample Applets Provided with the JDK 951

update the locations specified here to reflect your chosen installation directory and disk drive, or a different version of the JDK.

If you are using a Java development tool that does not come with the Sun Java demos, you can download the JDK (with the demos) from the Sun Microsystems Java website

```
java.sun.com/javase/6/
```

TicTacToe Applet

The TicTacToe demonstration applet allows you to play Tic-Tac-Toe against the computer. To execute this applet, open a command window and change directories to the JDK's `demo` directory.

The `demo` directory contains several subdirectories. You can list them by issuing the `dir` command on Windows or the `ls` command on UNIX/Linux/Max OS X. We discuss sample programs in the `applets` and `jfc` directories. The `applets` directory contains several demonstration applets. The `jfc` (Java Foundation Classes) directory contains applets and applications that demonstrate Java's graphics and GUI features.

Change directories to the `applets` directory and list its contents to see the directory names for the demonstration applets. Figure 20.1 provides a brief description of each sample applet. If your browser supports Java, you can test these applets by opening the site `java.sun.com/javase/6/docs/technotes/samples/demos.html` in your browser and clicking the **Applets Page** link. We will demonstrate three of these applets by using the `appletviewer` command in a command window.

Example	Description
<code>Animator</code>	Performs one of four separate animations.
<code>ArcTest</code>	Demonstrates drawing arcs. You can interact with the applet to change attributes of the arc that is displayed.
<code>BarChart</code>	Draws a simple bar chart.
<code>Blink</code>	Displays blinking text in different colors.
<code>CardTest</code>	Demonstrates several GUI components and layouts.
<code>Clock</code>	Draws a clock with rotating hands, the current date and the current time. The clock updates once per second.
<code>DitherTest</code>	Demonstrates drawing with a graphics technique known as dithering that allows gradual transformation from one color to another.
<code>DrawTest</code>	Allows the user mouse to draw lines and points in different colors by dragging the mouse.
<code>Fractal</code>	Draws a fractal. Fractals typically require complex calculations to determine how they are displayed.
<code>GraphicsTest</code>	Draws shapes to illustrate graphics capabilities.

Fig. 20.1 | The examples from the `applets` directory. (Part 1 of 2.)

952 Chapter 20 Introduction to Java Applets

Example	Description
GraphLayout	Draws a graph consisting of many nodes (represented as rectangles) connected by lines. Drag a node to see the other nodes in the graph adjust on the screen and demonstrate complex graphical interactions.
ImageMap	Demonstrates an image with hot spots. Positioning the mouse pointer over certain areas of the image highlights the area and displays a message in the lower-left corner of the applet container window. Position over the mouth in the image to hear the applet say "hi."
JumpingBox	Moves a rectangle randomly around the screen. Try to catch it by clicking it with the mouse!
MoleculeViewer	Presents a three-dimensional view of several chemical molecules. Drag the mouse to view the molecule from different angles.
NervousText	Draws text that jumps around the applet.
SimpleGraph	Draws a complex curve.
SortDemo	Compares three sorting techniques. Sorting (described in Chapter 16) arranges information in order—like alphabetizing words. When you execute this example from a command window, three <code>appletviewer</code> windows appear. When you execute this example in a browser, the three demos appear side by side. Click in each demo to start the sort. Note that the sorts all operate at different speeds.
SpreadSheet	Demonstrates a simple spreadsheet of rows and columns.
TicTacToe	Allows the user to play Tic-Tac-Toe against the computer.
WireFrame	Draws a three-dimensional shape as a wire frame. Drag the mouse to view the shape from different angles.

Fig. 20.1 | The examples from the `applets` directory. (Part 2 of 2.)

Change directories to subdirectory `TicTacToe`, where you will find the HTML document `example1.html` that is used to execute the applet. In the command window, type the command

```
appletviewer example1.html
```

and press *Enter*. This executes the `appletviewer` applet container, which loads the HTML document `example1.html` specified as its command-line argument. The `appletviewer` determines from the document which applet to load and executes the applet. Figure 20.2 shows several screen captures of playing Tic-Tac-Toe with this applet.

You are player **X**. To interact with the applet, point the mouse at the square where you want to place an **X** and click the mouse button. The applet plays a sound and places an **X** in the square if the square is open. If the square is occupied, this is an invalid move, and the applet plays a different sound indicating that you cannot make the specified move. After you make a valid move, the applet responds by making its own move.

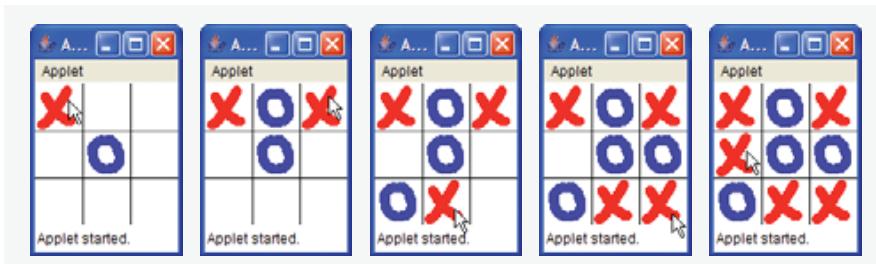

20.2 Sample Applets Provided with the JDK **953**

Fig. 20.2 | TicTacToe applet sample execution.

To play again, click the appletviewer's **Applet menu** and select the **Reload menu item** (Fig. 20.3). To terminate the appletviewer, click the appletviewer's **Applet menu** and select the **Quit menu item**.

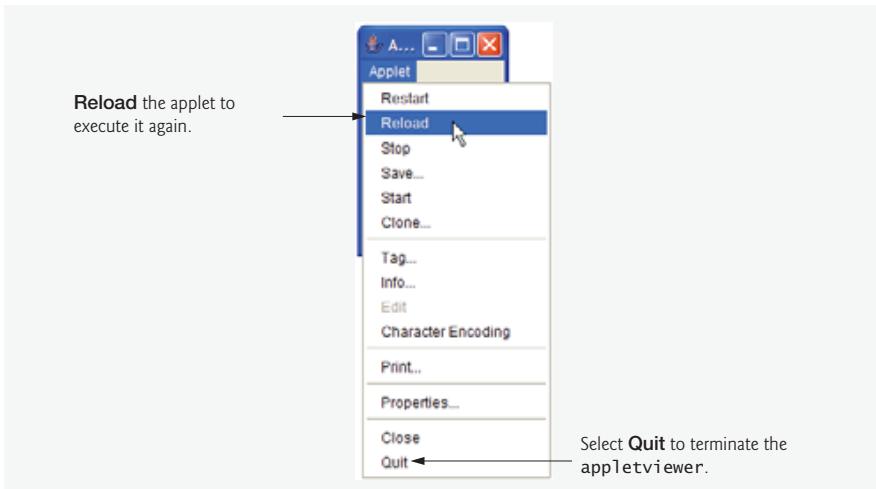

Fig. 20.3 | Applet menu in the appletviewer.

DrawTest Applet

The DrawTest applet allows you to draw lines and points in different colors. In the command window, change directories to directory `applets`, then to subdirectory `DrawTest`. You can move up the directory tree incrementally toward `demo` by issuing the command `"cd .."` in the command window. The `DrawTest` directory contains the `example1.html` document that is used to execute the applet. In the command window, type the command

```
appletviewer example1.html
```

and press *Enter*. The appletviewer loads `example1.html`, determines from the document which applet to load and executes the applet. Figure 20.4 shows a screen capture after some lines and points have been drawn.

954 Chapter 20 Introduction to Java Applets

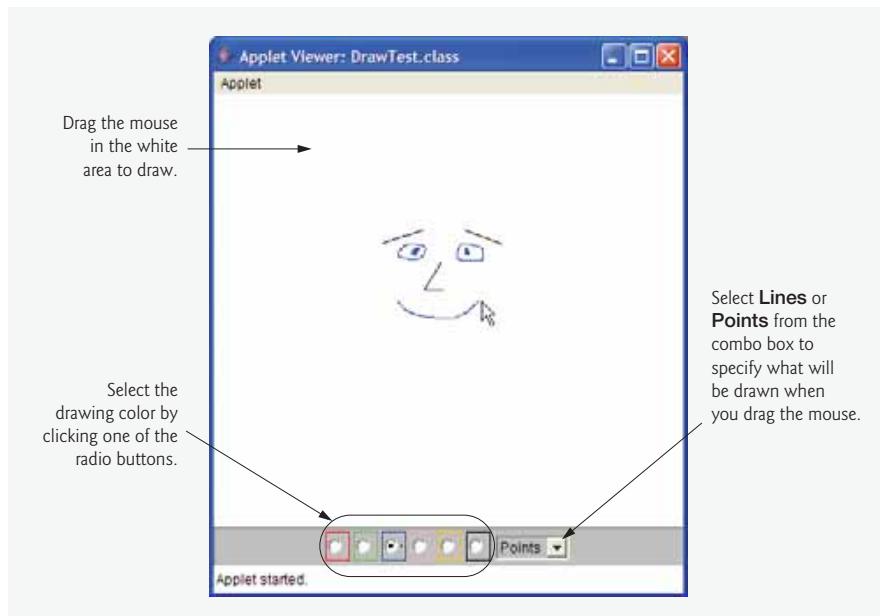

Fig. 20.4 | DrawTest applet sample execution.

By default the applet allows you to draw black lines by dragging the mouse across the applet. When you drag the mouse, note that the start point of the line always remains in the same place and the endpoint of the line follows the mouse pointer around the applet. The line is not permanent until you release the mouse button.

Select a color by clicking one of the radio buttons at the bottom of the applet. You can select from red, green, blue, pink, orange and black. Change the shape to draw from **Lines** to **Points** by selecting **Points** from the combo box. To start a new drawing, select **Reload** from the appletviewer's **Applet** menu.

Java2D Applet

The Java2D applet demonstrates many features of the Java 2D API (which we introduced in Chapter 12). Change directories to the `jfc` directory in the JDK's `demo` directory, then change to the Java2D directory. In the command window, type the command

```
appletviewer Java2Demo.html
```

and press *Enter*. The `appletviewer` loads `Java2Demo.html`, determines from the document which applet to load and executes the applet. Figure 20.5 shows a screen capture of one of this applet's many demonstrations of Java's two-dimensional graphics capabilities.

At the top of the applet are tabs that look like file folders in a filing cabinet. This demo provides 12 tabs with Java 2D API features demonstrated on each tab. To change to a different part of the demo, simply click a different tab. Also, try changing the options in the upper-right corner of the applet. Some of these affect the speed with which the applet draws the graphics. For example, click the checkbox to the left of the word **Anti-Aliasing** to

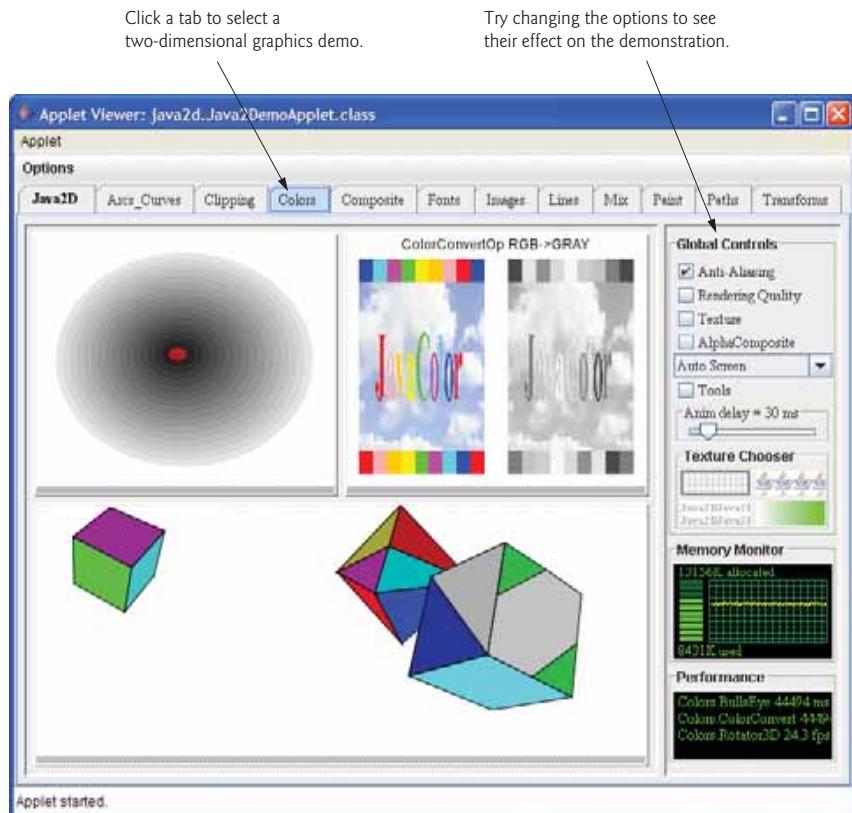

20.3 Simple Java Applet: Drawing a String **955**

Fig. 20.5 | Java2D applet sample execution.

turn off anti-aliasing (a graphics technique for producing smoother on-screen graphics in which the edges of the graphic are blurred). When this feature is turned off, the animation speed increases for the animated shapes at the bottom of the demo (Fig. 20.5). This performance increase occurs because shapes that are not anti-aliased are less complex to draw.

20.3 Simple Java Applet: Drawing a String

Every Java applet is a graphical user interface on which you can place GUI components using the techniques introduced in Chapter 11 or draw using the techniques demonstrated in Chapter 12. In this chapter, we will demonstrate drawing on an applet. Examples in Chapters 21, 23 and 24 demonstrate building an applet's graphical user interface.

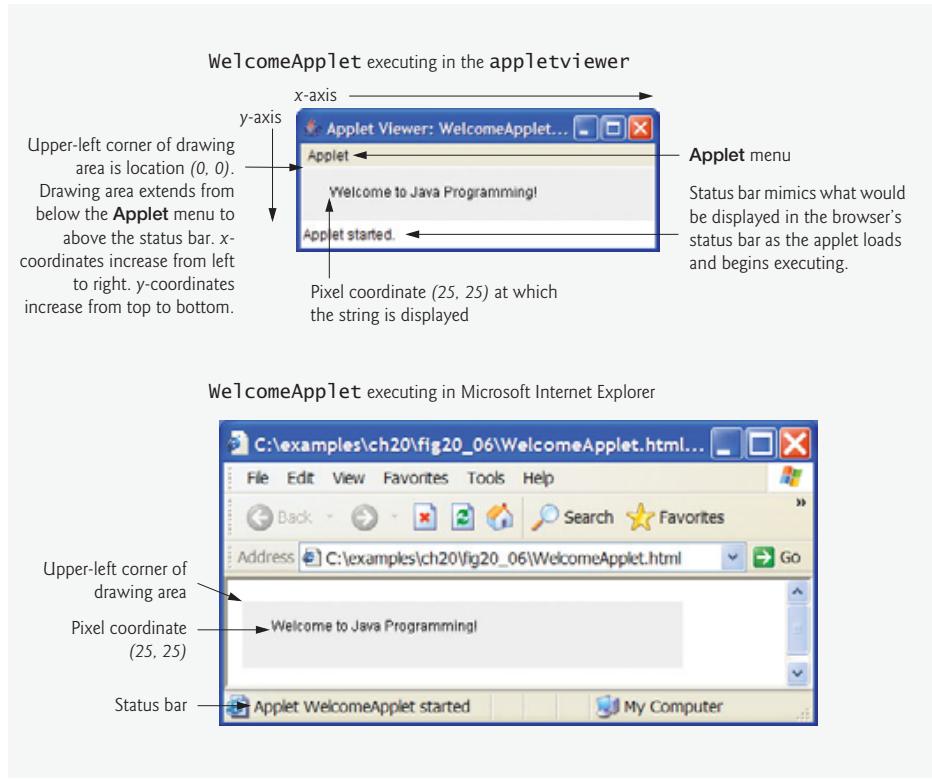

Now let's build an applet of our own. We begin with a simple applet (Fig. 20.6) that draws "Welcome to Java Programming!" on the applet. Figure 20.7 shows this applet executing in two applet containers—the appletviewer and the Microsoft Internet Explorer web browser. At the end of this section, you will learn how to execute the applet in a web browser.

956 Chapter 20 Introduction to Java Applets

```

1 // Fig. 20.6: WelcomeApplet.java
2 // A first applet in Java.
3 import java.awt.Graphics; // program uses class Graphics
4 import javax.swing.JApplet; // program uses class JApplet
5
6 public class WelcomeApplet extends JApplet
7 {
8     // draw text on applet's background
9     public void paint( Graphics g )
10    {
11        // call superclass version of method paint
12        super.paint( g );
13
14        // draw a String at x-coordinate 25 and y-coordinate 25
15        g.drawString( "Welcome to Java Programming!", 25, 25 );
16    } // end method paint
17 } // end class WelcomeApplet

```

Fig. 20.6 | Applet that draws a string.**Fig. 20.7** | Sample outputs of the WelcomeApplet in Fig. 20.6.

20.3 Simple Java Applet: Drawing a String 957

Creating the Applet Class

Line 3 imports class `Graphics` to enable the applet to draw graphics, such as lines, rectangles, ovals and strings of characters. Class `JApplet` (imported at line 4) from package `javax.swing` is used to create applets. As with applications, every Java applet contains at least one `public` class declaration. An applet container can create only objects of classes that are `public` and extend `JApplet` (or the `Applet` class from early versions of Java). For this reason, class `WelcomeApplet` (lines 6–17) extends `JApplet`.

An applet container expects every Java applet to have methods named `init`, `start`, `paint`, `stop` and `destroy`, each of which is declared in class `JApplet`. Each new applet class you create inherits default implementations of these methods from class `JApplet`. These methods can be overridden (redefined) to perform tasks that are specific to your applet. Section 20.4 discusses each of these methods in more detail.

When an applet container loads class `WelcomeApplet`, the container creates an object of type `WelcomeApplet`, then calls three of the applet's methods. In sequence, these three methods are `init`, `start` and `paint`. If you do not declare these methods in your applet, the applet container calls the inherited versions. The superclass methods `init` and `start` have empty bodies, so they do not perform any tasks. The superclass method `paint` does not draw anything on the applet.

You might wonder why it is necessary to inherit methods `init`, `start` and `paint` if their default implementations do not perform tasks. Some applets do not use all three of these methods. However, the applet container does not know that. Thus, it expects every applet to have these methods, so that it can provide a consistent start-up sequence for each applet. This is similar to applications' always starting execution with `main`. Inheriting the “default” versions of these methods guarantees that the applet container can execute each applet uniformly. Also, inheriting default implementations of these methods allows the programmer to concentrate on defining only the methods required for a particular applet.

Overriding Method `paint` for Drawing

To enable our applet to draw, class `WelcomeApplet` overrides method `paint` (lines 9–16) by placing statements in the body of `paint` that draw a message on the screen. Method `paint` receives a parameter of type `Graphics` (called `g` by convention), which is used to draw graphics on the applet. You do not call method `paint` explicitly in an applet. Rather, the applet container calls `paint` to tell the applet when to draw, and the applet container is responsible for passing a `Graphics` object as an argument.

Line 12 calls the superclass version of method `paint` that was inherited from `JApplet`. This statement should be the first statement in every applet's `paint` method. Omitting it can cause subtle drawing errors in applets that combine drawing and GUI components.

Line 15 uses `Graphics` method `drawString` to draw `Welcome to Java Programming!` on the applet. The method receives as arguments the `String` to draw and the *x-y* coordinates at which the bottom-left corner of the `String` should appear in the drawing area. When line 15 executes, it draws the `String` on the applet at the coordinates 25 and 25.

20.3.1 Executing an Applet in the appletviewer

As with application classes, you must compile an applet class before it can execute. After creating class `WelcomeApplet` and saving it in the file `WelcomeApplet.java`, open a com-

958 Chapter 20 Introduction to Java Applets

mand window, change to the directory in which you saved the applet class declaration and compile class `WelcomeApplet`.

Recall that applets are embedded in web pages for execution in an applet container (`appletviewer` or a browser). Before you can execute the applet, you must create an HTML (HyperText Markup Language) document that specifies which applet to execute in the applet container. Typically, an HTML document ends with an “`.html`” or “`.htm`” file-name extension. Figure 20.8 shows a simple HTML document—`WelcomeApplet.html`—that loads the applet defined in Fig. 20.6 into an applet container. [Note: If you are interested in learning more about HTML, the CD that accompanies this book contains three chapters from our book *Internet and World Wide Web How to Program, Third Edition*, that introduce the current version of HTML (known as XHTML) and the web page formatting capability known as Cascading Style Sheets (CSS).]

Most HTML elements are delimited by pairs of **tags**. For example, lines 1 and 4 of Fig. 20.8 indicate the beginning and the end, respectively, of the HTML document. All HTML tags begin with a left angle bracket, `<`, and end with a right angle bracket, `>`. Lines 2–3 specify an **applet element** that tells the applet container to load a specific applet and defines the size of the applet’s display area (its width and height in pixels) in the applet container. Normally, the applet and its corresponding HTML document are stored in the same directory on disk. Typically, a browser loads an HTML document from a computer (other than your own) connected to the Internet. However, HTML documents also can reside on your computer (as you saw in Section 20.2). When an applet container encounters an HTML document that contains an applet, the applet container automatically loads the applet’s `.class` file (or files) from the same directory on the computer in which the HTML document resides.

The **applet** element has several **attributes**. The first attribute in line 2, `code = "WelcomeApplet.class"`, indicates that the file `WelcomeApplet.class` contains the compiled applet class. The second and third attributes in line 2 indicate the `width` (300) and the `height` (45) of the applet in pixels. The `</applet>` tag (line 3) terminates the **applet** element that began at line 2. The `</html>` tag (line 4) terminates the HTML document.

Look-and-Feel Observation 20.1

To ensure that it can be viewed properly on most computer screens, an applet should generally be less than 1024 pixels wide and 768 pixels tall—dimensions supported by most computer screens.

Common Programming Error 20.1

Forgetting the ending `</applet>` tag prevents the applet from executing in some applet containers. The `appletviewer` terminates without indicating an error. Some web browsers simply ignore the incomplete **applet** element.

```

1 <html>
2 <applet code = "WelcomeApplet.class" width = "300" height = "45">
3 </applet>
4 </html>

```

Fig. 20.8 | `WelcomeApplet.html` loads `WelcomeApplet` (Fig. 20.6) into an applet container.

**Error-Prevention Tip 20.1**

If you receive a `MissingResourceException` error message when loading an applet into the appletviewer or a browser, check the `<applet>` tag in the HTML document carefully for syntax errors, such as commas (,) between the attributes.

The appletviewer understands only the `<applet>` and `</applet>` HTML tags and ignores all other tags in the document. The appletviewer is an ideal place to test an applet and ensure that it executes properly. Once the applet's execution is verified, you can add its HTML tags to a web page that others can view in their web browsers.

To execute `WelcomeApplet` in the appletviewer, open a command window, change to the directory containing your applet and HTML document, then type

```
appletviewer WelcomeApplet.html
```

**Error-Prevention Tip 20.2**

Test your applets in the appletviewer applet container before executing them in a web browser. Browsers often save a copy of an applet in memory until all the browser's windows are closed. If you change an applet, recompile it, then reload it in your browser, the browser may still execute the original version of the applet. Close all your browser windows to remove the old applet from memory. Open a new browser window and load the applet to see your changes.

**Error-Prevention Tip 20.3**

Test your applets in every web browser in which they will execute to ensure that they operate correctly.

20.3.2 Executing an Applet in a Web Browser

The sample program executions in Fig. 20.6 demonstrate `WelcomeApplet` executing in the appletviewer and in Microsoft Internet Explorer web browser. To execute an applet in Internet Explorer, perform the following steps:

1. Select **Open...** from the **File** menu.
2. In the dialog box that appears, click the **Browse...** button.
3. In the dialog box that appears, locate the directory containing the HTML document for the applet you wish to execute.
4. Select the HTML document.
5. Click the **Open** button.
6. Click the **OK** button.

[*Note:* The steps for executing applets in other web browsers are similar.]

If your applet executes in the appletviewer, but does not execute in your web browser, Java may not be installed and configured for your browser. In this case, visit the website java.com and click the **Download Now** button to install Java for your browser. In Internet Explorer, if this does not fix the problem, you might need to manually configure Internet Explorer to use Java. To do so, click the **Tools** menu and select **Internet Options...**, then click the **Advanced** tab in the window that appears. Locate the option “**Use JRE v1.6.0 for <applet> (requires restart)**” and ensure that it is checked, then click **OK**. Close all your browser windows before attempting to execute another applet in the browser.

960 Chapter 20 Introduction to Java Applets

20.4 Applet Life-Cycle Methods

Now that you have created an applet, let's consider the five applet methods that are called by the applet container from the time the applet is loaded into the browser to the time that it is terminated by the browser. These methods correspond to various aspects of an applet's life cycle. Figure 20.9 lists these methods, which are inherited into your applet classes from class `JApplet`. The table specifies when each method gets called and explains its purpose. Other than method `paint`, these methods have empty bodies by default. If you would like to declare any of these methods in your applets and have the applet container call them, you must use the method headers shown in Fig. 20.9. If you modify the method headers (e.g., by changing the method names or by providing additional parameters), the applet container will not call your methods. Instead, it will call the superclass methods inherited from `JApplet`.

Common Programming Error 20.2

Declaring methods `init`, `start`, `paint`, `stop` or `destroy` with method headers that differ from those shown in Figure 20.9 results in methods that will not be called by the applet container. The code specified in your versions of the methods will not execute.

Method	When the method is called and its purpose
<code>public void init()</code>	Called once by the applet container when an applet is loaded for execution. This method initializes an applet. Typical actions performed here are initializing fields, creating GUI components, loading sounds to play, loading images to display (see Chapter 20, Multimedia: Applets and Applications) and creating threads (see Chapter 23, Multithreading).
<code>public void start()</code>	Called by the applet container after method <code>init</code> completes execution. In addition, if the user browses to another website and later returns to the applet's HTML page, method <code>start</code> is called again. The method performs any tasks that must be completed when the applet is loaded for the first time and that must be performed every time the applet's HTML page is revisited. Actions performed here might include starting an animation (see Chapter 21) or starting other threads of execution (see Chapter 23).
<code>public void paint(Graphics g)</code>	Called by the applet container after methods <code>init</code> and <code>start</code> . Method <code>paint</code> is also called when the applet needs to be repainted. For example, if the user covers the applet with another open window on the screen and later uncovers the applet, the <code>paint</code> method is called. Typical actions performed here involve drawing with the <code>Graphics</code> object <code>g</code> that is passed to the <code>paint</code> method by the applet container.

Fig. 20.9 | `JApplet` life-cycle methods that are called by an applet container during an applet's execution. (Part 1 of 2.)

20.5 Initializing an Instance Variable with Method `init` **961**

Method	When the method is called and its purpose
<code>public void stop()</code>	This method is called by the applet container when the user leaves the applet's web page by browsing to another web page. Since it is possible that the user might return to the web page containing the applet, method <code>stop</code> performs tasks that might be required to suspend the applet's execution, so that the applet does not use computer processing time when it is not displayed on the screen. Typical actions performed here would stop the execution of animations and threads.
<code>public void destroy()</code>	This method is called by the applet container when the applet is being removed from memory. This occurs when the user exits the browsing session by closing all the browser windows and may also occur at the browser's discretion when the user has browsed to other web pages. The method performs any tasks that are required to clean up resources allocated to the applet.

Fig. 20.9 | JApplet life-cycle methods that are called by an applet container during an applet's execution. (Part 2 of 2.)

20.5 Initializing an Instance Variable with Method `init`

Our next applet (Fig. 20.10) computes the sum of two values input by the user and displays the result by drawing a String inside a rectangle on the applet. The sum is stored in an instance variable of class `AdditionApplet`, so it can be used in both method `init` and method `paint`. The HTML document to load this applet into the `appletviewer` is shown in Fig. 20.11.

```

1 // Fig. 20.10: AdditionApplet.java
2 // Adding two floating-point numbers.
3 import java.awt.Graphics;      // program uses class Graphics
4 import javax.swing.JApplet;    // program uses class JApplet
5 import javax.swing.JOptionPane; // program uses class JOptionPane
6
7 public class AdditionApplet extends JApplet
8 {
9     private double sum; // sum of values entered by user
10
11    // initialize applet by obtaining values from user
12    public void init()
13    {
14        String firstNumber; // first string entered by user
15        String secondNumber; // second string entered by user
16
17        double number1; // first number to add
18        double number2; // second number to add

```

Fig. 20.10 | Adding double values. (Part 1 of 2.)

962 Chapter 20 Introduction to Java Applets

```

19
20     // obtain first number from user
21     firstNumber = JOptionPane.showInputDialog(
22         "Enter first floating-point value" );
23
24     // obtain second number from user
25     secondNumber = JOptionPane.showInputDialog(
26         "Enter second floating-point value" );
27
28     // convert numbers from type String to type double
29     number1 = Double.parseDouble( firstNumber );
30     number2 = Double.parseDouble( secondNumber );
31
32     sum = number1 + number2; // add numbers
33 } // end method init
34
35 // draw results in a rectangle on applet's background
36 public void paint( Graphics g )
37 {
38     super.paint( g ); // call superclass version of method paint
39
40     // draw rectangle starting from (15, 10) that is 270
41     // pixels wide and 20 pixels tall
42     g.drawRect( 15, 10, 270, 20 );
43
44     // draw results as a String at (25, 25)
45     g.drawString( "The sum is " + sum, 25, 25 );
46 } // end method paint
47 } // end class AdditionApplet

```

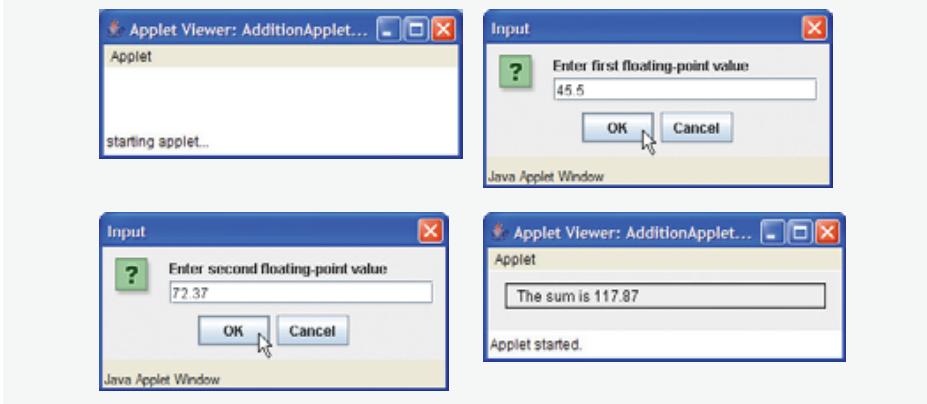

Fig. 20.10 | Adding double values. (Part 2 of 2.)

The applet requests that the user enter two floating-point numbers. Line 9 (Fig. 20.10) declares instance variable `sum` of type `double`. The applet contains two methods—`init` (lines 12–33) and `paint` (lines 36–46). When an applet container loads this applet, the container creates an instance of class `AdditionApplet` and calls its `init` method—this occurs only once during an applet’s execution. Method `init` normally initializes the applet’s fields

20.6 Sandbox Security Model **963**

```

1 <html>
2 <applet code = "AdditionApplet.class" width = "300" height = "65">
3 </applet>
4 </html>
```

Fig. 20.11 | AdditionApplet.html loads class AdditionApplet of Fig. 20.10 into an applet container.

(if they need to be initialized to values other than their defaults) and performs other tasks that should occur only once when the applet begins execution. The first line of `init` always appears as shown in line 12, which indicates that `init` is a `public` method that receives no arguments and returns no information when it completes.

Lines 14–30 declare variables to store the values entered by the user, obtain the user input and convert the `Strings` entered by the user to `double` values.

The assignment statement at line 32 sums the values stored in variables `number1` and `number2`, and assigns the result to instance variable `sum`. At this point, the applet's `init` method returns program control to the applet container, which then calls the applet's `start` method. We did not declare `start` in this applet, so the one inherited from class `JApplet` is called here. You will see typical uses of method `start` in Chapters 21 and 23.

Next, the applet container calls the applet's `paint` method, which draws a rectangle (line 42) where the addition result will appear. Line 45 calls the `Graphics` object's `drawString` method to display the results. The statement concatenates the value of instance variable `sum` to the `String` "The sum is " and displays the concatenated `String`.

Software Engineering Observation 20.1

The only statements that should be placed in an applet's init method are those that should execute only once when the applet is initialized.

20.6 Sandbox Security Model

It would be dangerous to allow applets, which are typically downloaded from the Internet, to read and write files on a client computer or access other system resources. For example, what would happen if you downloaded a malicious applet? The Java platform uses the **sandbox security model** to prevent code that is downloaded to your local computer from accessing local system resources, such as files. Code executing in the “sandbox” is not allowed to “play outside the sandbox.” For information on security and applets, visit

developer.java.sun.com/developer/technicalArticles/Security/Signed

For information on the Java 2 Platform security model, visit

java.sun.com/javase/6/docs/technotes/guides/security/index.html

20.7 Internet and Web Resources

If you have access to the Internet, a large number of Java applet resources are available to you. The best place to start is at the source—the Sun Microsystems Java website, java.sun.com. The web page

java.sun.com/applets

964 Chapter 20 Introduction to Java Applets

contains several Java applet resources, including the demonstration applets from the JDK and other applets (many of which you can download).

If you do not have Java installed and configured for your browser, you can visit

java.com

and click the **Download Now** button to download and install Java in your browser. Instructions are provided for various versions of Windows, Linux, Solaris and Mac OS.

The Sun Microsystems Java website

java.sun.com

includes technical support, discussion forums, technical articles, resources, announcements of new Java features and early access to new Java technologies.

For various free online tutorials, visit the site

java.sun.com/learning

Another useful website is **JARS**—originally called the [Java Applet Rating Service](#).
The JARS site

www.jars.com

was a Java applet repository that rated every applet registered at the site, so you could view the best applets on the web. Early in the development of the Java language, having your applet rated here was a great way to demonstrate your Java programming abilities. JARS is now an all-around ratings site for Java programmers.

The resources listed in this section provide hyperlinks to many other Java-related websites. Spend some time browsing these sites, executing applets and reading the applets' source code when it is available. This will help you to rapidly expand your Java knowledge.

20.8 Wrap-Up

In this chapter, you learned the fundamentals of Java applets. You leaned basic HTML concepts that allowed you to embed an applet in a web page and execute the applet in an applet container such as the `appletviewer` or a web browser. In addition, you learned the five methods that are called automatically by the applet container during an applet's life cycle. In the next chapter, you will see several additional applets as we present basic multimedia capabilities. In Chapter 23, Multithreading, you will see an applet with `start` and `stop` methods that are used to control multiple threads of execution. In Chapter 24, Networking, we demonstrate how to customize an applet via parameters that are specified in an `applet` HTML element.

Summary

Section 20.1 Introduction

- Applets are Java programs that can be embedded in HTML documents.
- When a browser loads a web page containing an applet, the applet downloads into the web browser and executes.
- The browser that executes an applet is known as the applet container. The JDK includes the `appletviewer` applet container for testing applets before you embed them in a web page.

Section 20.2 Sample Applets Provided with the JDK

- To reexecute an applet in the appletviewer, click the appletviewer's **Applet** menu and select the **Reload** menu item.
- To terminate the appletviewer, select **Quit** from the appletviewer's **Applet** menu.

Section 20.3 Simple Java Applet: Drawing a String

- Every Java applet is a graphical user interface on which you can place GUI components or draw.
- Class `JApplet` from package `javax.swing` is used to create applets.
- An applet container can create only objects of classes that are `public` and extend `JApplet` (or the `Applet` class from early versions of Java).
- An applet container expects every Java applet to have methods named `init`, `start`, `paint`, `stop` and `destroy`, each of which is declared in class `JApplet`. Each new applet class you create inherits default implementations of these methods from class `JApplet`.
- When an applet container loads an applet, the container creates an object of the applet's type, then calls the applet's `init`, `start` and `paint` methods. If you do not declare these methods in your applet, the applet container calls the inherited versions.
- The superclass methods `init` and `start` have empty bodies, so they do not perform any tasks. The superclass method `paint` does not draw anything on the applet.
- To enable an applet to draw, override its method `paint`. You do not call method `paint` explicitly in an applet. Rather, the applet container calls `paint` to tell the applet when to draw, and the applet container is responsible for passing a `Graphics` object as an argument.
- The first statement in method `paint` should be a call to the superclass method `paint`. Omitting this can cause subtle drawing errors in applets that combine drawing and GUI components.
- Before you can execute an applet, you must create an HTML (HyperText Markup Language) document that specifies which applet to execute in the applet container. Typically, an HTML document ends with an `".html"` or `".htm"` file-name extension.
- Most HTML elements are delimited by pairs of tags. All HTML tags begin with a left angle bracket, `<`, and end with a right angle bracket, `>`.
- An `applet` element tells the applet container to load a specific applet and defines the size of the applet's display area (its width and height in pixels) in the applet container.
- Normally, an applet and its corresponding HTML document are stored in the same directory.
- Typically, a browser loads an HTML document from a computer (other than your own) connected to the Internet.
- When an applet container encounters an HTML document that contains an applet, the applet container automatically loads the applet's `.class` file(s) from the same directory on the computer in which the HTML document resides.
- The `appletviewer` understands only the `<applet>` and `</applet>` HTML tags and ignores all other tags in the document.
- The `appletviewer` is an ideal place to test an applet and ensure that it executes properly. Once the applet's execution is verified, you can add its HTML tags to a web page that others can view in their web browsers.

Section 20.4 Applet Life-Cycle Methods

- There are five applet methods that are called by the applet container from the time the applet is loaded into the browser to the time that the applet is terminated by the browser. These methods correspond to various aspects of an applet's life cycle.

966 Chapter 20 Introduction to Java Applets

- Method `init` is called once by the applet container when an applet is loaded for execution. This method initializes the applet.
- Method `start` is called by the applet container after method `init` completes execution. In addition, if the user browses to another website and later returns to the applet's HTML page, method `start` is called again.
- Method `paint` is called by the applet container after methods `init` and `start`. Method `paint` is also called when the applet needs to be repainted.
- Method `stop` is called by the applet container when the user leaves the applet's web page by browsing to another web page.
- Method `destroy` is called by the applet container when the applet is being removed from memory. This occurs when the user exits the browsing session by closing all the browser windows and may also occur at the browser's discretion when the user has browsed to other web pages.

Terminology

applet	<code>init</code> method of <code>JApplet</code>
applet container	<code>JApplet</code> class
applet HTML element	left angle bracket (<)
<code>Applet</code> menu in <code>appletviewer</code>	<code>paint</code> method of <code>JApplet</code>
<code><applet></code> tag	<code>parseDouble</code> method of <code>Double</code>
<code>appletviewer</code>	<code>Quit</code> menu item in <code>appletviewer</code>
attribute	<code>Reload</code> menu item in <code>appletviewer</code>
demo directory of the JDK	right angle bracket (>)
height of an applet	<code>start</code> method of <code>JApplet</code>
<code>.htm</code> file-name extension	<code>stop</code> method of <code>JApplet</code>
HTML element	tag
<code>.html</code> file-name extension	width of an applet
HyperText Markup Language (HTML)	

Self-Review Exercise

20.1 Fill in the blanks in each of the following:

- Java applets begin execution with a series of three method calls: _____, _____ and _____.
- The _____ method is invoked for an applet each time the user of a browser leaves an HTML page on which the applet resides.
- Every applet should extend class _____.
- The _____ or a browser can be used to execute a Java applet.
- The _____ method is called each time the user of a browser revisits the HTML page on which an applet resides.
- To load an applet into a browser, you must first define a(n) _____ file.
- Method _____ is called once when an applet begins execution.
- Method _____ is invoked to draw on an applet.
- Method _____ is invoked for an applet when the browser removes it from memory.
- The _____ and _____ HTML tags specify that an applet should be loaded into an applet container and executed.

Answers to Self-Review Exercise

- 20.1** a) `init`, `start`, `paint`. b) `stop`. c) `JApplet` (or `Applet`). d) `appletviewer`. e) `start`. f) HT-ML. g) `init`. h) `paint`. i) `destroy`. j) `<applet>`, `</applet>`.

Exercises **967****Exercises**

20.2 Write an applet that asks the user to enter two floating-point numbers, obtains the two numbers from the user and draws their sum, product (multiplication), difference and quotient (division). Use the techniques shown in Fig. 20.10.

20.3 Write an applet that asks the user to enter two floating-point numbers, obtains the numbers from the user and displays the two numbers first and then the larger number followed by the words "is larger" as a string on the applet. If the numbers are equal, the applet should print the message "These numbers are equal." Use the techniques shown in Fig. 20.10.

20.4 Write an applet that inputs three floating-point numbers from the user and displays the sum, average, product, smallest and largest of these numbers as strings on the applet. Use the techniques shown in Fig. 20.10.

20.5 Write an applet that asks the user to input the radius of a circle as a floating-point number and draws the circle's diameter, circumference and area. Use the value 3.14159 for π . Use the techniques shown in Fig. 20.10. [Note: You may also use the predefined constant `Math.PI` for the value of π . This constant is more precise than the value 3.14159. Class `Math` is defined in the `java.lang` package, so you do not need to import it.] Use the following formulas (r is the radius):

$$\begin{aligned} \text{diameter} &= 2r \\ \text{circumference} &= 2\pi r \\ \text{area} &= \pi r^2 \end{aligned}$$

20.6 Write an applet that reads five integers, determines which are the largest and smallest integers in the group and prints them. Use only the programming techniques you learned in this chapter and Chapter 2. Draw the results on the applet.

20.7 Write an applet that draws a checkerboard pattern as follows:

```
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
* * * * * * * *
```

20.8 Write an applet that draws rectangles of different sizes and locations.

20.9 Write an applet that allows the user to input values for the arguments required by method `drawRect`, then draws a rectangle using the four input values.

20.10 Class `Graphics` contains method `drawOval`, which takes as arguments the same four arguments as method `drawRect`. The arguments for method `drawOval` specify the "bounding box" for the oval—the sides of the bounding box are the boundaries of the oval. Write a Java applet that draws an oval and a rectangle with the same four arguments. The oval will touch the rectangle at the center of each side.

20.11 Modify the solution to Exercise 20.10 to output ovals of different shapes and sizes.

20.12 Write an applet that allows the user to input the four arguments required by method `drawOval`, then draws an oval using the four input values.

21

Multimedia: Applets and Applications

OBJECTIVES

In this chapter you will learn:

- How to get, display and scale images.
- How to create animations from sequences of images.
- How to create image maps.
- How to get, play, loop and stop sounds, using an `AudioClip`.
- How to play video using interface `Player`.

The wheel that squeaks the loudest ... gets the grease.

—John Billings (Henry Wheeler Shaw)

We'll use a signal I have tried and found far-reaching and easy to yell. Waa-hoo!

—Zane Grey

There is a natural hootchy-kootchy motion to a goldfish.

—Walt Disney

Between the motion and the act falls the shadow.

—Thomas Stearns Eliot

Outline

- 21.1** Introduction
- 21.2** Loading, Displaying and Scaling Images
- 21.3** Animating a Series of Images
- 21.4** Image Maps
- 21.5** Loading and Playing Audio Clips
- 21.6** Playing Video and Other Media with Java Media Framework
- 21.7** Wrap-Up
- 21.8** Web Resources

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)
Special Section: Challenging Multimedia Projects

21.1 Introduction

Welcome to what may be the largest revolution in the history of the computer industry. Those who entered the field decades ago were interested in using computers primarily to perform arithmetic calculations at high speed. As the computer field evolved, we began to realize that the data-manipulation capabilities of computers are equally important. The “sizzle” of Java is **multimedia**—the use of **sound**, **images**, graphics and **video** to make applications “come alive.” Although most multimedia in Java applications is two-dimensional, Java programmers already can use the **Java 3D API** to create substantial 3D graphics applications (Sun provides an online tutorial for the Java 3D API at java.sun.com/developer/onlineTraining/java3d).

Multimedia programming offers many new challenges. The field is already enormous and is growing rapidly. Most new computers sold today are “multimedia ready,” with CD-RW and DVD drives, audio boards and special video capabilities. Economical desktop and laptop computers are so powerful that they can store and play DVD-quality sound and video, and we expect to see further advances in the kinds of programmable multimedia capabilities available through programming languages. One thing that we have learned is to plan for the “impossible”—in the computer and communications fields, the “impossible” has repeatedly become reality.

Among users who want graphics, many now want three-dimensional, high-resolution, color graphics. True three-dimensional imaging may become available within the next decade. Imagine having high-resolution, “theater-in-the-round,” three-dimensional television. Sporting and entertainment events will seem to take place on your living room floor! Medical students worldwide will see operations being performed thousands of miles away, as if they were occurring in the same room. People will be able to learn how to drive with extremely realistic driving simulators in their homes before they get behind the wheel. The possibilities are exciting and endless.

Multimedia demands extraordinary computing power. Until recently, affordable computers with that kind of power were not available. Today’s ultrapowerful processors make effective multimedia possible. The computer and communications industries will be primary beneficiaries of the multimedia revolution. Users will be willing to pay for the faster processors, larger memories and wider communications bandwidths that support demanding multimedia applications. Ironically, users may not have to pay more, because the fierce competition in these industries has historically driven prices down.

970 Chapter 21 Multimedia: Applets and Applications

We need programming languages that make creating multimedia applications easy. Most programming languages do not incorporate such capabilities. However, Java, through its class libraries, provides extensive multimedia facilities that enable you to start developing powerful multimedia applications immediately.

This chapter presents several examples of interesting multimedia features that you will need to build useful applications, including:

1. the basics of manipulating images.
2. creating smooth animations.
3. playing audio files with the `AudioClip` interface.
4. creating image maps that can sense when the cursor is over them, even without a mouse click.
5. playing video files using the `Player` interface.

This chapter's exercises suggest dozens of challenging and interesting projects. When we were creating these exercises, the ideas just kept flowing. Multimedia leverages creativity in ways that we did not experience with "conventional" computer capabilities. [Note: Java's multimedia capabilities go far beyond those presented in this chapter. They include the [Java Media Framework \(JMF\) API](#) (for adding audio and video media to an application), [Java Sound API](#) (for playing, recording and modifying audio), Java 3D API (for creating and modifying 3D graphics), [Java Advanced Imaging API](#) (for image-processing capabilities, such as cropping and scaling), [Java Speech API](#) (for inputting voice commands from the user or outputting voice commands to the user), Java 2D API (for creating and modifying 2D graphics, covered in Chapter 12) and [Java Image I/O API](#) (for reading from and outputting images to files). Section 21.8 provides web links for each of these APIs.]

21.2 Loading, Displaying and Scaling Images

Java's multimedia capabilities include graphics, images, animations, sounds and video. We begin our discussion with images. We will use several different images in this chapter. Developers can create such images with any image software, such as Adobe® Photoshop™, Jasc® Paint Shop Pro™ or Microsoft® Paint.

The applet of Fig. 21.1 demonstrates loading an `Image` (package `java.awt`) and loading an `ImageIcon` (package `javax.swing`). Both classes are used to load and display images. The applet displays the `Image` in its original size and scaled to a larger size, using

```

1 // Fig. 21.1: LoadImageAndScale.java
2 // Load an image and display it in its original size and twice its
3 // original size. Load and display the same image as an ImageIcon.
4 import java.awt.Graphics;
5 import java.awt.Image;
6 import javax.swing.ImageIcon;
7 import javax.swing.JApplet;
8
9 public class LoadImageAndScale extends JApplet
10 {

```

Fig. 21.1 | Loading and displaying an image in an applet. (Part I of 2.)

21.2 Loading, Displaying and Scaling Images **971**

```

11     private Image image1; // create Image object
12     private ImageIcon image2; // create ImageIcon object
13
14     // load image when applet is loaded
15     public void init()
16     {
17         image1 = getImage( getDocumentBase(), "redflowers.png" );
18         image2 = new ImageIcon( "yellowflowers.png" );
19     } // end method init
20
21     // display image
22     public void paint( Graphics g )
23     {
24         super.paint( g );
25
26         g.drawImage( image1, 0, 0, this ); // draw original image
27
28         // draw image to fit the width and the height less 120 pixels
29         g.drawImage( image1, 0, 120, getWidth(), getHeight() - 120, this );
30
31         // draw icon using its paintIcon method
32         image2.paintIcon( this, g, 180, 0 );
33     } // end method paint
34 } // end class LoadImageAndScale

```

Fig. 21.1 | Loading and displaying an image in an applet. (Part 2 of 2.)

two versions of `Graphics` method `drawImage`. The applet also draws the `ImageIcon`, using the icon's method `paintIcon`. Class `ImageIcon` implements interface `Serializable`, which allows `ImageIcon` objects to be easily written to a file or sent across the Internet. Class `ImageIcon` is also easier to use than `Image`, because its constructor can receive arguments of several different formats, including a byte array containing the bytes of an image,

972 Chapter 21 Multimedia: Applets and Applications

an `Image` already loaded in memory, and a `String` or a `URL` object, which both can be used to represent the location of the image. A `URL` object represents a Uniform Resource Locator that serves as a pointer to a resource on the World Wide Web, on your computer or on any networked machine. A `URL` object is more often used when accessing data over the Internet, while a simple string is more often used when accessing data on the current machine. Using a `URL` object also enables the programmer to access information from the web, such as searching for information from a database or through a search engine.

Lines 11 and 12 declare `Image` and `ImageIcon` variables, respectively. Class `Image` is an `abstract` class—the applet cannot create an object of class `Image` directly. Rather, we must call a method that causes the applet container to load and return the `Image` for use in the program. Class `Applet` (the direct superclass of `JApplet`) provides method `getImage` (line 17, in method `init`) that loads an `Image` into an applet. This version of `getImage` takes two arguments—the location of the image file and the file name of the image. In the first argument, `Applet` method `getDocumentBase` returns a `URL` representing the location of the image on the Internet (or on your computer if the applet was loaded from your computer). Method `getDocumentBase` returns the location of the HTML file as an object of class `URL`. The second argument specifies an image file name. The two arguments together specify the unique name and path of the file being loaded (in this case, the file `red-flowers.png` stored in the same directory as the HTML file that invoked the applet). Java supports several image formats, including **Graphics Interchange Format (GIF)**, **Joint Photographic Experts Group (JPEG)** and **Portable Network Graphics (PNG)**. File names for these types end with `.gif`, `.jpg` (or `.jpeg`) and `.png`, respectively.

Portability Tip 21.1

Class `Image` is an abstract class—as a result, programs cannot instantiate class `Image` to create objects. To achieve platform independence, the Java implementation on each platform provides its own subclass of `Image` to store image information. Methods that return references to `Image`s actually return references to objects of the Java implementation's `Image` subclass.

Line 17 begins loading the image from the local computer (or downloading it from the Internet). When the image is required by the program, it is loaded in a separate thread. Remember that a thread is a parallel activity, and that threads will be discussed in detail in Chapter 23, Multithreading. By using a separate thread to load an image, the program can continue execution while the image loads. [Note: If the requested file is not available, method `getImage` does not throw an exception. An `Image` object is returned, but when this `Image` is displayed using method `drawImage`, nothing will be displayed.]

Class `ImageIcon` is not an `abstract` class—a program can create an `ImageIcon` object. At line 18, in method `init` creates an `ImageIcon` object that loads `yellowflowers.png`. Class `ImageIcon` provides several constructors that enable programs to initialize `ImageIcon` objects with images from the local computer or stored on the Internet.

The applet's `paint` method (lines 22–33) displays the images. Line 26 uses `Graphics` method `drawImage` to display an `Image`. Method `drawImage` accepts four arguments. The first is a reference to the `Image` object to display (`image1`). The second and third are the *x*- and *y*-coordinates at which to display the image on the applet—the coordinates specify the location of the upper-left corner of the image. The last argument is a reference to an `ImageObserver`—an interface implemented by class `Component`. Since class `JApplet` indirectly extends `Component`, all `JApplets` are `ImageObservers`. This argument is important

21.3 Animating a Series of Images **973**

when displaying large images that require a long time to download from the Internet. It is possible that a program will attempt to display the image before it has downloaded completely. The `ImageObserver` receives notifications as the `Image` is loaded and updates the image on the screen if the image was not complete when it was displayed. When executing this applet, watch carefully as pieces of the image display while the image loads. [Note: On faster computers, you might not notice this effect.]

Line 29 uses an overloaded version method `drawImage` to output a scaled version of the image. The fourth and fifth arguments specify the *width* and *height* of the image for display purposes. Method `drawImage` scales the image to fit the specified width and height. In this example, the fourth argument indicates that the width of the scaled image should be the width of the applet, and the fifth argument indicates that the height should be 120 pixels less than the height of the applet. The width and height of the applet are determined by calling methods `getWidth` and `getHeight` (inherited from class `Component`).

Line 32 uses `ImageIcon` method `paintIcon` to display the image. The method requires four arguments—a reference to the `Component` on which to display the image, a reference to the `Graphics` object that will render the image, the *x*-coordinate of the upper-left corner of the image and the *y*-coordinate of the upper-left corner of the image.

21.3 Animating a Series of Images

The next example demonstrates animating a series of images that are stored in an array of `ImageIcons`. The animation presented in Figs. 21.2–21.3 is implemented using a subclass of `JPanel` called `LogoAnimatorJPanel` (Fig. 21.2) that can be attached to an application window or a `JApplet`. Class `LogoAnimator` (Fig. 21.3) declares a `main` method (lines 8–20 of Fig. 21.3) to execute the animation as an application. Method `main` declares an instance of class `JFrame` and attaches a `LogoAnimatorJPanel` object to the `JFrame` to display the animation.

```

1 // Fig. 21.2: LogoAnimatorJPanel.java
2 // Animation of a series of images.

```

20     private Timer animationTimer; // Timer drives animation
21
22     // constructor initializes LogoAnimatorJPanel by loading images
23     public LogoAnimatorJPanel()
24     {
25         images = new ImageIcon[ TOTAL_IMAGES ];
26
27         // load 30 images
28         for ( int count = 0; count < images.length; count++ )
29             images[ count ] = new ImageIcon( getClass().getResource(
30                 "images/" + IMAGE_NAME + count + ".gif" ) );
31
32         // this example assumes all images have the same width and height
33         width = images[ 0 ].getIconWidth(); // get icon width
34         height = images[ 0 ].getIconHeight(); // get icon height
35     } // end LogoAnimatorJPanel constructor
36
37
38     // display current image
39     public void paintComponent( Graphics g )
40     {
41         super.paintComponent( g ); // call superclass paintComponent
42
43         images[ currentImage ].paintIcon( this, g, 0, 0 );
44
45         // set next image to be drawn only if Timer is running
46         if ( animationTimer.isRunning() )
47             currentImage = ( currentImage + 1 ) % TOTAL_IMAGES;
48     } // end method paintComponent
49
50
51     // start animation, or restart if window is redisplayed
52     public void startAnimation()
53     {
54         if ( animationTimer == null )
55         {
56             currentImage = 0; // display first image
57
58             // create timer
59             animationTimer =
60                 new Timer( ANIMATION_DELAY, new TimerHandler() );
61
62             animationTimer.start(); // start Timer
63         } // end if
64         else // animationTimer already exists, restart animation
65         {
66             if ( ! animationTimer.isRunning() )
67                 animationTimer.restart();
68         } // end else
69     } // end method startAnimation
70
71     // stop animation Timer
72     public void stopAnimation()
73     {

```

Fig. 21.3 | Displaying animated images on a JFrame. (Part 1 of 2.)

976 Chapter 21 Multimedia: Applets and Applications

Fig. 21.3 | Displaying animated images on a JFrame. (Part 2 of 2.)

Class `LogoAnimatorJPanel` (Fig. 21.2) maintains an array of `ImageIcons` that are loaded in the constructor (lines 24–36). Lines 29–31 create each `ImageIcon` object and store the animation's 30 images in array `images`. The constructor argument uses string concatenation to assemble the file name from the pieces "images/", `IMAGE_NAME`, `count` and ".gif". Each image in the animation is in a file called `deitel#.gif`, where # is a value in the range 0–29 specified by the loop's control variable `count`. Lines 34–35 determine the width and height of the animation from the size of the first image in array `images`—we assume that all the images have the same width and height.

After the `LogoAnimatorJPanel` constructor loads the images, method `main` of Fig. 21.3 sets up the window in which the animation will appear (lines 12–17), and line 19 calls the `LogoAnimatorJPanel`'s `startAnimation` method (declared at lines 51–68 of Fig. 21.2). This method starts the program's animation for the first time or restarts the animation that the program stopped previously. [Note: This method is called when the program is first run, to begin the animation. Although we provide the functionality for this method to restart the animation if it has been stopped, the example does not call the method for this purpose. We have added the functionality, however, should the reader choose to add GUI components that enable the user to start and stop the animation.] For example, to make an animation "browser friendly" in an applet, the animation should stop when the user switches web pages. If the user returns to the web page with the animation, method `startAnimation` can be called to restart the animation. The animation is driven by an instance of class `Timer` (from package `javax.swing`).

A `Timer` generates `ActionEvents` at a fixed interval in milliseconds (normally specified as an argument to the `Timer`'s constructor) and notifies all its `ActionListeners` each time an `ActionEvent` occurs. Line 53 determines whether the `Timer` reference `animationTimer` is null. If it is, method `startAnimation` is being called for the first time, and a `Timer` needs to be created so that the animation can begin. Line 55 sets `currentImage` to 0, which indicates that the animation should begin with the image in the first element of array `images`. Lines 58–59 assign a new `Timer` object to `animationTimer`. The `Timer` constructor receives two arguments—the delay in milliseconds (`ANIMATION_DELAY` is 50, as specified in line 17) and the `ActionListener` that will respond to the `Timer`'s `ActionEvents`. For the second argument, an object of class `TimerHandler` is created. This class, which implements `ActionListener`, is declared in lines 89–96. Line 61 starts the `Timer` object. Once started, `animationTimer` will generate an `ActionEvent` every 50 milliseconds. Each time an `ActionEvent` is generated, the `Timer`'s event handler `actionPerformed` (lines 92–95) is called. Line 94 calls `LogoAnimatorJPanel`'s `repaint` method to schedule a call to `LogoAnimatorJPanel`'s `paintComponent` method (lines 39–48). Remember that any subclass of `JComponent` that draws should do so in its `paintComponent` method. Recall

21.3 Animating a Series of Images **977**

from Chapter 11 that the first statement in any `paintComponent` method should be a call to the superclass's `paintComponent` method, to ensure that Swing components are displayed correctly.

If the animation started earlier, then our `Timer` was created and the condition in line 53 evaluates to `false`. The program continues with lines 65–66, which restarts the animation that the program stopped previously. The `if` condition at line 65 uses `Timer` method `isRunning` to determine whether the `Timer` is running (i.e., generating events). If it is not running, line 66 calls `Timer` method `restart` to indicate that the `Timer` should start generating events again. Once this occurs, method `actionPerformed` (the `Timer`'s event handler) is again called at regular intervals. Each time, a call is made to method `repaint` (line 94), causing method `paintComponent` to be called and the next image to be displayed.

Line 43 paints the `ImageIcon` stored at element `currentImage` in the array. Lines 46–47 determine whether the `animationTimer` is running and, if so, prepare for the next image to be displayed by incrementing `currentImage` by 1. The remainder calculation ensures that the value of `currentImage` is set to 0 (to repeat the animation sequence) when it is incremented past 29 (the last element index in the array). The `if` statement ensures that the same image will be displayed if `paintComponent` is called while the `Timer` is stopped. This could be useful if a GUI is provided that enables the user to start and stop the animation. For example, if the animation is stopped and the user covers it with another window, then uncovers it, method `paintComponent` will be called. In this case, we do not want the animation to show the next image (because the animation has been stopped). We simply want the window to display the same image until the animation is restarted.

Method `stopAnimation` (lines 71–74) stops the animation by calling `Timer` method `stop` to indicate that the `Timer` should stop generating events. This prevents `actionPerformed` from calling `repaint` to initiate the painting of the next image in the array. [Note: Just as with restarting the animation, this example defines but does not use method `stopAnimation`. We have provided this method for demonstration purposes, or if the user wishes to modify this example so that the user can stop and restart the animation.]

**Software Engineering Observation 21.1**

When creating an animation for use in an applet, provide a mechanism for disabling the animation when the user browses a new web page different from the one on which the animation applet resides.

Remember that by extending class `JPanel`, we are creating a new GUI component. Thus, we must ensure that our new component works like other components for layout purposes. Layout managers often use a GUI component's `getPreferredSize` method (inherited from class `java.awt.Component`) to determine the preferred width and height of the component when laying it out as part of a GUI. If a new component has a preferred width and height, it should override method `getPreferredSize` (lines 83–86) to return that width and height as an object of class `Dimension` (package `java.awt`). The `Dimension` class represents the width and height of a GUI component. In this example, the images are 160 pixels wide and 80 pixels tall, so method `getPreferredSize` returns a `Dimension` object containing the numbers 160 and 80 (determined at lines 34–35).

**Look-and-Feel Observation 21.1**

The default size of a `JPanel` object is 10 pixels wide and 10 pixels tall.

978 Chapter 21 Multimedia: Applets and Applications

**Look-and-Feel Observation 21.2**

When subclassing JPanel (or any other JComponent), override method getPreferredSize if the new component is to have a specific preferred width and height.

Lines 77–80 override method `getMinimumSize`. This method determines the minimum width and height of the component. As with method `getPreferredSize`, new components should override method `getMinimumSize` (also inherited from class `Component`). Method `getMinimumSize` simply calls `getPreferredSize` (a common programming practice) to indicate that the minimum size and preferred size are the same. Some layout managers ignore the dimensions specified by these methods. For example, a `BorderLayout`'s NORTH and SOUTH regions use only the component's preferred height.

**Look-and-Feel Observation 21.3**

If a new GUI component has a minimum width and height (i.e., smaller dimensions would render the component ineffective on the display), override method getMinimumSize to return the minimum width and height as an instance of class Dimension.

**Look-and-Feel Observation 21.4**

For many GUI components, method getMinimumSize is implemented to return the result of a call to the component's getPreferredSize method.

21.4 Image Maps

Image maps are commonly used to create interactive web pages. An image map is an image with **hot areas** that the user can click to accomplish a task, such as loading a different web page into a browser. When the user positions the mouse pointer over a hot area, normally a descriptive message appears in the status area of the browser or in a tool tip.

Figure 21.4 loads an image containing several of the programming-tip icons used in this book. The program allows the user to position the mouse pointer over an icon to display a descriptive message associated with it. Event handler `mouseMoved` (lines 39–43) takes the mouse coordinates and passes them to method `translateLocation` (lines 58–69). Method `translateLocation` tests the coordinates to determine the icon over which the mouse was positioned when the `mouseMoved` event occurred—the method then returns a message indicating what the icon represents. This message is displayed in the applet container's status bar using method `showStatus` of class `Applet`.

```

Fig. 21.4 | Image map. (Part 4 of 4.)

Clicking in the applet of Fig. 21.4 will not cause any action. In Chapter 24, Networking, we discuss the techniques required to load another web page into a browser via URLs and the `AppletContext` interface. Using those techniques, this applet could associate each icon with a URL that the browser would display when the user clicks the icon.

21.5 Loading and Playing Audio Clips

Java programs can manipulate and play [audio clips](#). Users can capture their own audio clips, and many clips are available in software products and over the Internet. Your system needs to be equipped with audio hardware (speakers and a sound card) to be able to play the audio clips.

Java provides several mechanisms for playing sounds in an applet. The two simplest are the `Applet`'s `play` method and the `play` method of the `AudioClip` interface. Additional audio capabilities are available in the Java Media Framework and Java Sound APIs. If you would like to play a sound once in a program, the `Applet` method `play` loads the sound and plays it once—the sound is marked for garbage collection after it plays. The `Applet` method `play` has two versions:

```
public void play( URL location, String soundFileName );
public void play( URL soundURL );
```

The first version loads the audio clip stored in file `soundFileName` from `location` and plays the sound. The first argument is normally a call to the applet's `getDocumentBase` or `getCodeBase` method. Method `getDocumentBase` returns the location of the HTML file that loaded the applet. (If the applet is in a package, the method returns the location of the package or the JAR file containing the package.) Method `getCodeBase` indicates the location of the applet's `.class` file. The second version of method `play` takes a URL that contains the location and the file name of the audio clip. The statement

```
play( getDocumentBase(), "hi.au" );
```

loads the audio clip in file `hi.au` and plays the clip once.

982 Chapter 21 Multimedia: Applets and Applications

The **sound engine** that plays the audio clips supports several audio file formats, including **Sun Audio file format** (**.au** extension), **Windows Wave file format** (**.wav** extension), **Macintosh AIFF file format** (**.aif** or **.aiff** extensions) and **Musical Instrument Digital Interface (MIDI) file format** (**.mid** or **.rmi** extensions). The Java Media Framework (JMF) and Java Sound APIs support additional formats.

The program of Fig. 21.5 demonstrates loading and playing an **AudioClip** (package **java.applet**). This technique is more flexible than **Applet** method **play**. An applet can use an **AudioClip** to store audio for repeated use throughout a program's execution. **Applet** method **getAudioClip** has two forms that take the same arguments as method **play** described previously. Method **getAudioClip** returns a reference to an **AudioClip**. An **AudioClip** has three methods—**play**, **loop** and **stop**. As mentioned earlier, method **play** plays the audio clip once. Method **loop** continuously loops through the audio clip in the background. Method **stop** terminates an audio clip that is currently playing. In the program, each of these methods is associated with a button on the applet.

```

43 // set up button event handler and buttons
44 ButtonHandler handler = new ButtonHandler();
45
46 // create Play JButton
47 playJButton = new JButton( "Play" );
48 playJButton.addActionListener( handler );
49 add( playJButton );
50
51 // create Loop JButton
52 loopJButton = new JButton( "Loop" );
53 loopJButton.addActionListener( handler );
54 add( loopJButton );
55
56 // create Stop JButton
57 stopJButton = new JButton( "Stop" );
58 stopJButton.addActionListener( handler );
59 add( stopJButton );
60
61 // load sounds and set currentSound
62 sound1 = getAudioClip( getDocumentBase(), "welcome.wav" );
63 sound2 = getAudioClip( getDocumentBase(), "hi.au" );
64 currentSound = sound1;
65 } // end method init
66
67 // stop the sound when the user switches web pages
68 public void stop()
69 {
70     currentSound.stop(); // stop AudioClip
71 } // end method stop
72
73 // private inner class to handle button events
74 private class ButtonHandler implements ActionListener
75 {
76     // process play, loop and stop button events
77     public void actionPerformed( ActionEvent actionEvent )
78     {
79         if ( actionEvent.getSource() == playJButton )
80             currentSound.play(); // play AudioClip once
81         else if ( actionEvent.getSource() == loopJButton )
82             currentSound.loop(); // play AudioClip continuously
83         else if ( actionEvent.getSource() == stopJButton )
84             currentSound.stop(); // stop AudioClip
85     } // end method actionPerformed
86 } // end class ButtonHandler
87 } // end class LoadAudioAndPlay

```

Fig. 21.5 | Loading and playing an AudioClip. (Part 2 of 3.)

984 Chapter 21 Multimedia: Applets and Applications

Fig. 21.5 | Loading and playing an AudioClip. (Part 3 of 3.)

Lines 62–63 in the applet's `init` method use `getAudioClip` to load two audio files—a Windows Wave file (`welcome.wav`) and a Sun Audio file (`hi.au`). The user can select which audio clip to play from the `JComboBox` `soundJComboBox`. Note that the applet's `stop` method is overridden at lines 68–71. When the user switches web pages, the applet container calls the applet's `stop` method. This enables the applet to stop playing the audio clip. Otherwise, it continues to play in the background—even if the applet is not displayed in the browser. This is not necessarily a problem, but it can be annoying to the user if the audio clip is looping. The `stop` method is provided here as a convenience to the user.

Look-and-Feel Observation 21.5

When playing audio clips in an applet or application, provide a mechanism for the user to disable the audio.

21.6 Playing Video and Other Media with Java Media Framework

A simple video can concisely and effectively convey a great deal of information. Recognizing the value of bringing extensible multimedia capabilities to Java, Sun Microsystems, Intel and Silicon Graphics worked together to produce the multimedia API Java Media Framework (JMF), discussed briefly in Section 21.1. Using the JMF API, programmers can create Java applications that play, edit, stream and capture many popular media types. While the features of JMF are quite extensive, this section briefly introduces some popular media formats and demonstrates playing video using the JMF API.

IBM and Sun developed the latest JMF specification—version 2.0. Sun also provides a reference implementation of the JMF specification—JMF 2.1.1e—that supports media file types such as **Microsoft Audio/Video Interleave (.avi)**, **Macromedia Flash 2 movies (.swf)**, **Future Splash (.spl)**, **MPEG Layer 3 Audio (.mp3)**, Musical Instrument Digital Interface (MIDI; `.mid` or `.rmi` extensions), **MPEG-1 videos (.mpeg, .mpg)**, **QuickTime (.mov)**, Sun Audio file format (`.au` extension), and Macintosh AIFF file format (`.aif` or `.aiff` extensions). You have already seen some of these file types.

Currently, JMF is available as an extension separate from the Java 2 Software Development Kit. The most recent JMF implementation (2.1.1e) can be downloaded from:

java.sun.com/products/java-media/jmf/2.1.1/download.html

You need to accept the license agreement prior to downloading.

The JMF website provides versions of the JMF that take advantage of the performance features of certain platforms. For example, the JMF Windows Performance Pack provides

21.6 Playing Video and Other Media with Java Media Framework **985**

extensive media and device support for Java programs running on Microsoft Windows platforms. JMF's official website (java.sun.com/products/java-media/jmf) provides continually updated support, information and resources for JMF programmers.

Once the file finishes downloading, open it and follow the on-screen instructions to install the program. Leave all options at their defaults. You may need to restart your computer to finish the installation.

Creating a Simple Media Player

The JMF offers several mechanisms for playing media. The simplest mechanism is using objects that implement interface `Player` declared in package `javax.media`. Package `javax.media` and its subpackages contain the classes that compose the Java Media Framework. To play a media clip you must first create a `URL` object that refers to it. Then pass the `URL` as an argument to static method `createRealizedPlayer` of class `Manager` to obtain a `Player` for the media clip. Class `Manager` declares utility methods for accessing system resources to play and to manipulate media. Figure 21.6 declares a `JPanel` that demonstrates some of these methods.

```

1 // Fig. 21.6: MediaPanel.java
2 // A JPanel that plays media from a URL
3 import java.awt.BorderLayout;
4 import java.awt.Component;
5 import java.io.IOException;
6 import java.net.URL;
7 import javax.media.CannotRealizeException;
8 import javax.media.Manager;
9 import javax.media.NoPlayerException;
10 import javax.media.Player;
11 import javax.swing.JPanel;
12
13 public class MediaPanel extends JPanel
14 {
15     public MediaPanel( URL mediaURL )
16     {
17         setLayout( new BorderLayout() ); // use a BorderLayout
18
19         // Use lightweight components for Swing compatibility
20         Manager.setHint( Manager.LIGHTWEIGHT_RENDERER, true );
21
22         try
23         {
24             // create a player to play the media specified in the URL
25             Player mediaPlayer = Manager.createRealizedPlayer( mediaURL );
26
27             // get the components for the video and the playback controls
28             Component video = mediaPlayer.getVisualComponent();
29             Component controls = mediaPlayer.getControlPanelComponent();
30
31             if ( video != null )
32                 add( video, BorderLayout.CENTER ); // add video component
33

```

Fig. 21.6 | JPanel that plays a media file from a URL. (Part I of 2.)

986 Chapter 21 Multimedia: Applets and Applications

```

34         if ( controls != null )
35             add( controls, BorderLayout.SOUTH ); // add controls
36
37         mediaPlayer.start(); // start playing the media clip
38     } // end try
39     catch ( NoPlayerException noPlayerException )
40     {
41         System.err.println( "No media player found" );
42     } // end catch
43     catch ( CannotRealizeException cannotRealizeException )
44     {
45         System.err.println( "Could not realize media player" );
46     } // end catch
47     catch ( IOException iOException )
48     {
49         System.err.println( "Error reading from the source" );
50     } // end catch
51 } // end MediaPanel constructor
52 } // end class MediaPanel

```

Fig. 21.6 | JPanel that plays a media file from a URL. (Part 2 of 2.)

The constructor (lines 15–51) sets up the JPanel to play the media file specified by the constructor's URL parameter. MediaPanel uses a BorderLayout (line 17). Line 20 invokes static method `setHint` to set the flag `Manager.LIGHTWEIGHT_RENDERER` to true. This instructs the Manager to use a lightweight renderer that is compatible with lightweight Swing components, as opposed to the default heavyweight renderer. Inside the try block (lines 22–38), line 25 invokes static method `createRealizedPlayer` of class Manager to create and realize a Player that plays the media file. When a Player realizes, it identifies the system resources it needs to play the media. Depending on the file, realizing can be a resource-consuming and time-consuming process. Method `createRealizedPlayer` throws three checked exceptions, `NoPlayerException`, `CannotRealizeException` and `IOException`. A `NoPlayerException` indicates that the system could not find a player that can play the file format. A `CannotRealizeException` indicates that the system could not properly identify the resources a media file needs. An `IOException` indicates that there was an error while reading the file. These exceptions are handled in the catch block in lines 39–50.

Line 28 invokes method `getVisualComponent` of Player to get a Component that displays the visual (generally video) aspect of the media file. Line 29 invokes method `getControlPanelComponent` of Player to get a Component that provides playback and media controls. These components are assigned to local variables `video` and `control`, respectively. The `if` statements in lines 31–32 and lines 34–35 add the `video` and the `controls` if they exist. The `video` Component is added to the CENTER region (line 32), so it fills any available space on the JPanel. The `controls` Component, which is added to the SOUTH region, typically provides the following controls:

1. A positioning slider to jump to certain points in the media clip.
2. A pause button.

21.6 Playing Video and Other Media with Java Media Framework **987**

3. A volume button that provides volume control by right clicking and a mute function by left clicking.
4. A media properties button that provides detailed media information by left clicking and frame rate control by right clicking.

Line 37 calls `Player` method `start` to begin playing the media file. Lines 39–50 handle the various exceptions that `createRealizedPlayer` throws.

The application in Fig. 21.7 displays a `JFileChooser` dialog for the user to choose a media file. It then creates a `MediaPanel` that plays the selected file and creates a `JFrame` to display the `MediaPanel`.

```

1 // Fig. 21.7: MediaTest.java
2 // A simple media player
3 import java.io.File;
4 import java.net.MalformedURLException;
5 import java.net.URL;
6 import javax.swing.JFileChooser;
7 import javax.swing.JFrame;
8
9 public class MediaTest
10 {
11     // launch the application
12     public static void main( String args[] )
13     {
14         // create a file chooser
15         JFileChooser fileChooser = new JFileChooser();
16
17         // show open file dialog
18         int result = fileChooser.showOpenDialog( null );
19
20         if ( result == JFileChooser.APPROVE_OPTION ) // user chose a file
21         {
22             URL mediaURL = null;
23
24             try
25             {
26                 // get the file as URL
27                 mediaURL = fileChooser.getSelectedFile().toURL();
28             } // end try
29             catch ( MalformedURLException malformedURLException )
30             {
31                 System.err.println( "Could not create URL for the file" );
32             } // end catch
33
34             if ( mediaURL != null ) // only display if there is a valid URL
35             {
36                 JFrame mediaTest = new JFrame( "Media Tester" );
37                 mediaTest.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
38
39                 MediaPanel mediaPanel = new MediaPanel( mediaURL );
40                 mediaTest.add( mediaPanel );

```

Fig. 21.7 | Test application that creates a `MediaPanel` from a user-selected file. (Part I of 2.)

988 Chapter 21 Multimedia: Applets and Applications

```

41         mediaTest.setSize( 300, 300 );
42         mediaTest.setVisible( true );
43     } // end inner if
44   } // end outer if
45 } // end main
46 } // end class MediaTest

```

Fig. 21.7 | Test application that creates a MediaPanel from a user-selected file. (Part 2 of 2.)

Method `main` (lines 12–46) assigns a new `JFileChooser` to local variable `fileChooser` (line 15), shows an open file dialog (line 18) and assigns the return value to `result`. Line 20 checks `result` to determine whether the user chose a file. To create a `Player` to play the selected media file, you must convert the `File` object returned by `JFileChooser` to a `URL` object. Method `toURL` of class `File` returns a `URL` that points to the `File` on the system, possibly throwing a `MalformedURLException` if it cannot create a `URL` object for the `File`. The `try` statement (lines 24–32) creates a `URL` for the selected file and assigns it to `mediaURL`. The `if` statement in lines 34–44 checks that `mediaURL` is not `null` and creates the GUI components to play the media.

21.7 Wrap-Up

In this chapter, you learned how to make applications more exciting by including sound, images, graphics and video. We introduced Java's multimedia capabilities, including the Java Media Framework API, Java Sound API and Java 3D API. You used classes `Image` and `ImageIcon` to display and manipulate images stored in files, and you learned about the different image formats supported by Java. You created animation by displaying a series of images in a specific order. You used image maps to make an application more interactive. You then learned how to load audio clips, and how to play them either once or in a continuous loop. The chapter concluded with a demonstration of loading and playing video. In the next chapter, you will continue your study of GUI concepts, building on the techniques you learned in Chapter 11.

21.8 Web Resources

www.nasa.gov/multimedia/highlights/index.html

The *NASA Multimedia Gallery* contains a wide variety of images, audio clips and video clips that you can download and use to test your Java multimedia programs.

www.anbg.gov.au/anbg/index.html

The *Australian National Botanic Gardens* website provides links to the sounds of many animals. Try, for example, the *Common Birds* link under the “Animals in the Gardens” section.

www.thefreesite.com

TheFreeSite.com has links to free sounds and clip art.

www.soundcentral.com

SoundCentral provides audio clips in WAV, AU, AIFF and MIDI formats.

www.animationfactory.com

The *Animation Factory* provides thousands of free GIF animations for personal use.

www.clipart.com

ClipArt.com is a subscription-based service for images and sounds.

www.pngart.com

PNGART.com provides over 50,000 free images in PNG format.

java.sun.com/developer/techDocs/hi/repository/

The *Java look and feel Graphics Repository* provides images designed for use in a Swing GUI, including toolbar button images.

www.freebyte.com/graphicprograms/

This guide contains links to several free graphics software programs. The software can be used to modify images and draw graphics.

graphicssoft.about.com/od/pixelbasedfreewin/

This site provides links for free graphics programs designed for use on Windows machines.

Java Multimedia API References

java.sun.com/products/java-media/jmf/

This is the *Java Media Framework (JMF) API* home page. Here you can download the latest Sun implementation of the JMF. The site also contains the documentation for the JMF.

java.sun.com/products/java-media/speech/

The *Java Speech API* enables programs to perform speech synthesis and speech recognition.

freetts.sourceforge.net/docs/index.php

FreeTTS is an implementation of the Java Speech API.

java.sun.com/products/java-media/2D/

This is the *Java 2D API* home page. This API (introduced in Chapter 12) provides complex two-dimensional graphics capabilities.

java.sun.com/javase/6/docs/technotes/guides/imageio/index.html

This site contains a guide to the *Java Image I/O API*, which enables programs to load and save images using formats that are not currently supported by the Java APIs.

Summary

Section 21.2 Loading, Displaying and Scaling Images

- Applet method `getImage` loads an `Image`.
- Applet method `getDocumentBase` returns the location of the applet's HTML file on the Internet as an object of class `URL`.
- Java supports several image formats, including Graphics Interchange Format (GIF), Joint Photographic Experts Group (JPEG) and Portable Network Graphics (PNG). The file names for these types end with `.gif`, `.jpg` (or `.jpeg`) and `.png`, respectively.
- Class `ImageIcon` provides constructors that allow an `ImageIcon` object to be initialized with an image from the local computer or stored on a web server on the Internet.
- `Graphics` method `drawImage` accepts four arguments—a reference to the `Image` object in which the image is stored, the *x*- and *y*-coordinates where the image should be displayed and a reference to an `ImageObserver` object.
- Another version of `Graphics` method `drawImage` outputs a scaled image. The fourth and fifth arguments specify the width and height of the image for display purposes.
- Interface `ImageObserver` is implemented by class `Component`. `ImageObservers` receive notifications as an `Image` is loaded and update it on the screen if it was not complete when it was displayed.
- `ImageIcon` method `paintIcon` displays the `ImageIcon`'s image. The method requires four arguments—a reference to the `Component` on which the image will be displayed, a reference to the `Graphics` object used to render the image, the *x*-coordinate of the upper-left corner of the image and the *y*-coordinate of the upper-left corner of the image.
- A `URL` object represents a Uniform Resource Locator, which is as a pointer to a resource on the World Wide Web, on your computer or on any networked machine.

Section 21.3 Animating a Series of Images

- `Timer` objects generate `ActionEvents` at fixed millisecond intervals. The `Timer` constructor receives a delay in milliseconds and an `ActionListener`. `Timer` method `start` starts the `Timer`. Method `stop` indicates that the `Timer` should stop generating events. Method `restart` indicates that the `Timer` should start generating events again.

Section 21.4 Image Maps

- An image map is an image that has hot areas that the user can click to accomplish a task, such as loading a different web page into a browser.

Section 21.5 Loading and Playing Audio Clips

- Applet method `play` has two forms:

```
public void play( URL location, String soundFileName );
public void play( URL soundURL );
```

One version loads the audio clip stored in file `soundFileName` from `location` and plays the sound. The other version takes a URL that contains the location and the file name of the audio clip.

- Applet method `getDocumentBase` indicates the location of the HTML file that loaded the applet. Method `getCodeBase` indicates where the `.class` file for an applet is located.
- The sound engine that plays audio clips supports several audio file formats, including Sun Audio file format (`.au` extension), Windows Wave file format (`.wav` extension), Macintosh AIFF file format (`.aif` or `.aiff` extensions) and Musical Instrument Digital Interface (MIDI) file format (`.mid` or `.rmi` extensions). The Java Media Framework (JMF) supports additional formats.
- Applet method `getAudioClip` has two forms that take the same arguments as the `play` method. Method `getAudioClip` returns a reference to an `AudioClip`. `AudioClips` have three methods—`play`, `loop` and `stop`. Method `play` plays the audio clip once. Method `loop` continuously loops the audio clip. Method `stop` terminates an audio clip that is currently playing.

Section 21.6 Playing Video and Other Media with Java Media Framework

- Sun Microsystems, Intel and Silicon Graphics worked together to produce the Java Media Framework (JMF).
- Package `javax.media` and its subpackages contain the classes that compose the Java Media Framework.
- Class `Manager` declares utility methods for accessing system resources to play and to manipulate media.
- Method `toURL` of class `File` returns a URL that points to the `File` on the system.

Terminology

.aif file extension	<code>getMinimumSize</code> method of class <code>Component</code>
.aiff file extension	<code>getPreferredSize</code> method of class <code>Component</code>
.au file extension	<code>getVisualComponent</code> method of interface <code>Player</code>
audio clip	<code>.gif</code> file extension
<code>AudioClip</code> interface	<code>Graphics</code> class
.avi file extension	Graphics Interchange Format (GIF)
<code>CannotRealizePlayerException</code> exception	hot area
<code>createRealizedPlayer</code> method of class <code>Manager</code>	<code>Image</code> class
<code>Dimension</code> class	image map
<code>drawImage</code> method of class <code>Graphics</code>	<code>ImageIcon</code> class
Future Splash (<code>.spl</code>) files	<code>ImageObserver</code> interface
<code>getAudioClip</code> method of class <code>Applet</code>	Java 3D API
<code>getCodeBase</code> method of class <code>Applet</code>	Java Advanced Imaging API
<code>getControlPanelComponent</code> method of interface <code>Player</code>	Java Image I/O API
<code>getDocumentBase</code> method of class <code>Applet</code>	Java Media Framework (JMF) API
<code>getImage</code> method of class <code>Applet</code>	Java Sound API

992 Chapter 21 Multimedia: Applets and Applications

Java Speech API	paintIcon method of class ImageIcon
javax.media package	play method of class Applet
Joint Photographic Experts Group (JPEG)	play method of interface AudioClip
.jpeg file extension	Player interface
.jpg file extension	.png file extension
LIGHTWEIGHT_RENDERER constant of class Manager	Portable Network Graphics (PNG)
loop method of interface AudioClip	QuickTime (.mov) files
Macintosh AIFF file format (.aif or .aiff extensions)	.rmi file extension
Macromedia Flash 2 movies (.swf)	setHint method of class Manager
Manager class	showStatus method of class Applet
Microsoft Audio/Video Interleave (.avi) file	sound
.mid file extension	sound engine
.mov file extension	.spl file extension
.mp3 file extension	start method of interface Player
.mpeg file extension	stop method of class Timer
MPEG Layer 3 Audio (.mp3) files	stop method of interface AudioClip
MPEG-1 videos (.mpeg, .mpg)	Sun Audio file format (.au extension)
.mpg file extension	.swf file extension

NoPlayerException exception	video
	.wav file extension
	Windows Wave file format (.wav extension)

Self-Review Exercises

- 21.1** Fill in the blanks in each of the following statements:
- Applet method _____ loads an image into an applet.
 - Graphics method _____ displays an image on an applet.
 - Java provides two mechanisms for playing sounds in an applet—the Applet's play method and the play method of the _____ interface.
 - A(n) _____ is an image that has hot areas that the user can click to accomplish a task such as loading a web page.
 - Method _____ of class ImageIcon displays the ImageIcon's image.
 - Java supports several image formats, including _____, _____ and _____.
- 21.2** Determine whether each of the following statements is *true* or *false*. If *false*, explain why.
- A sound is marked for garbage collection after it plays.
 - Class ImageIcon provides constructors that allow an ImageIcon object to be initialized only with an image from the local computer.
 - Method play of class AudioClip continuously loops an audio clip.
 - The Java Image I/O API is used for adding 3D graphics to a Java application.
 - Applet method getDocumentBase returns, as an object of class URL, the location on the Internet of the HTML file that invoked the applet.

Answers to Self-Review Exercises

- 21.1** a) getImage. b) drawImage. c) AudioClip. d) image map. e) paintIcon. f) Graphics Interchange Format (GIF), Joint Photographic Experts Group (JPEG), Portable Network Graphics (PNG).

Exercises 993

21.2 a) True. b) False. `ImageIcon` can load images from the Internet as well. c) False. Method `play` of class `AudioClip` plays an audio clip once. Method `loop` of class `AudioClip` continuously loops an audio clip. d) False. The Java 3D API is used for creating and modifying 3D graphics. The Java Image I/O API is used for reading from and outputting images to files. e) True.

Exercises

21.3 Describe how to make an animation “browser friendly.”

21.4 Describe the Java methods for playing and manipulating audio clips.

21.5 Explain how image maps are used. List several examples of their use.

21.6 (*Randomly Erasing an Image*) Suppose an image is displayed in a rectangular screen area. One way to erase the image is simply to set every pixel to the same color immediately, but this is a dull visual effect. Write a Java program that displays an image and then erases it by using random-number generation to select individual pixels to erase. After most of the image is erased, erase all the remaining pixels at once. You can draw individual pixels as a line that starts and ends at the same coordinates. You might try several variants of this problem. For example, you might display lines randomly or display shapes randomly to erase regions of the screen.

21.7 (*Text Flasher*) Create a Java program that repeatedly flashes text on the screen. Do this by alternating the text with a plain background-color image. Allow the user to control the “blink speed” and the background color or pattern. You will need to use methods `getDelay` and `setDelay` of class `Timer`. These methods are used to retrieve and set the interval in milliseconds between Action-Events, respectively

21.8 (*Image Flasher*) Create a Java program that repeatedly flashes an image on the screen. Do this by alternating the image with a plain background-color image.

21.9 (*Digital Clock*) Implement a program that displays a digital clock on the screen.

21.10 (*Calling Attention to an Image*) If you want to emphasize an image, you might place a row of simulated light bulbs around it. You can let the light bulbs flash in unison or fire on and off in sequence one after the other.

21.11 (*Image Zooming*) Create a program that enables you to zoom in on or out from an image.

Special Section: Challenging Multimedia Projects

The preceding exercises are keyed to the text and designed to test the reader’s understanding of fundamental multimedia concepts. This section includes a collection of advanced multimedia projects. The reader should find these problems challenging, yet entertaining. The problems vary considerably in difficulty. Some require an hour or two of program writing and implementation. Others are useful for lab assignments that might require two or three weeks of study and implementation. Some are challenging term projects. [Note to Instructors: Solutions are not provided for these exercises.]

21.12 (*Animation*) Create a general-purpose Java animation program. It should allow the user to specify the sequence of frames to be displayed, the speed at which the images are displayed, audios to be played while the animation is running and so on.

21.13 (*Limericks*) Modify the limerick-writing program you wrote in Exercise 10.10 to sing the limericks your program creates.

21.14 (*Random Interimage Transition*) This provides a nice visual effect. If you are displaying one image in a given area on the screen and you would like to transition to another image in the same area, store the new screen image in an off-screen buffer and randomly copy pixels from it to the dis-

994 Chapter 21 Multimedia: Applets and Applications

play area, overlaying the pixels already at those locations. When the vast majority of the pixels have been copied, copy the entire new image to the display area to be sure you are displaying the complete new image. To implement this program, you may need to use the `PixelGrabber` and `MemoryImageSource` classes (see the Java API documentation for descriptions of these classes). You might try several variants of this problem. For example, try selecting all the pixels in a randomly selected straight line or shape in the new image, and overlay them above the corresponding positions of the old image.

21.15 (*Background Audio*) Add background audio to one of your favorite applications by using the `loop` method of class `AudioClip` to play the sound in the background while you interact with your application in the normal way.

21.16 (*Scrolling Marquee Sign*) Create a Java program that scrolls dotted characters from right to left (or from left to right if that is appropriate for your language) across a marquee-like display sign. As an option, display the text in a continuous loop, so that after the text disappears at one end, it reappears at the other.

21.17 (*Scrolling Image Marquee*) Create a Java program that scrolls an image across a marquee screen.

21.18 (*Analog Clock*) Create a Java program that displays an analog clock with hour, minute and second hands that move appropriately as the time changes.

21.19 (*Dynamic Audio and Graphical Kaleidoscope*) Write a kaleidoscope program that displays reflected graphics to simulate the popular children's toy. Incorporate audio effects that "mirror" your program's dynamically changing graphics.

21.20 (*Automatic Jigsaw Puzzle Generator*) Create a Java jigsaw puzzle generator and manipulator. The user specifies an image. Your program loads and displays the image, then breaks it into randomly selected shapes and shuffles them. The user then uses the mouse to move the pieces around to solve the puzzle. Add appropriate audio sounds as the pieces are moved around and snapped back into place. You might keep tabs on each piece and where it really belongs—then use audio effects to help the user get the pieces into the correct positions.

21.21 (*Maze Generator and Walker*) Develop a multimedia-based maze generator and traverser program based on the maze programs you wrote in Exercises 15.20–15.22. Let the user customize the maze by specifying the number of rows and columns and by indicating the level of difficulty. Have an animated mouse walk the maze. Use audio to dramatize the movement of your mouse character.

21.22 (*One-Armed Bandit*) Develop a multimedia simulation of a "one-armed bandit." Have three spinning wheels. Place images of various fruits and symbols on each wheel. Use true random-number generation to simulate the spinning of each wheel and the stopping of each wheel on a symbol.

21.23 (*Horse Race*) Create a Java simulation of a horse race. Have multiple contenders. Use audios for a race announcer. Play the appropriate audios to indicate the correct status of each contender throughout the race. Use audios to announce the final results. You might try to simulate the kinds of horse-racing games that are often played at carnivals. The players take turns at the mouse and have to perform some skill-oriented manipulation with it to advance their horses.

21.24 (*Shuffleboard*) Develop a multimedia-based simulation of the game of shuffleboard. Use appropriate audio and visual effects.

21.25 (*Game of Pool*) Create a multimedia-based simulation of the game of pool. Each player takes turns using the mouse to position a pool cue and hit it against the ball at the appropriate angle to try to make other balls fall into the pockets. Your program should keep score.

21.26 (*Artist*) Design a Java art program that will give an artist a great variety of capabilities to draw, use images and use animations to create a dynamic multimedia art display.

Special Section: Challenging Multimedia Projects **995**

21.27 (*Fireworks Designer*) Create a Java program that someone might use to create a fireworks display. Create a variety of fireworks demonstrations. Then orchestrate the firing of the fireworks for maximum effect.

21.28 (*Floor Planner*) Develop a Java program that will help someone arrange furniture in a home. Add features that enable the person to achieve the best possible arrangement.

21.29 (*Crossword*) Crossword puzzles are among the most popular pastimes. Develop a multimedia-based crossword-puzzle program. Your program should enable the player to place and erase words easily. Tie your program to a large computerized dictionary. Your program also should be able to suggest words on which letters have already been filled in. Provide other features that will make the crossword-puzzle enthusiast's job easier.

21.30 (*15 Puzzle*) Write a multimedia-based Java program that enables the user to play the game of 15. The game is played on a 4-by-4 board for a total of 16 slots. One slot is empty, the others are occupied by 15 tiles numbered 1 through 15. Any tile next to the currently empty slot can be moved into that slot by clicking on the tile. Your program should create the board with the tiles out of order. The goal is to arrange the tiles into sequential order, row by row.

21.31 (*Reaction Time/Reaction Precision Tester*) Create a Java program that moves a randomly created shape around the screen. The user moves the mouse to catch and click on the shape. The shape's speed and size can be varied. Keep statistics on how much time the user typically takes to catch a shape of a given size. The user will probably have more difficulty catching faster-moving, smaller shapes.

21.32 (*Calendar/Tickler File*) Using both audio and images, create a general-purpose calendar and "tickler" file. For example, the program should sing "Happy Birthday" when you use it on your birthday. Have the program display images and play audios associated with important events. Also, have the program remind you in advance of these important events. It would be nice, for example, to have the program give you a week's notice so you can pick up an appropriate greeting card for that special person.

21.33 (*Rotating Images*) Create a Java program that lets you rotate an image through some number of degrees (out of a maximum of 360 degrees). The program should let you specify that you want to spin the image continuously. It should let you adjust the spin speed dynamically.

21.34 (*Coloring Black-and-White Photographs and Images*) Create a Java program that lets you paint a black-and-white photograph with color. Provide a color palette for selecting colors. Your program should let you apply different colors to different regions of the image.

21.35 (*Multimedia-Based Simpletron Simulator*) Modify the Simpletron simulator that you developed in the exercises in the previous chapters (Exercises 7.34—7.36 and Exercises 17.26—17.30) to include multimedia features. Add computer-like sounds to indicate that the Simpletron is executing instructions. Add a breaking-glass sound when a fatal error occurs. Use flashing lights to indicate which cells of memory or which registers are currently being manipulated. Use other multimedia techniques, as appropriate, to make your Simpletron simulator more valuable to its users as an educational tool.

22

GUI Components: Part 2

OBJECTIVES

In this chapter you will learn:

- To create and manipulate sliders, menus, pop-up menus and windows.
- To change the look-and-feel of a GUI, using Swing's pluggable look-and-feel.
- To create a multiple-document interface with `JDesktopPane` and `JInternalFrame`.
- To use additional layout managers.

*An actor entering through
the door, you've got nothing.
But if he enters through the
window, you've got a
situation.*

—Billy Wilder

*...the force of events wakes
slumberous talents.*

—Edward Hoagland

*You and I would see more
interesting photography if
they would stop worrying,
and instead, apply horse-
sense to the problem of
recording the look and feel of
their own era.*

—Jessie Tarbox Beals

Outline

- 22.1** Introduction
- 22.2** `JSlider`
- 22.3** Windows: Additional Notes
- 22.4** Using Menus with Frames
- 22.5** `JPopupMenu`
- 22.6** Pluggable Look-and-Feel
- 22.7** `JDesktopPane` and `JInternalFrame`
- 22.8** `JTabbedPane`
- 22.9** Layout Managers: `BoxLayout` and `GridBagLayout`
- 22.10** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

22.1 Introduction

In this chapter, we continue our study of GUIs. We discuss additional components and layout managers and lay the groundwork for building more complex GUIs.

We begin our discussion with menus that enable the user to effectively perform tasks in the program. The look-and-feel of a Swing GUI can be uniform across all platforms on which a Java program executes, or the GUI can be customized by using Swing's [pluggable look-and-feel \(PLAF\)](#). We provide an example that illustrates how to change between Swing's default metal look-and-feel (which looks and behaves the same across platforms), a look-and-feel that simulates [Motif](#) (a popular UNIX look-and-feel) and one that simulates Microsoft's Windows look-and-feel.

Many of today's applications use a multiple-document interface (MDI)—a main window (often called the parent window) containing other windows (often called child windows) to manage several open documents in parallel. For example, many e-mail programs allow you to have several e-mail windows open at the same time so that you can compose or read multiple e-mail messages. We demonstrate Swing's classes for creating multiple-document interfaces. The chapter finishes with a series of examples discussing additional layout managers for organizing graphical user interfaces.

Swing is a large and complex topic. There are many more GUI components and capabilities than can be presented here. Several more Swing GUI components are introduced in the remaining chapters of this book as they are needed. Our book *Advanced Java 2 Platform How to Program* discusses other, more advanced Swing components and capabilities.

22.2 `JSlider`

[JSliders](#) enable a user to select from a range of integer values. Class `JSlider` inherits from `JComponent`. Figure 22.1 shows a horizontal `JSlider` with [tick marks](#) and the [thumb](#) that allows a user to select a value. `JSliders` can be customized to display major tick marks,

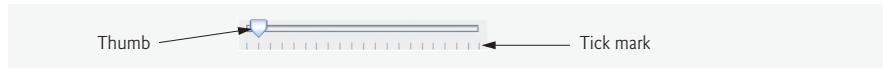

Fig. 22.1 | `JSlider` component with horizontal orientation.

998 Chapter 22 GUI Components: Part 2

minor tick marks and labels for the tick marks. They also support **snap-to ticks**, which cause the thumb, when positioned between two tick marks, to snap to the closest one.

Most Swing GUI components support user interactions through the mouse and the keyboard. For example, if a `JSlider` has the focus (i.e., it is the currently selected GUI component in the user interface), the left arrow key and right arrow key cause the thumb of the `JSlider` to decrease or increase by 1, respectively. The down arrow key and up arrow key also cause the thumb of the `JSlider` to decrease or increase by 1 tick, respectively. The `PgDn` (page down) key and `PgUp` (page up) key cause the thumb of the `JSlider` to decrease or increase by **block increments** of one-tenth of the range of values, respectively. The *Home* key moves the thumb to the minimum value of the `JSlider`, and the *End* key moves the thumb to the maximum value of the `JSlider`.

`JSliders` have either a horizontal orientation or a vertical orientation. For a horizontal `JSlider`, the minimum value is at the left end of the `JSlider` and the maximum is at the right end. For a vertical `JSlider`, the minimum value is at the bottom and the maximum is at the top. The minimum and maximum value positions on a `JSlider` can be reversed by invoking `JSlider` method `setInverted` with boolean argument `true`. The relative position of the thumb indicates the current value of the `JSlider`.

The program in Figs. 22.2–22.4 allows the user to size a circle drawn on a subclass of `JPanel` called `OvalPanel` (Fig. 22.2). The user specifies the circle's diameter with a horizontal `JSlider`. Class `OvalPanel` knows how to draw a circle on itself, using its own instance variable `diameter` to determine the diameter of the circle—the `diameter` is used as the width and height of the bounding box in which the circle is displayed. The `diameter` value is set when the user interacts with the `JSlider`. The event handler calls method `setDiameter` in class `OvalPanel` to set the `diameter` and calls `repaint` to draw the new circle. The `repaint` call results in a call to `OvalPanel`'s `paintComponent` method.

```

1 // Fig. 22.2: OvalPanel.java
2 // A customized JPanel class.
3 import java.awt.Graphics;
4 import java.awt.Dimension;
5 import javax.swing.JPanel;
6
7 public class OvalPanel extends JPanel
8 {
9     private int diameter = 10; // default diameter of 10
10
11    // draw an oval of the specified diameter
12    public void paintComponent( Graphics g )
13    {
14        super.paintComponent( g );
15
16        g.fillOval( 10, 10, diameter, diameter ); // draw circle
17    } // end method paintComponent
18
19    // validate and set diameter, then repaint
20    public void setDiameter( int newDiameter )
21    {

```

Fig. 22.2 | `JPanel` subclass for drawing circles of a specified diameter. (Part I of 2.)

22.2 JSlider 999

```

22     // if diameter invalid, default to 10
23     diameter = ( newDiameter >= 0 ? newDiameter : 10 );
24     repaint(); // repaint panel
25 } // end method setDiameter
26
27 // used by layout manager to determine preferred size
28 public Dimension getPreferredSize()
29 {
30     return new Dimension( 200, 200 );
31 } // end method getPreferredSize
32
33 // used by layout manager to determine minimum size
34 public Dimension getMinimumSize()
35 {
36     return getPreferredSize();
37 } // end method getMinimumSize
38 } // end class OvalPanel

```

Fig. 22.2 | JPanel subclass for drawing circles of a specified diameter. (Part 2 of 2.)

Class `OvalPanel` (Fig. 22.2) contains a `paintComponent` method (lines 12–17) that draws a filled oval (a circle in this example), a `setDiameter` method (lines 20–25) that changes the circle's diameter and repaints the `OvalPanel`, a `getPreferredSize` method (lines 28–31) that returns the preferred width and height of an `OvalPanel` and a `getMinimumSize` method (lines 34–37) that returns an `OvalPanel`'s minimum width and height.

Look-and-Feel Observation 22.1

If a new GUI component has a minimum width and height (i.e., smaller dimensions would render the component ineffective on the display), override method `getMinimumSize` to return the minimum width and height as an instance of class `Dimension`.

Software Engineering Observation 22.1

For many GUI components, method `getMinimumSize` is implemented to return the result of a call to the component's `getPreferredSize` method.

Class `SliderFrame` (Fig. 22.3) creates the `JSlider` that controls the diameter of the circle. Class `SliderFrame`'s constructor (lines 17–45) creates `OvalPanel` object `myPanel` (line 21) and sets its background color (line 22). Lines 25–26 create `JSlider` object `diameterSlider` to control the diameter of the circle drawn on the `OvalPanel`. The `JSlider` constructor takes four arguments. The first argument specifies the orientation of `diameterSlider`, which is `HORIZONTAL` (a constant in interface `SwingConstants`). The second and third arguments indicate the minimum and maximum integer values in the range of values for this `JSlider`. The last argument indicates that the initial value of the `JSlider` (i.e., where the thumb is displayed) should be 10.

Lines 27–28 customize the appearance of the `JSlider`. Method `setMajorTickSpacing` indicates that each major tick mark represents 10 values in the range of values supported by the `JSlider`. Method `setPaintTicks` with a true argument indicates that the tick marks should be displayed (they are not displayed by default). For other methods that are used to customize a `JSlider`'s appearance, see the `JSlider` on-line documentation (java.sun.com/javase/6/docs/api/javax/swing/JSlider.html).

2 // Using JSliders to size an oval.
3 import java.awt.BorderLayout;
4 import java.awt.Color;
5 import javax.swing.JFrame;
6 import javax.swing.JSlider;
7 import javax.swing.SwingConstants;
8 import javax.swing.event.ChangeListener;
9 import javax.swing.event.ChangeEvent;

10 public class SliderFrame extends JFrame
11 {
12     private JSlider diameterJSlider; // slider to select diameter
13     private OvalPanel myPanel; // panel to draw circle
14
15     // no-argument constructor
16     public SliderFrame()
17     {
18         super( "Slider Demo" );
19
20         myPanel = new OvalPanel(); // create panel to draw circle
21         myPanel.setBackground( Color.YELLOW ); // set background to yellow
22
23         // set up JSlider to control diameter value
24         diameterJSlider =
25             new JSlider( SwingConstants.HORIZONTAL, 0, 200, 10 );
26         diameterJSlider.setMajorTickSpacing( 10 ); // create tick every 10
27         diameterJSlider.setPaintTicks( true ); // paint ticks on slider
28
29         // register JSlider event listener
30         diameterJSlider.addChangeListener(
31
32             new ChangeListener() // anonymous inner class
33             {
34                 // handle change in slider value
35                 public void stateChanged( ChangeEvent e )
36                 {
37                     myPanel.setDiameter( diameterJSlider.getValue() );
38                 } // end method stateChanged
39             } // end anonymous inner class
40         ); // end call to addChangeListener
41
42         add( diameterJSlider, BorderLayout.SOUTH ); // add slider to frame
43         add( myPanel, BorderLayout.CENTER ); // add panel to frame
44     } // end SliderFrame constructor
45 } // end class SliderFrame

```

Fig. 22.3 | JSlider value used to determine the diameter of a circle.

JSliders generate **ChangeEvents** (package javax.swing.event) in response to user interactions. An object of a class that implements interface **ChangeListener** (package javax.swing.event) and declares method **stateChanged** can respond to ChangeEvents. Lines 31–41 register a ChangeListener to handle diameterSlider's events. When

```

1 // Fig. 22.4: SliderDemo.java
2 // Testing SliderFrame.
3 import javax.swing.JFrame;
4
5 public class SliderDemo
6 {
7     public static void main( String args[] )
8     {
9         SliderFrame sliderFrame = new SliderFrame();
10        sliderFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        sliderFrame.setSize( 220, 270 ); // set frame size
12        sliderFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class SliderDemo

```

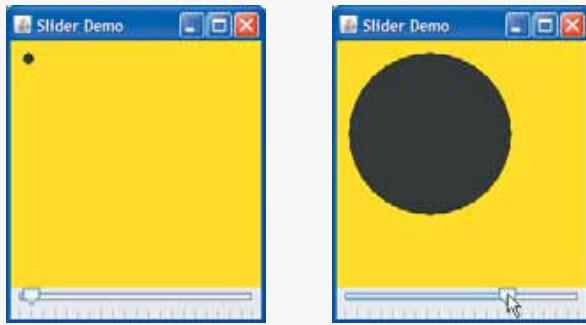

Fig. 22.4 | Test class for `SliderFrame`.

method `stateChanged` (lines 36–39) is called in response to a user interaction, line 38 calls `myPanel's setDiameter` method and passes the current value of the `JSlider` as an argument. `JSlider` method `getValue` returns the current thumb position.

22.3 Windows: Additional Notes

In this section, we discuss several important `JFrame` issues. A `JFrame` is a `window` with a `title bar` and a `border`. Class `JFrame` is a subclass of `java.awt.Frame` (which is a subclass of `java.awt.Window`). As such, `JFrame` is one of the few Swing GUI components that is not a lightweight GUI component. When you display a window from a Java program, the window is provided by the local platform's windowing toolkit, and therefore the window will look like every other window displayed on that platform. When a Java application executes on a Macintosh and displays a window, the window's title bar and borders will look like those of other Macintosh applications. When a Java application executes on a Microsoft Windows system and displays a window, the window's title bar and borders will look like those of other Microsoft Windows applications. And when a Java application executes on a UNIX platform and displays a window, the window's title bar and borders will look like other UNIX applications on that platform.

Class `JFrame` supports three operations when the user closes the window. By default, a window is hidden (i.e., removed from the screen). This can be controlled with `JFrame`

1002 Chapter 22 GUI Components: Part 2

method `setDefaultCloseOperation`. Interface `WindowConstants` (package `javax.swing`), which class `JFrame` implements, declares three constants—`DISPOSE_ON_CLOSE`, `DO NOTHING_ON_CLOSE` and `HIDE_ON_CLOSE` (the default)—for use with this method. Some platforms allow only a limited number of windows to be displayed on the screen. Thus, a window is a valuable resource that should be given back to the system when it is no longer needed. Class `Window` (an indirect superclass of `JFrame`) declares method `dispose` for this purpose. When a `Window` is no longer needed in an application, you should explicitly dispose of it. This can be done by calling the `Window`'s `dispose` method or by calling method `setDefaultCloseOperation` with the argument `WindowConstants.DISPOSE_ON_CLOSE`. Terminating an application will return window resources to the system. Setting the default close operation to `DO NOTHING_ON_CLOSE` indicates that the program will determine what to do when the user indicates that the window should be closed.

**Performance Tip 22.1**

A window is an expensive system resource. Return it to the system by calling its `dispose` method when the window is no longer needed.

By default, a window is not displayed on the screen until the program invokes the window's `setVisible` method (inherited from class `java.awt.Component`) with a `true` argument. A window's size should be set with a call to method `setSize` (inherited from class `java.awt.Component`). The position of a window when it appears on the screen is specified with method `setLocation` (inherited from class `java.awt.Component`).

**Common Programming Error 22.1**

Forgetting to call method `setVisible` on a window is a runtime logic error—the window is not displayed.

**Common Programming Error 22.2**

Forgetting to call the `setSize` method on a window is a runtime logic error—only the title bar appears.

When the user manipulates the window, this action generates `window events`. Event listeners are registered for window events with `Window` method `addWindowListener`. Interface `WindowListener` provides seven window-event-handling methods—`windowActivated` (called when the user makes a window the active window), `windowClosed` (called after the window is closed), `windowClosing` (called when the user initiates closing of the window), `windowDeactivated` (called when the user makes another window the active window), `windowDeiconified` (called when the user restores a window from being minimized), `windowIconified` (called when the user minimizes a window) and `windowOpened` (called when a program first displays a window on the screen).

22.4 Using Menus with Frames

Menus are an integral part of GUIs. Menus allow the user to perform actions without unnecessarily cluttering a GUI with extra components. In Swing GUIs, menus can be attached only to objects of the classes that provide method `setJMenuBar`. Two such classes are `JFrame` and `JApplet`. The classes used to declare menus are `JMenuBar`, `JMenu`, `JMenuItem`, `JCheckBoxMenuItem` and class `JRadioButtonMenuItem`.

Look-and-Feel Observation 22.2

Menus simplify GUIs because components can be hidden within them. These components will be visible only when the user looks for them by selecting the menu.

Class `JMenuBar` (a subclass of `JComponent`) contains the methods necessary to manage a **menu bar**, which is a container for menus. Class `JMenu` (a subclass of `javax.swing.JMenuItem`) contains the methods necessary for managing menus. Menus contain menu items and are added to menu bars or to other menus as submenus. When a menu is clicked, it expands to show its list of menu items.

Class `JMenuItem` (a subclass of `javax.swing.AbstractButton`) contains the methods necessary to manage **menu items**. A menu item is a GUI component inside a menu that, when selected, causes an action event. A menu item can be used to initiate an action, or it can be a **submenu** that provides more menu items from which the user can select. Submenus are useful for grouping related menu items in a menu.

Class `JCheckBoxMenuItem` (a subclass of `javax.swing.JMenuItem`) contains the methods necessary to manage menu items that can be toggled on or off. When a `JCheckBoxMenuItem` is selected, a check appears to the left of the menu item. When the `JCheckBoxMenuItem` is selected again, the check is removed.

Class `JRadioButtonMenuItem` (a subclass of `javax.swing.JMenuItem`) contains the methods necessary to manage menu items that can be toggled on or off like `JCheckBoxMenuItem`s. When multiple `JRadioButtonMenuItem`s are maintained as part of a **Button-Group**, only one item in the group can be selected at a given time. When a `JRadioButtonMenuItem` is selected, a filled circle appears to the left of the menu item. When another `JRadioButtonMenuItem` is selected, the filled circle of the previously selected menu item is removed.

The application in Figs. 22.5–22.6 demonstrates various menu items and how to specify special characters called **mnemonics** that can provide quick access to a menu or menu item from the keyboard. Mnemonics can be used with all subclasses of `javax.swing.AbstractButton`.

Class `MenuFrame` (Fig. 22.5) declares the GUI components and event handling for the menu items. Most of the code in this application appears in the class's constructor (lines 34–151).

7     public static void main( String args[] )
8     {
9         MenuFrame menuFrame = new MenuFrame(); // create MenuFrame
10        menuFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        menuFrame.setSize( 500, 200 ); // set frame size
12        menuFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class MenuTest

```

Fig. 22.6 | Test class for MenuFrame. (Part 1 of 2.)

1008 Chapter 22 GUI Components: Part 2

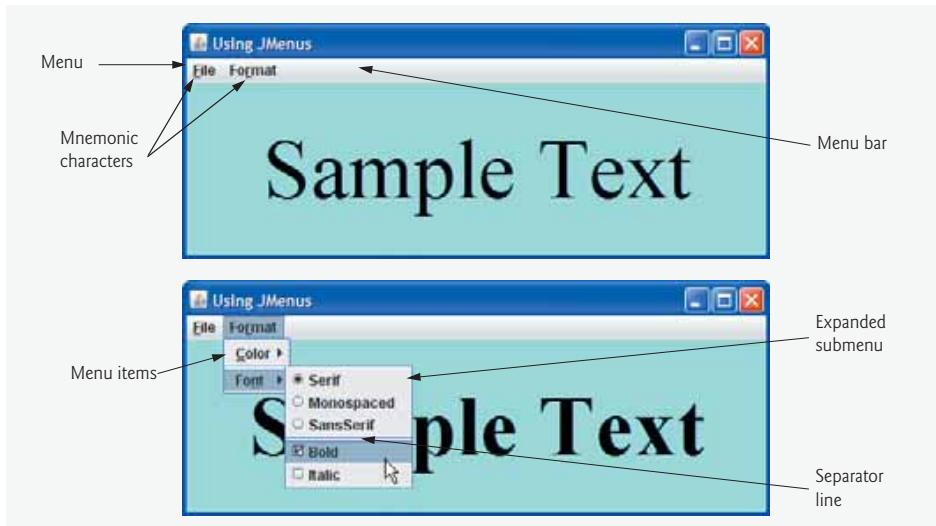

Fig. 22.6 | Test class for `MenuFrame`. (Part 2 of 2.)

Lines 38–76 set up the `File` menu and attach it to the menu bar. The `File` menu contains an `About...` menu item that displays a message dialog when the menu item is selected and an `Exit` menu item that can be selected to terminate the application.

Line 38 creates a `JMenu` and passes to the constructor the string "File" as the name of the menu. Line 39 uses `JMenu` method `setMnemonic` (inherited from class `AbstractButton`) to indicate that `F` is the mnemonic for this menu. Pressing the `Alt` key and the letter `F` opens the menu, just as clicking the menu name with the mouse would. In the GUI, the mnemonic character in the menu's name is displayed with an underline. (See the screen captures in Fig. 22.6.)

Look-and-Feel Observation 22.3

Mnemonics provide quick access to menu commands and button commands through the keyboard.

Look-and-Feel Observation 22.4

Different mnemonics should be used for each button or menu item. Normally, the first letter in the label on the menu item or button is used as the mnemonic. If several buttons or menu items start with the same letter, choose the next most prominent letter in the name (e.g., `x` is commonly chosen for a button or menu item called `Exit`).

Lines 42–43 create `JMenuItem` `aboutItem` with the text "About..." and set its mnemonic to the letter `A`. This menu item is added to `fileMenu` at line 44 with `JMenu` method `add`. To access the `About...` menu item through the keyboard, press the `Alt` key and letter `F` to open the `File` menu, then press `A` to select the `About...` menu item. Lines 47–56 create an `ActionListener` to process `aboutItem`'s action event. Lines 52–54 display a message dialog box. In most prior uses of `showMessageDialog`, the first argument was `null`. The purpose of the first argument is to specify the `parent window` that helps determine where

22.4 Using Menus with Frames 1009

the dialog box will be displayed. If the parent window is specified as `null`, the dialog box appears in the center of the screen. Otherwise, it appears centered over the specified parent window. In this example, the program specifies the parent window with `MenuTest.this`—the `this` reference of the `MenuTest` object. When using the `this` reference in an inner class, specifying `this` by itself refers to the inner-class object. To reference the outer-class object's `this` reference, qualify `this` with the outer-class name and a dot (.)).

Dialog boxes are typically modal. A **modal dialog box** does not allow any other window in the application to be accessed until the dialog box is dismissed. The dialogs displayed with class `JOptionPane` are modal dialogs. Class `JDialog` can be used to create your own modal or nonmodal dialogs.

Lines 59–72 create menu item `exitItem`, set its mnemonic to `x`, add it to `fileMenu` and register an `ActionListener` that terminates the application when the user selects `exitItem`.

Lines 74–76 create the `JMenuBar`, attach it to the application window with `JFrame` method `setJMenuBar` and use `JMenuBar` method `add` to attach the `fileMenu` to the `JMenuBar`.

**Common Programming Error 22.3**

Forgetting to set the menu bar with `JFrame` method `setJMenuBar` prevents the menu bar from displaying in the `JFrame`.

**Look-and-Feel Observation 22.5**

Menus appear left to right in the order that they are added to a `JMenuBar`.

Lines 78–79 create menu `formatMenu` and set its mnemonic to `r`. (`F` is not used because that is the `File` menu's mnemonic.)

Lines 84–85 create menu `colorMenu` (this will be a submenu in the `Format` menu) and set its mnemonic to `C`. Line 88 creates `JRadioButtonMenuItem` array `colorItems`, which refers to the menu items in `colorMenu`. Line 89 creates `ButtonGroup` `colorGroup`, which will ensure that only one of the menu items in the `Color` submenu is selected at a time. Line 90 creates an instance of inner class `ItemHandler` (declared at lines 154–181) that responds to selections from the `Color` and `Font` submenus (discussed shortly). The `for` statement at lines 93–100 creates each `JRadioButtonMenuItem` in array `colorItems`, adds each menu item to `colorMenu` and to `colorGroup` and registers the `ActionListener` for each menu item.

Line 102 invokes `AbstractButton` method `setSelected` to select the first element in array `colorItems`. Line 104 adds `colorMenu` as a submenu of `formatMenu`. Line 105 invokes `JMenu` method `addSeparator` to add a horizontal `separator` line to the menu.

**Look-and-Feel Observation 22.6**

A submenu is created by adding a menu as a menu item in another menu. When the mouse is positioned over a submenu (or the submenu's mnemonic is pressed), the submenu expands to show its menu items.

**Look-and-Feel Observation 22.7**

Separators can be added to a menu to group menu items logically.

1010 Chapter 22 GUI Components: Part 2**Look-and-Feel Observation 22.8**

Any lightweight GUI component (i.e., a component that is a subclass of JComponent) can be added to a JMenu or to a JMenuBar.

Lines 108–126 create the **Font** submenu and several **JRadioButtonMenuItem**s and select the first element of **JRadioButtonMenuItem** array **fonts**. Line 129 creates a **JCheckBoxMenuItem** array to represent the menu items for specifying bold and italic styles for the fonts. Line 130 creates an instance of inner class **StyleHandler** (declared at lines 184–203) to respond to the **JCheckBoxMenuItem** events. The **for** statement at lines 133–139 creates each **JCheckBoxMenuItem**, adds each menu item to **fontMenu** and registers the **ItemListener** for each menu item. Line 141 adds **fontMenu** as a submenu of **formatMenu**. Line 142 adds the **formatMenu** to **bar** (the menu bar).

Lines 145–147 create a **JLabel** for which the **Format** menu items control the font, font color and font style. The initial foreground color is set to the first element of array **colorValues** (**Color.BLACK**) by invoking **JComponent** method **setForeground**, and the initial font is set to **Serif** with **PLAIN** style and 72-point size. Line 149 sets the background color of the window's content pane to cyan, and line 150 attaches the **JLabel** to the **CENTER** of the content pane's **BorderLayout**.

ItemHandler method **actionPerformed** (lines 157–180) uses two **for** statements to determine which font or color menu item generated the event and sets the font or color of the **JLabel** **displayLabel**, respectively. The **if** condition at line 162 uses **AbstractButton** method **isSelected** to determine the selected **JRadioButtonMenuItem**. The **if** condition at line 172 invokes the event object's **getSource** method to get a reference to the **JRadioButtonMenuItem** that generated the event. Line 175 invokes **AbstractButton** method **getText** to obtain the name of the font from the menu item.

The program calls **StyleHandler** method **itemStateChanged** (lines 187–202) if the user selects a **JCheckBoxMenuItem** in the **fontMenu**. Lines 192 and 196 determine whether either or both of the **JCheckBoxMenuItem**s are selected and use their combined state to determine the new style of the font.

22.5 JPopupMenu

Many of today's computer applications provide so-called **context-sensitive pop-up menus**. In Swing, such menus are created with class **JPopupMenu** (a subclass of **JComponent**). These menus provide options that are specific to the component for which the **pop-up trigger event** was generated. On most systems, the pop-up trigger event occurs when the user presses and releases the right mouse button.

**Look-and-Feel Observation 22.9**

The pop-up trigger event is platform specific. On most platforms that use a mouse with multiple buttons, the pop-up trigger event occurs when the user clicks the right mouse button on a component that supports a pop-up menu.

The application in Figs. 22.7–22.8 creates a **JPopupMenu** that allows the user to select one of three colors and change the background color of the window. When the user clicks the right mouse button on the **PopupTest** window's background, a **JPopupMenu** containing colors appears. If the user clicks a **JRadioButtonMenuItem** for a color, **ItemHandler** method **actionPerformed** changes the background color of the window's content pane.

```

Fig. 22.7 | JPopupMenu for selecting colors. (Part 2 of 2.)

Line 25 of the `PopupFrame` constructor (lines 21–69) creates an instance of class `ItemHandler` (declared in lines 72–87) that will process the item events from the menu items in the pop-up menu. Line 29 creates the `JPopupMenu`. The `for` statement (lines 33–39) creates a `JRadioButtonMenuItem` object (line 35), adds it to `popupMenu` (line 36), adds it to `ButtonGroup` `colorGroup` (line 37) to maintain one selected `JRadioButtonMenuItem` at a time and registers its `ActionListener` (line 38). Line 41 sets the initial background to white by invoking method `setBackground`.

Lines 44–68 register a `MouseListener` to handle the mouse events of the application window. Methods `mousePressed` (lines 49–52) and `mouseReleased` (lines 55–58) check for the pop-up trigger event. Each method calls private utility method `checkForTriggerEvent` (lines 61–66) to determine whether the pop-up trigger event occurred. If it did, `MouseEvent` method `isPopupTrigger` returns `true`, and `JPopupMenu` method `show` displays the `JPopupMenu`. The first argument to method `show` specifies the `origin component`,

```

1 // Fig. 22.8: PopupTest.java
2 // Testing PopupFrame.
3 import javax.swing.JFrame;
4
5 public class PopupTest
6 {
7     public static void main( String args[] )
8     {
9         PopupFrame popupFrame = new PopupFrame(); // create PopupFrame
10        popupFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        popupFrame.setSize( 300, 200 ); // set frame size
12        popupFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class PopupTest

```

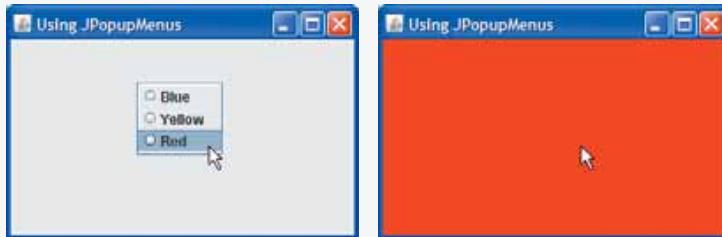

Fig. 22.8 | Test class for PopupFrame.

whose position helps determine where the JPopupMenu will appear on the screen. The last two arguments are the *x-y* coordinates (measured from the origin component's upper-left corner) at which the JPopupMenu is to appear.

Look-and-Feel Observation 22.10

Displaying a JPopupMenu for the pop-up trigger event of multiple GUI components requires registering mouse-event handlers for each of those GUI components.

When the user selects a menu item from the pop-up menu, class ItemHandler's method actionPerformed (lines 75–86) determines which JRadioButtonMenuItem the user selected and sets the background color of the window's content pane.

22.6 Pluggable Look-and-Feel

A program that uses Java's Abstract Window Toolkit GUI components (package `java.awt`) takes on the look-and-feel of the platform on which the program executes. A Java application running on a Macintosh looks like other applications running on a Macintosh. A Java application running on Microsoft Windows looks like other applications running on Microsoft Windows. A Java application running on a UNIX platform looks like other applications running on that UNIX platform. This is sometimes desirable, because it allows users of the application on each platform to use GUI components with which they are already familiar. However, it also introduces interesting portability issues.

1014 Chapter 22 GUI Components: Part 2**Portability Tip 22.1**

GUI components look different on different platforms and may require different amounts of space to display. This could change their layout and alignments.

**Portability Tip 22.2**

GUI components on different platforms have different default functionality (e.g., some platforms allow a button with the focus to be “pressed” with the space bar, and some do not).

Swing’s lightweight GUI components eliminate many of these issues by providing uniform functionality across platforms and by defining a uniform cross-platform look-and-feel (known as the [metal look-and-feel](#)). Swing also provides the flexibility to customize the look-and-feel to appear as a Microsoft Windows-style look-and-feel (on Window systems), a Motif-style (UNIX) look-and-feel (across all platforms) or a Macintosh look-and-feel (Mac systems).

The application in Figs. 22.9–22.10 demonstrates how to change the look-and-feel of a Swing GUI. It creates several GUI components, so you can see the change in the look-and-feel of several GUI components at the same time. The first output window shows the standard metal look-and-feel, the second shows the Motif look-and-feel, and the third shows the Windows look-and-feel.

All the GUI components and event handling in this example have been covered before, so we concentrate on the mechanism for changing the look-and-feel. Class [UIManager](#) (package `javax.swing`) contains nested class [LookAndFeelInfo](#) (a public static class) that maintains information about a look-and-feel. Line 22 declares an array of type [UIManager.LookAndFeelInfo](#) (note the syntax used to identify the inner class [LookAndFeelInfo](#)). Line 68 uses [UIManager](#) static method [getInstalledLookAndFeels](#) to get the array of [UIManager.LookAndFeelInfo](#) objects that describe each look-and-feel available on your system.

**Performance Tip 22.2**

Each look-and-feel is represented by a Java class. [UIManager](#) method [getInstalledLookAndFeels](#) does not load each class. Rather, it provides the names of the available look-and-feel classes so that a choice can be made (presumably once at program start-up). This reduces the overhead of having to load all the look-and-feel classes even if the program will not use some of them.

106 } // end private inner class ItemHandler
107 } // end class LookAndFeelFrame

```

Fig. 22.9 | Look-and-feel of a Swing-based GUI. (Part 3 of 3.)

Our utility method `changeTheLookAndFeel` (lines 73–87) is called by the event handler for the `JRadioButtons` at the bottom of the user interface. The event handler (declared in private inner class `ItemHandler` at lines 90–106) passes an integer representing the element in array `looks` that should be used to change the look-and-feel. Line 78 invokes static method `setLookAndFeel` of `UIManager` to change the look-and-feel. Method `getClassName` of class `UIManager.LookAndFeelInfo` determines the name of the look-and-feel class that corresponds to the `UIManager.LookAndFeelInfo` object. If the look-and-feel class is not already loaded, it will be loaded as part of the call to `setLookAndFeel`. Line 81 invokes static method `updateComponentTreeUI` of class `SwingUtilities` (package

22.7 JDesktopPane and JInternalFrame 1017

`javax.swing`) to change the look-and-feel of every GUI component attached to its argument (this instance of our application class `LookAndFeelDemo`) to the new look-and-feel.

22.7 JDesktopPane and JInternalFrame

Many of today's applications use a **multiple-document interface (MDI)**—a main window (called the **parent window**) containing other windows (called **child windows**), to manage several open **documents** that are being processed in parallel. For example, many e-mail programs allow you to have several windows open at the same time, so you can compose or read multiple e-mail messages simultaneously. Similarly, many word processors allow the user to open multiple documents in separate windows, making it possible to switch between them without having to close one to open another. The application in Figs. 22.11–22.12 demonstrates Swing's `JDesktopPane` and `JInternalFrame` classes for implementing multiple-document interfaces.

12     desktopFrame.setVisible( true ); // display frame
13 } // end main
14 } // end class DesktopTest

```

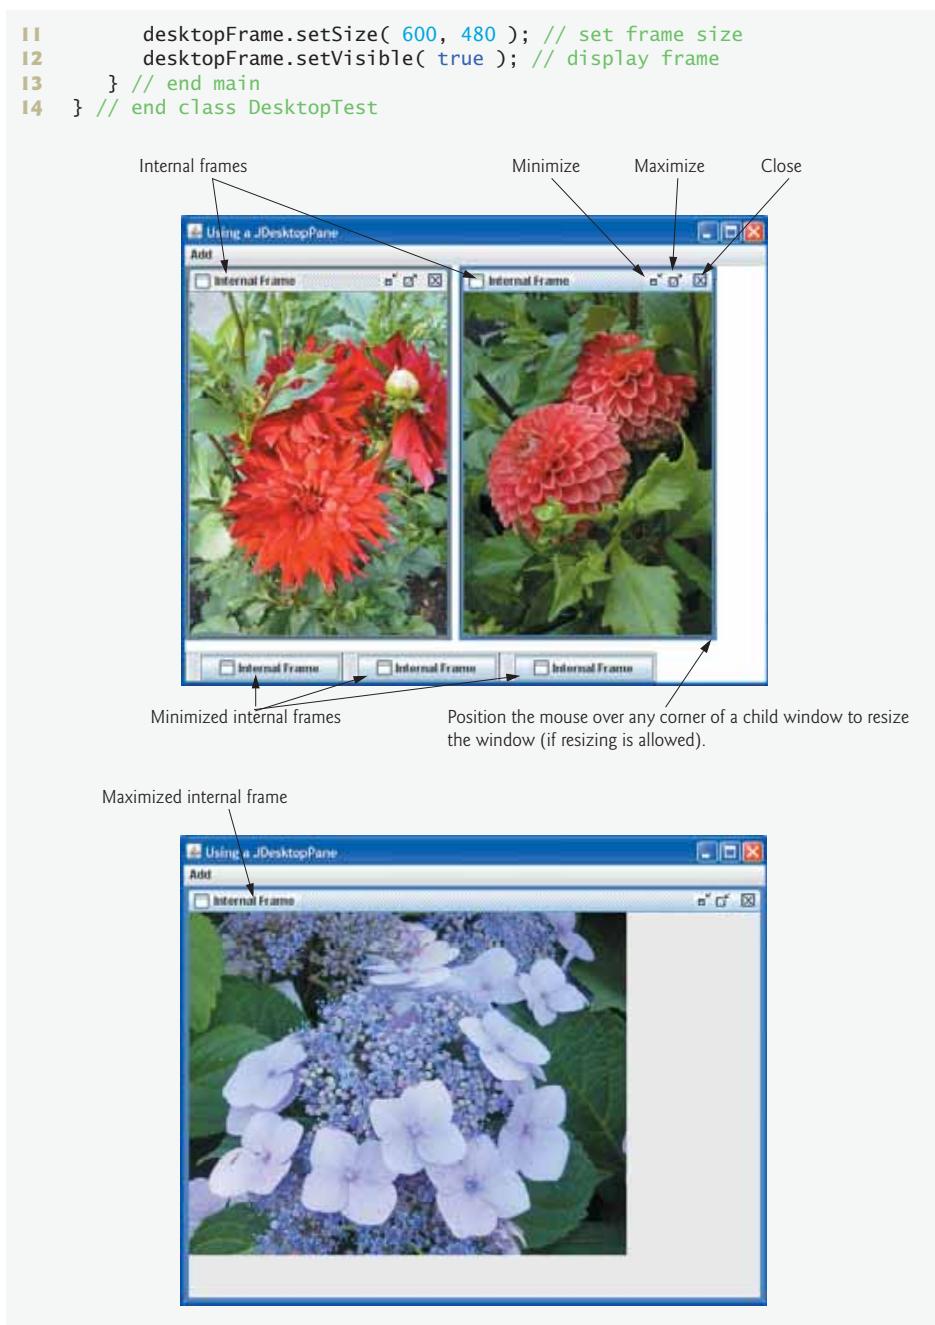

Fig. 22.12 | Test class for DeskTopFrame. (Part 2 of 2.)

22.8 JTabbedPane **1021**

Lines 27–33 create a `JMenuBar`, a `JMenu` and a `JMenuItem`, add the `JMenuItem` to the `JMenu`, add the `JMenu` to the `JMenuBar` and set the `JMenuBar` for the application window. When the user selects the `JMenuItem newFrame`, the application creates and displays a new `JInternalFrame` object containing an image.

Line 35 assigns `JDesktopPane` (package `javax.swing`) variable `theDesktop` a new `JDesktopPane` object that will be used to manage the `JInternalFrame` child windows. Line 36 adds the `JDesktopPane` to the `JFrame`. By default, the `JDesktopPane` is added to the center of the content pane's `BorderLayout`, so the `JDesktopPane` expands to fill the entire application window.

Lines 39–58 register an `ActionListener` to handle the event when the user selects the `newFrame` menu item. When the event occurs, method `actionPerformed` (lines 44–56) creates a `JInternalFrame` object in lines 47–48. The `JInternalFrame` constructor used here takes five arguments—a string for the title bar of the internal window, a `boolean` indicating whether the internal frame can be resized by the user, a `boolean` indicating whether the internal frame can be closed by the user, a `boolean` indicating whether the internal frame can be maximized by the user and a `boolean` indicating whether the internal frame can be minimized by the user. For each of the `boolean` arguments, a `true` value indicates that the operation should be allowed (as is the case here).

As with `JFrames` and `JApplets`, a `JInternalFrame` has a content pane to which GUI components can be attached. Line 50 creates an instance of our class `MyJPanel1` (declared at lines 63–90) that is added to the `JInternalFrame` at line 51.

Line 52 uses `JInternalFrame` method `pack` to set the size of the child window. Method `pack` uses the preferred sizes of the components to determine the window's size. Class `MyJPanel1` declares method `getPreferredSize` (lines 85–89) to specify the panel's preferred size for use by the `pack` method. Line 54 adds the `JInternalFrame` to the `JDesktopPane`, and line 55 displays the `JInternalFrame`.

Classes `JInternalFrame` and `JDesktopPane` provide many methods for managing child windows. See the `JInternalFrame` and `JDesktopPane` online API documentation for complete lists of these methods:

```
java.sun.com/javase/6/docs/api/javax/swing/JInternalFrame.html
java.sun.com/javase/6/docs/api/javax/swing/JDesktopPane.html
```

22.8 JTabbedPane

A `JTabbedPane` arranges GUI components into layers, of which only one is visible at a time. Users access each layer via a tab—similar to folders in a file cabinet. When the user clicks a tab, the appropriate layer is displayed. The tabs appear at the top by default but also can be positioned at the left, right or bottom of the `JTabbedPane`. Any component can be placed on a tab. If the component is a container, such as a panel, it can use any layout manager to lay out several components on the tab. Class `JTabbedPane` is a subclass of `JComponent`. The application in Figs. 22.13–22.14 creates one tabbed pane with three tabs. Each tab displays one of the `JPanels`—`panel11`, `panel12` or `panel13`.

The constructor (lines 15–46) builds the GUI. Line 19 creates an empty `JTabbedPane` with default settings—that is, tabs across the top. If the tabs do not fit on one line, they will wrap to form additional lines of tabs. Next the constructor creates the `JPanels` `panel11`, `panel12` and `panel13` and their GUI components. As we set up each panel, we add it to `tabbedPane`, using `JTabbedPane` method `addTab` with four arguments. The first argument

9         JTabbedPaneFrame tabbedPaneFrame = new JTabbedPaneFrame();
10        tabbedPaneFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        tabbedPaneFrame.setSize( 250, 200 ); // set frame size
12        tabbedPaneFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class JTabbedPaneDemo

```

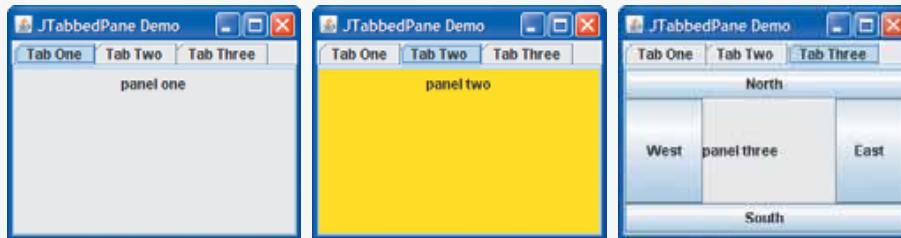

Fig. 22.14 | Test class for JTabbedPaneFrame.

for the tab. For example, line 25 adds JPanel panel11 to tabbedPane with title "Tab One" and the tool tip "First Panel". JPanels pane12 and pane13 are added to tabbedPane at lines 32 and 43. To view a tab, click it with the mouse or use the arrow keys to cycle through the tabs.

22.9 Layout Managers: BoxLayout and GridBagLayout

In Chapter 11, we introduced three layout managers—FlowLayout, BorderLayout and GridLayout. This section presents two additional layout managers (summarized in Fig. 22.15). We discuss these layout managers in the examples that follow.

Layout manager	Description
BoxLayout	A layout manager that allows GUI components to be arranged left-to-right or top-to-bottom in a container. Class Box declares a container with BoxLayout as its default layout manager and provides static methods to create a Box with a horizontal or vertical BoxLayout.
GridBagLayout	A layout manager similar to GridLayout, but unlike it in that components can vary in size and can be added in any order.

Fig. 22.15 | Additional layout managers.

1024 Chapter 22 GUI Components: Part 2***BoxLayout Layout Manager***

The `BoxLayout` layout manager (in package `javax.swing`) arranges GUI components horizontally along a container's *x*-axis or vertically along its *y*-axis. The application in Figs. 22.16–22.17 demonstrates `BoxLayout` and the container class `Box` that uses `BoxLayout` as its default layout manager.

```

1 // Fig. 22.16: BoxLayoutFrame.java
2 // Demonstrating BoxLayout.
3 import java.awt.Dimension;
4 import javax.swing.JFrame;
5 import javax.swing.Box;
6 import javax.swing.JButton;
7 import javax.swing.BoxLayout;
8 import javax.swing.JPanel;
9 import javax.swing.JTabbedPane;
10
11 public class BoxLayoutFrame extends JFrame
12 {
13     // set up GUI
14     public BoxLayoutFrame()
15     {
16         super( "Demonstrating BoxLayout" );
17
18         // create Box containers with BoxLayout
19         Box horizontal1 = Box.createHorizontalBox();
20         Box vertical1 = Box.createVerticalBox();
21         Box horizontal2 = Box.createHorizontalBox();
22         Box vertical2 = Box.createVerticalBox();
23
24         final int SIZE = 3; // number of buttons on each Box
25
26         // add buttons to Box horizontal1
27         for ( int count = 0; count < SIZE; count++ )
28             horizontal1.add( new JButton( "Button " + count ) );
29
30         // create strut and add buttons to Box vertical1
31         for ( int count = 0; count < SIZE; count++ )
32         {
33             vertical1.add( Box.createVerticalStrut( 25 ) );
34             vertical1.add( new JButton( "Button " + count ) );
35         } // end for
36
37         // create horizontal glue and add buttons to Box horizontal2
38         for ( int count = 0; count < SIZE; count++ )
39         {
40             horizontal2.add( Box.createHorizontalGlue() );
41             horizontal2.add( new JButton( "Button " + count ) );
42         } // end for
43
44         // create rigid area and add buttons to Box vertical2
45         for ( int count = 0; count < SIZE; count++ )
46         {

```

22.9 Layout Managers: BoxLayout and GridBagLayout 1025

```

47         vertical2.add( Box.createRigidArea( new Dimension( 12, 8 ) ) );
48         vertical2.add( new JButton( "Button " + count ) );
49     } // end for
50
51     // create vertical glue and add buttons to panel
52     JPanel panel = new JPanel();
53     panel.setLayout( new BoxLayout( panel, BoxLayout.Y_AXIS ) );
54
55     for ( int count = 0; count < SIZE; count++ )
56     {
57         panel.add( Box.createGlue() );
58         panel.add( new JButton( "Button " + count ) );
59     } // end for
60
61     // create a JTabbedPane
62     JTabbedPane tabs = new JTabbedPane(
63         JTabbedPane.TOP, JTabbedPane.SCROLL_TAB_LAYOUT );
64
65     // place each container on tabbed pane
66     tabs.addTab( "Horizontal Box", horizontal1 );
67     tabs.addTab( "Vertical Box with Struts", vertical1 );
68     tabs.addTab( "Horizontal Box with Glue", horizontal2 );
69     tabs.addTab( "Vertical Box with Rigid Areas", vertical2 );
70     tabs.addTab( "Vertical Box with Glue", panel );
71
72     add( tabs ); // place tabbed pane on frame
73 } // end BoxLayoutFrame constructor
74 } // end class BoxLayoutFrame

```

Fig. 22.16 | BoxLayout layout manager. (Part 2 of 2.)

Lines 19–22 create Box containers. References `horizontal1` and `horizontal2` are initialized with static Box method `createHorizontalBox`, which returns a Box container with a horizontal BoxLayout in which GUI components are arranged left-to-right. Variables `vertical1` and `vertical2` are initialized with static Box method `createVerticalBox`, which returns references to Box containers with a vertical BoxLayout in which GUI components are arranged top-to-bottom.

The for statement at lines 27–28 adds three JButtons to `horizontal1`. The for statement at lines 31–35 adds three JButtons to `vertical1`. Before adding each button, line 33 adds a vertical strut to the container with static Box method `createVerticalStrut`. A vertical strut is an invisible GUI component that has a fixed pixel height and is used to guarantee a fixed amount of space between GUI components. The `int` argument to method `createVerticalStrut` determines the height of the strut in pixels. When the container is resized, the distance between GUI components separated by struts does not change. Class Box also declares method `createHorizontalStrut` for horizontal BoxLayouts.

The for statement at lines 38–42 adds three JButtons to `horizontal2`. Before adding each button, line 40 adds horizontal glue to the container with static Box method `createHorizontalGlue`. Horizontal glue is an invisible GUI component that can be used between fixed-size GUI components to occupy additional space. Normally, extra space appears to the right of the last horizontal GUI component or below the last vertical one in

1026 Chapter 22 GUI Components: Part 2

```

1 // Fig. 22.17: BoxLayoutDemo.java
2 // Demonstrating BoxLayout.
3 import javax.swing.JFrame;
4
5 public class BoxLayoutDemo
6 {
7     public static void main( String args[] )
8     {
9         BoxLayoutFrame boxLayoutFrame = new BoxLayoutFrame();
10        boxLayoutFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        boxLayoutFrame.setSize( 400, 220 ); // set frame size
12        boxLayoutFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class BoxLayoutDemo

```

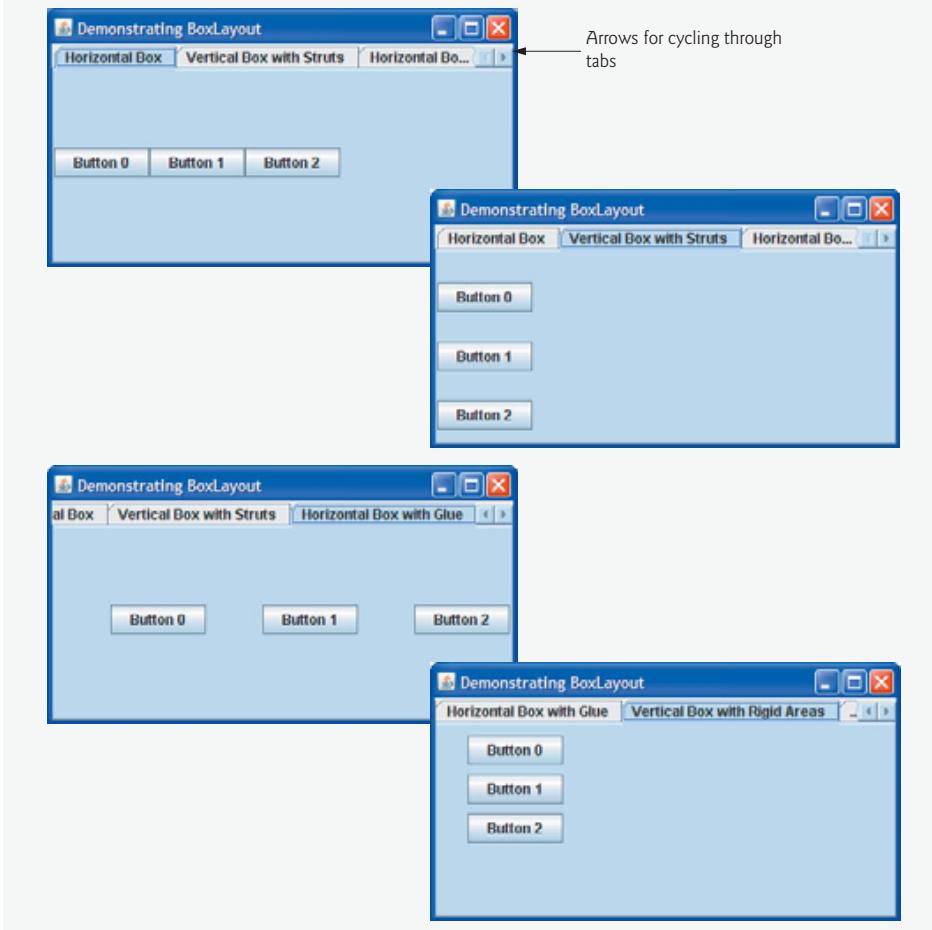

Fig. 22.17 | Test class for `BoxLayoutFrame`. (Part 1 of 2.)

22.9 Layout Managers: BoxLayout and GridBagLayout

1027

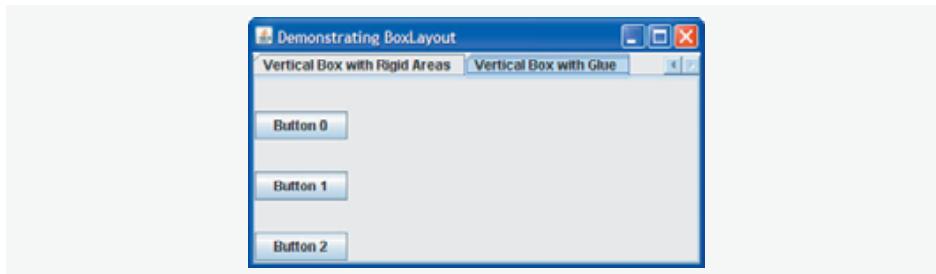

Fig. 22.17 | Test class for `BoxLayoutFrame`. (Part 2 of 2.)

a `BoxLayout`. `Glue` allows the extra space to be placed between GUI components. When the container is resized, components separated by glue components remain the same size, but the glue stretches or contracts to occupy the space between them. Class `Box` also declares method `createVerticalGlue` for vertical `BoxLayouts`.

The for statement at lines 45–49 adds three `JButtons` to `vertical12`. Before each button is added, line 47 adds a `rigid area` to the container with static `Box` method `createRigidArea`. A rigid area is an invisible GUI component that always has a fixed pixel width and height. The argument to method `createRigidArea` is a `Dimension` object that specifies the area's width and height.

Lines 52–53 create a `JPanel1` object and set its layout to a `BoxLayout` in the conventional manner, using `Container` method `setLayout`. The `BoxLayout` constructor receives a reference to the container for which it controls the layout and a constant indicating whether the layout is horizontal (`BoxLayout.X_AXIS`) or vertical (`BoxLayout.Y_AXIS`).

The for statement at lines 55–59 adds three `JButtons` to `panel1`. Before adding each button, line 57 adds a glue component to the container with static `Box` method `createGlue`. This component expands or contracts based on the size of the `Box`.

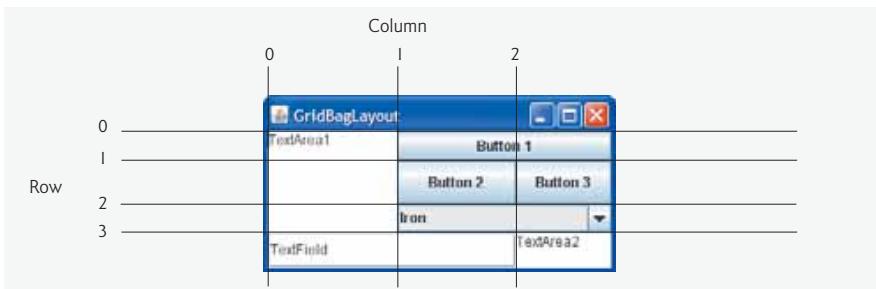

Lines 62–63 create a `JTabbedPane` to display the five containers in this program. The argument `JTabbedPane.TOP` sent to the constructor indicates that the tabs should appear at the top. The argument `JTabbedPane.SCROLL_TAB_LAYOUT` specifies that the tabs should scroll if there are too many to fit on one line.

The `Box` containers and the `JPanel1` are attached to the `JTabbedPane` at lines 66–70. Try executing the application. When the window appears, resize the window to see how the glue components, strut components and rigid area affect the layout on each tab.

GridBagLayout Layout Manager

One of the most powerful predefined layout managers is `GridBagLayout` (in package `java.awt`). This layout is similar to `GridLayout` in that it arranges components in a grid. However, `GridBagLayout` is more flexible. The components can vary in size (i.e., they can occupy multiple rows and columns) and can be added in any order.

The first step in using `GridBagLayout` is determining the appearance of the GUI. For this step you need only a piece of paper. Draw the GUI and then draw a grid over it, dividing the components into rows and columns. The initial row and column numbers should be 0, so that the `GridBagLayout` layout manager can use the row and column numbers to properly place the components in the grid. Figure 22.18 demonstrates drawing the lines for the rows and columns over a GUI.

1028 Chapter 22 GUI Components: Part 2**Fig. 22.18** | Designing a GUI that will use `GridBagLayout`.

A `GridBagConstraints` object describes how a component is placed in a `GridBagLayout`. Several `GridBagConstraints` fields are summarized in Fig. 22.19.

`GridBagConstraints` field `anchor` specifies the relative position of the component in an area that it does not fill. The variable `anchor` is assigned one of the following `GridBagConstraints` constants: `NORTH`, `NORTHEAST`, `EAST`, `SOUTHEAST`, `SOUTH`, `SOUTHWEST`, `WEST`, `NORTHWEST` or `CENTER`. The default value is `CENTER`.

`GridBagConstraints` field `fill` defines how the component grows if the area in which it can be displayed is larger than the component. The variable `fill` is assigned one of the following `GridBagConstraints` constants: `NONE`, `VERTICAL`, `HORIZONTAL` or `BOTH`. The default value is `NONE`, which indicates that the component will not grow in either direction. `VERTICAL` indicates that it will grow vertically. `HORIZONTAL` indicates that it will grow horizontally. `BOTH` indicates that it will grow in both directions.

<code>GridBagConstraints</code> field	Description
<code>anchor</code>	Specifies the relative position (<code>NORTH</code> , <code>NORTHEAST</code> , <code>EAST</code> , <code>SOUTHEAST</code> , <code>SOUTH</code> , <code>SOUTHWEST</code> , <code>WEST</code> , <code>NORTHWEST</code> , <code>CENTER</code>) of the component in an area that it does not fill.
<code>fill</code>	Resizes the component in specified direction (<code>NONE</code> , <code>HORIZONTAL</code> , <code>VERTICAL</code> , <code>BOTH</code>) when the display area is larger than the component.
<code>gridx</code>	The column in which the component will be placed.
<code>gridy</code>	The row in which the component will be placed.
<code>gridwidth</code>	The number of columns the component occupies.
<code>gridheight</code>	The number of rows the component occupies.
<code>weightx</code>	The amount of extra space to allocate horizontally. The grid slot can become wider when extra space is available.
<code>weighty</code>	The amount of extra space to allocate vertically. The grid slot can become taller when extra space is available.

Fig. 22.19 | `GridBagConstraints` fields.

22.9 Layout Managers: BoxLayout and GridBagLayout 1029

Variables `gridx` and `gridy` specify where the upper-left corner of the component is placed in the grid. Variable `gridx` corresponds to the column, and variable `gridy` corresponds to the row. In Fig. 22.18, the JComboBox (displaying “Iron”) has a `gridx` value of 1 and a `gridy` value of 2.

Variable `gridwidth` specifies the number of columns a component occupies. The JComboBox occupies two columns. Variable `gridheight` specifies the number of rows a component occupies. The JTextArea on the left side of Fig. 22.18 occupies three rows.

Variable `weightx` specifies how to distribute extra horizontal space to grid slots in a GridBagLayout when the container is resized. A zero value indicates that the grid slot does not grow horizontally on its own. However, if the component spans a column containing a component with nonzero `weightx` value, the component with zero `weightx` value will grow horizontally in the same proportion as the other component(s) in the same column. This is because each component must be maintained in the same row and column in which it was originally placed.

Variable `weighty` specifies how to distribute extra vertical space to grid slots in a GridBagLayout when the container is resized. A zero value indicates that the grid slot does not grow vertically on its own. However, if the component spans a row containing a component with nonzero `weighty` value, the component with zero `weighty` value grows vertically in the same proportion as the other component(s) in the same row.

In Fig. 22.18, the effects of `weighty` and `weightx` cannot easily be seen until the container is resized and additional space becomes available. Components with larger weight values occupy more of the additional space than those with smaller weight values.

Components should be given nonzero positive weight values—otherwise they will “huddle” together in the middle of the container. Figure 22.20 shows the GUI of Fig. 22.18 with all weights set to zero.

The application in Figs. 22.21–22.22 uses the `GridBagLayout` layout manager to arrange the components of the GUI in Fig. 22.18. The application does nothing except demonstrate how to use `GridBagLayout`.

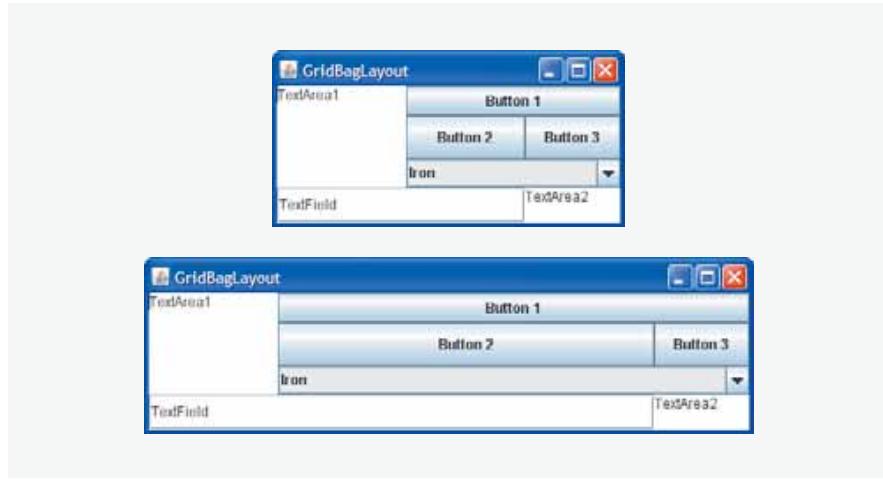

Fig. 22.20 | GridBagLayout with the weights set to zero.

78 } // end method addComponent
79 } // end class GridBagFrame

```

Fig. 22.21 | GridBagLayout layout manager. (Part 2 of 2.)

The GUI consists of three `JButtons`, two `JTextAreas`, a `JComboBox` and a `JTextField`. The layout manager for the content pane is `GridBagLayout`. Lines 21–22 create the `GridBagLayout` object and set the layout manager for the `JFrame` to `layout`. Line 23 creates the `GridBagConstraints` object used to determine the location and size of each component in the grid. Lines 26–35 create each GUI component that will be added to the content pane.

Lines 39–40 configure `JTextArea` `textArea1` and add it to the content pane. The values for `weightx` and `weighty` values are not specified in `constraints`, so each has the value zero by default. Thus, the `JTextArea` will not resize itself even if space is available. However, it spans multiple rows, so the vertical size is subject to the `weighty` values of `JButtons` `button2` and `button3`. When either button is resized vertically based on its `weighty` value, the `JTextArea` is also resized.

Line 39 sets variable `fill` in `constraints` to `GridBagConstraints.BOTH`, causing the `JTextArea` to always fill its entire allocated area in the grid. An anchor value is not specified in `constraints`, so the default `CENTER` is used. We do not use variable `anchor` in this application, so all the components will use the default. Line 40 calls our utility method `addComponent` (declared at lines 69–78). The `JTextArea` object, the row, the column, the number of columns to span and the number of rows to span are passed as arguments.

`JButton` `button1` is the next component added (lines 43–44). By default, the `weightx` and `weighty` values are still zero. The `fill` variable is set to `HORIZONTAL`—the component will always fill its area in the horizontal direction. The vertical direction is not filled. The

1032 Chapter 22 GUI Components: Part 2

```

1 // Fig. 22.22: GridBagDemo.java
2 // Demonstrating GridBagLayout.
3 import javax.swing.JFrame;
4
5 public class GridBagDemo
6 {
7     public static void main( String args[] )
8     {
9         GridBagConstraints gridBagConstraints = new GridBagConstraints();
10        gridBagConstraints.gridwidth = 1;
11        gridBagConstraints.gridheight = 1;
12        gridBagConstraints.fill = GridBagConstraints.BOTH;
13        gridBagConstraints.anchor = GridBagConstraints.CENTER;
14        gridBagConstraints.insets = new Insets( 5, 5, 5, 5 );
15
16        JFrame gridBagFrame = new JFrame("GridBagLayout");
17        gridBagFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
18        gridBagFrame.setSize( 300, 150 ); // set frame size
19        gridBagFrame.setVisible( true ); // display frame
20    } // end main
21 } // end class GridBagDemo

```

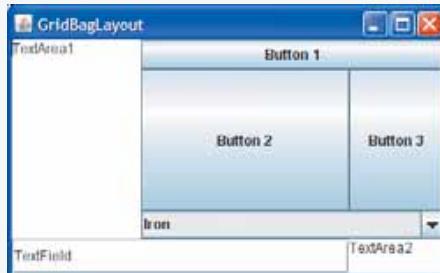

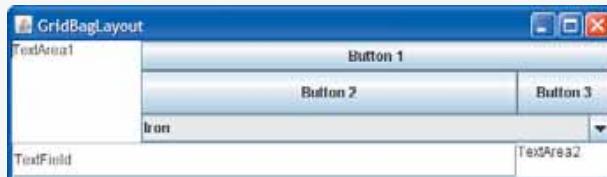

Fig. 22.22 | Test class for `GridBagFrame`.

`weighty` value is zero, so the button will become taller only if another component in the same row has a nonzero `weighty` value. `JButton button1` is located at row 0, column 1. One row and two columns are occupied.

`JComboBox comboBox` is the next component added (line 48). By default, the `weightx` and `weighty` values are zero, and the `fill` variable is set to `HORIZONTAL`. The `JComboBox` button will grow only in the horizontal direction. Note that the `weightx`, `weighty` and `fill` variables retain the values set in `constraints` until they are changed. The `JComboBox` button is placed at row 2, column 1. One row and two columns are occupied.

22.9 Layout Managers: BoxLayout and GridBagLayout

1033

`JButton button2` is the next component added (lines 51–54). It is given a `weightx` value of 1000 and a `weighty` value of 1. The area occupied by the button is capable of growing in the vertical and horizontal directions. The `fill` variable is set to `BOTH`, which specifies that the button will always fill the entire area. When the window is resized, `button2` will grow. The button is placed at row 1, column 1. One row and one column are occupied.

`JButton button3` is added next (lines 57–59). Both the `weightx` value and `weighty` value are set to zero, and the value of `fill` is `BOTH`. `JButton button3` will grow if the window is resized—it is affected by the weight values of `button2`. Note that the `weightx` value for `button2` is much larger than that for `button3`. When resizing occurs, `button2` will occupy a larger percentage of the new space. The button is placed at row 1, column 2. One row and one column are occupied.

Both the `JTextField textField` (line 62) and `JTextArea textArea2` (line 65) have a `weightx` value of 0 and a `weighty` value of 0. The value of `fill` is `BOTH`. The `JTextField` is placed at row 3, column 0, and the `JTextArea` at row 3, column 2. The `JTextField` occupies one row and two columns, the `JTextArea` one row and one column.

Method `addComponent`'s parameters are a `Component` reference `component` and integers `row`, `column`, `width` and `height`. Lines 72–73 set the `GridBagConstraints` variables `gridx` and `gridy`. The `gridx` variable is assigned the column in which the `Component` will be placed, and the `gridy` value is assigned the row in which the `Component` will be placed. Lines 74–75 set the `GridBagConstraints` variables `gridwidth` and `gridheight`. The `gridwidth` variable specifies the number of columns the `Component` will span in the grid, and the `gridheight` variable specifies the number of rows the `Component` will span in the grid. Line 76 sets the `GridBagConstraints` for a component in the `GridBagLayout`. Method `setConstraints` of class `GridBagLayout` takes a `Component` argument and a `GridBagConstraints` argument. Line 77 adds the component to the `JFrame`.

When you execute this application, try resizing the window to see how the constraints for each GUI component affect its position and size in the window.

GridBagConstraints Constants RELATIVE and REMAINDER

Instead of `gridx` and `gridy`, a variation of `GridBagLayout` uses `GridBagConstraints` constants `RELATIVE` and `REMAINDER`. `RELATIVE` specifies that the next-to-last component in a particular row should be placed to the right of the previous component in the row. `REMAINDER` specifies that a component is the last component in a row. Any component that is not the second-to-last or last component on a row must specify values for `GridBagConstraints` variables `gridwidth` and `gridheight`. The application in Figs. 22.23–22.24 arranges components in `GridBagLayout`, using these constants.

Lines 21–22 create a `GridBagLayout` and use it to set the `JFrame`'s layout manager. The components that are placed in `GridBagLayout` are created in lines 27–38—they are a `JComboBox`, a `JTextField`, a `JList` and five `JButtons`.

The `JTextField` is added first (lines 41–45). The `weightx` and `weighty` values are set to 1. The `fill` variable is set to `BOTH`. Line 44 specifies that the `JTextField` is the last component on the line. The `JTextField` is added to the content pane with a call to our utility method `addComponent` (declared at lines 79–83). Method `addComponent` takes a `Component` argument and uses `GridBagLayout` method `setConstraints` to set the constraints for the `Component`. Method `add` attaches the component to the content pane.

25         // Create GUI components
26         String metals[] = { "Copper", "Aluminum", "Silver" };
27         JComboBox comboBox = new JComboBox( metals );
28
29         JTextField textField = new JTextField( "TextField" );
30
31         String fonts[] = { "Serif", "Monospaced" };
32         JList list = new JList( fonts );
33
34         String names[] = { "zero", "one", "two", "three", "four" };
35         JButton buttons[] = new JButton[ names.length ];
36
37         for ( int count = 0; count < buttons.length; count++ )
38             buttons[ count ] = new JButton( names[ count ] );
39
40         // Define GUI component constraints for textField
41         constraints.weightx = 1;
42         constraints.weighty = 1;
43         constraints.fill = GridBagConstraints.BOTH;
44         constraints.gridwidth = GridBagConstraints.REMAINDER;
45         addComponent( textField );
46
47         // buttons[0] -- weightx and weighty are 1: fill is BOTH
48         constraints.gridwidth = 1;
49         addComponent( buttons[ 0 ] );
50
51         // buttons[1] -- weightx and weighty are 1: fill is BOTH
52         constraints.gridwidth = GridBagConstraints.RELATIVE;
53         addComponent( buttons[ 1 ] );

```

Fig. 22.23 | GridBagConstraints constants RELATIVE and REMAINDER. (Part I of 2.)

22.9 Layout Managers: BoxLayout and GridBagLayout

1035

```

54     // buttons[2] -- weightx and weighty are 1: fill is BOTH
55     constraints.gridwidth = GridBagConstraints.REMAINDER;
56     addComponent( buttons[ 2 ] );
57
58     // comboBox -- weightx is 1: fill is BOTH
59     constraints.weighty = 0;
60     constraints.gridwidth = GridBagConstraints.REMAINDER;
61     addComponent( comboBox );
62
63     // buttons[3] -- weightx is 1: fill is BOTH
64     constraints.weighty = 1;
65     constraints.gridwidth = GridBagConstraints.REMAINDER;
66     addComponent( buttons[ 3 ] );
67
68     // buttons[4] -- weightx and weighty are 1: fill is BOTH
69     constraints.gridwidth = GridBagConstraints.RELATIVE;
70     addComponent( buttons[ 4 ] );
71
72     // list -- weightx and weighty are 1: fill is BOTH
73     constraints.gridwidth = GridBagConstraints.REMAINDER;
74     addComponent( list );
75 }
76 // end GridBagFrame2 constructor
77
78 // add a component to the container
79 private void addComponent( Component component )
80 {
81     layout.setConstraints( component, constraints );
82     add( component ); // add component
83 }
84 } // end class GridBagFrame2

```

Fig. 22.23 | GridBagConstraints constants RELATIVE and REMAINDER. (Part 2 of 2.)

JButton buttons[0] (lines 48–49) has weightx and weighty values of 1. The fill variable is BOTH. Because buttons[0] is not one of the last two components on the row, it is given a gridwidth of 1 and so will occupy one column. The JButton is added to the content pane with a call to utility method addComponent.

JButton buttons[1] (lines 52–53) has weightx and weighty values of 1. The fill variable is BOTH. Line 52 specifies that the JButton is to be placed relative to the previous component. The Button is added to the JFrame with a call to addComponent.

JButton buttons[2] (lines 56–57) has weightx and weighty values of 1. The fill variable is BOTH. This JButton is the last component on the line, so REMAINDER is used. The JButton is added to the content pane with a call to addComponent.

The JComboBox (lines 60–62) has a weightx of 1 and a weighty of 0. The JComboBox will not grow in the vertical direction. The JComboBox is the only component on the line, so REMAINDER is used. The JComboBox is added to the content pane with a call to addComponent.

JButton buttons[3] (lines 65–67) has weightx and weighty values of 1. The fill variable is BOTH. This JButton is the only component on the line, so REMAINDER is used. The JButton is added to the content pane with a call to addComponent.

1036 Chapter 22 GUI Components: Part 2

```

1 // Fig. 22.24: GridBagDemo2.java
2 // Demonstrating GridBagLayout constants.
3 import javax.swing.JFrame;
4
5 public class GridBagDemo2
6 {
7     public static void main( String args[] )
8     {
9         GridBagConstraints gridBagFrame = new GridBagFrame2();
10        gridBagFrame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
11        gridBagFrame.setSize( 300, 200 ); // set frame size
12        gridBagFrame.setVisible( true ); // display frame
13    } // end main
14 } // end class GridBagDemo2

```

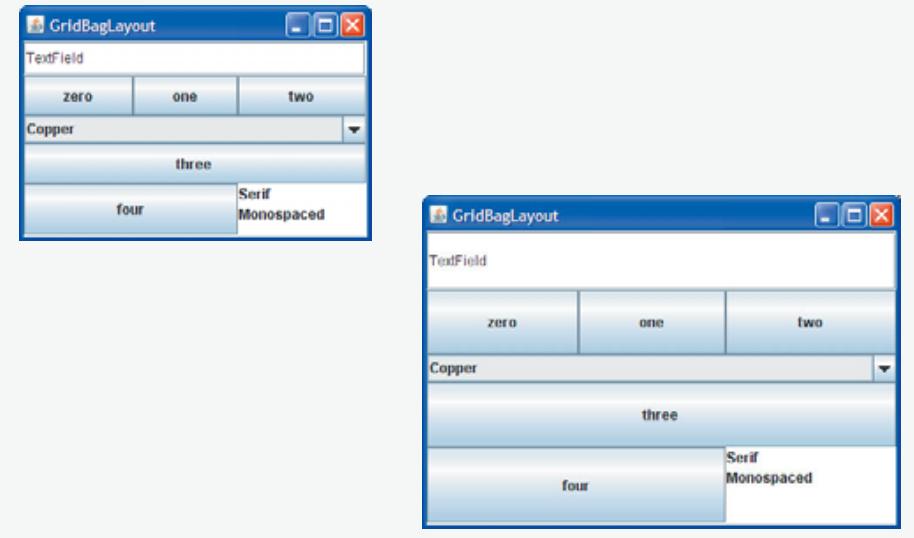

Fig. 22.24 | Test class for GridBagDemo2.

JButton buttons[4] (lines 70–71) has weightx and weighty values of 1. The fill variable is BOTH. This JButton is the next-to-last component on the line, so RELATIVE is used. The JButton is added to the content pane with a call to addComponent.

The JList (lines 74–75) has weightx and weighty values of 1. The fill variable is BOTH. The JList is added to the content pane with a call to addComponent.

22.10 Wrap-Up

This chapter completes our introduction to GUI. In this chapter, you learned about more advanced GUI topics, such as menus, sliders, pop-up menus and the multiple-document interface. All these components can be added to existing applications to make them easier to use and understand. In the next chapter, you will learn about multithreading, a powerful capability that allows applications to use threads to perform multiple tasks at once.

Summary**1037**

Summary

Section 22.2 *JSlider*

- *JSliders* enable the user to select from a range of integer values. *JSliders* can display major tick marks, minor tick marks and labels for the tick marks. They also support snap-to ticks, where positioning the thumb between two tick marks causes the thumb to snap to the closest tick mark.
- If a *JSlider* has the focus, the left and right arrow keys cause the thumb of the *JSlider* to decrease or increase by 1. The down and up arrow keys also cause the thumb of the *JSlider* to decrease or increase by 1, respectively. The *PgDn* (page down) key and *PgUp* (page up) key cause the thumb of the *JSlider* to decrease or increase by block increments of one-tenth of the range of values, respectively. The *Home* key moves the thumb to the minimum value of the *JSlider*, and the *End* key moves it to the maximum value.
- *JSliders* have either horizontal or vertical orientation. For a horizontal *JSlider*, the minimum value is at the extreme left and the maximum value at the extreme right. For a vertical *JSlider*, the minimum value is at the extreme bottom and the maximum value at the extreme top. The position of the thumb indicates the current value of the *JSlider*. Method *getValue* of class *JSlider* returns the current thumb position.
- Method *setMajorTickSpacing* of class *JSlider* sets the spacing for tick marks on a *JSlider*. Method *setPaintTicks* with a *true* argument indicates that the tick marks should be displayed.
- *JSliders* generate *ChangeEvent*s when the user interacts with a *JSlider*. A *ChangeListener* declares method *stateChanged* that can respond to *ChangeEvent*s.

Section 22.3 *Windows: Additional Notes*

- Every window generates window events when the user manipulates it. Interface *WindowListener* provides seven window-event-handling methods—*windowActivated*, *windowClosed*, *windowClosing*, *windowDeactivated*, *windowDeiconified*, *windowIconified* and *windowOpened*.
- Menus are an integral part of GUIs. Menus allow the user to perform actions without unnecessarily cluttering a graphical user interface with extra GUI components. In Swing GUIs, menus can be attached only to objects of classes with method *setJMenuBar* (e.g., *JFrame* and *JApplet*).

Section 22.4 *Using Menus with Frames*

- The classes used to declare menus are *JMenuBar*, *JMenuItem*, *JMenu*, *JCheckBoxMenuItem* and *JRadioButtonMenuItem*.
- A *JMenuBar* is a container for menus. A *JMenuItem* is a GUI component inside a menu that, when selected, causes an action to be performed. A *JMenu* contains menu items and can be added to a *JMenuBar* or to other *JMenus* as submenus.
- When a menu is clicked, it expands to show its list of menu items. *JMenu* method *addSeparator* adds a separator line to a menu.
- When a *JCheckBoxMenuItem* is selected, a check appears to the left of the menu item. When the *JCheckBoxMenuItem* is selected again, the check is removed.
- When multiple *JRadioButtonMenuItem*s are maintained as part of a *ButtonGroup*, only one item in the group can be selected at a given time. When an item is selected, a filled circle appears to its left. When another *JRadioButtonMenuItem* is selected, the filled circle to the left of the previously selected item is removed.
- *AbstractButton* method *setMnemonic* specifies the mnemonic for an *AbstractButton*. Mnemonic characters are normally displayed with an underline.

1038 [Chapter 22](#) [GUI Components: Part 2](#)

- A modal dialog box does not allow access to any other window in the application until the dialog is dismissed. The dialogs displayed with class `JOptionPane` are modal dialogs. Class `JDialog` can be used to create your own modal or nonmodal dialogs.

Section 22.5 JPopupMenu

- Context-sensitive pop-up menus are created with class `JPopupMenu`. On most systems, the pop-up trigger event occurs when the user presses and releases the right mouse button. `MouseEvent` method `isPopupTrigger` returns `true` if the pop-up trigger event occurred.
- `JPopupMenu` method `show` displays a `JPopupMenu`. The first argument specifies the origin component, which helps determine where the `JPopupMenu` will appear. The last two arguments are the coordinates from the origin component's upper-left corner, at which the `JPopupMenu` appears.

Section 22.6 Pluggable Look-and-Feel

- Class `UIManager` contains nested class `LookAndFeelInfo` that maintains information about a look-and-feel.
- `UIManager` static method `getInstalledLookAndFeels` gets an array of `UIManager.LookAndFeelInfo` objects that describe the available look-and-feels.
- `UIManager` static method `setLookAndFeel` changes the look-and-feel. `SwingUtilities` static method `updateComponentTreeUI` changes the look-and-feel of every component attached to its `Component` argument to the new look-and-feel.

Section 22.7 JDesktopPane and JInternalFrame

- Many of today's applications use a multiple-document interface (MDI) to manage several open documents that are being processed in parallel. Swing's `JDesktopPane` and `JInternalFrame` classes provide support for creating multiple-document interfaces.

Section 22.8 JTabbedPane

- A `JTabbedPane` arranges GUI components into layers, of which only one is visible at a time. Users access each layer via a tab similar to those on folders in a file cabinet. When the user clicks a tab, the appropriate layer is displayed.

Section 22.9 Layout Managers: BoxLayout and GridBagLayout

- `BoxLayout` is a layout manager that allows GUI components to be arranged left-to-right or top-to-bottom in a container.
- Class `Box` declares a container with `BoxLayout` as its default layout manager and provides static methods to create a `Box` with a horizontal or vertical `BoxLayout`.
- `GridBagLayout` is a layout manager similar to `GridLayout`. It differs in that each component size can vary, and components can be added in any order.
- A `GridBagConstraints` object specifies how a component is placed in a `GridBagLayout`. Method `setConstraints` of class `GridBagLayout` takes a `Component` argument and a `GridBagConstraints` argument and sets the constraints of the `Component`.

Terminology

<code>add</code> method of class <code>JMenuBar</code>	<code>Box</code> class
<code>addWindowListener</code> method of class <code>Window</code>	<code>BoxLayout</code> class
<code>anchor</code> field of class <code>GridBagConstraints</code>	<code>CENTER</code> constant of class <code>GridBagConstraints</code>
<code>border</code>	<code>ChangeEvent</code> class
<code>BOTH</code> constant of class <code>GridBagConstraints</code>	<code>ChangeListener</code> interface

Terminology **1039**

child window

 major tick marks
 menu
 menu bar
 menu item
 metal look-and-feel
 minor tick marks of `JSlider`
 mnemonic
 modal dialog box
 multiple document interface (MDI)
`NONE` constant of class `GridBagConstraints`
`NORTH` constant of class `GridBagConstraints`
`NORTHEAST` constant of class
`GridBagConstraints`
`NORTHWEST` constant of class
`GridBagConstraints`
 opaque
 origin component
`pack` method of class `Window`
`paintComponent` method of class `JComponent`
 parent window
 parent window for a dialog box
 pluggable look and feel (PLAF)
 pop-up trigger event
`RELATIVE` constant of class `GridBagConstraints`
`REMAINDER` constant of class
`GridBagConstraints`
 rigid area
 scrollbar policies
 separator line in a menu
`setConstraints` method of class `GridBagLayout`
`setDefaultCloseOperation` method of class
`JFrame`
`setInverted` method of class `JSlider`
`setJMenuBar` method of class `JFrame`
`setLocation` method of class `Component`
`setLookAndFeel` method of class `UIManager`
`setMajorTickSpacing` method of class `JSlider`
`setMnemonic` method of class `AbstractButton`
`setOpaque` method of class `JComponent`
`setPaintTicks` method of class `JSlider`
 `setSelected` method of class `AbstractButton`
`setVerticalScrollBarPolicy` method of
`JSlider`
 shortcut key
`show` method of class `JPopupMenu`
 snap-to ticks for `JSlider`
`SOUTH` constant of class `GridBagConstraints`
`SOUTHEAST` constant of class
`GridBagConstraints`
`SOUTHWEST` constant of class
`GridBagConstraints`
`stateChanged` method of interface
`ChangeListener`
 submenu
`SwingUtilities` class

Self-Review Exercises

- 22.1** Fill in the blanks in each of the following statements:
- The _____ class is used to create a menu object.
 - The _____ method of class `JMenu` places a separator bar in a menu.
 - `JSlider` events are handled by the _____ method of interface _____.
 - The `GridBagConstraints` instance variable _____ is set to CENTER by default.
- 22.2** State whether each of the following is *true* or *false*. If *false*, explain why.
- When the programmer creates a `JFrame`, a minimum of one menu must be created and added to the `JFrame`.
 - The variable `fill` belongs to the `GridLayout` class.
 - Drawing on a GUI component is performed with respect to the (0, 0) upper-left corner coordinate of the component.
 - The default layout for a `Box` is `BoxLayout`.
- 22.3** Find the error(s) in each of the following and explain how to correct the error(s).
- ```

a) JMenubar b;
b) mySlider = JSlider(1000, 222, 100, 450);
c) gbc.fill = GridBagConstraints.NORTHWEST; // set fill
d) // override to paint on a customized Swing component
 public void paintcomponent(Graphics g)
{
 g.drawString("HELLO", 50, 50);
} // end method paintComponent
e) // create a JFrame and display it
JFrame f = new JFrame("A Window");
f.setVisible(true);

```

**Answers to Self-Review Exercises**

- 22.1** a) `JMenu`. b) `addSeparator`. c) `stateChanged`, `ChangeListener`. d) anchor.
- 22.2** a) False. A `JFrame` does not require any menus.  
 b) False. The variable `fill` belongs to the `GridBagConstraints` class.  
 c) True.  
 d) True.

Exercises **1041**

- 22.3** a) `JMenubar` should be `JMenuBar`.  
 b) The first argument to the constructor should be either `SwingConstants.HORIZONTAL` or `SwingConstants.VERTICAL`, and the keyword `new` must be used after the `=` operator.  
 c) The constant should be either `BOTH`, `HORIZONTAL`, `VERTICAL` or `NONE`.  
 d) `paintcomponent` should be `paintComponent`, and the method should call `super.paintComponent(g)` as its first statement.  
 e) The `JFrame`'s `setSize` method must also be called to establish the size of the window.

**Exercises**

- 22.4** Fill in the blanks in each of the following statements:
- A `JMenuItem` that is a `JMenu` is called a(n) \_\_\_\_\_.
  - Method \_\_\_\_\_ attaches a `JMenuBar` to a `JFrame`.
  - Container class \_\_\_\_\_ has a default `BoxLayout`.
  - A(n) \_\_\_\_\_ manages a set of child windows declared with class `JInternalFrame`.
- 22.5** State whether each of the following is *true* or *false*. If *false*, explain why.
- Menus require a `JMenuBar` object so they can be attached to a `JFrame`.
  - `BoxLayout` is the default layout manager for a `JFrame`.
  - Method `setEditable` is a `JTextComponent` method.
  - Class `JFrame` directly extends class `Container`.
  - `JApplets` can contain menus.
- 22.6** Find the error(s) in each of the following. Explain how to correct the error(s).
- `x.add(new JMenuItem("Submenu Color")); // create submenu`
  - `container.setLayout(m = new GridbagLayout());`
- 22.7** Write a program that displays a circle of random size and calculates and displays the area, radius, diameter and circumference. Use the following equations:  $diameter = 2 \times radius$ ,  $area = \pi \times radius^2$ ,  $circumference = 2 \times \pi \times radius$ . Use the constant `Math.PI` for pi ( $\pi$ ). All drawing should be done on a subclass of `JPanel`, and the results of the calculations should be displayed in a read-only `JTextArea`.
- 22.8** Enhance the program in Exercise 22.7 by allowing the user to alter the radius with a `JSlider`. The program should work for all radii in the range from 100 to 200. As the radius changes, the diameter, area and circumference should be updated and displayed. The initial radius should be 150. Use the equations from Exercise 22.7. All drawing should be done on a subclass of `JPanel`, and the results of the calculations should be displayed in a read-only `JTextArea`.
- 22.9** Explore the effects of varying the `weightx` and `weighty` values of the program in Fig. 22.21. What happens when a slot has a nonzero weight but is not allowed to fill the whole area (i.e., the `fill` value is not `BOTH`)?
- 22.10** Write a program that uses the `paintComponent` method to draw the current value of a `JSlider` on a subclass of `JPanel`. In addition, provide a `JTextField` where a specific value can be entered. The `JTextField` should display the current value of the `JSlider` at all times. A `JLabel` should be used to identify the `JTextField`. The `JSlider` methods `setValue` and `getValue` should be used. [Note: The `setValue` method is a `public` method that does not return a value and takes one integer argument, the `JSlider` value, which determines the position of the thumb.]
- 22.11** Modify the program in Fig. 22.13 by adding a minimum of two new tabs.
- 22.12** Declare a subclass of `JPanel` called `MyColorChooser` that provides three `JSlider` objects and three `JTextField` objects. Each `JSlider` represents the values from 0 to 255 for the red, green and blue parts of a color. Use these values as the arguments to the `Color` constructor to create a new `Color` object. Display the current value of each `JSlider` in the corresponding `JTextField`. When the

**1042**    [Chapter 22](#)   [GUI Components: Part 2](#)

user changes the value of the `JSlider`, the `JTextField` should be changed accordingly. Use your new GUI component as part of an application that displays the current color value by drawing a filled rectangle.

**22.13** Modify the `MyColorChooser` class of Exercise 22.12 to allow the user to enter an integer value into a `JTextField` to set the red, green or blue value. When the user presses *Enter* in the `JTextField`, the corresponding `JSlider` should be set to the appropriate value.

**22.14** Modify the application in Exercise 22.13 to draw the current color as a rectangle on an instance of a subclass of `JPanel` which provides its own `paintComponent` method to draw the rectangle and provides *set* methods to set the red, green and blue values for the current color. When any *set* method is invoked, the drawing panel should automatically repaint itself.

**22.15** Modify the application in Exercise 22.14 to allow the user to drag the mouse across the drawing panel (a subclass of `JPanel`) to draw a shape in the current color. Enable the user to choose what shape to draw.

**22.16** Modify the application in Exercise 22.15 to provide the user with the ability to terminate the application by clicking the close box on the window that is displayed and by selecting `Exit` from a `File` menu. Use the techniques shown in Fig. 22.5.

**22.17** (*Complete Drawing Application*) Using the techniques developed in this chapter and Chapter 11, create a complete drawing application. The program should use the GUI components from Chapter 11 and Chapter 22 to enable the user to select the shape, color and fill characteristics. Each shape should be stored in an array of `MyShape` objects, where `MyShape` is the superclass in your hierarchy of shape classes. Use a `JDesktopPane` and `JInternalFrames` to allow the user to create multiple separate drawings in separate child windows. Create the user interface as a separate child window containing all the GUI components that allow the user to determine the characteristics of the shape to be drawn. The user can then click in any `JInternalFrame` to draw the shape.

# Multithreading

## OBJECTIVES

In this chapter you will learn:

- What threads are and why they are useful.
  - How threads enable you to manage concurrent activities.
  - The life cycle of a thread.
  - Thread priorities and scheduling.
  - To create and execute **Runnables**.
  - Thread synchronization.
  - What producer/consumer relationships are and how they are implemented with multithreading.
  - To enable multiple threads to update Swing GUI components in a thread-safe manner.
  - About interfaces **Callable** and **Future**, which you can use with threading to execute tasks that return results.

**1044    Chapter 23    Multithreading****Outline**

- 23.1** Introduction
- 23.2** Thread States: Life Cycle of a Thread
- 23.3** Thread Priorities and Thread Scheduling
- 23.4** Creating and Executing Threads
  - 23.4.1** Runnable and the `Thread` Class
  - 23.4.2** Thread Management with the `Executor` Framework
- 23.5** Thread Synchronization
- 23.6** Producer/Consumer Relationship without Synchronization
  - 23.5.1** Un同步ized Data Sharing
  - 23.5.2** Synchronized Data Sharing—Making Operations Atomic
- 23.7** Producer/Consumer Relationship: `ArrayBlockingQueue`
- 23.8** Producer/Consumer Relationship with Synchronization
- 23.9** Producer/Consumer Relationship: Bounded Buffers
- 23.10** Producer/Consumer Relationship: The `Lock` and `Condition` Interfaces
- 23.11** Multithreading with GUI
- 23.12** Other Classes and Interfaces in `java.util.concurrent`
  - 23.11.1** Performing Computations in a Worker Thread
  - 23.11.2** Processing Intermediate Results with `SwingWorker`
- 23.13** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 23.1 Introduction

It would be nice if we could focus our attention on performing only one action at a time and performing it well, but that is usually difficult to do. The human body performs a great variety of operations **in parallel**—or, as we will say throughout this chapter, **concurrently**. Respiration, blood circulation, digestion, thinking and walking, for example, can occur concurrently. All the senses—sight, touch, smell, taste and hearing—can be employed at once. Computers, too, can perform operations concurrently. It is common for personal computers to compile a program, send a file to a printer and receive electronic mail messages over a network concurrently. Only computers that have multiple processors can truly execute multiple instructions concurrently. Operating systems on single-processor computers create the illusion of concurrent execution by rapidly switching between activities, but on such computers only a single instruction can execute at once.

Most programming languages do not enable you to specify concurrent activities. Rather, the languages provide sequential control statements which enable you to specify that only one action at a time should be performed, with execution proceeding to the next action after the previous one has finished. Historically, concurrency has been implemented with operating system primitives available only to experienced systems programmers.

The Ada programming language, developed by the United States Department of Defense, made concurrency primitives widely available to defense contractors building military command-and-control systems. However, Ada has not been widely used in academia and industry.

Java makes concurrency available to you through the language and APIs. You specify that an application contains separate **threads of execution**, where each thread has its own method-call stack and program counter, allowing it to execute concurrently with other threads while sharing application-wide resources such as memory with these other threads. This capability, called **multithreading**, is not available in the core C and C++ languages, which influenced the design of Java.

### Performance Tip 23.1

*A problem with single-threaded applications that can lead to poor responsiveness is that lengthy activities must complete before others can begin. In a multithreaded application, threads can be distributed across multiple processors (if available) so that multiple tasks execute concurrently and the application can operate more efficiently. Multithreading can also increase performance on single-processor systems that simulate concurrency—when one thread cannot proceed (because, for example, it is waiting for the result of an I/O operation), another can use the processor.*

Unlike languages that do not have built-in multithreading capabilities (such as C and C++) and must therefore make nonportable calls to operating system multithreading primitives, Java includes multithreading primitives as part of the language itself and as part of its libraries. This facilitates manipulating threads in a portable manner across platforms.

We'll discuss many applications of **concurrent programming**. For example, when downloading a large file (e.g., an image, an audio clip or a video clip) over the Internet, the user may not want to wait until the entire clip downloads before starting the playback. To solve this problem, we can put multiple threads to work—one to download the clip, and another to play it. These activities proceed concurrently. To avoid choppy playback, we **synchronize** (coordinate the actions of) the threads so that the player thread doesn't begin until there is a sufficient amount of the clip in memory to keep the player thread busy.

The Java Virtual Machine (JVM) uses threads as well. In addition to creating threads to run a program, the JVM also may create threads for performing housekeeping tasks such as garbage collection.

Writing multithreaded programs can be tricky. Although the human mind can perform functions concurrently, people find it difficult to jump between parallel trains of thought. To see why multithreaded programs can be difficult to write and understand, try the following experiment: Open three books to page 1, and try reading the books concurrently. Read a few words from the first book, then a few from the second, then a few from the third, then loop back and read the next few words from the first book, and so on. After this experiment, you will appreciate many of the challenges of multithreading—switching between the books, reading briefly, remembering your place in each book, moving the book you're reading closer so that you can see it and pushing the books you are not reading aside—and, amid all this chaos, trying to comprehend the content of the books!

Programming concurrent applications is a difficult and error-prone undertaking. If you find that you must use synchronization in a program, you should follow some simple guidelines. First, *use existing classes from the Java API* (such as the `ArrayBlockingQueue` class we discuss in Section 23.7, Producer/Consumer Relationship: `ArrayBlockingQueue`) *that manage synchronization for you*. The classes in the Java API are written by experts, have been fully tested and debugged, operate efficiently and help you avoid common traps and pitfalls. Second, if you find that you need more custom functionality than that provided in the Java APIs, you should use the `synchronized` keyword and `Object` methods `wait`,

## 1046 Chapter 23 Multithreading

`notify` and `notifyAll` (discussed in Section 23.5 and Section 23.8). Finally, if you need even more complex capabilities, then you should use the `Lock` and `Condition` interfaces that are introduced in Section 23.10.

The `Lock` and `Condition` interfaces should be used only by advanced programmers who are familiar with the common traps and pitfalls of concurrent programming. We explain these topics in this chapter for several reasons—they provide a solid basis for understanding how concurrent applications synchronize access to shared memory; the concepts are important to understand, even if an application does not use these tools explicitly; and by showing you the complexity involved in using these low-level features, we hope to impress upon you the importance of using prepackaged concurrency capabilities whenever possible.

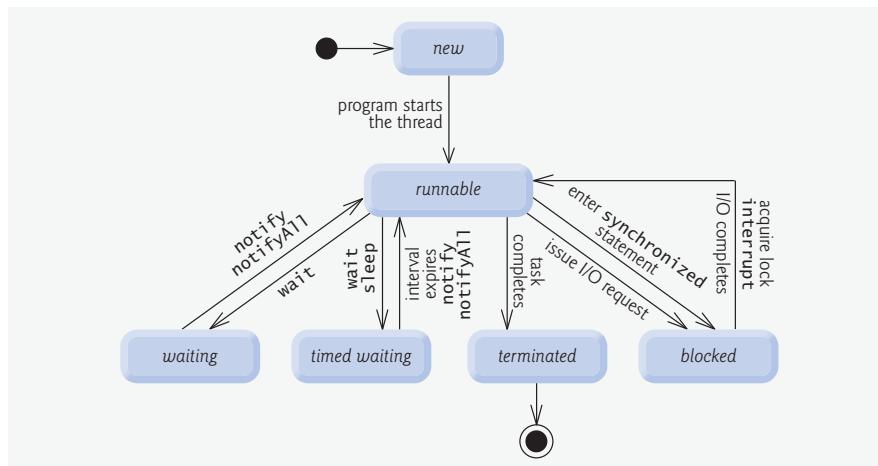

### 23.2 Thread States: Life Cycle of a Thread

At any time, a thread is said to be in one of several `thread states`—illustrated in the UML state diagram in Fig. 23.1. Several of the terms in the diagram are defined in later sections.

A new thread begins its life cycle in the `new` state. It remains in this state until the program starts the thread, which places it in the `Runnable` state. A thread in the `Runnable` state is considered to be executing its task.

Sometimes a `Runnable` thread transitions to the `Waiting` state while it waits for another thread to perform a task. A `Waiting` thread transitions back to the `Runnable` state only when another thread notifies the waiting thread to continue executing.

A `Runnable` thread can enter the `Timed Waiting` state for a specified interval of time. It transitions back to the `Runnable` state when that time interval expires or when the event it is waiting for occurs. `Timed Waiting` and `Waiting` threads cannot use a processor, even if one is available. A `Runnable` thread can transition to the `Timed Waiting` state if it provides an optional wait interval when it is waiting for another thread to perform a task. Such a thread returns to the `Runnable` state when it is notified by another thread or when the timed

**Fig. 23.1** | Thread life-cycle UML state diagram.

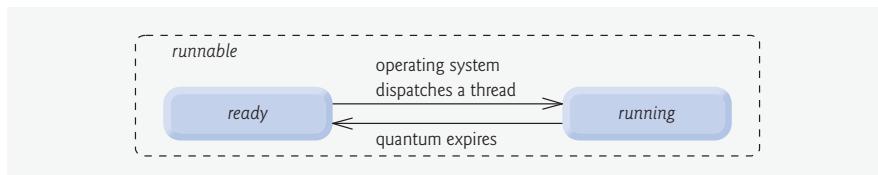

## 23.2 Thread States: Life Cycle of a Thread 1047

interval expires—whichever comes first. Another way to place a thread in the *timed waiting* state is to put a *runnable* thread to sleep. A *sleeping thread* remains in the *timed waiting* state for a designated period of time (called a *sleep interval*), after which it returns to the *runnable* state. Threads sleep when they momentarily do not have work to perform. For example, a word processor may contain a thread that periodically backs up (i.e., writes a copy of) the current document to disk for recovery purposes. If the thread did not sleep between successive backups, it would require a loop in which it continually tested whether it should write a copy of the document to disk. This loop would consume processor time without performing productive work, thus reducing system performance. In this case, it is more efficient for the thread to specify a sleep interval (equal to the period between successive backups) and enter the *timed waiting* state. This thread is returned to the *runnable* state when its sleep interval expires, at which point it writes a copy of the document to disk and reenters the *timed waiting* state.

A *runnable* thread transitions to the *blocked* state when it attempts to perform a task that cannot be completed immediately and it must temporarily wait until that task completes. For example, when a thread issues an input/output request, the operating system blocks the thread from executing until that I/O request completes—at that point, the *blocked* thread transitions to the *runnable* state, so it can resume execution. A *blocked* thread cannot use a processor, even if one is available.

A *runnable* thread enters the *terminated* state (sometimes called the *dead* state) when it successfully completes its task or otherwise terminates (perhaps due to an error). In the UML state diagram of Fig. 23.1, the *terminated* state is followed by the UML final state (the bull's-eye symbol) to indicate the end of the state transitions.

At the operating system level, Java's *runnable* state typically encompasses two separate states (Fig. 23.2). The operating system hides these states from the Java Virtual Machine (JVM), which sees only the *runnable* state. When a thread first transitions to the *runnable* state from the *new* state, the thread is in the *ready* state. A *ready* thread enters the *running* state (i.e., begins executing) when the operating system assigns the thread to a processor—also known as *dispatching the thread*. In most operating systems, each thread is given a small amount of processor time—called a *quantum* or *timeslice*—with which to perform its task. (Deciding how large the quantum should be is a key topic in operating systems courses.) When its quantum expires, the thread returns to the *ready* state and the operating system assigns another thread to the processor (see Section 23.3). Transitions between the *ready* and *running* states are handled solely by the operating system. The JVM does not “see” the transitions—it simply views the thread as being *runnable* and leaves it up to the operating system to transition the thread between *ready* and *running*. The process that an operating system uses to determine which thread to dispatch is called *thread scheduling* and is dependent on thread priorities (discussed in the next section).

**Fig. 23.2** | Operating system's internal view of Java's *runnable* state.

### 23.3 Thread Priorities and Thread Scheduling

Every Java thread has a [thread priority](#) that helps the operating system determine the order in which threads are scheduled. Java priorities range between `MIN_PRIORITY` (a constant of 1) and `MAX_PRIORITY` (a constant of 10). By default, every thread is given priority `NORM_PRIORITY` (a constant of 5). Each new thread inherits the priority of the thread that created it. Informally, higher-priority threads are more important to a program and should be allocated processor time before lower-priority threads. However, thread priorities cannot guarantee the order in which threads execute.

[*Note:* The constants (`MAX_PRIORITY`, `MIN_PRIORITY` and `NORM_PRIORITY`) are declared in the `Thread` class. It is recommended that you do not explicitly create and use `Thread` objects to implement concurrency, but rather use the `Executor` interface (which is described in Section 23.4.2). The `Thread` class contains some useful `static` methods, which we discuss later in the chapter.]

Most operating systems support timeslicing, which enables threads of equal priority to share a processor. Without timeslicing, each thread in a set of equal-priority threads runs to completion (unless it leaves the *Runnable* state and enters the *Waiting* or *Timed Waiting* state, or gets interrupted by a higher-priority thread) before other threads of equal priority get a chance to execute. With timeslicing, even if a thread has not finished executing when its quantum expires, the processor is taken away from the thread and given to the next thread of equal priority, if one is available.

An operating system's [thread scheduler](#) determines which thread runs next. One simple thread scheduler implementation keeps the highest-priority thread *running* at all times and, if there is more than one highest-priority thread, ensures that all such threads execute for a quantum each in [round-robin](#) fashion. Figure 23.3 illustrates a [multilevel priority queue](#) for threads. In the figure, assuming a single-processor computer, threads A and B each execute for a quantum in round-robin fashion until both threads complete execution. This means that A gets a quantum of time to run. Then B gets a quantum. Then A gets another quantum. Then B gets another quantum. This continues until one thread completes. The processor then devotes all its power to the thread that remains (unless another priority 10 thread becomes ready). Next, thread C runs to completion (assuming that no higher-priority threads arrive). Threads D, E and F each execute for a quantum in round-robin fashion until they all complete execution (again assuming that no higher-priority threads arrive). This process continues until all threads run to completion.

When a higher-priority thread enters the *ready* state, the operating system generally preempts the currently *running* thread (an operation known as [preemptive scheduling](#)). Depending on the operating system, higher-priority threads could postpone—possibly indefinitely—the execution of lower-priority threads. Such [indefinite postponement](#) is sometimes referred to more colorfully as [starvation](#).

Java provides higher-level concurrency utilities to hide some of this complexity and make multithreaded programs less error prone. Thread priorities are used behind the scenes to interact with the operating system, but most programmers who use Java multithreading will not be concerned with setting and adjusting thread priorities.

#### Portability Tip 23.1

*Thread scheduling is platform dependent—the behavior of a multithreaded program could vary across different Java implementations.*

## 23.3 Thread Priorities and Thread Scheduling 1049

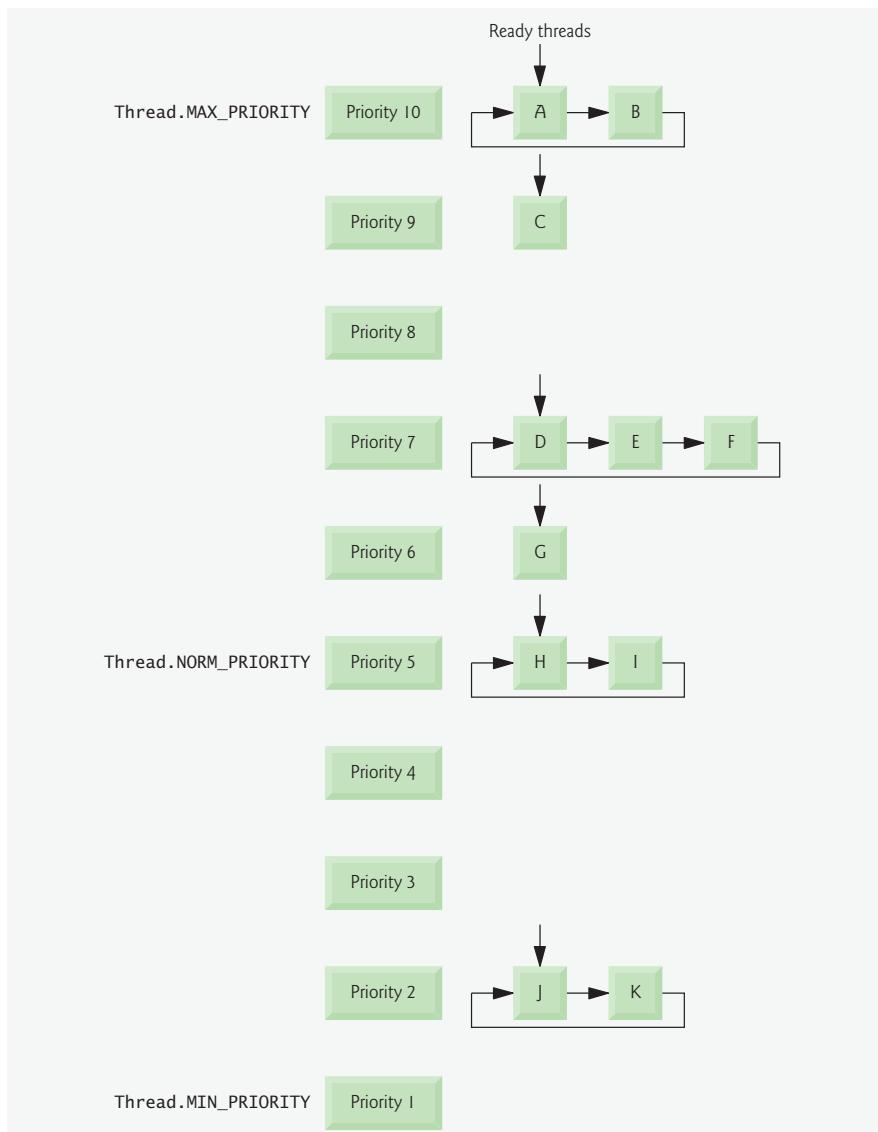

Fig. 23.3 | Thread-priority scheduling.

**Portability Tip 23.2**

When designing multithreaded programs consider the threading capabilities of all the platforms on which the programs will execute. Using priorities other than the default will make your programs' behavior platform specific. If portability is your goal, don't adjust thread priorities.

**1050** Chapter 23 Multithreading

## 23.4 Creating and Executing Threads

The preferred means of creating multithreaded Java applications is by implementing the `Runnable` interface (of package `java.lang`). A `Runnable` object represents a “task” that can execute concurrently with other tasks. The `Runnable` interface declares a single method, `run`, which contains the code that defines the task that a `Runnable` object should perform. When a thread executing a `Runnable` is created and started, the thread calls the `Runnable` object’s `run` method, which executes in the new thread.

### 23.4.1 Runnables and the Thread Class

Class `PrintTask` (Fig. 23.4) implements `Runnable` (line 5), so that multiple `PrintTasks` can execute concurrently. Variable `sleepTime` (line 7) stores a random integer value from 0 to 5 seconds created in the `PrintTask` constructor (line 16). Each thread running a `PrintTask` sleeps for the amount of time specified by `sleepTime`, then outputs its task’s name and a message indicating that it’s done sleeping.

```

1 // Fig. 23.4: PrintTask.java
2 // PrintTask class sleeps for a random time from 0 to 5 seconds
3 import java.util.Random;
4
5 public class PrintTask implements Runnable
6 {
7 private final int sleepTime; // random sleep time for thread
8 private final String taskName; // name of task
9 private final static Random generator = new Random();
10
11 public PrintTask(String name)
12 {
13 taskName = name; // set task name
14
15 // pick random sleep time between 0 and 5 seconds
16 sleepTime = generator.nextInt(5000); // milliseconds
17 } // end PrintTask constructor
18
19 // method run contains the code that a thread will execute
20 public void run()
21 {
22 try // put thread to sleep for sleepTime amount of time
23 {
24 System.out.printf("%s going to sleep for %d milliseconds.\n",
25 taskName, sleepTime);
26 Thread.sleep(sleepTime); // put thread to sleep
27 } // end try
28 catch (InterruptedException exception)
29 {
30 System.out.printf("%s %s\n",
31 taskName,
32 "terminated prematurely due to interruption");
33 } // end catch
34 }
35}
```

**Fig. 23.4** | `PrintTask` class sleeps for a random time from 0 to 5 seconds. (Part I of 2.)

## 23.4 Creating and Executing Threads

1051

```

34 // print task name
35 System.out.printf("%s done sleeping\n", taskName);
36 } // end method run
37 } // end class PrintTask

```

**Fig. 23.4** | PrintTask class sleeps for a random time from 0 to 5 seconds. (Part 2 of 2.)

A PrintTask executes when a thread calls the PrintTask's run method. Lines 24–25 display a message indicating the name of the currently executing task and that the task is going to sleep for sleepTime milliseconds. Line 26 invokes static method sleep of class Thread to place the thread in the *timed waiting* state for the specified amount of time. At this point, the thread loses the processor, and the system allows another thread to execute. When the thread awakens, it reenters the *runnable* state. When the PrintTask is assigned to a processor again, line 35 outputs a message indicating that the task is done sleeping, then method run terminates. Note that the catch at lines 28–32 is required because method sleep might throw a (checked) **InterruptedException** if the sleeping thread's **interrupt** method is called.

Figure 23.5 creates Thread objects to execute PrintTasks. Lines 12–14 create three threads, each of which specifies a new PrintTask to execute. Lines 19–21 call Thread method start on each of the threads—each call invokes the corresponding Runnable's run method to execute the task. Line 23 outputs a message indicating that all of the threads' tasks have been started and that the main method is finished executing.

```

1 // Fig. 23.5: ThreadCreator.java
2 // Creating and starting three threads to execute Runnables.
3 import java.lang.Thread;
4
5 public class ThreadCreator
6 {
7 public static void main(String[] args)
8 {
9 System.out.println("Creating threads");
10
11 // create each thread with a new targeted runnable
12 Thread thread1 = new Thread(new PrintTask("task1"));
13 Thread thread2 = new Thread(new PrintTask("task2"));
14 Thread thread3 = new Thread(new PrintTask("task3"));
15
16 System.out.println("Threads created, starting tasks.");
17
18 // start threads and place in runnable state
19 thread1.start(); // invokes task1's run method
20 thread2.start(); // invokes task2's run method
21 thread3.start(); // invokes task3's run method
22
23 System.out.println("Tasks started, main ends.\n");
24 } // end main
25 } // end class ThreadCreator

```

**Fig. 23.5** | Creating and starting three threads to execute Runnables. (Part 1 of 2.)

**1052**    Chapter 23 Multithreading

```

Creating threads
Threads created, starting tasks
Tasks started, main ends

task3 going to sleep for 491 milliseconds
task2 going to sleep for 71 milliseconds
task1 going to sleep for 3549 milliseconds
task2 done sleeping
task3 done sleeping
task1 done sleeping

```

```

Creating threads
Threads created, starting tasks
task1 going to sleep for 4666 milliseconds
task2 going to sleep for 48 milliseconds
task3 going to sleep for 3924 milliseconds
Tasks started, main ends

thread2 done sleeping
thread3 done sleeping
thread1 done sleeping

```

**Fig. 23.5** | Creating and starting three threads to execute `Runnables`. (Part 2 of 2.)

The code in method `main` executes in the **main thread**, a thread created by the JVM. The code in the `run` method of `PrintTask` (lines 20–36 of Fig. 23.4) executes in the threads created in lines 12–14 of Fig. 23.5. When method `main` terminates, the program itself continues running because there are still threads that are alive (i.e., any of the three threads we created that have not yet reached the *terminated* state). The program will not terminate until its last thread completes execution, at which point the JVM will also terminate.

The sample outputs for this program show each task's name and sleep time as the thread goes to sleep. The thread with the shortest sleep time normally awakens first, indicates that it's done sleeping and terminates. In Section 23.9, we discuss multithreading issues that could prevent the thread with the shortest sleep time from awakening first. In the first output, the main thread terminates before any of the other threads output their names and sleep times. This shows that the main thread runs to completion before any of the other threads get a chance to run. In the second output, all of the threads output their names and sleep times before the main thread terminates. This shows that the operating system allowed other threads to execute before the main thread terminated. This is an example of the round-robin scheduling we discussed in Section 23.3. Also notice that in the first example output, `task3` goes to sleep first and `task1` goes to sleep last, even though we started `task1`'s thread first. This illustrates the fact that we cannot predict the order in which threads will be scheduled, even if we know the order in which they were created and started. Finally, in each of the outputs, notice that the order in which the threads indicate that they are done sleeping matches the smallest to largest sleep times of the three threads. Although this is the reasonable and intuitive order for these threads to finish their tasks, the threads are not guaranteed to finish in this order.

### 23.4.2 Thread Management with the Executor Framework

Though it is possible to create threads explicitly as in Figure 23.5, it is recommended that you use the `Executor` interface to manage the execution of `Runnable` objects for you. An `Executor` object typically creates and manages a group of threads called a `thread pool` to execute `Runnables`. Using an `Executor` has many advantages over creating threads yourself. `Executors` can reuse existing threads to eliminate the overhead of creating a new thread for each task and can improve performance by optimizing the number of threads to ensure that the processor stays busy, without creating so many threads that the application runs out of resources.

The `Executor` interface declares a single method named `execute` which accepts a `Runnable` as an argument. The `Executor` assigns every `Runnable` passed to its `execute` method to one of the available threads in the thread pool. If there are no available threads, the `Executor` creates a new thread or waits for a thread to become available and assigns that thread the `Runnable` that was passed to method `execute`.

Interface `ExecutorService` (of package `java.util.concurrent`) is an interface that extends `Executor` and declares a number of other methods for managing the life cycle of an `Executor`. An object that implements the `ExecutorService` interface can be created using static methods declared in class `Executors` (of package `java.util.concurrent`). We use interface `ExecutorService` and a method of class `Executors` in the next application, which executes three tasks.

Figure 23.6 uses an `ExecutorService` object to manage threads that execute `PrintTasks`. Method `main` (lines 8–29) creates and names three `PrintTask` objects (lines 11–13). Line 18 uses `Executors` method `newCachedThreadPool` to obtain an `ExecutorService` that creates new threads as they are needed by the application. These threads are used by `threadExecutor` to execute the `Runnables`.

```

1 // Fig. 23.6: TaskExecutor.java
2 // Using an ExecutorService to execute Runnables.
3 import java.util.concurrent.Executors;
4 import java.util.concurrent.ExecutorService;
5
6 public class TaskExecutor
7 {
8 public static void main(String[] args)
9 {
10 // create and name each runnable
11 PrintTask task1 = new PrintTask("task1");
12 PrintTask task2 = new PrintTask("task2");
13 PrintTask task3 = new PrintTask("task3");
14
15 System.out.println("Starting Executor");
16
17 // create ExecutorService to manage threads
18 ExecutorService threadExecutor = Executors.newCachedThreadPool();
19
20 // start threads and place in runnable state
21 threadExecutor.execute(task1); // start task1

```

**Fig. 23.6** | Using an `ExecutorService` to execute `Runnables`. (Part I of 2.)

**1054**    Chapter 23 Multithreading

```

22 threadExecutor.execute(task2); // start task2
23 threadExecutor.execute(task3); // start task3
24
25 // shut down worker threads when their tasks complete
26 threadExecutor.shutdown();
27
28 System.out.println("Tasks started, main ends.\n");
29 } // end main
30 } // end class TaskExecutor

```

Starting Executor  
 Tasks started, main ends

task1 going to sleep for 4806 milliseconds  
 task2 going to sleep for 2513 milliseconds  
 task3 going to sleep for 1132 milliseconds  
 thread3 done sleeping  
 thread2 done sleeping  
 thread1 done sleeping

Starting Executor  
 task1 going to sleep for 1342 milliseconds  
 task2 going to sleep for 277 milliseconds  
 task3 going to sleep for 2737 milliseconds  
 Tasks started, main ends

task2 done sleeping  
 task1 done sleeping  
 task3 done sleeping

**Fig. 23.6** | Using an ExecutorService to execute Runnables. (Part 2 of 2.)

Lines 21–23 each invoke the `ExecutorService`'s `execute` method. This method executes the `Runnable` passed to it as an argument (in this case a `PrintTask`) some time in the future. The specified task may execute in one of the threads in the `ExecutorService`'s thread pool, in a new thread created to execute it, or in the thread that called the `execute` method; the `ExecutorService` manages these details. Method `execute` returns immediately from each invocation—the program does not wait for each `PrintTask` to finish. Line 26 calls `ExecutorService` method `shutdown`, which notifies the `ExecutorService` to stop accepting new tasks, but continues executing tasks that have already been submitted. Once all of the previously submitted `Runnables` have completed, the `threadExecutor` terminates. Line 28 outputs a message indicating that the tasks were started and the main thread is finishing its execution. The sample outputs for this program are similar to those of the previous program and again demonstrate the nondeterminism of thread scheduling.

## 23.5 Thread Synchronization

When multiple threads share an object and that object is modified by one or more of the threads, indeterminate results may occur (as we will see in the examples) unless access to the shared object is managed properly. If one thread is in the process of updating a shared object and another thread also tries to update it, it is unclear which thread's update takes

effect. When this happens, the program's behavior cannot be trusted—sometimes the program will produce the correct results, and sometimes it won't. In either case, there will be no indication that the shared object was manipulated incorrectly.

The problem can be solved by giving only one thread at a time *exclusive access* to code that manipulates the shared object. During that time, other threads desiring to manipulate the object are kept waiting. When the thread with exclusive access to the object finishes manipulating it, one of the threads that was waiting is allowed to proceed. This process, called **thread synchronization**, coordinates access to shared data by multiple concurrent threads. By synchronizing threads in this manner, you can ensure that each thread accessing a shared object excludes all other threads from doing so simultaneously—this is called **mutual exclusion**.

A common way to perform synchronization is to use Java's built-in **monitors**. Every object has a monitor and a **monitor lock** (or **intrinsic lock**). The monitor ensures that its object's monitor lock is held by a maximum of only one thread at any time. Monitors and monitor locks can thus be used to enforce mutual exclusion. If an operation requires the executing thread to hold a lock while the operation is performed, a thread must acquire the lock before proceeding with the operation. Other threads attempting to perform an operation that requires the same lock will be *blocked* until the first thread releases the lock, at which point the *blocked* threads may attempt to acquire the lock and proceed with the operation.

To specify that a thread must hold a monitor lock to execute a block of code, the code should be placed in a **synchronized statement**. Such code is said to be **guarded** by the monitor lock; a thread must **acquire the lock** to execute the synchronized statements. The monitor allows only one thread at a time to execute statements within synchronized blocks that lock on the same object, as only one thread at a time can hold the monitor lock. The synchronized statements are declared using the **synchronized keyword**:

```
synchronized (object)
{
 statements
} // end synchronized statement
```

where *object* is the object whose monitor lock will be acquired; *object* is normally *this* if it is the object in which the synchronized statement appears. If several synchronized statements are trying to execute on an object at the same time, only one of them may be active on the object—all the other threads attempting to enter a synchronized statement on the same object are placed in the *blocked* state.

When a synchronized statement finishes executing, the object's monitor lock is released and the operating system can allow one of the *blocked* threads attempting to enter a synchronized statement to acquire the lock to proceed. Java also allows **synchronized methods**. Such a method is equivalent to a synchronized statement enclosing the entire body of a method and using *this* as the object whose monitor lock will be acquired. You can specify a method as synchronized by placing the synchronized keyword before the method's return type in the method declaration.

### 23.5.1 Unsynchronized Data Sharing

We now present an example to illustrate the dangers of sharing an object across threads without proper synchronization. In this example, two `Runnables` maintain references to a

**1056**    Chapter 23 Multithreading

single integer array. Each `Runnable` writes five values to the array, then terminates. This may seem harmless, but it can result in errors if the array is manipulated without synchronization.

***Class SimpleArray***

An object of class `SimpleArray` (Fig. 23.7) will be shared across multiple threads. `SimpleArray` will enable those threads to place `int` values into `array` (declared at line 7). Line 8 initializes variable `writeIndex`, which will be used to determine the array element that should be written to next. The constructor (lines 12–15) creates an integer array of the desired size.

```

1 // Fig. 23.7: SimpleArray.java
2 // Class that manages an integer array to be shared by multiple threads.
3 import java.util.Random;
4
5 public class SimpleArray // CAUTION: NOT THREAD SAFE!
6 {
7 private final int array[]; // the shared integer array
8 private int writeIndex = 0; // index of next element to be written
9 private final static Random generator = new Random();
10
11 // construct a SimpleArray of a given size
12 public SimpleArray(int size)
13 {
14 array = new int[size];
15 } // end constructor
16
17 // add a value to the shared array
18 public void add(int value)
19 {
20 int position = writeIndex; // store the write index
21
22 try
23 {
24 // put thread to sleep for 0-499 milliseconds
25 Thread.sleep(generator.nextInt(500));
26 } // end try
27 catch (InterruptedException ex)
28 {
29 ex.printStackTrace();
30 } // end catch
31
32 // put value in the appropriate element
33 array[position] = value;
34 System.out.printf("%s wrote %d to element %d.\n",
35 Thread.currentThread().getName(), value, position);
36
37 ++writeIndex; // increment index of element to be written next
38 System.out.printf("Next write index: %d\n", writeIndex);
39 } // end method add
40

```

**Fig. 23.7** | Class that manages an integer array to be shared by multiple threads. (Part I of 2.)

23.5 Thread Synchronization **1057**

```

41 // used for outputting the contents of the shared integer array
42 public String toString()
43 {
44 String arrayString = "\nContents of SimpleArray:\n";
45
46 for (int i = 0; i < array.length; i++)
47 arrayString += array[i] + " ";
48
49 return arrayString;
50 } // end method toString
51 } // end class SimpleArray

```

**Fig. 23.7** | Class that manages an integer array to be shared by multiple threads. (Part 2 of 2.)

Method add (lines 18–39) allows new values to be inserted at the end of the array. Line 20 stores the current `writeIndex` value. Line 25 puts the thread that invokes add to sleep for a random interval from 0 to 499 milliseconds. This is done to make the problems associated with unsynchronized access to shared data more obvious. After the thread is done sleeping, line 33 inserts the value passed to add into the array at the element specified by `position`. Lines 34–35 output a message indicating the executing thread's name, the value that was inserted in the array and where it was inserted. Line 37 increments `writeIndex` so that the next call to add will insert a value in the array's next element. Lines 42–50 override method `toString` to create a `String` representation of the array's contents.

#### *Class ArrayWriter*

Class `ArrayWriter` (Fig. 23.8) implements the interface `Runnable` to define a task for inserting values in a `SimpleArray` object. The constructor (lines 10–14) takes two arguments—an integer `value`, which is the first value this task will insert in the `SimpleArray` object, and a reference to the `SimpleArray` object. Line 20 invokes method `add` on the `SimpleArray` object. The task completes after three consecutive integers beginning with `startValue` are added to the `SimpleArray` object.

```

1 // Fig. 23.8: ArrayWriter.java
2 // Adds integers to an array shared with other Runnables
3 import java.lang.Runnable;
4
5 public class ArrayWriter implements Runnable
6 {
7 private final SimpleArray sharedSimpleArray;
8 private final int startValue;
9
10 public ArrayWriter(int value, SimpleArray array)
11 {
12 startValue = value;
13 sharedSimpleArray = array;
14 } // end constructor
15

```

**Fig. 23.8** | Adds integers to an array shared with other `Runnables`. (Part 1 of 2.)

**1058 Chapter 23 Multithreading**

```

16 public void run()
17 {
18 for (int i = startValue; i < startValue + 3; i++)
19 {
20 sharedSimpleArray.add(i); // add an element to the shared array
21 } // end for
22 } // end method run
23 } // end class ArrayWriter

```

**Fig. 23.8** | Adds integers to an array shared with other `Runnables`. (Part 2 of 2.)***Class SharedArrayTest***

Class `SharedArrayTest` executes two `ArrayWriter` tasks that add values to a single `SimpleArray` object. Line 12 constructs a six-element `SimpleArray` object. Lines 15–16 create two new `ArrayWriter` tasks, one that places the values 1–3 in the `SimpleArray` object, and one that places the values 11–13. Lines 19–21 create an `ExecutorService` and execute the two `ArrayWriters`. Line 23 invokes the `ExecutorService`'s `shutdown` method to prevent additional tasks from starting and to enable the application to terminate when the currently executing tasks complete execution.

```

1 // Fig. 23.9: SharedArrayTest.java

```

Contents of SimpleArray:  
11 2 3 0 12 13

First pool-1-thread-1 wrote the value  
1 to element 0. Later pool-1-thread-2  
wrote the value 11 to element 0, thus  
overwriting the previously stored value.

**Fig. 23.9** | Executes two Runnables to insert values in a shared array. (Part 2 of 2.)

Recall that `ExecutorService` method `shutdown` returns immediately. Thus any code that appears after the call to `ExecutorService` method `shutdown` in line 23 will continue executing as long as the `main` thread is still assigned to a processor. We'd like to output the `SimpleArray` object to show you the results *after* the threads complete their tasks. So, we need the program to wait for the threads to complete before `main` outputs the `SimpleArray` object's contents. Interface `ExecutorService` provides the `awaitTermination` method for this purpose. This method returns control to its caller either when all tasks executing in the `ExecutorService` complete or when the specified timeout elapses. If all tasks are completed before `awaitTermination` times out, this method returns `true`; otherwise it returns `false`. The two arguments to `awaitTermination` represent a timeout value and a unit of measure specified with a constant from class `TimeUnit` (in this case, `TimeUnit.MINUTES`). In this example, if both tasks complete before `awaitTermination` times out, line 32 displays the `SimpleArray` object's contents. Otherwise, lines 34–35 print a message indicating that the tasks did not finish executing before `awaitTermination` timed out.

The output in Fig. 23.9 demonstrates the problems (highlighted in the output) that can be caused by failure to synchronize access to shared data. The value 1 was written to element 0, then overwritten later by the value 11. Also, when `writeIndex` was incremented to 3, nothing was written to that element, as indicated by the 0 in that element of the printed array.

**1060**    [Chapter 23](#) Multithreading

Recall that we have added calls to `Thread` method `sleep` between operations on the shared data to emphasize the unpredictability of thread scheduling and increase the likelihood of producing erroneous output. It is important to note that even if these operations were allowed to proceed at their normal pace, you could still see errors in the program's output. However, modern processors can handle the simple operations of the `SimpleArray` method `add` so quickly that you might not see the errors caused by the two threads executing this method concurrently, even if you tested the program dozens of times. One of the challenges of multithreaded programming is spotting the errors—they may occur so infrequently that a broken program does not produce incorrect results during testing, creating the illusion that the program is correct.

### 23.5.2 Synchronized Data Sharing—Making Operations Atomic

The output errors of Fig. 23.9 can be attributed to the fact that the shared object, `SimpleArray`, is not **thread safe**—`SimpleArray` is susceptible to errors if it is accessed concurrently by multiple threads. The problem lies in method `add`, which stores the value of `writeIndex`, places a new value in that element, then increments `writeIndex`. Such a method would present no problem in a single-threaded program. However, if one thread obtains the value of `writeIndex`, there is no guarantee that another thread cannot come along and increment `writeIndex` before the first thread has had a chance to place a value in the array. If this happens, the first thread will be writing to the array based on a **stale value** of `writeIndex`—a value that is no longer valid. Another possibility is that one thread might obtain the value of `writeIndex` after another thread adds an element to the array but before `writeIndex` is incremented. In this case, too, the first thread would write to the array based on an invalid value for `writeIndex`.

`SimpleArray` is not thread safe because it allows any number of threads to read and modify shared data concurrently, which can cause errors. To make `SimpleArray` thread safe, we must ensure that no two threads can access it at the same time. We also must ensure that while one thread is in the process of storing `writeIndex`, adding a value to the array, and incrementing `writeIndex`, no other thread may read or change the value of `writeIndex` or modify the contents of the array at any point during these three operations. In other words, we want these three operations—storing `writeIndex`, writing to the array, incrementing `writeIndex`—to be an **atomic operation**, which cannot be divided into smaller suboperations. While no processor can carry out all three stages of the `add` method in a single clock cycle to make the operation truly atomic, we can simulate atomicity by ensuring that only one thread carries out the three operations at a time. Any other threads that need to perform the operation must wait until the first thread has finished the `add` operation in its entirety.

Atomicity can be achieved using the `synchronized` keyword. By placing our three suboperations in a `synchronized` statement or `synchronized` method, only one thread at a time will be allowed to acquire the lock and perform the operations. When that thread has completed all of the operations in the `synchronized` block and releases the lock, another thread may acquire the lock and begin executing the operations. This ensures that a thread executing the operations will see the actual values of the shared data and that these values will not change unexpectedly in the middle of the operations as a result of another thread's modifying them.

23.5 Thread Synchronization **1061****Software Engineering Observation 23.1**

*Place all accesses to mutable data that may be shared by multiple threads inside synchronized statements or synchronized methods that synchronize on the same lock. When performing multiple operations on shared data, hold the lock for the entirety of the operation to ensure that the operation is effectively atomic.*

Figure 23.10 displays class SimpleArray with the proper synchronization. Notice that it's identical to the SimpleArray class of Fig. 23.7, except that add is now a synchronized method (line 19). So, only one thread at a time can execute this method. We reuse classes ArrayWriter (Fig. 23.8) and SharedArrayTest (Fig. 23.9) from the previous example.

```

1 // Fig. 23.10: SimpleArray.java
2 // Class that manages an integer array to be shared by multiple threads.
3 import java.util.Random;
4
5 public class SimpleArray
6 {
7 private final int array[]; // the shared integer array
8 private int writeIndex = 0; // index of next element to be written
9 private final static Random generator = new Random();
10
11 // construct a SimpleArray of a given size
12 public SimpleArray(int size)
13 {
14 array = new int[size];
15 } // end constructor
16
17 // add a value to the shared array
18 public synchronized void add(int value)
19 {
20 int position = writeIndex; // store the write index
21
22 try
23 {
24 // put thread to sleep for 0-499 milliseconds
25 Thread.sleep(generator.nextInt(500));
26 } // end try
27 catch (InterruptedException ex)
28 {
29 ex.printStackTrace();
30 } // end catch
31
32 // put value in the appropriate element
33 array[position] = value;
34 System.out.printf("%s wrote %2d to element %d.\n",
35 Thread.currentThread().getName(), value, position);
36
37 ++writeIndex; // increment index of element to be written next
38 System.out.printf("Next write index: %d\n", writeIndex);
39 } // end method add

```

Contents of SimpleArray:
1 11 12 13 2 3

```

**Fig. 23.10** | Class that manages an integer array to be shared by multiple threads with synchronization. (Part 2 of 2.)

Line 18 declares method as `synchronized`, making all of the operations in this method behave as a single, atomic operation. Line 20 performs the first suboperation—storing the value of `writeIndex`. Line 33 defines the second suboperation, writing an element to the element at the index position. Line 37 increments `writeIndex`. When the method finishes executing at line 39, the executing thread releases the `SimpleArray` lock, making it possible for another thread to begin executing the `add` method.

In the `synchronized add` method, we print messages to the console indicating the progress of threads as they execute this method, in addition to performing the actual operations required to insert a value in the array. We do this so that the messages will be printed in the correct order, allowing you to see whether the method is properly synchronized by comparing these outputs with those of the previous, unsynchronized example. We continue to output messages from `synchronized` blocks in later examples for demonstration purposes; typically, however, I/O *should not* be performed in `synchronized` blocks, because it's important to minimize the amount of time that an object is “locked.”

### Performance Tip 23.2

*Keep the duration of synchronized statements as short as possible while maintaining the needed synchronization. This minimizes the wait time for blocked threads. Avoid performing I/O, lengthy calculations and operations that do not require synchronization with a lock held.*

## 23.6 Producer/Consumer Relationship without Synchronization

1063

Another note on thread safety: We have said that it is necessary to synchronize access to all data that may be shared across multiple threads. Actually, this synchronization is necessary only for **mutable data**, or data that may change in its lifetime. If the shared data will not change in a multithreaded program, then it is not possible for a thread to see old or incorrect values as a result of another thread's manipulating that data.

When you share immutable data across threads, declare the corresponding data fields `final` to indicate that variables' values will not change after they are initialized. This prevents accidental modification of the shared data later in a program, which could compromise thread safety. Labeling object references as `final` indicates that the reference will not change, but it does not guarantee that the object itself is immutable—this depends entirely on the properties of the object. However, it is still good practice to mark references that will not change as `final`, as doing so forces the object's constructor to be atomic—the object will be fully constructed with all its fields initialized before it is accessed by the program.

**Good Programming Practice 23.1**

*Always declare data fields that you do not expect to change as final. Primitive variables that are declared as final can safely be shared across threads. An object reference that is declared as final ensures that the object it refers to will be fully constructed and initialized before it is used by the program and prevents the reference from pointing to another object.*

## 23.6 Producer/Consumer Relationship without Synchronization

In a **producer/consumer relationship**, the **producer** portion of an application generates data and stores it in a shared object, and the **consumer** portion of an application reads data from the shared object. The producer/consumer relationship separates the task of identifying work to be done from the tasks involved in actually carrying out the work. One example of a common producer/consumer relationship is **print spooling**. Although a printer might not be available when you want to print from an application (i.e., the producer), you can still “complete” the print task, as the data is temporarily placed on disk until the printer becomes available. Similarly, when the printer (i.e., a consumer) is available, it doesn't have to wait until a current user wants to print. The spooled print jobs can be printed as soon as the printer becomes available. Another example of the producer/consumer relationship is an application that copies data onto CDs by placing data in a fixed-size buffer, which is emptied as the CD-RW drive “burns” the data onto the CD.

In a multithreaded producer/consumer relationship, a **producer thread** generates data and places it in a shared object called a **buffer**. A **consumer thread** reads data from the buffer. This relationship requires synchronization to ensure that values are produced and consumed properly. All operations on mutable data that is shared by multiple threads (e.g., the data in the buffer) must be guarded with a lock to prevent corruption, as discussed in Section 23.5. Operations on the buffer data shared by a producer and consumer thread are also **state dependent**—the operations should proceed only if the buffer is in the correct state. If the buffer is in a not-full state, the producer may produce; if the buffer is in a not-empty state, the consumer may consume. All operations that access the buffer must use synchronization to ensure that data is written to the buffer or read from the buffer only if the buffer is in the proper state. If the producer attempting to put the next data into the buffer determines that it is full, the producer thread should wait until there is space to

**1064**    Chapter 23 Multithreading

write a new value. If a consumer thread finds the buffer empty or finds that the previous data has already been read, the consumer must also wait for new data to become available.

Consider how logic errors can arise if we do not synchronize access among multiple threads manipulating shared data. Our next example (Fig. 23.11–Fig. 23.15) implements a producer/consumer relationship without the proper synchronization. A producer thread writes the numbers 1 through 10 into a shared buffer—a single memory location shared between two threads (a single int variable called `buffer` in line 6 of Fig. 23.14 in this example). The consumer thread reads this data from the shared buffer and displays the data. The program’s output shows the values that the producer writes (produces) into the shared buffer and the values that the consumer reads (consumes) from the shared buffer.

Each value the producer thread writes to the shared buffer must be consumed exactly once by the consumer thread. However, the threads in this example erroneously are not synchronized. Therefore, data can be lost or garbled if the producer places new data into the shared buffer before the consumer reads the previous data. Also, data can be incorrectly duplicated if the consumer consumes data again before the producer produces the next value. To show these possibilities, the consumer thread in the following example keeps a total of all the values it reads. The producer thread produces values from 1 through 10. If the consumer reads each value produced once and only once, the total will be 55. However, if you execute this program several times, you will see that the total is not always 55 (as shown in the outputs in Fig. 23.10). To emphasize the point, the producer and consumer threads in the example each sleep for random intervals of up to three seconds between performing their tasks. Thus, we do not know when the producer thread will attempt to write a new value, or when the consumer thread will attempt to read a value.

The program consists of interface `Buffer` (Fig. 23.11) and four classes—`Producer` (Fig. 23.12), `Consumer` (Fig. 23.13), `UnsynchronizedBuffer` (Fig. 23.14) and `SharedBufferTest` (Fig. 23.15). Interface `Buffer` declares methods `set` (line 6) and `get` (line 9) that a `Buffer` must implement to enable the `Producer` thread to place a value in the `Buffer` and the `Consumer` thread to retrieve a value from the `Buffer`, respectively. Some programmers prefer to call these methods `put` and `take`, respectively. In subsequent examples, methods `set` and `get` will call methods that throw `InterruptedExceptions`. We declare each method with a `throws` clause here so that we don’t have to modify this interface for the later examples. Figure 23.14 shows the implementation of this interface.

Class `Producer` (Fig. 23.12) implements the `Runnable` interface, allowing it to be executed as a task in a separate thread. The constructor (lines 11–14) initializes the `Buffer` reference `sharedLocation` with an object created in `main` (line 14 of Fig. 23.15) and

```

1 // Fig. 23.11: Buffer.java
2 // Buffer interface specifies methods called by Producer and Consumer.
3 public interface Buffer {
4 ...
5 // place int value into Buffer
6 public void set(int value) throws InterruptedException;
7
8 // return int value from Buffer
9 public int get() throws InterruptedException;
10 } // end interface Buffer

```

**Fig. 23.11** | Buffer interface specifies methods called by Producer and Consumer.

23.6 Producer/Consumer Relationship without Synchronization 1065

passed to the constructor in the parameter shared. As we will see, this is an `UnsyncrhonizedBuffer` object that implements the interface `Buffer` without synchronizing access to the shared object. The Producer thread in this program executes the tasks specified in the method `run` (lines 17–39). Each iteration of the loop (lines 21–35) invokes `Thread` method `sleep` (line 25) to place the Producer thread into the *timed waiting* state for a random time interval between 0 and 3 seconds. When the thread awakens, line 26 passes the value of control variable `count` to the `Buffer` object's `set` method to set the shared buffer's value. Line 27 keeps a total of all the values produced so far and line 28 outputs that value. When the loop completes, lines 37–38 display a message indicating that the Producer has finished producing data and is terminating. Next, method `run` terminates, which indicates that the Producer completed its task. It is important to note that any method called from a `Runnable`'s `run` method (e.g., `Buffer` method `set`) executes as part of that task's thread of execution. This fact becomes important in Section 23.7 when we add synchronization to the producer/consumer relationship.

```

1 // Fig. 23.12: Producer.java
2 // Producer with a run method that inserts the values 1 to 10 in buffer.
3 import java.util.Random;
4
5 public class Producer implements Runnable
6 {
7 private final static Random generator = new Random();
8 private final Buffer sharedLocation; // reference to shared object
9
10 // constructor
11 public Producer(Buffer shared)
12 {
13 sharedLocation = shared;
14 } // end Producer constructor
15
16 // store values from 1 to 10 in sharedLocation
17 public void run()
18 {
19 int sum = 0;
20
21 for (int count = 1; count <= 10; count++)
22 {
23 try // sleep 0 to 3 seconds, then place value in Buffer
24 {
25 Thread.sleep(generator.nextInt(3000)); // random sleep
26 sharedLocation.set(count); // set value in buffer
27 sum += count; // increment sum of values
28 System.out.printf("\t%2d\n", sum);
29 } // end try
30 // if lines 25 or 26 get interrupted, print stack trace
31 catch (InterruptedException exception)
32 {
33 exception.printStackTrace();
34 } // end catch
35 } // end for

```

**Fig. 23.12** | Producer with a `run` method that inserts the values 1 to 10 in buffer. (Part I of 2.)

**1066** Chapter 23 Multithreading

```

36 System.out.println(
37 "Producer done producing\nTerminating Producer");
38 } // end method run
39 } // end class Producer

```

**Fig. 23.12** | Producer with a run method that inserts the values 1 to 10 in buffer. (Part 2 of 2.)

Class Consumer (Fig. 23.13) also implements interface `Runnable`, allowing the Consumer to execute concurrently with the Producer. The constructor (lines 11–14) initializes `Buffer` reference `sharedLocation` with an object that implements the `Buffer` interface created in `main` (Fig. 23.15) and passed to the constructor as the parameter `shared`. As we will see, this is the same `UnsynchronizedBuffer` object that is used to initialize the `Producer` object—thus, the two threads share the same object. The Consumer thread in this program performs the tasks specified in method `run` (lines 17–39). The loop at lines 21–35 iterates 10 times. Each iteration invokes `Thread` method `sleep` (line 26) to put the Consumer thread into the *timed waiting* state for up to 3 seconds. Next, line 27 uses the `Buffer`'s `get` method to retrieve the value in the shared buffer, then adds the value to variable `sum`. Line 28 displays the total of all the values consumed so far. When the loop completes, lines 37–38 display a line indicating the sum of the consumed values. Then method `run` terminates, which indicates that the Consumer completed its task. Once both threads enter the *terminated* state, the program ends.

```

1 // Fig. 23.13: Consumer.java
2 // Consumer with a run method that loops, reading 10 values from buffer.
3 import java.util.Random;
4
5 public class Consumer implements Runnable
6 {
7 private final static Random generator = new Random();
8 private final Buffer sharedLocation; // reference to shared object
9
10 // constructor
11 public Consumer(Buffer shared)
12 {
13 sharedLocation = shared;
14 } // end Consumer constructor
15
16 // read sharedLocation's value 10 times and sum the values
17 public void run()
18 {
19 int sum = 0;
20
21 for (int count = 1; count <= 10; count++)
22 {
23 // sleep 0 to 3 seconds, read value from buffer and add to sum
24 try
25 {
26 Thread.sleep(generator.nextInt(3000));

```

**Fig. 23.13** | Consumer with a run method that loops, reading 10 values from buffer. (Part 1 of 2.)

## 23.6 Producer/Consumer Relationship without Synchronization

1067

```

27 sum += sharedLocation.get();
28 System.out.printf("\t\t\t%2d\n", sum);
29 } // end try
30 // if lines 26 or 27 get interrupted, print stack trace
31 catch (InterruptedException exception)
32 {
33 exception.printStackTrace();
34 } // end catch
35 } // end for
36
37 System.out.printf("\n%s %d\n%s\n",
38 "Consumer read values totaling", sum, "Terminating Consumer");
39 } // end method run
40 } // end class Consumer

```

**Fig. 23.13** | Consumer with a run method that loops, reading 10 values from buffer. (Part 2 of 2.)

[Note: We call method `sleep` in method `run` of the `Producer` and `Consumer` classes to emphasize the fact that in multithreaded applications, it is unpredictable when each thread will perform its task and for how long it will perform the task when it has a processor. Normally, these thread scheduling issues are the job of the computer's operating system, beyond the control of the Java developer. In this program, our thread's tasks are quite simple—the `Producer` writes the values 1 to 10 to the buffer, and the `Consumer` reads 10 values from the buffer and adds each value to variable `sum`. Without the `sleep` method call, and if the `Producer` executes first, given today's phenomenally fast processors, the `Producer` would likely complete its task before the `Consumer` got a chance to execute. If the `Consumer` executed first, it would likely consume garbage data ten times, then terminate before the `Producer` could produce the first real value.]

Class `UnsynchronizedBuffer` (Fig. 23.14) implements interface `Buffer` (line 4). An object of this class is shared between the `Producer` and the `Consumer`. Line 6 declares instance variable `buffer` and initializes it with the value `-1`. This value is used to demonstrate the case in which the `Consumer` attempts to consume a value before the `Producer` ever places a value in `buffer`. Methods `set` (lines 9–13) and `get` (lines 16–20) do not synchronize access to the field `buffer`. Method `set` simply assigns its argument to `buffer` (line 12), and method `get` simply returns the value of `buffer` (line 19).

```

1 // Fig. Fig. 23.14: UnsynchronizedBuffer.java
2 // UnsynchronizedBuffer maintains the shared integer that is accessed by
3 // a producer thread and a consumer thread via methods set and get.
4 public class UnsynchronizedBuffer implements Buffer
5 {
6 private int buffer = -1; // shared by producer and consumer threads
7
8 // place value into buffer
9 public void set(int value) throws InterruptedException
10 {
11 System.out.printf("Producer writes\t%2d", value);

```

**Fig. 23.14** | `UnsynchronizedBuffer` maintains the shared integer that is accessed by a producer thread and a consumer thread via methods `set` and `get`. (Part 1 of 2.)

**1068** Chapter 23 Multithreading

```

12 buffer = value;
13 } // end method set
14
15 // return value from buffer
16 public int get() throws InterruptedException
17 {
18 System.out.printf("Consumer reads\t%d", buffer);
19 return buffer;
20 } // end method get
21 } // end class UnsynchronizedBuffer

```

**Fig. 23.14** | UnsynchronizedBuffer maintains the shared integer that is accessed by a producer thread and a consumer thread via methods set and get. (Part 2 of 2.)

Class SharedBufferTest contains method main (lines 9–25). Line 11 creates an ExecutorService to execute the Producer and Consumer Runnables. Line 14 creates an UnsynchronizedBuffer object and assigns it to Buffer variable sharedLocation. This object stores the data that the Producer and Consumer threads will share. Lines 23–24 create and execute the Producer and Consumer. Note that the Producer and Consumer constructors are each passed the same Buffer object (sharedLocation), so each object is initialized with a reference to the same Buffer. These lines also implicitly launch the threads and call each Runnable's run method. Finally, line 26 calls method shutdown so that the application can terminate when the threads executing the Producer and Consumer complete their tasks. When main terminates (line 27), the main thread of execution enters the *terminated* state. Recall from the overview of this example that we would like the Producer to execute first and every value produced by the Producer to be consumed exactly once by the Consumer. However, when we study the first output of Fig. 23.15, we see that the Producer writes the values 1, 2 and 3 before the Consumer reads its first value (3). Therefore, the values 1 and 2 are lost. Later, the values 5, 6 and 9 are lost, while 7 and 8 are read twice and 10 is read four times. So the first output produces an incorrect total of 77, instead of the correct total of 55. In the second output, the Consumer reads the value -1 before the Producer ever writes a value. The Consumer reads the value 1 five times before the Producer writes the value 2. Meanwhile, the values 5, 7, 8, 9 and 10 are all lost—the last four because the Consumer terminates before the Producer. An incorrect consumer total of 19 is displayed. (Lines in the output where the Producer or Consumer has acted out of order are highlighted.) This example clearly demonstrates that access to a shared object by concurrent threads must be controlled carefully or a program may produce incorrect results.

To solve the problems of lost and duplicated data, Section 23.7 presents an example in which we use an ArrayBlockingQueue (from package java.util.concurrent) to synchronize access to the shared object, guaranteeing that each and every value will be processed once and only once.

```

1 // Fig. 23.15: SharedBufferTest.java
2 // Application with two threads manipulating an unsynchronized buffer.
3 import java.util.concurrent.ExecutorService;
4 import java.util.concurrent.Executors;

```

## 23.6 Producer/Consumer Relationship without Synchronization

1069

```

5 public class SharedBufferTest
6 {
7 public static void main(String[] args)
8 {
9 // create new thread pool with two threads
10 ExecutorService application = Executors.newCachedThreadPool();
11
12 // create UnsynchronizedBuffer to store ints
13 Buffer sharedLocation = new UnsynchronizedBuffer();
14
15 System.out.println(
16 "Action\t\tValue\tSum of Produced\tSum of Consumed");
17 System.out.println(
18 "-----\t-----\t-----\t-----\n");
19
20 // execute the Producer and Consumer, giving each of them access
21 // to sharedLocation
22 application.execute(new Producer(sharedLocation));
23 application.execute(new Consumer(sharedLocation));
24
25 application.shutdown(); // terminate application when tasks complete
26 } // end main
27 } // end class SharedBufferTest

```

| Action                           | Value | Sum of Produced | Sum of Consumed    |
|----------------------------------|-------|-----------------|--------------------|
| -----                            | ----- | -----           | -----              |
| Producer writes                  | 1     | 1               |                    |
| Producer writes                  | 2     | 3               | — 1 is lost        |
| Producer writes                  | 3     | 6               | — 2 is lost        |
| Consumer reads                   | 3     |                 | 3                  |
| Producer writes                  | 4     | 10              |                    |
| Consumer reads                   | 4     |                 | 7                  |
| Producer writes                  | 5     | 15              |                    |
| Producer writes                  | 6     | 21              | — 5 is lost        |
| Producer writes                  | 7     | 28              | — 6 is lost        |
| Consumer reads                   | 7     |                 | 14                 |
| Consumer reads                   | 7     |                 | 21 — 7 read again  |
| Producer writes                  | 8     | 36              |                    |
| Consumer reads                   | 8     |                 | 29                 |
| Consumer reads                   | 8     |                 | 37 — 8 read again  |
| Producer writes                  | 9     | 45              |                    |
| Producer writes                  | 10    | 55              | — 9 is lost        |
| Producer done producing          |       |                 |                    |
| Terminating Producer             |       |                 |                    |
| Consumer reads                   | 10    |                 | 47                 |
| Consumer reads                   | 10    |                 | 57 — 10 read again |
| Consumer reads                   | 10    |                 | 67 — 10 read again |
| Consumer reads                   | 10    |                 | 77 — 10 read again |
| Consumer read values totaling 77 |       |                 |                    |
| Terminating Consumer             |       |                 |                    |

Fig. 23.15 | Application with two threads manipulating an unsynchronized buffer. (Part 2 of 3.)

## 1070 Chapter 23 Multithreading

| Action                           | Value | Sum of Produced | Sum of Consumed         |
|----------------------------------|-------|-----------------|-------------------------|
| Consumer reads                   | -1    |                 | -1 —— reads -1 bad data |
| Producer writes                  | 1     | 1               |                         |
| Consumer reads                   | 1     |                 | 0                       |
| Consumer reads                   | 1     |                 | 1 —— I read again       |
| Consumer reads                   | 1     |                 | 2 —— I read again       |
| Consumer reads                   | 1     |                 | 3 —— I read again       |
| Consumer reads                   | 1     |                 | 4 —— I read again       |
| Producer writes                  | 2     | 3               |                         |
| Consumer reads                   | 2     |                 | 6                       |
| Producer writes                  | 3     | 6               |                         |
| Consumer reads                   | 3     |                 | 9                       |
| Producer writes                  | 4     | 10              |                         |
| Consumer reads                   | 4     |                 | 13                      |
| Producer writes                  | 5     | 15              |                         |
| Producer writes                  | 6     | 21              | —— 5 is lost            |
| Consumer reads                   | 6     |                 | 19                      |
| Consumer read values totaling 19 |       |                 |                         |
| Terminating Consumer             |       |                 |                         |
| Producer writes                  | 7     | 28              | —— 7 never read         |
| Producer writes                  | 8     | 36              | —— 8 never read         |
| Producer writes                  | 9     | 45              | —— 9 never read         |
| Producer writes                  | 10    | 55              | —— 10 never read        |
| Producer done producing          |       |                 |                         |
| Terminating Producer             |       |                 |                         |

Fig. 23.15 | Application with two threads manipulating an unsynchronized buffer. (Part 3 of 3.)

### 23.7 Producer/Consumer Relationship: ArrayBlockingQueue

One way to synchronize producer and consumer threads is to use classes from Java's concurrency package that encapsulate the synchronization for you. Java includes the class **ArrayBlockingQueue** (from package `java.util.concurrent`)—a fully implemented, thread-safe buffer class that implements interface **BlockingQueue**. This interface extends the **Queue** interface discussed in Chapter 19 and declares methods **put** and **take**, the blocking equivalents of **Queue** methods **offer** and **poll**, respectively. Method **put** places an element at the end of the **BlockingQueue**, waiting if the queue is full. Method **take** removes an element from the head of the **BlockingQueue**, waiting if the queue is empty. These methods make class **ArrayBlockingQueue** a good choice for implementing a shared buffer. Because method **put** blocks until there is room in the buffer to write data, and method **take** blocks until there is new data to read, the producer must produce a value first, the consumer correctly consumes only after the producer writes a value and the producer correctly produces the next value (after the first) only after the consumer reads the previous (or first) value. **ArrayBlockingQueue** stores the shared data in an array. The array's size is specified as an argument to the **ArrayBlockingQueue** constructor. Once created, an **ArrayBlockingQueue** is fixed in size and will not expand to accommodate extra elements.

The program in Fig. 23.16 and Fig. 23.17 demonstrates a **Producer** and a **Consumer** accessing an **ArrayBlockingQueue**. Class **BlockingBuffer** (Fig. 23.16) uses an **Array-**

23.7 Producer/Consumer Relationship: `ArrayBlockingQueue` 1071

`BlockingQueue` object that stores an `Integer` (line 7). Line 11 creates the `ArrayBlockingQueue` and passes 1 to the constructor so that the object holds a single value, as we did with the `UnsynchronizedBuffer` of Fig. 23.14. Note that lines 7 and 11 use generics, which we discussed in Chapters 18–19. We discuss multiple-element buffers in Section 23.9. Because our `BlockingBuffer` class uses the thread-safe `ArrayBlockingQueue` class to manage access to the shared buffer, `BlockingBuffer` is itself thread safe, even though we have not implemented the synchronization ourselves.

`BlockingBuffer` implements interface `Buffer` (Fig. 23.11) and use classes `Producer` (Fig. 23.12 modified to remove line 28) and `Consumer` (Fig. 23.13 modified to remove line 28) from the example in Section 23.6. This approach demonstrates that the threads accessing the shared object are unaware that their buffer accesses are now synchronized. The synchronization is handled entirely in the `set` and `get` methods of `BlockingBuffer` by calling the synchronized `ArrayBlockingQueue` methods `put` and `take`, respectively. Thus, the `Producer` and `Consumer` `Runnables` are properly synchronized simply by calling the shared object's `set` and `get` methods.

```

1 // Fig. 23.16: BlockingBuffer.java
2 // Creates a synchronized buffer using an ArrayBlockingQueue.
3 import java.util.concurrent.ArrayBlockingQueue;
4
5 public class BlockingBuffer implements Buffer
6 {
7 private final ArrayBlockingQueue<Integer> buffer; // shared buffer
8
9 public BlockingBuffer()
10 {
11 buffer = new ArrayBlockingQueue<Integer>(1);
12 } // end BlockingBuffer constructor
13
14 // place value into buffer
15 public void set(int value) throws InterruptedException
16 {
17 buffer.put(value); // place value in buffer
18 System.out.printf("%s%2d\t%s%d\n", "Producer writes ", value,
19 "Buffer cells occupied: ", buffer.size());
20 } // end method set
21
22 // return value from buffer
23 public int get() throws InterruptedException
24 {
25 int readValue = 0; // initialize value read from buffer
26
27 readValue = buffer.take(); // remove value from buffer
28 System.out.printf("%s %2d\t%s%d\n", "Consumer reads ",
29 readValue, "Buffer cells occupied: ", buffer.size());
30
31 return readValue;
32 } // end method get
33 } // end class BlockingBuffer

```

**Fig. 23.16** | Creates a synchronized buffer using an `ArrayBlockingQueue`.

**1072**    Chapter 23 Multithreading

Line 17 in method `set` (lines 15–20) calls the `ArrayBlockingQueue` object's `put` method. This method call blocks if necessary until there is room in the buffer to place the value. Method `get` (lines 23–32) calls the `ArrayBlockingQueue` object's `take` method (line 27). This method call blocks if necessary until there is an element in the buffer to remove. Lines 18–19 and 28–29 use the `ArrayBlockingQueue` object's `size` method to display the total number of elements currently in the `ArrayBlockingQueue`.

Class `BlockingBufferTest` (Fig. 23.17) contains the `main` method that launches the application. Line 11 creates an `ExecutorService`, and line 14 creates a `BlockingBuffer` object and assigns its reference to the `Buffer` variable `sharedLocation`. Lines 16–17 execute the `Producer` and `Consumer` `Runnables`. Line 19 calls method `shutdown` to end the application when the threads finish executing the `Producer` and `Consumer` tasks.

Note that while methods `put` and `take` of `ArrayBlockingQueue` are properly synchronized, `BlockingBuffer` methods `set` and `get` (Fig. 23.16) are not declared to be synchronized. Thus, the statements performed in method `set`—the `put` operation (line 19) and the output (lines 20–21)—are not atomic; nor are the statements in method `get`—the `take` operation (line 36) and the output (lines 37–38). So there is no guarantee that each output will occur immediately after the corresponding `put` or `take` operation, and the outputs may appear out of order. Even they do, the `ArrayBlockingQueue` object is properly synchronizing access to the data, as evidenced by the fact that the sum of values read by the consumer is always correct.

```

1 // Fig. 23.17: BlockingBufferTest.java
2 // Two threads manipulating a blocking buffer.
3 import java.util.concurrent.ExecutorService;
4 import java.util.concurrent.Executors;
5
6 public class BlockingBufferTest
7 {
8 public static void main(String[] args)
9 {
10 // create new thread pool with two threads
11 ExecutorService application = Executors.newCachedThreadPool();
12
13 // create BlockingBuffer to store ints
14 Buffer sharedLocation = new BlockingBuffer();
15
16 application.execute(new Producer(sharedLocation));
17 application.execute(new Consumer(sharedLocation));
18
19 application.shutdown();
20 } // end main
21 } // end class BlockingBufferTest

```

```

Producer writes 1 Buffer cells occupied: 1
Consumer reads 1 Buffer cells occupied: 0
Producer writes 2 Buffer cells occupied: 1
Consumer reads 2 Buffer cells occupied: 0

```

## 23.8 Producer/Consumer Relationship with Synchronization

1073

```

Producer writes 3 Buffer cells occupied: 1
Consumer reads 3 Buffer cells occupied: 0
Producer writes 4 Buffer cells occupied: 1
Consumer reads 4 Buffer cells occupied: 0
Producer writes 5 Buffer cells occupied: 1
Consumer reads 5 Buffer cells occupied: 0
Producer writes 6 Buffer cells occupied: 1
Consumer reads 6 Buffer cells occupied: 0
Producer writes 7 Buffer cells occupied: 1
Consumer reads 7 Buffer cells occupied: 0
Producer writes 8 Buffer cells occupied: 1
Consumer reads 8 Buffer cells occupied: 0
Producer writes 9 Buffer cells occupied: 1
Consumer reads 9 Buffer cells occupied: 0
Producer writes 10 Buffer cells occupied: 1

Producer done producing
Terminating Producer
Consumer reads 10 Buffer cells occupied: 0

Consumer read values totaling 55
Terminating Consumer

```

**Fig. 23.17** | Two threads manipulating a blocking buffer. (Part 2 of 2.)

## 23.8 Producer/Consumer Relationship with Synchronization

The previous example showed how multiple threads can share a single-element buffer in a thread-safe manner by using the `ArrayBlockingQueue` class that encapsulates the synchronization necessary to protect the shared data. For educational purposes, we now explain how you can implement a shared buffer yourself using the `synchronized` keyword. Using an `ArrayBlockingQueue` will result in more maintainable and better performing code.

The first step in synchronizing access to the buffer is to implement methods `get` and `set` as `synchronized` methods. This requires that a thread obtain the monitor lock on the `Buffer` object before attempting to access the buffer data, but it does not solve the state-dependence problem associated with producer/consumer relationships. We must ensure that threads proceed with an operation only if the buffer is in the proper state. We need a way to allow our threads to wait, depending on whether certain conditions are true. In the case of placing a new item in the buffer, the condition that allows the operation to proceed is that the buffer is not full. In the case of fetching an item from the buffer, the condition that allows the operation to proceed is that the buffer is not empty. If the condition in question is true, the operation may proceed; if it is false, the thread must wait until it becomes true. When a thread is waiting on a condition, it is removed from contention for the processor, placed in the object's wait queue and the lock it holds is released.

### **Methods `wait`, `notify` and `notifyAll`**

Methods `wait`, `notify` and `notifyAll`, which are declared in class `Object` and inherited by all other classes, can be used with conditions to make threads wait when they cannot perform their tasks. If a thread obtains the monitor lock on an object, then determines that it cannot continue with its task on that object until some condition is satisfied, the thread can

**1074** Chapter 23 Multithreading

call `Object` method `wait`; this releases the monitor lock on the object, and the thread waits in the *waiting* state while the other threads try to enter the object's *synchronized* statement(s) or method(s). When a thread executing a *synchronized* statement (or method) completes or satisfies the condition on which another thread may be waiting, it can call `Object` method `notify` to allow a waiting thread to transition to the *runnable* state again. At this point, the thread that was transitioned from the *wait* state to the *runnable* state can attempt to reacquire the monitor lock on the object. Even if the thread is able to reacquire the monitor lock, it still might not be able to perform its task at this time—in which case the thread will reenter the *waiting* state and implicitly release the monitor lock. If a thread calls `notifyAll`, then all the threads waiting for the monitor lock become eligible to reacquire the lock (that is, they all transition to the *runnable* state). Remember that only one thread at a time can obtain the monitor lock on the object—other threads that attempt to acquire the same monitor lock will be *blocked* until the monitor lock becomes available again (i.e., until no other thread is executing in a *synchronized* statement on that object).

**Common Programming Error 23.1**

*It is an error if a thread issues a `wait`, a `notify` or a `notifyAll` on an object without having acquired a lock for it. This causes an `IllegalMonitorStateException`.*

**Error-Prevention Tip 23.1**

*It is a good practice to use `notifyAll` to notify waiting threads to become runnable. Doing so avoids the possibility that your program would forget about waiting threads, which would otherwise starve.*

The application in Fig. 23.18 and Fig. 23.19 demonstrates a Producer and a Consumer accessing a shared buffer with synchronization. In this case, the Producer always produces a value first, the Consumer correctly consumes only after the Producer produces a value and the Producer correctly produces the next value only after the Consumer consumes the previous (or first) value. We reuse interface `Buffer` and classes `Producer` and `Consumer` from the example in Section 23.6. The synchronization is handled in the `set` and `get` methods of class `SynchronizedBuffer` (Fig. 23.18), which implements interface `Buffer` (line 4). Thus, the Producer's and Consumer's `run` methods simply call the shared object's *synchronized* `set` and `get` methods.

```

1 // Fig. 23.18: SynchronizedBuffer.java
2 // Synchronizing access to shared data using Object
3 // methods wait and notify.
4 public class SynchronizedBuffer implements Buffer
5 {
6 private int buffer = -1; // shared by producer and consumer threads
7 private boolean occupied = false; // whether the buffer is occupied
8
9 // place value into buffer
10 public synchronized void set(int value)
11 {

```

**Fig. 23.18** | Synchronizing access to shared data using `Object` methods `wait` and `notify`.  
(Part I of 2.)

23.8 Producer/Consumer Relationship with Synchronization **1075**

```

12 // while there are no empty locations, place thread in waiting state
13 while (occupied)
14 {
15 // output thread information and buffer information, then wait
16 System.out.println("Producer tries to write.");
17 displayState("Buffer full. Producer waits.");
18 wait();
19 } // end while
20
21 buffer = value; // set new buffer value
22
23 // indicate producer cannot store another value
24 // until consumer retrieves current buffer value
25 occupied = true;
26
27 displayState("Producer writes " + buffer);
28
29 notifyAll(); // tell waiting thread(s) to enter runnable state
30 } // end method set; releases lock on SynchronizedBuffer
31
32 // return value from buffer
33 public synchronized int get()
34 {
35 // while no data to read, place thread in waiting state
36 while (!occupied)
37 {
38 // output thread information and buffer information, then wait
39 System.out.println("Consumer tries to read.");
40 displayState("Buffer empty. Consumer waits.");
41 wait();
42 } // end while
43
44 // indicate that producer can store another value
45 // because consumer just retrieved buffer value
46 occupied = false;
47
48 displayState("Consumer reads " + buffer);
49
50 notifyAll(); // tell waiting thread(s) to enter runnable state
51
52 return buffer;
53 } // end method get; releases lock on SynchronizedBuffer
54
55 // display current operation and buffer state
56 public void displayState(String operation)
57 {
58 System.out.printf("%-40s%d\t\t%b\n\n", operation, buffer,
59 occupied);
60 } // end method displayState
61 } // end class SynchronizedBuffer

```

**Fig. 23.18** | Synchronizing access to shared data using Object methods `wait` and `notify`.  
(Part 2 of 2.)

## 23.8 Producer/Consumer Relationship with Synchronization

1077

the `SynchronizedBuffer` object. If the lock is available, the `Consumer` thread acquires it. Then the `while` loop at lines 36–42 determines whether `occupied` is `false`. If so, the buffer is empty, so line 39 outputs a message indicating that the `Consumer` thread is trying to read a value, and line 40 invokes method `displayState` to output a message indicating that the buffer is empty and that the `Consumer` thread is waiting. Line 41 invokes method `wait` to place the thread that called method `get` (i.e., the `Consumer`) in the *waiting* state for the `SynchronizedBuffer` object. Again, the call to `wait` causes the calling thread to implicitly release the lock on the `SynchronizedBuffer` object, so another thread can attempt to acquire the `SynchronizedBuffer` object's lock and invoke the object's `set` or `get` method. If the lock on the `SynchronizedBuffer` is not available (e.g., if the `Producer` has not yet returned from method `set`), the `Consumer` is blocked until the lock becomes available.

The `Consumer` thread remains in the *waiting* state until it is notified by another thread that it may proceed—at which point the `Consumer` thread returns to the *runnable* state and attempts to implicitly reacquire the lock on the `SynchronizedBuffer` object. If the lock is available, the `Consumer` reacquires the lock, and method `get` continues executing with the next statement after `wait`. Because `wait` is called in a loop, the loop-continuation condition is tested again to determine whether the thread can proceed with its execution. If not, `wait` is invoked again—otherwise, method `get` continues with the next statement after the loop. Line 46 sets `occupied` to `false` to indicate that buffer is now empty (i.e., a `Consumer` cannot read the value, but a `Producer` can place another value in buffer), line 48 calls method `displayState` to indicate that the consumer is reading and line 50 invokes method `notifyAll`. If any threads are in the *waiting* state for the lock on this `SynchronizedBuffer` object, they enter the *runnable* state and can now attempt to reacquire the lock. Method `notifyAll` returns immediately, then method `get` returns the value of `buffer` to its caller. When method `get` returns, the lock on the `SynchronizedBuffer` object is implicitly released.

**Error-Prevention Tip 23.2**

*Always invoke method `wait` in a loop that tests the condition the task is waiting on. It is possible that a thread will reenter the runnable state (via a timed wait or another thread calling `notifyAll`) before the condition is satisfied. Testing the condition again ensures that the thread will not erroneously execute if it was notified early.*

**Testing Class `SynchronizedBuffer`**

Class `SharedBufferTest2` (Fig. 23.19) is similar to class `SharedBufferTest` (Fig. 23.15). `SharedBufferTest2` contains method `main` (lines 8–24), which launches the application. Line 11 creates an `ExecutorService` to run the `Producer` and `Consumer` tasks. Line 14 creates a `SynchronizedBuffer` object and assigns its reference to `Buffer` variable `sharedLocation`. This object stores the data that will be shared between the `Producer` and

| Producer tries to write.<br>Buffer full. Producer waits. | 6      | true     |

**Fig. 23.19** | Two threads manipulating a synchronized buffer. (Part 2 of 3.)

**1076**    [Chapter 23](#)   Multithreading***Fields and Methods of Class SynchronizedBuffer***

Class `SynchronizedBuffer` contains two fields—`buffer` (line 6) and `occupied` (line 7). Method `set` (lines 10–30) and method `get` (lines 33–53) are declared as `synchronized`—only one thread can call either of these methods at a time on a particular `SynchronizedBuffer` object. Field `occupied` is used to determine whether it is the Producer's or the Consumer's turn to perform a task. This field is used in conditional expressions in both the `set` and `get` methods. If `occupied` is `false`, then `buffer` is empty, so the Consumer cannot read the value of `buffer`, but the Producer can place a value into `buffer`. If `occupied` is `true`, the Consumer can read a value from `buffer`, but the Producer cannot place a value into `buffer`.

***Method set and the Producer Thread***

When the Producer thread's `run` method invokes `synchronized` method `set`, the thread implicitly attempts to acquire the `SynchronizedBuffer` object's monitor lock. If the monitor lock is available, the Producer thread implicitly acquires the lock. Then the loop at lines 13–19 first determines whether `occupied` is `true`. If so, `buffer` is full, so line 16 outputs a message indicating that the Producer thread is trying to write a value, and line 17 invokes method `displayState` (lines 56–60) to output another message indicating that `buffer` is full and that the Producer thread is waiting until there is space. Line 18 invokes method `wait` (inherited from `Object` by `SynchronizedBuffer`) to place the thread that called method `set` (i.e., the Producer thread) in the *waiting* state for the `SynchronizedBuffer` object. The call to `wait` causes the calling thread to implicitly release the lock on the `SynchronizedBuffer` object. This is important because the thread cannot currently perform its task and because other threads (in this case, the Consumer) should be allowed to access the object to allow the condition (`occupied`) to change. Now another thread can attempt to acquire the `SynchronizedBuffer` object's lock and invoke the object's `set` or `get` method.

The Producer thread remains in the *waiting* state until another thread notifies the Producer that it may proceed—at which point the Producer returns to the *runnable* state and attempts to implicitly reacquire the lock on the `SynchronizedBuffer` object. If the lock is available, the Producer thread reacquires the lock, and method `set` continues executing with the next statement after the `wait` call. Because `wait` is called in a loop, the loop-continuation condition is tested again to determine whether the thread can proceed. If not, then `wait` is invoked again—otherwise, method `set` continues with the next statement after the loop.

Line 21 in method `set` assigns the value to the `buffer`. Line 25 sets `occupied` to `true` to indicate that the `buffer` now contains a value (i.e., a consumer can read the value, but a Producer cannot yet put another value there). Line 27 invokes method `displayState` to output a message indicating that the Producer is writing a new value into the `buffer`. Line 29 invokes method `notifyAll` (inherited from `Object`). If any threads are waiting on the `SynchronizedBuffer` object's monitor lock, those threads enter the *runnable* state and can now attempt to reacquire the lock. Method `notifyAll` returns immediately, and method `set` then returns to the calling method (i.e., the Producer's `run` method). When method `set` returns, it implicitly releases the monitor lock on the `SynchronizedBuffer` object.

***Method get and the Consumer Thread***

Methods `get` and `set` are implemented similarly. When the Consumer thread's `run` method invokes `synchronized` method `get`, the thread attempts to acquire the monitor lock on

23.9 Producer/Consumer Relationship: Bounded Buffers **1079**

|                                                          |    |       |
|----------------------------------------------------------|----|-------|
| Consumer reads 6                                         | 6  | false |

| Producer done producing<br>Terminating Producer          |    |       |
| Consumer read values totaling 55<br>Terminating Consumer |    |       |

**Fig. 23.19** | Two threads manipulating a synchronized buffer. (Part 3 of 3.)

Consumer. Lines 16–17 display the column heads for the output. Lines 20–21 execute a Producer and a Consumer. Finally, line 23 calls method `shutdown` to end the application when the Producer and Consumer complete their tasks. When method `main` ends (line 24), the main thread of execution terminates.

Study the outputs in Fig. 23.19. Observe that every integer produced is consumed exactly once—no values are lost, and no values are consumed more than once. The synchronization ensures that the Producer produces a value only when the buffer is empty and the Consumer consumes only when the buffer is full. The Producer always goes first, the Consumer waits if the Producer has not produced since the Consumer last consumed, and the Producer waits if the Consumer has not yet consumed the value that the Producer most recently produced. Execute this program several times to confirm that every integer produced is consumed exactly once. In the sample output, note the highlighted lines indicating when the Producer and Consumer must wait to perform their respective tasks.

### 23.9 Producer/Consumer Relationship: Bounded Buffers

The program in Section 23.8 uses thread synchronization to guarantee that two threads manipulate data in a shared buffer correctly. However, the application may not perform optimally. If the two threads operate at different speeds, one of the threads will spend more (or most) of its time waiting. For example, in the program in Section 23.8 we shared a sin-

**1080**    [Chapter 23](#) Multithreading

gle integer variable between the two threads. If the Producer thread produces values faster than the Consumer can consume them, then the Producer thread waits for the Consumer, because there are no other locations in the buffer in which to place the next value. Similarly, if the Consumer consumes values faster than the Producer produces them, the Consumer waits until the Producer places the next value in the shared buffer. Even when we have threads that operate at the same relative speeds, those threads may occasionally become “out of sync” over a period of time, causing one of them to wait for the other. We cannot make assumptions about the relative speeds of concurrent threads—interactions that occur with the operating system, the network, the user and other components can cause the threads to operate at different speeds. When this happens, threads wait. When threads wait excessively, programs become less efficient, interactive programs become less responsive and applications suffer longer delays.

#### *Bounded Buffers*

To minimize the amount of waiting time for threads that share resources and operate at the same average speeds, we can implement a **bounded buffer** that provides a fixed number of buffer cells into which the Producer can place values, and from which the Consumer can retrieve those values. (In fact, we have already done this with the `ArrayBlockingQueue` class in Section 23.7.) If the Producer temporarily produces values faster than the Consumer can consume them, the Producer can write additional values into the extra buffer space (if any are available). This capability enables the Producer to perform its task even though the Consumer is not ready to retrieve the current value being produced. Similarly, if the Consumer consumes faster than the Producer produces new values, the Consumer can read additional values (if there are any) from the buffer. This enables the Consumer to keep busy even though the Producer is not ready to produce additional values.

Note that even a bounded buffer is inappropriate if the Producer and the Consumer operate consistently at different speeds. If the Consumer always executes faster than the Producer, then a buffer containing one location is enough. Additional locations would simply waste memory. If the Producer always executes faster, only a buffer with an “infinite” number of locations would be able to absorb the extra production. However, if the Producer and Consumer execute at about the same average speed, a bounded buffer helps to smooth the effects of any occasional speeding up or slowing down in either thread’s execution.

The key to using a bounded buffer with a Producer and Consumer that operate at about the same speed is to provide the buffer with enough locations to handle the anticipated “extra” production. If, over a period of time, we determine that the Producer often produces as many as three more values than the Consumer can consume, we can provide a buffer of at least three cells to handle the extra production. Making the buffer too small would cause threads to wait longer; making the buffer too large would waste memory.

#### Performance Tip 23.3

*Even when using a bounded buffer, it is possible that a producer thread could fill the buffer, which would force the producer to wait until a consumer consumed a value to free an element in the buffer. Similarly, if the buffer is empty at any given time, a consumer thread must wait until the producer produces another value. The key to using a bounded buffer is to optimize the buffer size to minimize the amount of thread wait time, while not wasting space..*

23.9 Producer/Consumer Relationship: Bounded Buffers **1081*****Bounded Buffers Using ArrayBlockingQueue***

The simplest way to implement a bounded buffer is to use an `ArrayBlockingQueue` for the buffer so that all of the synchronization details are handled for you. This can be done by reusing the example from Section 23.7 and simply passing the desired size for the bounded buffer into the `ArrayBlockingQueue` constructor. Rather than repeat our previous `ArrayBlockingQueue` example with a different size, we instead present an example that illustrates how you can build a bounded buffer yourself. Again, note that using an `ArrayBlockingQueue` will result in more maintainable and better performing code.

***Implementing Your Own Bounded Buffer as a Circular Buffer***

The program in Fig. 23.20 and Fig. 23.21 demonstrates a *Producer* and a *Consumer* accessing a bounded buffer with synchronization. We implement the bounded buffer in class `CircularBuffer` (Fig. 23.20) as a *circular buffer* that uses a shared array of three elements. A circular buffer writes into and reads from the array elements in order, beginning at the

```

1 // Fig. 23.20: CircularBuffer.java
2 // Synchronizing access to a shared three-element bounded buffer.
3 public class CircularBuffer implements Buffer
4 {
5 private final int[] buffer = { -1, -1, -1 }; // shared buffer
6
7 private int occupiedCells = 0; // count number of buffers used
8 private int writeIndex = 0; // index of next element to write to
9 private int readIndex = 0; // index of next element to read
10
11 // place value into buffer
12 public synchronized void set(int value) throws InterruptedException
13 {
14 // output thread information and buffer information, then wait;
15 // while no empty locations, place thread in blocked state
16 while (occupiedCells == buffer.length)
17 {
18 System.out.printf("Buffer is full. Producer waits.\n");
19 wait(); // wait until a buffer cell is free
20 } // end while
21
22 buffer[writeIndex] = value; // set new buffer value
23
24 // update circular write index
25 writeIndex = (writeIndex + 1) % buffer.length;
26
27 ++occupiedCells; // one more buffer cell is full
28 displayState("Producer writes " + value);
29 notifyAll(); // notify threads waiting to read from buffer
30 } // end method set
31
32 // return value from buffer
33 public synchronized int get() throws InterruptedException
34 {

```

**Fig. 23.20** | Synchronizing access to a shared three-element bounded buffer. (Part I of 2.)

**1082** Chapter 23 Multithreading

```

35 // wait until buffer has data, then read value;
36 // while no data to read, place thread in waiting state
37 while (occupiedCells == 0)
38 {
39 System.out.printf("Buffer is empty. Consumer waits.\n");
40 wait(); // wait until a buffer cell is filled
41 } // end while
42
43 int readValue = buffer[readIndex]; // read value from buffer
44
45 // update circular read index
46 readIndex = (readIndex + 1) % buffer.length;
47
48 --occupiedCells; // one fewer buffer cells are occupied
49 displayState("Consumer reads " + readValue);
50 notifyAll(); // notify threads waiting to write to buffer
51
52 return readValue;
53 } // end method get
54
55 // display current operation and buffer state
56 public void displayState(String operation)
57 {
58 // output operation and number of occupied buffer cells
59 System.out.printf("%s%d)\n%s",
60 operation,
61 " (buffer cells occupied: ", occupiedCells, "buffer cells: ");
62
63 for (int value : buffer)
64 System.out.printf(" %2d ", value); // output values in buffer
65
66 System.out.print("\n");
67
68 for (int i = 0; i < buffer.length; i++)
69 System.out.print("---- ");
70
71 System.out.print("\n");
72
73 for (int i = 0; i < buffer.length; i++)
74 {
75 if (i == writeIndex && i == readIndex)
76 System.out.print(" WR"); // both write and read index
77 else if (i == writeIndex)
78 System.out.print(" W "); // just write index
79 else if (i == readIndex)
80 System.out.print(" R "); // just read index
81 else
82 System.out.print(" "); // neither index
83 } // end for
84
85 System.out.println("\n");
86 } // end method displayState
87 } // end class CircularBuffer

```

**Fig. 23.20** | Synchronizing access to a shared three-element bounded buffer. (Part 2 of 2.)

23.9 Producer/Consumer Relationship: Bounded Buffers **1083**

first cell and moving toward the last. When a Producer or Consumer reaches the last element, it returns to the first and begins writing or reading, respectively, from there. In this version of the producer/consumer relationship, the Consumer consumes a value only when the array is not empty and the Producer produces a value only when the array is not full. The statements that created and started the thread objects in the main method of class SharedBufferTest2 (Fig. 23.19) now appear in class CircularBufferTest (Fig. 23.21).

Line 5 initializes array buffer as a three-element integer array that represents the circular buffer. Variable occupiedCells (line 7) counts the number of elements in buffer that contain data to be read. When occupiedBuffers is 0, there is no data in the circular buffer and the Consumer must wait—when occupiedCells is 3 (the size of the circular buffer), the circular buffer is full and the Producer must wait. Variable writeIndex (line 8) indicates the next location in which a value can be placed by a Producer. Variable readIndex (line 9) indicates the position from which the next value can be read by a Consumer.

`CircularBuffer` method `set` (lines 12–30) performs the same tasks as in Fig. 23.18, with a few modifications. The loop at lines 16–20 determines whether the Producer must wait (i.e., all buffers are full). If so, line 18 indicates that the Producer is waiting to perform its task. Then line 19 invokes method `wait`, causing the Producer thread to release the `CircularBuffer`'s lock and wait until there is space for a new value to be written into the buffer. When execution continues at line 22 after the `while` loop, the value written by the Producer is placed in the circular buffer at location `writeIndex`. Then line 25 updates `writeIndex` for the next call to `CircularBuffer` method `set`. This line is the key to the “circularity” of the buffer. When `writeIndex` is incremented past the end of the buffer, the line sets it to 0. Line 27 increments `occupiedCells`, because there is now one more value in the buffer that the Consumer can read. Next, line 28 invokes method `displayState` (lines 56–85) to update the output with the value produced, the number of occupied buffers, the contents of the buffers and the current `writeIndex` and `readIndex`. Line 29 invokes method `notifyAll` to transition `waiting` threads to the runnable state, so that a waiting Consumer thread (if there is one) can now try again to read a value from the buffer.

`CircularBuffer` method `get` (lines 33–53) also performs the same tasks as it did in Fig. 23.18, with a few minor modifications. The loop at lines 37–41 determines whether the Consumer must wait (i.e., all buffer cells are empty). If the Consumer must wait, line 39 updates the output to indicate that the Consumer is waiting to perform its task. Then line 40 invokes method `wait`, causing the current thread to release the lock on the `CircularBuffer` and wait until data is available to read. When execution eventually continues at line 43 after a `notifyAll` call from the Producer, `readValue` is assigned the value at location `readIndex` in the circular buffer. Then line 46 updates `readIndex` for the next call to `CircularBuffer` method `get`. This line and line 25 implement the “circularity” of the buffer. Line 48 decrements `occupiedCells`, because there is now one more position in the buffer in which the Producer thread can place a value. Line 49 invokes method `displayState` to update the output with the consumed value, the number of occupied buffers, the contents of the buffers and the current `writeIndex` and `readIndex`. Line 50 invokes method `notifyAll` to allow any Producer threads waiting to write into the `CircularBuffer` object to attempt to write again. Then line 52 returns the consumed value to the caller.

Method `displayState` (lines 56–85) outputs the state of the application. Lines 62–63 output the current values of the buffer cells. Line 63 uses method `printf` with a "%2d"

**1084**    Chapter 23 Multithreading

format specifier to print the contents of each buffer with a leading space if it is a single digit. Lines 70–82 output the current `writeIndex` and `readIndex` with the letters `W` and `R`, respectively.

***Testing Class CircularBuffer***

Class `CircularBufferTest` (Fig. 23.21) contains the `main` method that launches the application. Line 11 creates the `ExecutorService`, and line 14 creates a `CircularBuffer` object and assigns its reference to `sharedLocation`. Line 17 invokes the `CircularBuffer`'s `displayState` method to show the initial state of the buffer. Lines 20–21 execute the `Producer` and `Consumer` tasks. Line 23 calls method `shutdown` to end the application when the threads complete the `Producer` and `Consumer` tasks.

Each time the `Producer` writes a value or the `Consumer` reads a value, the program outputs a message indicating the action performed (a read or a write), the contents of `buffer`, and the location of `writeIndex` and `readIndex`. In the output of Fig. 23.21, the `Producer` first writes the value 1. The buffer then contains the value 1 in the first cell and the value `-1` (the default value that we use for output purposes) in the other two cells. The write index is updated to the second cell, while the read index stays at the first cell. Next, the `Consumer` reads 1. The buffer contains the same values, but the read index has been updated to the second cell. The `Consumer` then tries to read again, but the buffer is empty and the `Consumer` is forced to wait. Note that only once in this execution of the program was it necessary for either thread to wait.

```

## 23.10 Producer/Consumer Relationship: The Lock and Condition Interfaces

Though the `synchronized` keyword provides for most basic thread synchronization needs, Java provides other tools to assist in developing concurrent programs. In this section, we discuss the `Lock` and `Condition` interfaces, which were introduced in Java SE 5. These interfaces give programmers more precise control over thread synchronization, but are more complicated to use.

### *Interface Lock and Class ReentrantLock*

Any object can contain a reference to an object that implements the `Lock` interface (of package `java.util.concurrent.locks`). A thread calls the `Lock`'s `lock` method to acquire the lock. Once a `Lock` has been obtained by one thread, the `Lock` object will not allow another thread to obtain the `Lock` until the first thread releases the `Lock` (by calling the `Lock`'s `unlock` method). If several threads are trying to call method `lock` on the same `Lock` object at the same time, only one of these threads can obtain the lock—all the others are placed in the *waiting* state for that lock. When a thread calls method `unlock`, the lock on the object is released and a waiting thread attempting to lock the object proceeds.

Class `ReentrantLock` (of package `java.util.concurrent.locks`) is a basic implementation of the `Lock` interface. The constructor for a `ReentrantLock` takes a boolean argument that specifies whether the lock has a *fairness policy*. If the argument is `true`, the `ReentrantLock`'s fairness policy is “the longest-waiting thread will acquire the lock when it is available.” Such a fairness policy guarantees that indefinite postponement (also called starvation) cannot occur. If the fairness policy argument is set to `false`, there is no guarantee as to which waiting thread will acquire the lock when it is available.

### Software Engineering Observation 23.2

*Using a ReentrantLock with a fairness policy avoids indefinite postponement.*

### Performance Tip 23.4

*Using a ReentrantLock with a fairness policy can decrease program performance significantly.*

### *Condition Objects and Interface Condition*

If a thread that owns a `Lock` determines that it cannot continue with its task until some condition is satisfied, the thread can wait on a `condition object`. Using `Lock` objects allows you to explicitly declare the condition objects on which a thread may need to wait. For example, in the producer/consumer relationship, producers can wait on one object and consumers can wait on another. This is not possible when using the `synchronized` keywords and an object's built-in monitor lock. Condition objects are associated with a specific `Lock` and are created by calling a `Lock`'s `newCondition` method, which returns an object that implements the `Condition` interface (of package `java.util.concurrent.locks`). To wait on a condition object, the thread can call the `Condition`'s `await` method. This immediately releases the associated `Lock` and places the thread in the *waiting* state for that `Condition`. Other threads can then try to obtain the `Lock`. When a *runnable* thread completes a task and determines that the *waiting* thread can now continue, the *runnable* thread can call `Condition` method `signal` to allow a thread in that `Condition`'s

**1088** Chapter 23 Multithreading

*waiting* state to return to the *runnable* state. At this point, the thread that transitioned from the *waiting* state to the *runnable* state can attempt to reacquire the Lock. Even if it is able to reacquire the Lock, the thread still might not be able to perform its task at this time—in which case the thread can call the Condition’s `await` method to release the Lock and reenter the *waiting* state. If multiple threads are in a Condition’s *waiting* state when `signal` is called, the default implementation of Condition signals the longest-waiting thread to transition to the *runnable* state. If a thread calls Condition method `signalAll`, then all the threads waiting for that condition transition to the *runnable* state and become eligible to reacquire the Lock. Only one of those threads can obtain the Lock on the object—the others will wait until the Lock becomes available again. If the Lock has a fairness policy, the longest-waiting thread acquires the Lock. When a thread is finished with a shared object, it must call method `unlock` to release the Lock.

**Common Programming Error 23.2**

*Deadlock occurs when a waiting thread (let us call this thread1) cannot proceed because it is waiting (either directly or indirectly) for another thread (let us call this thread2) to proceed, while simultaneously thread2 cannot proceed because it is waiting (either directly or indirectly) for thread1 to proceed. The two threads are waiting for each other, so the actions that would enable each thread to continue execution can never occur.*

**Error-Prevention Tip 23.3**

*When multiple threads manipulate a shared object using locks, ensure that if one thread calls method `await` to enter the waiting state for a condition object, a separate thread eventually will call Condition method `signal` to transition the thread waiting on the condition object back to the runnable state. If multiple threads may be waiting on the condition object, a separate thread can call Condition method `signalAll` as a safeguard to ensure that all the waiting threads have another opportunity to perform their tasks. If this is not done, starvation might occur.*

**Common Programming Error 23.3**

*An `IllegalMonitorStateException` occurs if a thread issues an `await`, a `signal`, or a `signalAll` on a condition object without having acquired the lock for that condition object.*

**Lock and Condition vs. the synchronized Keyword**

In some applications, using Lock and Condition objects may be preferable to using the `synchronized` keyword. Locks allow you to interrupt waiting threads or to specify a timeout for waiting to acquire a lock, which is not possible using the `synchronized` keyword. Also, a Lock is not constrained to be acquired and released in the same block of code, which is the case with the `synchronized` keyword. Condition objects allow you to specify multiple condition objects on which threads may wait. Thus, it is possible indicate to waiting threads that a specific condition object is now true by calling `signal` or `signalAll` on that Condition object. With the `synchronized` keyword, there is no way to explicitly state the condition on which threads are waiting, and thus there is no way to notify threads waiting on one condition that they may proceed without also signaling threads waiting on any other conditions. There are other possible advantages to using Lock and Condition objects, but note that generally it is best to use the `synchronized` keyword unless your application requires advanced synchronization capabilities. Using interfaces Lock and Condition is error prone—`unlock` is not guaranteed to be called, whereas the monitor in a `synchronized` statement will always be released when the statement completes execution.

23.10 The Lock and Condition Interfaces **1089*****Using Locks and Conditions to Implement Synchronization***

To illustrate how to use the Lock and Condition interfaces, we now implement the producer/consumer relationship using Lock and Condition objects to coordinate access to a shared single-element buffer (Fig. 23.22 and Fig. 23.23). In this case, each produced value is correctly consumed exactly once.

Class `SynchronizedBuffer` (Fig. 23.22) contains five fields. Line 11 creates a new object of type `ReentrantLock` and assigns its reference to `Lock` variable `accessLock`. The `ReentrantLock` is created without the fairness policy because at any time only a single Producer or Consumer will be waiting to acquire the Lock in this example. Lines 14–15 create two Conditions using `Lock` method `newCondition`. `Condition canWrite` contains a queue for a Producer thread waiting while the buffer is full (i.e., there is data in the buffer that the Consumer has not read yet). If the buffer is full, the Producer calls method `await` on this Condition. When the Consumer reads data from a full buffer, it calls method `signal` on this Condition. `Condition canRead` contains a queue for a Consumer thread waiting while the buffer is empty (i.e., there is no data in the buffer for the Consumer to read). If the buffer is empty, the Consumer calls method `await` on this Condition. When the Producer writes to the empty buffer, it calls method `signal` on this Condition. The `int` variable `buffer` (line 17) holds the shared data. The `boolean` variable `occupied` (line 18) keeps track of whether the buffer currently holds data (that the Consumer should read).

```

14 private final Condition canWrite = accessLock.newCondition();
15 private final Condition canRead = accessLock.newCondition();
16
17 private int buffer = -1; // shared by producer and consumer threads
18 private boolean occupied = false; // whether buffer is occupied
19
20 // place int value into buffer
21 public void set(int value) throws InterruptedException
22 {
23 accessLock.lock(); // lock this object
24
25 // output thread information and buffer information, then wait
26 try
27 {

```

**Fig. 23.22** | Synchronizing access to a shared integer using the Lock and Condition interfaces. (Part I of 3.)

**1090** Chapter 23 Multithreading

```

28 // while buffer is not empty, place thread in waiting state
29 while (occupied)
30 {
31 System.out.println("Producer tries to write.");
32 displayState("Buffer full. Producer waits.");
33 canWrite.await(); // wait until buffer is empty
34 } // end while
35
36 buffer = value; // set new buffer value
37
38 // indicate producer cannot store another value
39 // until consumer retrieves current buffer value
40 occupied = true;
41
42 displayState("Producer writes " + buffer);
43
44 // signal thread waiting to read from buffer
45 canRead.signal();
46 } // end try
47 finally
48 {
49 accessLock.unlock(); // unlock this object
50 } // end finally
51 } // end method set
52
53 // return value from buffer
54 public int get() throws InterruptedException
55 {
56 int readValue = 0; // initialize value read from buffer
57 accessLock.lock(); // lock this object
58
59 // output thread information and buffer information, then wait
60 try
61 {
62 // while no data to read, place thread in waiting state
63 while (!occupied)
64 {
65 System.out.println("Consumer tries to read.");
66 displayState("Buffer empty. Consumer waits.");
67 canRead.await(); // wait until buffer is full
68 } // end while
69
70 // indicate that producer can store another value
71 // because consumer just retrieved buffer value
72 occupied = false;
73
74 readValue = buffer; // retrieve value from buffer
75 displayState("Consumer reads " + readValue);
76
77 // signal thread waiting for buffer to be empty
78 canWrite.signal();
79 } // end try

```

**Fig. 23.22** | Synchronizing access to a shared integer using the Lock and Condition interfaces. (Part 2 of 3.)

23.10 The Lock and Condition Interfaces **1091**

```

80 finally
81 {
82 accessLock.unlock(); // unlock this object
83 } // end finally
84
85 return readValue;
86 } // end method get
87
88 // display current operation and buffer state
89 public void displayState(String operation)
90 {
91 System.out.printf("%-40s%d\t\t%b\n\n", operation, buffer,
92 occupied);
93 } // end method displayState
94 } // end class SynchronizedBuffer

```

**Fig. 23.22** | Synchronizing access to a shared integer using the Lock and Condition interfaces. (Part 3 of 3.)

Line 23 in method set calls method lock on the SynchronizedBuffer's accessLock. If the lock is available (i.e., no other thread has acquired this lock), method lock returns immediately (this thread now owns the lock) and the thread continues. If the lock is unavailable (i.e., it is held by another thread), this method waits until the lock is released by the other thread. After the lock is acquired, the try block in lines 26–46 executes. Line 29 tests occupied to determine whether buffer is full. If it is, lines 31–32 display a message indicating that the thread will wait. Line 33 calls Condition method await on the canWrite condition object, which temporarily releases the SynchronizedBuffer's Lock and waits for a signal from the Consumer that buffer is available for writing. When buffer is available, the method proceeds, writing to buffer (line 36), setting occupied to true (line 40) and displaying a message indicating that the producer wrote a value (line 42). Line 45 calls Condition method signal on condition object canRead to notify the waiting Consumer (if there is one) that the buffer has new data to be read. Line 49 calls method unlock from a finally block to release the lock and allow the Consumer to proceed.

#### Error-Prevention Tip 23.4

*Place calls to Lock method unlock in a finally block. If an exception is thrown, unlock must still be called or deadlock could occur.*

Line 57 of method get (lines 54–86) calls method lock to acquire the Lock. This method waits until the Lock is available. Once the Lock is acquired, line 63 tests whether occupied is false, indicating that the buffer is empty. If the buffer is empty, line 67 calls method await on condition object canRead. Recall that method signal is called on variable canRead in the set method (line 45). When the Condition object is signaled, the get method continues. Line 72 sets occupied to false, line 74 stores the value of buffer in readValue and line 75 outputs the readValue. Then line 78 signals the condition object canWrite. This will awaken the Producer if it is indeed waiting for the buffer to be emptied. Line 82 calls method unlock from a finally block to release the lock, and line 85 returns readValue to the calling method.

**1092** Chapter 23 Multithreading**Common Programming Error 23.4**

*Forgetting to signal a waiting thread is a logic error. The thread will remain in the waiting state, which will prevent the thread from proceeding. Such waiting can lead to indefinite postponement or deadlock.*

Class SharedBufferTest2 (Fig. 23.23) is identical to that of Fig. 23.19. Study the outputs in Fig. 23.23. Observe that every integer produced is consumed exactly once—no values are lost, and no values are consumed more than once. The Lock and Condition objects ensure that the Producer and Consumer cannot perform their tasks unless it is their turn. The Producer must go first, the Consumer must wait if the Producer has not produced since the Consumer last consumed and the Producer must wait if the Consumer has not yet consumed the value that the Producer most recently produced. Execute this program several times to confirm that every integer produced is consumed exactly once. In the sample output, note the highlighted lines indicating when the Producer and Consumer must wait to perform their respective tasks.

**Fig. 23.23** | Two threads manipulating a synchronized buffer. (Part 2 of 2.)

### 23.11 Multithreading with GUI

Swing applications present a unique set of challenges for multithreaded programming. All Swing applications have a single thread, called the **event dispatch thread**, to handle interactions with the application's GUI components. Typical interactions include updating GUI components or processing user actions such as mouse clicks. All tasks that require in-

**1094**    [Chapter 23](#)   Multithreading

teraction with an application's GUI are placed in an event queue and are executed sequentially by the event dispatch thread.

Swing GUI components are not thread safe—they cannot be manipulated by multiple threads without the risk of incorrect results. Unlike the other examples presented in this chapter, thread safety in GUI applications is achieved not by synchronizing thread actions, but by ensuring that Swing components are accessed from only a single thread—the event dispatch thread. This technique is called **thread confinement**. Allowing just one thread to access non-thread-safe objects eliminates the possibility of corruption due to multiple threads accessing these objects concurrently.

Usually it is sufficient to perform simple calculations on the event dispatch thread in sequence with GUI component manipulations. If an application must perform a lengthy computation in response to a user interface interaction, the event dispatch thread cannot attend to other tasks in the event queue while the thread is tied up in that computation. This causes the GUI components to become unresponsive. It is preferable to handle a long-running computation in a separate thread, freeing the event dispatch thread to continue managing other GUI interactions. Of course, to update the GUI based on the computation's results, you must update the GUI from the event dispatch thread, rather than from the worker thread that performed the computation.

#### *Class SwingWorker*

Java SE 6 provides class **SwingWorker** (in package `javax.swing`) to perform long-running computations in a worker thread and to update Swing components from the event dispatch thread based on the computations' results. **SwingWorker** implements the `Runnable` interface, meaning that a **SwingWorker** object can be scheduled to execute in a separate thread. The **SwingWorker** class provides several methods to simplify performing computations in a worker thread and making the results available for display in a GUI. Some common **SwingWorker** methods are described in Fig. 23.24.

| Method                      | Description                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>doInBackground</code> | Defines a long computation and is called in a worker thread.                                                                                           |
| <code>done</code>           | Executes on the event dispatch thread when <code>doInBackground</code> returns.                                                                        |
| <code>execute</code>        | Schedules the <b>SwingWorker</b> object to be executed in a worker thread.                                                                             |
| <code>get</code>            | Waits for the computation to complete, then returns the result of the computation (i.e., the return value of <code>doInBackground</code> ).            |
| <code>publish</code>        | Sends intermediate results from the <code>doInBackground</code> method to the <code>process</code> method for processing on the event dispatch thread. |
| <code>process</code>        | Receives intermediate results from the <code>publish</code> method and processes these results on the event dispatch thread.                           |
| <code>setProgress</code>    | Sets the progress property to notify any property change listeners on the event dispatch thread of progress bar updates.                               |

**Fig. 23.24** | Commonly used **SwingWorker** methods.

### 23.11.1 Performing Computations in a Worker Thread

In the next example, a GUI provides components for a user to enter a number  $n$  and get the  $n^{\text{th}}$  Fibonacci number, which we calculate using the recursive algorithm discussed in Section 15.4. Since the recursive algorithm is time consuming for large values, we use a `SwingWorker` object to perform the calculation in a worker thread. The GUI also provides a separate set of components that get the next Fibonacci number in the sequence with each click of a button, beginning with `fibonacci(1)`. This set of components performs its short computation directly in the event dispatch thread.

Class `BackgroundCalculator` (Fig. 23.25) performs the recursive Fibonacci calculation in a worker thread. This class extends `SwingWorker` (line 8), overriding the methods `doInBackground` and `done`. Method `doInBackground` (lines 21–25) computes the  $n^{\text{th}}$  Fibonacci number in a worker thread and returns the result. Method `done` (lines 28–44) displays the result in a `JLabel`.

```

1 // Fig. 23.25: BackgroundCalculator.java
2 // SwingWorker subclass for calculating Fibonacci numbers
3 // in a background thread.
4 import javax.swing.SwingWorker;
5 import javax.swing.JLabel;
6 import java.util.concurrent.ExecutionException;
7
8 public class BackgroundCalculator extends SwingWorker< String, Object >
9 {
10 private final int n; // Fibonacci number to calculate
11 private final JLabel resultJLabel; // JLabel to display the result
12
13 // constructor
14 public BackgroundCalculator(int number, JLabel label)
15 {
16 n = number;
17 resultJLabel = label;
18 } // end BackgroundCalculator constructor
19
20 // long-running code to be run in a worker thread

53 } // end method fibonacci
54 } // end class BackgroundCalculator

```

**Fig. 23.25** | SwingWorker subclass for calculating Fibonacci numbers in a background thread.  
(Part 2 of 2.)

Note that `SwingWorker` is a generic class. In line 8, the first type parameter is `String` and the second is `Object`. The first type parameter indicates the type returned by the `doInBackground` method; the second indicates the type that is passed between the `publish` and `process` methods to handle intermediate results. Since we do not use `publish` and `process` in this example, we simply use `Object` as the second type parameter. We discuss `publish` and `process` in Section 23.11.2.

A `BackgroundCalculator` object can be instantiated from a class that controls a GUI. A `BackgroundCalculator` maintains instance variables for an integer that represents the Fibonacci number to be calculated and a `JLabel` that displays the results of the calculation (lines 10–11). The `BackgroundCalculator` constructor (lines 14–18) initializes these instance variables with the arguments that are passed to the constructor.

### Software Engineering Observation 23.3

*Any GUI components that will be manipulated by SwingWorker methods, such as components that will be updated from methods process or done, should be passed to the SwingWorker subclass's constructor and stored in the subclass object. This gives these methods access to the GUI components they will manipulate.*

When method `execute` is called on a `BackgroundCalculator` object, the object is scheduled for execution in a worker thread. Method `doInBackground` is called from the worker thread and invokes the `fibonacci` method (lines 47–53), passing instance variable `n` as an argument (line 23). Method `fibonacci` uses recursion to compute the Fibonacci of `n`. When `fibonacci` returns, method `doInBackground` returns the result.

After `doInBackground` returns, method `done` is called from the event dispatch thread. This method attempts to set the result `JLabel` to the return value of `doInBackground` by calling method `get` to retrieve this return value (line 33). Method `get` waits for the result

23.11 Multithreading with GUI **1097**

to be ready if necessary, but since we call it from method `done`, the computation will be complete before `get` is called. Lines 35–38 catch `InterruptedException` if the current thread is interrupted while waiting for `get` to return. Lines 39–43 catch `ExecutionException`, which is thrown if an exception occurs during the computation.

Class `FibonacciNumbers` (Fig. 23.26) displays a window containing two sets of GUI components—one set to compute a Fibonacci number in a worker thread and another to get the next Fibonacci number in response to the user's clicking a JButton. The constructor (lines 38–109) places these components in separate titled JPanels. Lines 46–47 and 78–79 add two JLabels, a JTextField and a JButton to the workerJPanel to allow the user to enter an integer whose Fibonacci number will be calculated by the BackgroundWorker. Lines 84–85 and 103 add two JLabels and a JButton to the event dispatch thread panel to allow the user to get the next Fibonacci number in the sequence. Instance variables `n1` and `n2` contain the previous two Fibonacci numbers in the sequence and are initialized to 0 and 1, respectively (lines 29–30). Instance variable `count` stores the most recently computed sequence number and is initialized to 1 (line 31). The two JLabels display `count` and `n2` initially, so that the user will see the text `Fibonacci of 1: 1` in the eventThreadJPanel when the GUI starts.

```

**Fig. 23.26** | Using SwingWorker to perform a long calculation with intermediate results displayed in a GUI. (Part 3 of 4.)

**1100**    Chapter 23 Multithreading

**Fig. 23.26** | Using `SwingWorker` to perform a long calculation with intermediate results displayed in a GUI. (Part 4 of 4.)

Lines 48–77 register the event handler for the `goJButton`. If the user clicks this `JButton`, line 58 gets the value entered in the `numberJTextField` and attempts to parse it as an integer. Lines 72–73 create a new `BackgroundCalculator` object, passing in the user-entered value and the `fibonacciJLabel1` that is used to display the calculation's results. Line 74 calls method `execute` on the `BackgroundCalculator`, scheduling it for execution in a separate worker thread. Method `execute` does not wait for the `BackgroundCalculator` to finish executing. It returns immediately, allowing the GUI to continue processing other events while the computation is performed.

If the user clicks the `nextNumberJButton` in the `eventThreadJPanel1`, the event handler registered in lines 86–102 executes. The previous two Fibonacci numbers stored in `n1` and `n2` are added together and `count` is incremented to determine the next number in the sequence (lines 92–95). Then lines 98–99 update the GUI to display the next number. The code to perform these calculations is written directly in method `actionPerformed`, so these calculations are performed on the event dispatch thread. Handling such short computations in the event dispatch thread does not cause the GUI to become unresponsive, like the recursive algorithm for calculating the Fibonacci of a large number. Because the longer Fibonacci computation is performed in a separate worker thread using the `SwingWorker`, it is possible to get the next Fibonacci number while the recursive computation is still in progress.

### 23.11.2 Processing Intermediate Results with `SwingWorker`

We have presented an example that uses the `SwingWorker` class to execute a long process in a background thread and update the GUI when the process is finished. We now present an example of updating the GUI with intermediate results before the long process completes. Figure 23.27 presents class `PrimeCalculator`, which extends `SwingWorker` to compute the first  $n$  primes in a worker thread. In addition to the `doInBackground` and `done` methods used in the previous example, this class uses `SwingWorker` methods `publish`, `process` and `setProgress`. In this example, method `publish` sends prime numbers to method `process` as they are found, method `process` displays these primes in a GUI component and method `setProgress` updates the `progress` property. We later show how to use this property to update a `JProgressBar`.

## 23.11 Multithreading with GUI 1103

```

105 statusJLabel.setText("Found " + numPrimes + " primes.");
106 } // end method done
107
108 // sets flag to stop looking for primes
109 public void stopCalculation()
110 {
111 stopped = true;
112 } // end method stopCalculation
113 } // end class PrimeCalculator

```

**Fig. 23.27** | Calculates the first  $n$  primes, displaying them as they are found. (Part 3 of 3.)

Class `PrimeCalculator` extends `SwingWorker` (line 11), with the first type parameter indicating the return type of method `doInBackground` and the second indicating the type of intermediate results passed between methods `publish` and `process`. In this case, both type parameters are `Integers`. The constructor (lines 22–34) takes as arguments an integer that indicates the upper limit of the prime numbers to locate, a `JTextArea` used to display primes in the GUI, one `JButton` for initiating a calculation and one for canceling it, and a `JLabel` used to display the status of the calculation.

Lines 32–33 initialize the elements of the boolean array `primes` to `true`. `PrimeCalculator` uses this array and the [Sieve of Eratosthenes](#) algorithm (described in Exercise 7.27) to find all primes less than `max`. The Sieve of Eratosthenes takes a list of natural numbers of any length and, beginning with the first prime number, filters out all multiples of that prime. It then moves to the next prime, which will be the next number that is not yet filtered out, and eliminates all of its multiples. It continues until the end of the list is reached and all non-primes have been filtered out. Algorithmically, we begin with element 2 of the boolean array and set the cells corresponding to all values that are multiples of 2 to `false` to indicate that they are divisible by 2 and thus not prime. We then move to the next array element, check whether it is `true`, and if so set all of its multiples to `false` to indicate that they are divisible by the current index. When the whole array has been traversed in this way, all indices that contain `true` are prime, as they have no divisors.

In method `doInBackground` (lines 37–73), the control variable `i` for the loop (lines 43–70) controls the current index for implementing the Sieve of Eratosthenes. Line 45 tests the `stopped` boolean flag, which indicates whether the user has clicked the `Cancel` button. If `stopped` is `true`, the method returns the number of primes found so far (line 46) without finishing the computation.

If the calculation is not canceled, line 49 calls method `setProgress` to update the `progress` property with the percentage of the array that has been traversed so far. Line 53 puts the currently executing thread to sleep for up to 4 milliseconds. We discuss the reason for this shortly. Line 61 tests whether the element of array `primes` at the current index is `true` (and thus prime). If so, line 63 passes the index to method `publish` so that it can be displayed as an intermediate result in the GUI and line 64 increments the number of primes found. Lines 66–67 set all multiples of the current index to `false` to indicate that they are not prime. When the entire boolean array has been traversed, the number of primes found is returned at line 72.

Lines 76–80 declare method `process`, which executes in the event dispatch thread and receives its argument `publishedVals` from method `publish`. The passing of values

## 1104 Chapter 23 Multithreading

between `publish` in the worker thread and `process` in the event dispatch thread is asynchronous; `process` is not necessarily invoked for every call to `publish`. All `Integers` published since the last call to `process` are received as a `List` by method `process`. Lines 78–79 iterate through this list and display the published values in a `JTextArea`. Because the computation in method `doInBackground` progresses quickly, publishing values often, updates to the `JTextArea` can pile up on the event dispatch thread, causing the GUI to become sluggish. In fact, when searching for a large enough number of primes, the event dispatch thread may receive so many requests in quick succession to update the `JTextArea` that the thread will run out of memory in its event queue. This is why we put the worker thread to sleep for a few milliseconds between each potential call to `publish`. The calculation is slowed just enough to allow the event dispatch thread to keep up with requests to update the `JTextArea` with new primes, enabling the GUI to update smoothly and remain responsive.

Lines 83–106 define method `done`. When the calculation is finished or canceled, method `done` enables the **Get Primes** button and disables the **Cancel** button (lines 85–86). Line 92 gets the return value—the number of primes found—from method `doInBackground`. Lines 94–103 catch the exceptions thrown by method `get` and display an appropriate error message in the `statusJLabel`. If no exceptions occur, line 105 sets the `statusJLabel` to indicate the number of primes found.

Lines 109–112 define public method `stopCalculation`, which is invoked when the **Cancel** button is clicked. This method sets the flag `stopped` at line 111 so that `doInBackground` will return without finishing its calculation the next time it tests this flag. Though `SwingWorker` provides a method `cancel`, this method simply calls `Thread` method `interrupt` on the worker thread. Using the boolean flag instead of `cancel` allows us to stop the calculation cleanly, return a value from `doInBackground` and ensure that method `done` is called even though the calculation did not run to completion, without the risk of throwing an `InterruptedException` associated with interrupting the worker thread.

Class `FindPrimes` (Fig. 23.28) displays a `JTextField` that allows the user to enter a number, a `JButton` to begin finding all primes less than that number and a `JTextArea` to display the primes. A `JButton` allows the user to cancel the calculation, and a `JProgressBar` indicates the calculation's progress. The `FindPrimes` constructor (lines 32–125) initializes these components and displays them in a `JFrame` using `BorderLayout`.

Lines 42–94 register the event handler for the `getPrimesJButton`. When the user clicks this `JButton`, lines 47–49 reset the `JProgressBar` and clear the `displayPrimesJTextArea` and the `statusJLabel`. Lines 53–63 parse the value in the `JTextField` and display an error message if the value is not an integer. Lines 66–68 construct a new `PrimeCalculator` object, passing as arguments the integer the user entered, the `displayPrimesJTextArea` for displaying the primes, the `statusJLabel` and the two `JButtons`.

Lines 71–85 register a `PropertyChangeListener` for the new `PrimeCalculator` object using an anonymous inner class. `PropertyChangeListener` is an interface from package `java.beans` that defines a single method, `propertyChange`. Every time method `setProgress` is invoked on a `PrimeCalculator`, the `PrimeCalculator` generates a `PropertyChangeEvent` to indicate that the `progress` property has changed. Method `propertyChange` listens for these events. Line 78 tests whether a given `PropertyChangeEvent` indicates a change to the `progress` property. If so, line 80 gets the new value of the property and line 81 updates the `JProgressBar` with the new `progress` property value. The **Get Primes**

## 23.11 Multithreading with GUI 1105

`JButton` is disabled (line 88) so that only one calculation that updates the GUI can execute at a time, and the `Cancel JButton` is enabled (line 89) to allow the user to stop the computation before it completes. Line 91 executes the `PrimesCalculator` to begin finding primes. If the user clicks the `cancelJButton`, the event handler registered at lines 107–115 calls `PrimeCalculator` method `stopCalculation` (line 112) and the calculation returns early.

### 23.12 Other Classes and Interfaces in `java.util.concurrent`

Interface `Runnable` provides only the most basic functionality for multithreaded programming. In fact, this interface has several limitations. Suppose a `Runnable` encounters a problem and tries to throw a checked exception. The `run` method is not declared to throw any exceptions, so the problem must be handled within the `Runnable`—the exception cannot be passed to the calling thread. Now suppose a `Runnable` is performing a long calculation and the application wants to retrieve the result of that calculation. The `run` method cannot return a value, so the application must use shared data to pass the value back to the calling thread. This also involves the overhead of synchronizing access to the data. The developers of the concurrency APIs introduced in Java SE 5 recognized these limitations and created a new interface to fix them. The `Callable` interface (of package `java.util.concurrent`) declares a single method named `call`. This interface is designed to be similar to the `Runnable` interface—allowing an action to be performed concurrently in a separate thread—but the `call` method allows the thread to return a value or to throw a checked exception.

An application that creates a `Callable` likely wants to run the `Callable` concurrently with other `Runnables` and `Callables`. The `ExecutorService` interface provides method `submit`, which will execute a `Callable` passed in as its argument. The `submit` method returns an object of type `Future` (of package `java.util.concurrent`), which is an interface that represents the executing `Callable`. The `Future` interface declares method `get` to return the result of the `Callable` and provides other methods to manage a `Callable`'s execution.

### 23.13 Wrap-Up

In this chapter, you learned that concurrency has historically been implemented with operating system primitives available only to experienced systems programmers, but that Java makes concurrency available to you through the language and APIs. You also learned that the JVM itself creates threads to run a program, and that it also may create threads to perform housekeeping tasks such as garbage collection.

We discussed the life cycle of a thread and the states that a thread may occupy during its lifetime. We also discussed Java's thread priorities, which help the system schedule

## 23.13 Wrap-Up 1109

threads for execution. You learned that you should avoid manipulating Java thread priorities directly and you learned about problems associated with thread priorities, such as indefinite postponement (sometimes called starvation).

Next, we presented the interface `Runnable`, which is used to specify a task that can execute concurrently with other tasks. This interface's `run` method is invoked by the thread executing the task. We showed how to execute a `Runnable` object by associating it with an object of class `Thread`. Then we showed how to use the `Executor` interface to manage the execution of `Runnable` objects via thread pools, which can reuse existing threads to eliminate the overhead of creating a new thread for each task and can improve performance by optimizing the number of threads to ensure that the processor stays busy.

You learned that when multiple threads share an object and one or more of them modify that object, indeterminate results may occur unless access to the shared object is managed properly. We showed you how to solve this problem via thread synchronization, which coordinates access to shared data by multiple concurrent threads. You learned several techniques for performing synchronization—first with the built-in class `ArrayBlockingQueue` (which handles all the synchronization details for you), then with Java's built-in monitors and the `synchronized` keyword, and finally with interfaces `Lock` and `Condition`.

We discussed the fact that Swing GUIs are not thread safe, so all interactions with and modifications to the GUI must be performed in the event dispatch thread. We also discussed the problems associated with performing long-running calculations in the event dispatch thread. Then we showed how you can use Java SE 6's `SwingWorker` class to perform long-running calculations in worker threads. You learned how to display the results of a `SwingWorker` in a GUI when the calculation completed and how to display intermediate results while the calculation was still in process.

Finally, we discussed the `Callable` and `Future` interfaces, which enable you to execute tasks that return results and to obtain those results, respectively. We use the multithreading techniques introduced here again in Chapter 24, Networking, to help build multithreaded servers that can interact with multiple clients concurrently.

## Summary

### Section 23.1 Introduction

- Historically, concurrency has been implemented with operating system primitives available only to experienced systems programmers.
- The Ada programming language, developed by the United States Department of Defense, made concurrency primitives widely available to defense contractors building military command-and-control systems.
- Java makes concurrency available to you through the language and APIs. You specify that an application contains separate threads of execution, where each thread has its own method-call stack and program counter, allowing it to execute concurrently with other threads while sharing application-wide resources such as memory with these other threads.
- In addition to creating threads to run a program, the JVM also may create threads for performing housekeeping tasks such as garbage collection.

### Section 23.2 Thread States: Life Cycle of a Thread

- At any time, a thread is said to be in one of several thread states.

## 1110 Chapter 23 Multithreading

- A new thread begins its life cycle in the *new* state. It remains in this state until the program starts the thread, which places the thread in the *Runnable* state. A thread in the *Runnable* state is considered to be executing its task.
- Sometimes a *Runnable* thread transitions to the *Waiting* state while it waits for another thread to perform a task. A *Waiting* thread transitions back to the *Runnable* state only when another thread notifies it to continue executing.
- A *Runnable* thread can enter the *Timed Waiting* state for a specified interval of time. A *Timed Waiting* thread transitions back to the *Runnable* state when that time interval expires or when the event it is waiting for occurs.
- A *Runnable* thread can transition to the *Timed Waiting* state if it provides an optional wait interval when it is waiting for another thread to perform a task. Such a thread will return to the *Runnable* state when it is notified by another thread or when the timed interval expires.
- A sleeping thread remains in the *Timed Waiting* state for a designated period of time, after which it returns to the *Runnable* state.
- A *Runnable* thread transitions to the *Blocked* state when it attempts to perform a task that cannot be completed immediately and the thread must temporarily wait until that task completes. At that point, the *Blocked* thread transitions to the *Runnable* state, so it can resume execution. A *Blocked* thread cannot use a processor, even if one is available.
- A *Runnable* thread enters the *Terminated* state when it successfully completes its task or otherwise terminates (perhaps due to an error).
- At the operating system level, Java's *Runnable* state typically encompasses two separate states. When a thread first transitions to the *Runnable* state from the *New* state, the thread is in the *Ready* state. A *Ready* thread enters the *Running* state when the operating system assigns the thread to a processor—also known as dispatching the thread.
- In most operating systems, each thread is given a small amount of processor time—called a quantum or timeslice—with which to perform its task. When the thread's quantum expires, the thread returns to the *Ready* state and the operating system assigns another thread to the processor.
- The process that an operating system uses to determine which thread to dispatch is called thread scheduling and is dependent on thread priorities (discussed in the next section).

### Section 23.3 Thread Priorities and Thread Scheduling

- Every Java thread has a thread priority (from `MIN_PRIORITY` to `MAX_PRIORITY`) that helps the operating system determine the order in which threads are scheduled.
- By default, every thread is given priority `NORM_PRIORITY` (a constant of 5). Each new thread inherits the priority of the thread that created it.
- Most operating systems enable threads of equal priority to share a processor with timeslicing.
- The job of an operating system's thread scheduler is to determine which thread runs next.
- When a higher-priority thread enters the *Ready* state, the operating system generally preempts the currently *Running* thread (an operation known as preemptive scheduling).
- Depending on the operating system, higher-priority threads could postpone—possibly indefinitely—the execution of lower-priority threads. Such indefinite postponement is sometimes referred to more colorfully as starvation.

### Section 23.4 Creating and Executing Threads

- The preferred means of creating multithreaded Java applications is by implementing interface `Runnable` (of package `java.lang`). A `Runnable` object represents a “task” that can execute concurrently with other tasks.

[Summary](#)

- Interface `Runnable` declares method `run` in which you place the code that defines the task to perform. The thread executing a `Runnable` calls method `run` to perform the task.
- A program will not terminate until its last thread completes execution, at which point the JVM will also terminate.
- You cannot predict the order in which threads will be scheduled, even if you know the order in which they were created and started.
- Though it is possible to create threads explicitly, it is recommended that you use the `Executor` interface to manage the execution of `Runnable` objects for you. An `Executor` object typically creates and manages a group of threads called a thread pool to execute `Runnables`.
- Executors can reuse existing threads to eliminate the overhead of creating a new thread for each task and can improve performance by optimizing the number of threads to ensure that the processor stays busy.
- Interface `Executor` declares method `execute`, which accepts a `Runnable` as an argument and assigns it to one of the available threads in the thread pool. If there are no available threads, the `Executor` creates a new thread or waits for a thread to become available.
- Interface `ExecutorService` (of package `java.util.concurrent`) extends interface `Executor` and declares other methods for managing the life cycle of an `Executor`.
- An object that implements the `ExecutorService` interface can be created using `static` methods declared in class `Executors` (of package `java.util.concurrent`).
- `Executors` method `newCachedThreadPool` returns an `ExecutorService` that creates new threads as they are needed by the application.
- `ExecutorService` method `execute` executes its `Runnable` sometime in the future. The method returns immediately from each invocation—the program does not wait for each task to finish.
- `ExecutorService` method `shutdown` notifies the `ExecutorService` to stop accepting new tasks, but continues executing tasks that have already been submitted. Once all of the previously submitted `Runnables` have completed, the `ExecutorService` terminates.

### Section 23.5 Thread Synchronization

- When multiple threads share an object and one or more of them modify that object, indeterminate results may occur unless access to the shared object is managed properly. The problem can be solved by giving only one thread at a time *exclusive access* to code that manipulates the shared object. During that time, other threads desiring to manipulate the object are kept waiting. When the thread with exclusive access to the object finishes manipulating it, one of the threads that was waiting is allowed to proceed. This process, called *thread synchronization*, coordinates access to shared data by multiple concurrent threads.
- By synchronizing threads, you can ensure that each thread accessing a shared object excludes all other threads from doing so simultaneously—this is called *mutual exclusion*.
- A common way to perform synchronization is to use Java’s built-in monitors. Every object has a monitor and a monitor lock. The monitor ensures that its object’s monitor lock is held by a maximum of only one thread at any time, and thus can be used to enforce mutual exclusion.
- If an operation requires the executing thread to hold a lock while the operation is performed, a thread must acquire the lock before it can proceed with the operation. Any other threads attempting to perform an operation that requires the same lock will be *blocked* until the first thread releases the lock, at which point the *blocked* threads may attempt to acquire the lock.
- To specify that a thread must hold a monitor lock in order to execute a block of code, the code should be placed in a `synchronized` statement. Such code is said to be guarded by the monitor lock; a thread must acquire the lock to execute the `synchronized` statements.

## 11.2 Chapter 23 Multithreading

- The synchronized statements are declared using the synchronized keyword:

```
synchronized (object)
{
 statements
} // end synchronized statement
```

where *object* is the object whose monitor lock will be acquired; *object* is normally *this* if it's the object in which the synchronized statement appears.

- A synchronized methods is equivalent to a synchronized statement that encloses the entire body of a method and with *this* as the object whose monitor lock will be acquired.
- Interface ExecutorService provides the awaitTermination method to force a program to wait for threads to complete execution. This method returns control to its caller either when all tasks executing in the ExecutorService complete or when the specified timeout elapses. If all tasks are completed before awaitTermination times out, this method returns true; otherwise it returns false. The two arguments to awaitTermination represent a timeout value and a unit of measure specified with a constant from class TimeUnit.
- You can simulate atomicity by ensuring that only one thread carries out a set of operations at a time. Atomicity can be achieved using the synchronized keyword to create a synchronized statement or synchronized method.
- When you share immutable data across threads, you should declare the corresponding data fields final to indicate that variables' values will not change after they are initialized.

### Section 23.6 Producer/Consumer Relationship Without Synchronization

- In a multithreaded producer/consumer relationship, a producer thread generates data and places it in a shared object called a buffer. A consumer thread reads data from the buffer.
- Operations on the buffer data shared by a producer and a consumer are state dependent—they should proceed only if the buffer is in the correct state. If the buffer is in a not-full state, the producer may produce; if the buffer is in a not-empty state, the consumer may consume.
- Threads with access to a buffer must be synchronized to ensure that data is written to the buffer or read from the buffer only if the buffer is in the proper state. If the producer attempting to put the next data into the buffer determines that the buffer is full, the producer thread should wait until there is space. If a consumer thread finds the buffer empty or finds that the previous data has already been read, the consumer must also wait for new data to become available.

### Section 23.7 Producer/Consumer Relationship: ArrayBlockingQueue

- Java includes a fully implemented buffer class named `ArrayBlockingQueue` in package `java.util.concurrent`, which implements the `BlockingQueue` interface. The `BlockingQueue` interface extends the `Queue` interface and declares methods `put` and `take`, the blocking equivalents of `Queue` methods `offer` and `poll`, respectively.
- Method `put` places an element at the end of the `BlockingQueue`, waiting if the queue is full. Method `take` removes an element from the head of the `BlockingQueue`, waiting if the queue is empty. These methods make class `ArrayBlockingQueue` a good choice for implementing a shared buffer. Because method `put` blocks until there is room in the buffer to write data and method `take` blocks until there is new data to read, the producer must produce a value first, the consumer correctly consumes only after the producer writes a value and the producer correctly produces the next value (after the first) only after the consumer reads the previous (or first) value.
- `ArrayBlockingQueue` stores shared data in an array. The array's size is specified as an argument to the `ArrayBlockingQueue` constructor. Once created, an `ArrayBlockingQueue` is fixed in size and will not expand to accommodate extra elements.

[Summary](#)

1113

**Section 23.8 Producer/Consumer Relationship with Synchronization**

- You can implement a shared buffer yourself using the `synchronized` keyword and `Object` methods `wait`, `notify` and `notifyAll`, which can be used with conditions to make threads wait when they cannot perform their tasks.
- If a thread obtains the monitor lock on an object, then determines that it cannot continue with its task on that object until some condition is satisfied, the thread can call `Object` method `wait`; this releases the monitor lock on the object, and the thread waits in the *waiting* state while the other threads try to enter the object's `synchronized` statement(s) or method(s).
- When a thread executing a `synchronized` statement (or method) completes or satisfies the condition on which another thread may be waiting, it can call `Object` method `notify` to allow a waiting thread to transition to the *runnable* state again. At this point, the thread that was transitioned from the *wait* state to the *runnable* state can attempt to reacquire the monitor lock on the object.
- If a thread calls `notifyAll`, then all the threads waiting for the monitor lock become eligible to reacquire the lock (that is, they all transition to the *runnable* state).

**Section 23.9 Producer/Consumer Relationship: Bounded Buffers**

- You cannot make assumptions about the relative speeds of concurrent threads—interactions that occur with the operating system, the network, the user and other components can cause the threads to operate at different speeds. When this happens, threads wait.
- A bounded buffer can be used to minimize the amount of waiting time for threads that share resources and operate at the same average speeds. If the producer temporarily produces values faster than the consumer can consume them, the producer can write additional values into the extra buffer space (if any are available). If the consumer consumes faster than the producer produces new values, the consumer can read additional values (if there are any) from the buffer.
- The key to using a bounded buffer with a producer and consumer that operate at about the same speed is to provide the buffer with enough locations to handle the anticipated “extra” production.
- The simplest way to implement a bounded buffer is to use an `ArrayBlockingQueue` for the buffer so that all of the synchronization details are handled for you.

**Section 23.10 Producer/Consumer Relationship: The Lock and Condition Interfaces**

- The `Lock` and `Condition` interfaces, which were introduced in Java SE 5, give programmers more precise control over thread synchronization, but are more complicated to use.
- Any object can contain a reference to an object that implements the `Lock` interface (of package `java.util.concurrent.locks`). A thread calls the `Lock`'s `lock` method to acquire the lock. Once a `Lock` has been obtained by one thread, the `Lock` object will not allow another thread to obtain the `Lock` until the first thread releases the `Lock` (by calling the `Lock`'s `unlock` method).
- If several threads are trying to call method `lock` on the same `Lock` object at the same time, only one thread can obtain the lock—all other threads attempting to obtain that `Lock` are placed in the *waiting* state. When a thread calls method `unlock`, the lock on the object is released and a waiting thread attempting to lock the object proceeds.
- Class `ReentrantLock` (of package `java.util.concurrent.locks`) is a basic implementation of the `Lock` interface.
- The constructor for a `ReentrantLock` takes a `boolean` argument that specifies whether the lock has a fairness policy. If the argument is `true`, the `ReentrantLock`'s fairness policy is “the longest-waiting thread will acquire the lock when it is available.” This guarantees that indefinite postponement (also called starvation) cannot occur. If the fairness policy argument is set to `false`, there is no guarantee as to which waiting thread will acquire the lock when it is available.

## 1114 Chapter 23 Multithreading

- If a thread that owns a Lock determines that it cannot continue with its task until some condition is satisfied, the thread can wait on a condition object. Using Lock objects allows you to explicitly declare the condition objects on which a thread may need to wait.
- Condition objects are associated with a specific Lock and are created by calling a Lock's newCondition method, which returns an object that implements the Condition interface (of package java.util.concurrent.locks). To wait on a condition object, the thread can call the Condition's await method. This immediately releases the associated Lock and places the thread in the *waiting* state for that Condition. Other threads can then try to obtain the Lock.
- When a *runnable* thread completes a task and determines that the *waiting* thread can now continue, the *runnable* thread can call Condition method signal to allow a thread in that Condition's *waiting* state to return to the *runnable* state. At this point, the thread that transitioned from the *waiting* state to the *runnable* state can attempt to reacquire the Lock.
- If multiple threads are in a Condition's *waiting* state when signal is called, the default implementation of Condition signals the longest-waiting thread to transition to the *runnable* state.
- If a thread calls Condition method signalAll, then all the threads waiting for that condition transition to the *runnable* state and become eligible to reacquire the Lock.
- When a thread is finished with a shared object, it must call method unlock to release the Lock.
- In some applications, using Lock and Condition objects may be preferable to using the synchronized keyword. Lock objects allow you to interrupt waiting threads or to specify a timeout for waiting to acquire a lock, which is not possible using the synchronized keyword. Also, a Lock object is not constrained to be acquired and released in the same block of code, which is the case with the synchronized keyword.
- Condition objects allow you to specify multiple conditions on which threads may wait. Thus, it is possible to indicate to waiting threads that a specific condition object is now true by calling signal or signalAll on that Condition object. With synchronized, there is no way to explicitly state the condition on which threads are waiting, so there is no way to notify threads waiting on one condition that they may proceed without also notifying threads waiting on any other conditions.

### Section 23.11 Multithreading with GUI

- Swing applications have a thread, called the event dispatch thread, to handle interactions with the application's GUI components. All tasks that require interaction with an application's GUI are placed in an event queue and are executed sequentially by the event dispatch thread.
- Swing GUI components are not thread safe. Thread safety in GUI applications is achieved by ensuring that Swing components are accessed from only the event dispatch thread. This technique is called thread confinement.
- If an application must perform a lengthy computation in response to a user interface interaction, the event dispatch thread cannot attend to other tasks in the event queue while the thread is tied up in that computation. This causes the GUI components to become unresponsive. It is preferable to handle a long-running computation in a separate thread, freeing the event dispatch thread to continue managing other GUI interactions.
- Java SE 6 provides class SwingWorker (in package javax.swing), which implements the Runnable interface, to perform long-running computations in a worker thread and to update Swing components from the event dispatch thread based on the computations' results.
- To use SwingWorker's capabilities, create a class that extends SwingWorker and overrides the methods doInBackground and done. Method doInBackground performs the computation and returns the result. Method done displays the results in the GUI.

## Terminology 1115

- **SwingWorker** is a generic class. Its first type parameter indicates the type returned by the `doInBackground` method; the second indicates the type that is passed between the `publish` and `process` methods to handle intermediate results.
- Method `doInBackground` is called from a worker thread. After `doInBackground` returns, method `done` is called from the event dispatch thread to display the results.
- An `ExecutionException` is thrown if an exception occurs during the computation.
- **SwingWorker** also provides methods `publish`, `process` and `setProgress`. Method `publish` repeatedly sends intermediate results to method `process`, which displays the results in a GUI component. Method `setProgress` updates the progress property.
- Method `process` executes in the event dispatch thread and receives data from method `publish`. The passing of values between `publish` in the worker thread and `process` in the event dispatch thread is asynchronous; `process` is not necessarily invoked for every call to `publish`.
- **PropertyChangeListener** is an interface from package `java.beans` that defines a single method, `propertyChange`. Every time method `setProgress` is invoked, a `PropertyChangeEvent` is generated to indicate that the progress property has changed.

### **Section 23.12 Other Classes and Interfaces in `java.util.concurrent`**

- The `Callable` interface (of package `java.util.concurrent`) declares a single method named `call`. This interface is designed to be similar to the `Runnable` interface—allowing an action to be performed concurrently in a separate thread—but the `call` method allows the thread to return a value or to throw a checked exception.
- An application that creates a `Callable` likely wants to run it concurrently with other `Runnables` and `Callables`. The `ExecutorService` interface provides method `submit`, which will execute a `Callable` passed in as its argument.
- Method `submit` returns an object of type `Future` (of package `java.util.concurrent`) that represents the executing `Callable`. Interface `Future` declares method `get` to return the result of the `Callable` and provides other methods to manage a `Callable`'s execution.

## Terminology

|                                                                                |                                                                |

 unlock method of interface Lock  
 wait method of class Object  
*waiting* state

### Self-Review Exercises

**23.1** Fill in the blanks in each of the following statements:

- C and C++ are \_\_\_\_\_-threaded languages, whereas Java is a(n) \_\_\_\_\_-threaded language.
- A thread enters the *terminated* state when \_\_\_\_\_.
- To pause for a designated number of milliseconds and resume execution, a thread should call method \_\_\_\_\_ of class \_\_\_\_\_.
- Method \_\_\_\_\_ of class Condition moves a single thread in an object's *waiting* state to the *runnable* state.
- Method \_\_\_\_\_ of class Condition moves every thread in an object's *waiting* state to the *runnable* state.
- A(n) \_\_\_\_\_ thread enters the \_\_\_\_\_ state when it completes its task or otherwise terminates.
- A *runnable* thread can enter the \_\_\_\_\_ state for a specified interval of time.
- At the operating system level, the *runnable* state actually encompasses two separate states, \_\_\_\_\_ and \_\_\_\_\_.

**Answers to Self-Review Exercises    1117**

- i) Runnableables are executed using a class that implements the \_\_\_\_\_ interface.
  - j) ExecutorService method \_\_\_\_\_ ends each thread in an ExecutorService as soon as it finishes executing its current Runnable, if any.
  - k) A thread can call method \_\_\_\_\_ on a Condition object to release the associated Lock and place that thread in the \_\_\_\_\_ state.
  - l) In a(n) \_\_\_\_\_ relationship, the \_\_\_\_\_ portion of an application generates data and stores it in a shared object, and the \_\_\_\_\_ portion of an application reads data from the shared object.
  - m) Class \_\_\_\_\_ implements the BlockingQueue interface using an array.
  - n) The keyword \_\_\_\_\_ indicates that only one thread at a time should execute on an object.
- 23.2** State whether each of the following is *true* or *false*. If *false*, explain why.
- a) A thread is not *Runnable* if it has terminated.
  - b) A higher-priority *Runnable* thread preempts threads of lower priority.
  - c) Some operating systems use timeslicing with threads. Therefore, they can enable threads to preempt threads of the same priority.
  - d) When the thread's quantum expires, the thread returns to the *running* state as the operating system assigns the thread to a processor.
  - e) On a single-processor system without timeslicing, each thread in a set of equal-priority threads (with no other threads present) runs to completion before other threads of equal priority get a chance to execute.

**Answers to Self-Review Exercises**

- 23.1** a) single, multi. b) its run method ends. c) sleep, Thread. d) signal. e) signalAll. f) runnable, terminated. g) timed waiting. h) ready, running. i) Executor. j) shutdown. k) await, waiting. l) producer/consumer, producer, consumer. m) ArrayBlockingQueue. n) synchronized.
- 23.2** a) True. b) True. c) False. Timeslicing allows a thread to execute until its timeslice (or quantum) expires. Then other threads of equal priority can execute. d) False. When a thread's quantum expires, the thread returns to the *ready* state and the operating system assigns to the processor another thread. e) True.

**Exercises**

- 23.3** State whether each of the following is *true* or *false*. If *false*, explain why.
- a) Method *sleep* does not consume processor time while a thread sleeps.
  - b) Declaring a method *synchronized* guarantees that deadlock cannot occur.
  - c) Once a *Lock* has been obtained by a thread, the *Lock* object will not allow another thread to obtain the lock until the first thread releases it.
  - d) Swing components are thread safe.
- 23.4** Define each of the following terms.
- a) thread
  - b) multithreading
  - c) *Runnable* state
  - d) *timed waiting* state
  - e) preemptive scheduling
  - f) *Runnable* interface
  - g) *notifyAll* method
  - h) producer/consumer relationship
  - i) quantum

**1118 Chapter 23 Multithreading**

**23.5** Discuss each of the following terms in the context of Java's threading mechanisms:

- a) synchronized
- b) producer
- c) consumer
- d) wait
- e) notify
- f) Lock
- g) Condition

**23.6** List the reasons for entering the *blocked* state. For each of these, describe how the program will normally leave the *blocked* state and enter the *runnable* state.

**23.7** Two problems that can occur in systems that allow threads to wait are deadlock, in which one or more threads will wait forever for an event that cannot occur, and indefinite postponement, in which one or more threads will be delayed for some unpredictably long time. Give an example of how each of these problems can occur in multithreaded Java programs.

**23.8** Write a program that bounces a blue ball inside a JPanel. The ball should begin moving with a mousePressed event. When the ball hits the edge of the JPanel, it should bounce off the edge and continue in the opposite direction. The ball should be updated using a Runnable.

**23.9** Modify the program in Exercise 23.8 to add a new ball each time the user clicks the mouse. Provide for a minimum of 20 balls. Randomly choose the color for each new ball.

**23.10** Modify the program in Exercise 23.9 to add shadows. As a ball moves, draw a solid black oval at the bottom of the JPanel. You may consider adding a 3-D effect by increasing or decreasing the size of each ball when it hits the edge of the JPanel.

## Networking

### OBJECTIVES

In this chapter you will learn:

- To understand Java networking with URLs, sockets and datagrams.
- To implement Java networking applications by using sockets and datagrams.
- To understand how to implement Java clients and servers that communicate with one another.
- To understand how to implement network-based collaborative applications.
- To construct a multithreaded server.

**1120 Chapter 24 Networking****Outline**

- 24.1** Introduction
- 24.2** Manipulating URLs
- 24.3** Reading a File on a Web Server
- 24.4** Establishing a Simple Server Using Stream Sockets
- 24.5** Establishing a Simple Client Using Stream Sockets
- 24.6** Client/Server Interaction with Stream Socket Connections
- 24.7** Connectionless Client/Server Interaction with Datagrams
- 24.8** Client/Server Tic-Tac-Toe Using a Multithreaded Server
- 24.9** Security and the Network
- 24.10** [Web Bonus] Case Study: DeitelMessenger Server and Client
- 24.11** Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 24.1 Introduction

There is much excitement about the Internet and the World Wide Web. The Internet ties the information world together. The World Wide Web makes the Internet easy to use and gives it the flair and sizzle of multimedia. Organizations see the Internet and the web as crucial to their information-systems strategies. Java provides a number of built-in networking capabilities that make it easy to develop Internet-based and web-based applications. Java can enable programs to search the world for information and to collaborate with programs running on other computers internationally, nationally or just within an organization. Java can enable applets and applications to communicate with one another (subject to security constraints).

Networking is a massive and complex topic. Computer science and computer engineering students typically take a full-semester, upper-level course in computer networking and continue with further study at the graduate level. Java is often used as an implementation vehicle in computer networking courses. In *Java How to Program, Seventh Edition*, we introduce a portion of Java's networking concepts and capabilities.

Java's fundamental networking capabilities are declared by classes and interfaces of package `java.net`, through which Java offers **stream-based communications** that enable applications to view networking as streams of data. The classes and interfaces of package `java.net` also offer **packet-based communications** for transmitting individual **packets** of information—commonly used to transmit audio and video over the Internet. In this chapter, we show how to create and manipulate sockets and how to communicate with packets and streams of data.

Our discussion of networking focuses on both sides of the **client/server relationship**. The **client** requests that some action be performed, and the **server** performs the action and responds to the client. A common implementation of the request-response model is between web browsers and web servers. When a user selects a website to browse through a browser (the client application), a request is sent to the appropriate web server (the server application). The server normally responds to the client by sending an appropriate HTML web page.

## 24.2 Manipulating URLs 1121

We introduce Java's **socket-based communications**, which enable applications to view networking as if it were file I/O—a program can read from a **socket** or write to a socket as simply as reading from a file or writing to a file. The socket is simply a software construct that represents one endpoint of a connection. We show how to create and manipulate stream sockets and datagram sockets.

With **stream sockets**, a process establishes a **connection** to another process. While the connection is in place, data flows between the processes in continuous **streams**. Stream sockets are said to provide a **connection-oriented service**. The protocol used for transmission is the popular **TCP (Transmission Control Protocol)**.

With **datagram sockets**, individual **packets** of information are transmitted. This is not appropriate for everyday programmers, because the protocol used—**UDP**, the **User Datagram Protocol**—is a **connectionless service**, and thus does not guarantee that packets arrive in any particular order. With UDP, packets can even be lost or duplicated. Significant extra programming is required on your part to deal with these problems (if you choose to do so). UDP is most appropriate for network applications that do not require the error checking and reliability of TCP. Stream sockets and the TCP protocol will be more desirable for the vast majority of Java programmers.

### Performance Tip 24.1

*Connectionless services generally offer greater performance but less reliability than connection-oriented services.*

### Portability Tip 24.1

*TCP, UDP and related protocols enable a great variety of heterogeneous computer systems (i.e., computer systems with different processors and different operating systems) to intercommunicate.*

We also introduce a case study in which we implement a client/server chat application similar to the instant-messaging services popular on the web today. This case study is provided as a web bonus at [www.deitel.com/books/jhttp7/](http://www.deitel.com/books/jhttp7/). The application incorporates many networking techniques introduced in this chapter. It also introduces **multicasting**, in which a server can publish information and clients can subscribe to that information. Each time the server publishes more information, all subscribers receive it. Throughout the examples of this chapter, we will see that many of the networking details are handled by the Java APIs.

## 24.2 Manipulating URLs

The Internet offers many protocols. The **Hypertext Transfer Protocol (HTTP)**, which forms the basis of the World Wide Web, uses **URIs (Uniform Resource Identifiers)** to identify data on the Internet. URIs that specify the locations of documents are called **URLs (Uniform Resource Locators)**. Common URLs refer to files or directories and can reference objects that perform complex tasks, such as database lookups and Internet searches. If you know the HTTP URL of a publicly available HTML document anywhere on the web, you can access it through HTTP.

Java makes it easy to manipulate URLs. When you use a URL that refers to the exact location of a resource (e.g., a web page) as an argument to the **showDocument** method of interface **AppletContext**, the browser in which the applet is executing will display that

**1122** Chapter 24 Networking

resource. The applet in Figs. 24.1–24.2 demonstrates simple networking capabilities. It enables the user to select a web page from a `JList` and causes the browser to display the corresponding page. In this example, the networking is performed by the browser.

```

1 <html>
2 <title>Site Selector</title>
3 <body>
4 <applet code = "SiteSelector.class" width = "300" height = "75">
5 <param name = "title0" value = "Java Home Page">
6 <param name = "location0" value = "http://java.sun.com/">
7 <param name = "title1" value = "Deitel">
8 <param name = "location1" value = "http://www.deitel.com/">
9 <param name = "title2" value = "JGuru">
10 <param name = "location2" value = "http://www.jGuru.com/">
11 <param name = "title3" value = "JavaWorld">
12 <param name = "location3" value = "http://www.javaworld.com/">
13 </applet>
14 </body>
15 </html>
```

87 title = getParameter("title" + counter); // get next site title
88 } // end while
89 } // end method getSitesFromHTMLParameters
90 } // end class SiteSelector

```

**Fig. 24.2 |** Loading a document from a URL into a browser. (Part 3 of 3.)

This applet takes advantage of **applet parameters** specified in the HTML document that invokes the applet. When browsing the World Wide Web, you will often come across applets that are in the public domain—you can use them free of charge on your own web pages (normally in exchange for crediting the applet's creator). Many applets can be customized via parameters supplied from the HTML file that invokes the applet. For example, Fig. 24.1 contains the HTML that invokes the applet `SiteSelector` in Fig. 24.2.

## 24.2 Manipulating URLs 1125

The HTML document contains eight parameters specified with the `param` tag—these lines must appear between the starting and ending `applet` tags. The applet can read these values and use them to customize itself. Any number of `param` tags can appear between the starting and ending `applet` tags. Each parameter has a `name` and a `value`. Applet method `getParameter` retrieves the value associated with a specific parameter name and returns it as a string. The argument passed to `getParameter` is a string containing the name of the parameter in the `param` element. In this example, parameters represent the title and location of each website the user can select. Parameters specified for this applet are named `title#`, where the value of # starts at 0 and increments by 1 for each new title. Each title should have a corresponding location parameter of the form `location#`, where the value of # starts at 0 and increments by 1 for each new location. The statement

```
String title = getParameter("title0");
```

gets the value associated with parameter "title0" and assigns it to reference `title`. If there is no `param` tag containing the specified parameter, `getParameter` returns `null`.

The applet (Fig. 24.2) obtains from the HTML document (Fig. 24.1) the choices that will be displayed in the applet's `JList`. Class `SiteSelector` uses a `HashMap` (package `java.util`) to store the website names and URLs. In this example, the *key* is the string in the `JList` that represents the website name, and the *value* is a `URL` object that stores the location of the website to display in the browser.

Class `SiteSelector` also contains an `ArrayList` (package `java.util`) in which the site names are placed so that they can be used to initialize the `JList` (one version of the `JList` constructor receives an array of `Objects` which is returned by `ArrayList`'s `toArray` method). An `ArrayList` is a dynamically resizable array of references. Class `ArrayList` provides method `add` to add a new element to the end of the `ArrayList`. (We provide discussions of classes `ArrayList` and `HashMap` in Chapter 19.)

Lines 25–26 in the applet's `init` method (lines 23–57) create a `HashMap` object and an `ArrayList` object. Line 29 calls our utility method `getSitesFromHTMLParameters` (declared at lines 60–89) to obtain the HTML parameters from the HTML document that invoked the applet.

Method `getSitesFromHTMLParameters` uses `Applet` method `getParameter` (line 67) to obtain a website title. If the `title` is not `null`, the loop in lines 70–88 begins executing. Line 73 uses `Applet` method `getParameter` to obtain the website location. Line 77 uses the `location` as the value of a new `URL` object. The `URL` constructor determines whether its argument represents a valid URL. If not, the `URL` constructor throws a `MalformedURLException`. Note that the `URL` constructor must be called in a `try` block. If the `URL` constructor generates a `MalformedURLException`, the call to `printStackTrace` (line 83) causes the program to output a stack trace to the Java console. On Windows machines, the Java console can be viewed by right clicking the Java icon in the notification area of the taskbar. Then the program attempts to obtain the next website title. The program does not add the site for the invalid URL to the `HashMap`, so the title will not be displayed in the `JList`.

For a proper URL, line 78 places the `title` and `URL` into the `HashMap`, and line 79 adds the `title` to the `ArrayList`. Line 87 gets the next title from the HTML document. When the call to `getParameter` at line 87 returns `null`, the loop terminates.

When method `getSitesFromHTMLParameters` returns to `init`, lines 32–56 construct the applet's GUI. Line 32 adds the `JLabel` "Choose a site to browse" to the NORTH of the

## 1126 Chapter 24 Networking

JFrame's BorderLayout. Line 34 creates JList siteChooser to allow the user to select a web page to view. Lines 35–54 register a ListSelectionListener to handle the siteChooser's events. Line 56 adds siteChooser to the CENTER of the JFrame's BorderLayout.

When the user selects one of the websites listed in siteChooser, the program calls method valueChanged (lines 39–52). Line 42 obtains the selected site name from the JList. Line 45 passes the selected site name (the *key*) to HashMap method get, which locates and returns a reference to the corresponding URL object (the *value*) that is assigned to reference newDocument.

Line 48 uses Applet method `getAppletContext` to get a reference to an AppletContext object that represents the applet container. Line 51 uses the AppletContext reference browser to invoke method `showDocument`, which receives a URL object as an argument and passes it to the AppletContext (i.e., the browser). The browser displays in the current browser window the World Wide Web resource associated with that URL. In this example, all the resources are HTML documents.

For programmers familiar with **HTML frames**, there is a second version of AppletContext method `showDocument` that enables an applet to specify the so-called **target frame** in which to display the web resource. This second version takes two arguments—a URL object specifying the resource to display and a string representing the target frame. There are some special target frames that can be used as the second argument. The target frame `_blank` results in a new web browser window to display the content from the specified URL. The target frame `_self` specifies that the content from the specified URL should be displayed in the same frame as the applet (the applet's HTML page is replaced in this case). The target frame `_top` specifies that the browser should remove the current frames in the browser window, then display the content from the specified URL in the current window. [Note: If you are interested in learning more about HTML, the CD that accompanies this book contains three chapters from our book *Internet and World Wide Web How to Program, Third Edition* that introduce the current version of HTML (known as XHTML) and the web page formatting capability known as Cascading Style Sheets (CSS).]

### Error-Prevention Tip 24.1

*The applet in Fig. 24.2 must be run from a web browser, such as Mozilla or Microsoft Internet Explorer, to see the results of displaying another web page. The appletviewer is capable only of executing applets—it ignores all other HTML tags. If the websites in the program contained Java applets, only those applets would appear in the appletviewer when the user selected a website. Each applet would execute in a separate appletviewer window.*

## 24.3 Reading a File on a Web Server

Our next example once again hides the networking details from us. The application in Fig. 24.3 uses Swing GUI component `JEditorPane` (from package `javax.swing`) to display the contents of a file on a web server. The user enters a URL in the JTextField at the top of the window, and the application displays the corresponding document (if it exists) in the `JEditorPane`. Class `JEditorPane` is able to render both plain text and HTML-formatted text, as illustrated in the two screen captures (Fig. 24.4), so this application acts as a simple web browser. The application also demonstrates how to process `HyperlinkEvents` when the user clicks a hyperlink in the HTML document. The techniques shown in this

4
5 public class ReadServerFileTest
6 {
7 public static void main(String args[])
8 {
9 ReadServerFile application = new ReadServerFile();
10 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 } // end main
12 } // end class ReadServerFileTest
```

**Fig. 24.4** | Test class for ReadServerFile. (Part 1 of 2.)

24.3 Reading a File on a Web Server **1129**

**Fig. 24.4** | Test class for `ReadServerFile`. (Part 2 of 2.)

example can also be used in applets. However, an applet is allowed to read files only on the server from which it was downloaded.

The application class `ReadServerFile` contains `JTextField enterField`, in which the user enters the URL of the file to read and `JEditorPane contentsArea` to display the contents of the file. When the user presses the *Enter* key in `enterField`, the application calls method `actionPerformed` (lines 31–34). Line 33 uses `ActionEvent` method `getActionCommand` to get the string the user input in the `JTextField` and passes the string to utility method `getThePage` (lines 61–74).

Line 65 invokes `JEditorPane` method `setPage` to download the document specified by `location` and display it in the `JEditorPane`. If there is an error downloading the document, method `setPage` throws an `IOException`. Also, if an invalid URL is specified, a `MalformedURLException` (a subclass of `IOException`) occurs. If the document loads successfully, line 66 displays the current location in `enterField`.

Typically, an HTML document contains **hyperlinks**—text, images or GUI components which, when clicked, provide quick access to another document on the web. If a `JEditorPane` contains an HTML document and the user clicks a hyperlink, the `JEditorPane` generates a `HyperlinkEvent` (package `javax.swing.event`) and notifies all registered `HyperlinkListeners` (package `javax.swing.event`) of that event. Lines 42–53 register a `HyperlinkListener` to handle `HyperlinkEvents`. When a `HyperlinkEvent` occurs, the program calls method `hyperlinkUpdate` (lines 46–51). Lines 48–49 use `HyperlinkEvent` method `getEventType` to determine the type of the `HyperlinkEvent`. Class `HyperlinkEvent` contains a public nested class called `EventType` that declares three static `EventType` objects, which represent the hyperlink event types. `ACTIVATED` indicates that the user clicked a hyperlink to change web pages, `ENTERED` indicates that the user moved the mouse over a hyperlink and `EXITED` indicates that the user moved the mouse away from a hyperlink. If a hyperlink was `ACTIVATED`, line 50 uses `HyperlinkEvent` method `getURL` to obtain the URL represented by the hyperlink. Method `toString` converts the returned URL to a string that can be passed to utility method `getThePage`.

### Look-and-Feel Observation 24.1

A `JEditorPane` generates `HyperlinkEvents` only if it is uneditable.

## 24.4 Establishing a Simple Server Using Stream Sockets

The two examples discussed so far use high-level Java networking capabilities to communicate between applications. In the examples, it was not your responsibility to establish the connection between a client and a server. The first program relied on the web browser to communicate with a web server. The second program relied on a `JEditorPane` to perform the connection. This section begins our discussion of creating your own applications that can communicate with one another.

Establishing a simple server in Java requires five steps. *Step 1* is to create a `ServerSocket` object. A call to the `ServerSocket` constructor, such as

```
ServerSocket server = new ServerSocket(portNumber, queueLength);
```

`registers` an available TCP **port number** and specifies the maximum number of clients that can wait to connect to the server (i.e., the **queue length**). The port number is used by clients to locate the server application on the server computer. This is often called the **handshake point**. If the queue is full, the server refuses client connections. The constructor establishes the port where the server waits for connections from clients—a process known as **binding the server to the port**. Each client will ask to connect to the server on this **port**. Only one application at a time can be bound to a specific port on the server.

### Software Engineering Observation 24.1

Port numbers can be between 0 and 65,535. Most operating systems reserve port numbers below 1024 for system services (e.g., e-mail and World Wide Web servers). Generally, these ports should not be specified as connection ports in user programs. In fact, some operating systems require special access privileges to bind to port numbers below 1024.

Programs manage each client connection with a `Socket` object. In *Step 2*, the server listens indefinitely (or **blocks**) for an attempt by a client to connect. To listen for a client connection, the program calls `ServerSocket` method `accept`, as in

```
Socket connection = server.accept();
```

which returns a `Socket` when a connection with a client is established. The `Socket` allows the server to interact with the client. The interactions with the client actually occur at a different server port from the handshake point. This allows the port specified in *Step 1* to be used again in a multithreaded server to accept another client connection. We demonstrate this concept in Section 24.8.

*Step 3* is to get the `OutputStream` and `InputStream` objects that enable the server to communicate with the client by sending and receiving bytes. The server sends information to the client via an `OutputStream` and receives information from the client via an `InputStream`. The server invokes method `getOutputStream` on the `Socket` to get a reference to the `Socket`'s `OutputStream` and invokes method `getInputStream` on the `Socket` to get a reference to the `Socket`'s `InputStream`.

The stream objects can be used to send or receive individual bytes or sequences of bytes with the `OutputStream`'s method `write` and the `InputStream`'s method `read`,

**24.5 Establishing a Simple Client Using Stream Sockets****1131**

respectively. Often it is useful to send or receive values of primitive types (e.g., `int` and `double`) or `Serializable` objects (e.g., `Strings` or other serializable types) rather than sending bytes. In this case, we can use the techniques discussed in Chapter 14 to wrap other stream types (e.g., `ObjectOutputStream` and `ObjectInputStream`) around the `OutputStream` and `InputStream` associated with the `Socket`. For example,

```
ObjectInputStream input =
 new ObjectInputStream(connection.getInputStream());

ObjectOutputStream output =
 new ObjectOutputStream(connection.getOutputStream());
```

The beauty of establishing these relationships is that whatever the server writes to the `ObjectOutputStream` is sent via the `OutputStream` and is available at the client's `InputStream`, and whatever the client writes to its `OutputStream` (with a corresponding `ObjectOutputStream`) is available via the server's `InputStream`. The transmission of the data over the network is seamless and is handled completely by Java.

*Step 4* is the *processing* phase, in which the server and the client communicate via the `OutputStream` and `InputStream` objects. In *Step 5*, when the transmission is complete, the server closes the connection by invoking the `close` method on the streams and on the `Socket`.

**Software Engineering Observation 24.2**

*With sockets, network I/O appears to Java programs to be similar to sequential file I/O. Sockets hide much of the complexity of network programming from the programmer.*

**Software Engineering Observation 24.3**

*With Java's multithreading, we can create multithreaded servers that can manage many simultaneous connections with many clients. This multithreaded-server architecture is precisely what popular network servers use.*

**Software Engineering Observation 24.4**

*A multithreaded server can take the `Socket` returned by each call to `accept` and create a new thread that manages network I/O across that `Socket`. Alternatively, a multithreaded server can maintain a pool of threads (a set of already existing threads) ready to manage network I/O across the new `Sockets` as they are created. See Chapter 23 for more information on multithreading.*

**Performance Tip 24.2**

*In high-performance systems in which memory is abundant, a multithreaded server can be implemented to create a pool of threads that can be assigned quickly to handle network I/O across each new `Socket` as it is created. Thus, when the server receives a connection, it need not incur the overhead of thread creation. When the connection is closed, the thread is returned to the pool for reuse.*

**24.5 Establishing a Simple Client Using Stream Sockets**

Establishing a simple client in Java requires four steps. In *Step 1*, we create a `Socket` to connect to the server. The `Socket` constructor establishes the connection to the server. For example, the statement

## 1132 Chapter 24 Networking

```
Socket connection = new Socket(serverAddress, port);
```

uses the `Socket` constructor with two arguments—the server's address (`serverAddress`) and the `port` number. If the connection attempt is successful, this statement returns a `Socket`. A connection attempt that fails throws an instance of a subclass of `IOException`, so many programs simply catch `IOException`. An `UnknownHostException` occurs specifically when the system is unable to resolve the server address specified in the call to the `Socket` constructor to a corresponding IP address.

In *Step 2*, the client uses `Socket` methods `getInputStream` and `getOutputStream` to obtain references to the `Socket`'s `InputStream` and `OutputStream`. As we mentioned in the preceding section, we can use the techniques of Chapter 14 to wrap other stream types around the `InputStream` and `OutputStream` associated with the `Socket`. If the server is sending information in the form of actual types, the client should receive the information in the same format. Thus, if the server sends values with an `ObjectOutputStream`, the client should read those values with an `ObjectInputStream`.

*Step 3* is the processing phase in which the client and the server communicate via the `InputStream` and `OutputStream` objects. In *Step 4*, the client closes the connection when the transmission is complete by invoking the `close` method on the streams and on the `Socket`. The client must determine when the server is finished sending information so that it can call `close` to close the `Socket` connection. For example, the `InputStream` method `read` returns the value `-1` when it detects end-of-stream (also called EOF—end-of-file). If an `ObjectInputStream` is used to read information from the server, an `EOFException` occurs when the client attempts to read a value from a stream on which end-of-stream is detected.

## 24.6 Client/Server Interaction with Stream Socket Connections

Figures 24.5 and 24.7 use stream sockets to demonstrate a simple [client/server chat application](#). The server waits for a client connection attempt. When a client connects to the server, the server application sends the client a `String` object (recall that `Strings` are `Serializable` objects) indicating that the connection was successful. Then the client displays the message. The client and server applications each provide textfields that allow the user to type a message and send it to the other application. When the client or the server sends the string "TERMINATE", the connection terminates. Then the server waits for the next client to connect. The declaration of class `Server` appears in Fig. 24.5. The declaration of class `Client` appears in Fig. 24.7. The screen captures showing the execution between the client and the server are shown as part of Fig. 24.7.

### Server Class

`Server`'s constructor (lines 30–55) creates the server's GUI, which contains a `JTextField` and a `JTextArea`. `Server` displays its output in the `JTextArea`. When the `main` method (lines 7–12 of Fig. 24.6) executes, it creates a `Server` object, specifies the window's default close operation and calls method `runServer` (declared at lines 58–87).

Method `runServer` sets up the server to receive a connection and processes one connection at a time. Line 62 creates a `ServerSocket` called `server` to wait for connections. The `ServerSocket` listens for a connection from a client at port 12345. The second argu-

24.6 Client/Server Interaction with Stream Socket Connections 1133

ment to the constructor is the number of connections that can wait in a queue to connect to the server (100 in this example). If the queue is full when a client attempts to connect, the server refuses the connection.

```

12 } // end main
13 } // end class ServerTest

```

**Fig. 24.6** | Test class for Server. (Part 2 of 2.)**Common Programming Error 24.1**

*Specifying a port that is already in use or specifying an invalid port number when creating a ServerSocket results in a BindException.*

Line 68 calls method `waitForConnection` (declared at lines 90–96) to wait for a client connection. After the connection is established, line 69 calls method `getStreams` (declared at lines 99–109) to obtain references to the streams for the connection. Line 70 calls method `processConnection` (declared at lines 112–133) to send the initial connection message to the client and to process all messages received from the client. The `finally` block (lines 76–80) terminates the client connection by calling method `closeConnection` (lines 136–151) even if an exception occurs. Method `displayMessage` (lines 169–180) is called from these methods to use the event dispatch thread to display messages in the application's `JTextArea`.

Method `waitForConnection` (lines 90–96) uses `ServerSocket` method `accept` (line 93) to wait for a connection from a client. When a connection occurs, the resulting `Socket` is assigned to `connection`. Method `accept` blocks until a connection is received (i.e., the thread in which `accept` is called stops executing until a client connects). Lines 94–95 output the host name of the computer that made the connection. `Socket` method `getInetAddress` returns an `InetAddress` (package `java.net`) containing information about the client computer. `InetAddress` method `getHostName` returns the host name of the client computer. For example, there is a special IP address (127.0.0.1) and host name (`localhost`) that is useful for testing networking applications on your local computer (this is also known as the `loopback address`). If `getHostName` is called on an `InetAddress` containing 127.0.0.1, the corresponding host name returned by the method would be `localhost`.

Method `getStreams` (lines 99–109) obtains the `Socket`'s streams and uses them to initialize an `ObjectOutputStream` (line 102) and an `ObjectInputStream` (line 106), respectively. Note the call to `ObjectOutputStream` method `flush` at line 103. This statement causes the `ObjectOutputStream` on the server to send a `stream header` to the corresponding client's `ObjectInputStream`. The stream header contains such information as the version of object serialization being used to send objects. This information is required by the `ObjectInputStream` so that it can prepare to receive those objects correctly.

**Software Engineering Observation 24.5**

*When using an `ObjectOutputStream` and `ObjectInputStream` to send and receive data over a network connection, always create the `ObjectOutputStream` first and `flush` the stream so that the client's `ObjectInputStream` can prepare to receive the data. This is required only for networking applications that communicate using `ObjectOutputStream` and `ObjectInputStream`.*

### Performance Tip 24.3

*A computer's input and output components are typically much slower than its memory. Output buffers typically are used to increase the efficiency of an application by sending larger amounts of data fewer times, thus reducing the number of times an application accesses the computer's input and output components.*

Line 114 of method `processConnection` (lines 112–133) calls method `sendData` to send "SERVER>>> Connection successful" as a string to the client. The loop at lines 120–132 executes until the server receives the message "CLIENT>>> TERMINATE". Line 124 uses `ObjectInputStream` method `readObject` to read a `String` from the client. Line 125 invokes method `displayMessage` to append the message to the `JTextArea`.

When the transmission is complete, method `processConnection` returns, and the program calls method `closeConnection` (lines 136–151) to close the streams associated with the `Socket` and close the `Socket`. Then the server waits for the next connection attempt from a client by continuing with line 68 at the beginning of the `while` loop.

When the user of the server application enters a string in the text field and presses the *Enter* key, the program calls method `actionPerformed` (lines 40–44), which reads the string from the text field and calls utility method `sendData` (lines 154–166) to send the string to the client. Method `sendData` writes the object, flushes the output buffer and appends the same string to the `textarea` in the server window. It is not necessary to invoke `displayMessage` to modify the `textarea` here, because method `sendData` is called from an event handler—thus, `sendData` executes as part of the event-dispatch thread.

Note that `Server` receives a connection, processes it, closes it and waits for the next connection. A more likely scenario would be a `Server` that receives a connection, sets it up to be processed as a separate thread of execution, then immediately waits for new connections. The separate threads that process existing connections can continue to execute while the `Server` concentrates on new connection requests. This makes the server more efficient, because multiple client requests can be processed concurrently. We demonstrate a multithreaded server in Section 24.8.

#### **Client Class**

Like class `Server`, class `Client`'s (Fig. 24.7) constructor (lines 29–56) creates the GUI of the application (a `JTextField` and a `JTextArea`). `Client` displays its output in the `textarea`. When method `main` (lines 7–19 of Fig. 24.8) executes, it creates an instance of class `Client`, specifies the window's default close operation and calls method `runClient` (declared at lines 59–79). In this example, you can execute the client from any computer on the Internet and specify the IP address or host name of the server computer as a command-line argument to the program. For example, the command

```
java Client 192.168.1.15
```

attempts to connect to the `Server` on the computer with IP address 192.168.1.15.

`Client` method `runClient` (lines 59–79) sets up the connection to the server, processes messages received from the server and closes the connection when communication is complete. Line 63 calls method `connectToServer` (declared at lines 82–92) to perform the connection. After connecting, line 64 calls method `getStreams` (declared at lines 95–105) to obtain references to the `Socket`'s stream objects. Then line 65 calls method `processConnection` (declared at lines 108–126) to receive and display messages sent from the

24.6 Client/Server Interaction with Stream Socket Connections **1139**

server. The `finally` block (lines 75–78) calls `closeConnection` (lines 129–144) to close the streams and the `Socket` even if an exception has occurred. Method `displayMessage` (lines 162–173) is called from these methods to use the event-dispatch thread to display messages in the application's `textarea`.

186); // end call to SwingUtilities.invokeLater
187 } // end method setTextFieldEditable
188 } // end class Client

```

**Fig. 24.7** | Client portion of a stream-socket connection between client and server. (Part 4 of 4.)

Method `connectToServer` (lines 82–92) creates a `Socket` called `client` (line 87) to establish a connection. The method passes two arguments to the `Socket` constructor—the IP address of the server computer and the port number (12345) where the server application is awaiting client connections. In the first argument, `InetAddress` static method `getByName` returns an `InetAddress` object containing the IP address specified as a command-line argument to the application (or 127.0.0.1 if no command-line arguments are specified). Method `getByName` can receive a string containing either the actual IP address or the host name of the server. The first argument also could have been written other ways. For the localhost address 127.0.0.1, the first argument could be specified with either of the following expressions:

```

InetAddress.getByName("localhost")
InetAddress.getLocalHost()

```

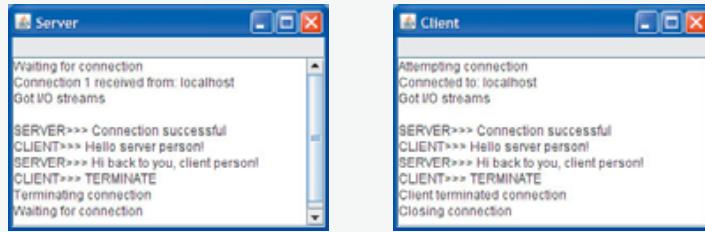

## 24.6 Client/Server Interaction with Stream Socket Connections

1143

```

1 // Fig. 24.8: ClientTest.java
2 // Test the Client class.
3 import javax.swing.JFrame;
4
5 public class ClientTest
6 {
7 public static void main(String args[])
8 {
9 Client application; // declare client application
10
11 // if no command line args
12 if (args.length == 0)
13 application = new Client("127.0.0.1"); // connect to localhost
14 else
15 application = new Client(args[0]); // use args to connect
16
17 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
18 application.runClient(); // run client application
19 } // end main
20 } // end class ClientTest

```

**Fig. 24.8** | Class that tests the Client.

Also, there are versions of the `Socket` constructor that receive a string for the IP address or host name. The first argument could have been specified as "127.0.0.1" or "localhost". We chose to demonstrate the client/server relationship by connecting between applications executing on the same computer (`localhost`). Normally, this first argument would be the IP address of another computer. The `InetAddress` object for another computer can be obtained by specifying the computer's IP address or host name as the argument to `InetAddress` method `getByName`. The `Socket` constructor's second argument is the server port number. This must match the port number at which the server is waiting for connections (called the handshake point). Once the connection is made, lines 90–91 display a message in the text area indicating the name of the server computer to which the client has connected.

The `Client` uses an `ObjectOutputStream` to send data to the server and an `ObjectInputStream` to receive data from the server. Method `getStreams` (lines 95–105) creates the `ObjectOutputStream` and `ObjectInputStream` objects that use the streams associated with the `client` socket.

Method `processConnection` (lines 108–126) contains a loop that executes until the client receives the message "SERVER>>> TERMINATE". Line 117 reads a `String` object from the server. Line 118 invokes `displayMessage` to append the message to the text area.

**1144** Chapter 24 Networking

When the transmission is complete, method `closeConnection` (lines 129–144) closes the streams and the `Socket`.

When the user of the client application enters a string in the text field and presses the *Enter* key, the program calls method `actionPerformed` (lines 41–45) to read the string and invoke utility method `sendData` (147–159) to send the string to the server. Method `sendData` writes the object, flushes the output buffer and appends the same string to the `JTextArea` in the client window. Once again, it is not necessary to invoke utility method `displayMessage` to modify the `textarea` here, because method `sendData` is called from an event handler.

## 24.7 Connectionless Client/Server Interaction with Datagrams

We have been discussing connection-oriented, streams-based transmission. Now we consider **connectionless transmission with datagrams**.

Connection-oriented transmission is like the telephone system in which you dial and are given a connection to the telephone of the person with whom you wish to communicate. The connection is maintained for the duration of your phone call, even when you are not talking.

Connectionless transmission with datagrams is more like the way mail is carried via the postal service. If a large message will not fit in one envelope, you break it into separate message pieces that you place in separate, sequentially numbered envelopes. Each of the letters is then mailed at the same time. The letters could arrive in order, out of order or not at all (the last case is rare, but it does happen). The person at the receiving end reassembles the message pieces into sequential order before attempting to make sense of the message. If your message is small enough to fit in one envelope, you need not worry about the “out-of-sequence” problem, but it is still possible that your message might not arrive. One difference between datagrams and postal mail is that duplicates of datagrams can arrive at the receiving computer.

Figures 24.9–24.12 use datagrams to send packets of information via the User Datagram Protocol (UDP) between a client application and a server application. In the `Client` application (Fig. 24.11), the user types a message into a text field and presses *Enter*. The program converts the message into a byte array and places it in a datagram packet that is sent to the server. The `Server` (Fig. 24.9) receives the packet and displays the information in it, then `echoes` the packet back to the client. Upon receiving the packet, the client displays the information it contains.

### **Server Class**

Class `Server` (Fig. 24.9) declares two `DatagramPackets` that the server uses to send and receive information and one `DatagramSocket` that sends and receives the packets. The `Server` constructor (lines 19–37) creates the graphical user interface in which the packets of information will be displayed. Line 30 creates the `DatagramSocket` in a `try` block. Line 30 uses the `DatagramSocket` constructor that takes an integer port number argument (5000 in this example) to bind the server to a port where it can receive packets from clients. Clients sending packets to this `Server` specify the same port number in the packets they send. A `SocketException` is thrown if the `DatagramSocket` constructor fails to bind the `DatagramSocket` to the specified port.

*Specifying a port that is already in use or specifying an invalid port number when creating a DatagramSocket results in a SocketException.*

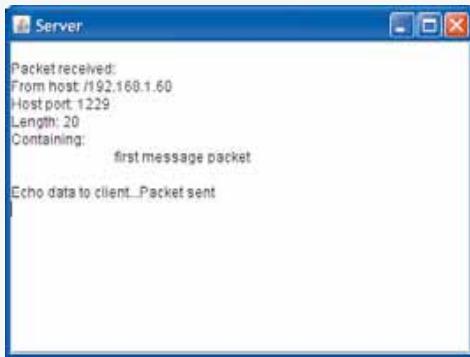

## 24.7 Connectionless Client/Server Interaction with Datagrams

1147

```

1 // Fig. 24.10: ServerTest.java
2 // Tests the Server class.
3 import javax.swing.JFrame;
4
5 public class ServerTest
6 {
7 public static void main(String args[])
8 {
9 Server application = new Server(); // create server
10 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 application.waitForPackets(); // run server application
12 } // end main
13 } // end class ServerTest

```

Server window after packet of data is received from Client

**Fig. 24.10** | Class that tests the Server.

Server method `waitForPackets` (lines 40–68) uses an infinite loop to wait for packets to arrive at the Server. Lines 47–48 create a `DatagramPacket` in which a received packet of information can be stored. The `DatagramPacket` constructor for this purpose receives two arguments—a byte array in which the data will be stored and the length of the array. Line 50 uses `DatagramSocket` method `receive` to wait for a packet to arrive at the Server. Method `receive` blocks until a packet arrives, then stores the packet in its `DatagramPacket` argument. The method throws an `IOException` if an error occurs while receiving a packet.

When a packet arrives, lines 53–58 call method `displayMessage` (declared at lines 86–97) to append the packet's contents to the textarea. `DatagramPacket` method `getAddress` (line 54) returns an `InetAddress` object containing the host name of the computer from which the packet was sent. Method `getPort` (line 55) returns an integer specifying the port number through which the host computer sent the packet. Method `getLength` (line 56) returns an integer representing the number of bytes of data sent. Method `getData` (line 57) returns a byte array containing the data. Lines 57–58 initialize a `String` object using a three-argument constructor that takes a byte array, the offset and the length. This `String` is then appended to the text to display.

After displaying a packet, line 60 calls method `sendPacketToClient` (declared at lines 71–83) to create a new packet and send it to the client. Lines 77–79 create a `Datagram-`

**1148** Chapter 24 Networking

Packet and pass four arguments to its constructor. The first argument specifies the byte array to send. The second argument specifies the number of bytes to send. The third argument specifies the client computer's Internet address, to which the packet will be sent. The fourth argument specifies the port where the client is waiting to receive packets. Line 81 sends the packet over the network. Method `send` of `DatagramSocket` throws an `IOException` if an error occurs while sending a packet.

***Client Class***

Class `Client` (Fig. 24.11) works similarly to class `Server`, except that the `Client` sends packets only when the user types a message in a text field and presses the *Enter* key. When this occurs, the program calls method `actionPerformed` (lines 32–57), which converts the string the user entered into a byte array (line 41). Lines 44–45 create a `DatagramPacket` and initialize it with the byte array, the length of the string that was entered by the user, the IP address to which the packet is to be sent (`InetAddress.getLocalHost()` in this example) and the port number at which the `Server` is waiting for packets (5000 in this example). Line 47 sends the packet. Note that the client in this example must know that the server is receiving packets at port 5000—otherwise, the server will not receive the packets.

84 {

```

**Fig. 24.11** | Client side of connectionless client/server computing with datagrams. (Part 2 of 3.)

## 1150 Chapter 24 Networking

```

85 try // receive packet and display contents
86 {
87 byte data[] = new byte[100]; // set up packet
88 DatagramPacket receivePacket = new DatagramPacket(
89 data, data.length);
90
91 socket.receive(receivePacket); // wait for packet
92
93 // display packet contents
94 displayMessage("\nPacket received:" +
95 "\nFrom host: " + receivePacket.getAddress() +
96 "\nHost port: " + receivePacket.getPort() +
97 "\nLength: " + receivePacket.getLength() +
98 "\nContaining:\n\t" + new String(receivePacket.getData(),
99 0, receivePacket.getLength()));
100 } // end try
101 catch (IOException exception)
102 {
103 displayMessage(exception.toString() + "\n");
104 exception.printStackTrace();
105 } // end catch
106 } // end while
107 } // end method waitForPackets
108
109 // manipulates displayArea in the event-dispatch thread
110 private void displayMessage(final String messageToDisplay)
111 {
112 SwingUtilities.invokeLater(
113 new Runnable()
114 {
115 public void run() // updates displayArea
116 {
117 displayArea.append(messageToDisplay);
118 } // end method run
119 } // end inner class
120 }; // end call to SwingUtilities.invokeLater
121 } // end method displayMessage
122 } // end class Client

```

**Fig. 24.11** | Client side of connectionless client/server computing with datagrams. (Part 3 of 3.)

Note that the `DatagramSocket` constructor call (line 71) in this application does not specify any arguments. This no-argument constructor allows the computer to select the next available port number for the `DatagramSocket`. The client does not need a specific port number, because the server receives the client's port number as part of each `DatagramPacket` sent by the client. Thus, the server can send packets back to the same computer and port number from which it receives a packet of information.

Client method `waitForPackets` (lines 81–107) uses an infinite loop to wait for packets from the server. Line 91 blocks until a packet arrives. This does not prevent the user from sending a packet, because the GUI events are handled in the event-dispatch thread. It only prevents the `while` loop from continuing until a packet arrives at the Client. When a packet arrives, line 91 stores it in `receivePacket`, and lines 94–99 call

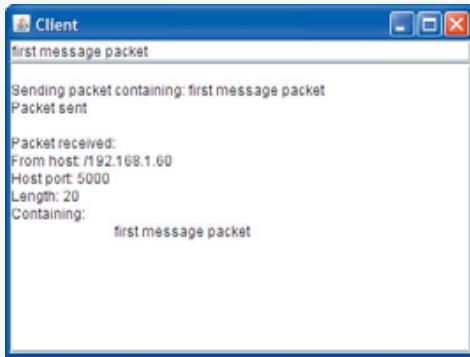

## 24.8 Client/Server Tic-Tac-Toe Using a Multithreaded Server

method `displayMessage` (declared at lines 110–121) to display the packet's contents in the textarea.

## 24.8 Client/Server Tic-Tac-Toe Using a Multithreaded Server

In this section, we present the popular game Tic-Tac-Toe implemented by using client/server techniques with stream sockets. The program consists of a `TicTacToeServer` application (Figs. 24.13–24.14) that allows two `TicTacToeClient` applications (Figs. 24.15–24.16) to connect to the server and play Tic-Tac-Toe. Sample outputs are shown in Fig. 24.17.

### *TicTacToeServer Class*

As the `TicTacToeServer` receives each client connection, it creates an instance of inner-class `Player` (lines 182–301 of Fig. 24.13) to process the client in a separate thread. These threads enable the clients to play the game independently. The first client to connect to the server is player X and the second is player O. Player X makes the first move. The server maintains the information about the board so it can determine whether a player's move is valid or invalid.

**Fig. 24.13** | Server side of client/server Tic-Tac-Toe program. (Part 6 of 6.)

We begin with a discussion of the server side of the Tic-Tac-Toe game. When the `TicTacToeServer` application executes, the `main` method (lines 7–12 of Fig. 24.14) creates a `TicTacToeServer` object called `application`. The constructor (lines 34–69 of Fig. 24.13) attempts to set up a `ServerSocket`. If successful, the program displays the server window, then `main` invokes the `TicTacToeServer` method `execute` (lines 72–100). Method `execute` loops twice, blocking at line 79 each time while waiting for a client con-

**1158** Chapter 24 Networking

nection. When a client connects, line 79 creates a new `Player` object to manage the connection as a separate thread, and line 80 executes the `Player` in the `runGame` thread pool.

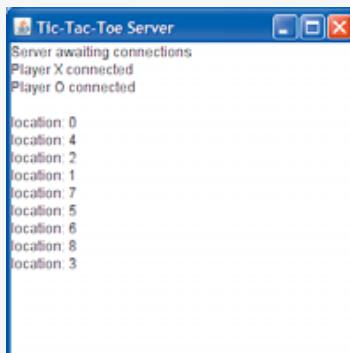

When the `TicTacToeServer` creates a `Player`, the `Player` constructor (lines 192–208) receives the `Socket` object representing the connection to the client and gets the associated input and output streams. Line 201 creates a `Formatter` (see Chapter 28) by wrapping it around the output stream of the socket. The `Player`'s `run` method (lines 219–297) controls the information that is sent to and received from the client. First, it passes to the client the character that the client will place on the board when a move is made (line 225). Line 226 calls `Formatter` method `flush` to force this output to the client. Line 241 suspends player X's thread as it starts executing, because player X can move only after player O connects.

After player O connects, the game can be played, and the `run` method begins executing its `while` statement (lines 264–283). Each iteration of this loop reads an integer (line 269) representing the location where the client wants to place a mark, and line 272 invokes the `TicTacToeServer` method `validateAndMove` (declared at lines 118–163) to check the move. If the move is valid, line 275 sends a message to the client to this effect. If not, line 280 sends a message indicating that the move was invalid. The program maintains board locations as numbers from 0 to 8 (0 through 2 for the first row, 3 through 5 for the second row and 6 through 8 for the third row).

```

1 // Fig. 24.14: TicTacToeServerTest.java
2 // Tests the TicTacToeServer.
3 import javax.swing.JFrame;
4
5 public class TicTacToeServerTest
6 {
7 public static void main(String args[])
8 {
9 TicTacToeServer application = new TicTacToeServer();
10 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 application.execute();
12 } // end main
13 } // end class TicTacToeServerTest

```

**Fig. 24.14** | Class that tests Tic-Tac-Toe server.

24.8 Client/Server Tic-Tac-Toe Using a Multithreaded Server **1159**

Method `validateAndMove` (lines 118–163 in class `TicTacToeServer`) allows only one player at a time to move, thereby preventing them from modifying the state information of the game simultaneously. If the `Player` attempting to validate a move is not the current player (i.e., the one allowed to make a move), it is placed in a *wait* state until its turn to move. If the position for the move being validated is already occupied on the board, `validMove` returns `false`. Otherwise, the server places a mark for the player in its local representation of the board (line 142), notifies the other `Player` object (line 146) that a move has been made (so that the client can be sent a message), invokes method `signal` (line 152) so that the waiting `Player` (if there is one) can validate a move and returns `true` (line 159) to indicate that the move is valid.

***TicTacToeClient Class***

Each `TicTacToeClient` application (Fig. 24.15) maintains its own GUI version of the Tic-Tac-Toe board on which it displays the state of the game. The clients can place a mark only in an empty square on the board. Inner class `Square` (lines 205–262 of Fig. 24.15) implements each of the nine squares on the board. When a `TicTacToeClient` begins execution, it creates a `JTextArea` in which messages from the server and a representation of the board using nine `Square` objects are displayed. The `startClient` method (lines 80–100) opens a connection to the server and gets the associated input and output streams from the `Socket` object. Lines 85–86 make a connection to the server. Class `TicTacToeClient` implements interface `Runnable` so that a separate thread can read messages from the server. This approach enables the user to interact with the board (in the event dispatch thread) while waiting for messages from the server. After establishing the connection to the server, line 99 executes the client with the worker `ExecutorService`. The `run` method (lines 103–124) controls the separate thread of execution. The method first reads the mark character (X or O) from the server (line 105), then loops continuously (lines 121–125) and reads messages from the server (line 124). Each message is passed to the `processMessage` method (lines 129–156) for processing.

239
240 // set mark for Square
241 public void setMark(String newMark)
242 {
243 mark = newMark; // set mark of square
244 repaint(); // repaint square
245 } // end method setMark
246
247 // return Square location
248 public int getSquareLocation()
249 {
250 return location; // return location of square
251 } // end method getSquareLocation
252
253 // draw Square
254 public void paintComponent(Graphics g)
255 {
256 super.paintComponent(g);
257
258 g.drawRect(0, 0, 29, 29); // draw square
259 g.drawString(mark, 11, 20); // draw mark
260 } // end method paintComponent
261 } // end inner-class Square
262 } // end class TicTacToeClient

```

**Fig. 24.15** | Client side of client/server Tic-Tac-Toe program. (Part 6 of 6.)

If the message received is "Valid move.", lines 134–135 display the message "Valid move, please wait." and call method `setMark` (lines 173–184) to set the client's mark in the current square (the one in which the user clicked), using `SwingUtilities` method `invokeLater` to ensure that the GUI updates occur in the event dispatch thread. If the message received is "Invalid move, try again.", line 139 displays the message so that the user can click a different square. If the message received is "Opponent moved.", line 145 reads an integer from the server indicating where the opponent moved, and lines 149–150 place a mark in that square of the board (again using `SwingUtilities` method `invokeLater` to ensure that the GUI updates occur in the event dispatch thread). If any other message is received, line 155 simply displays the message. Figure 24.17 shows sample screen captures of two applications interacting via the `TicTacToeServer`.

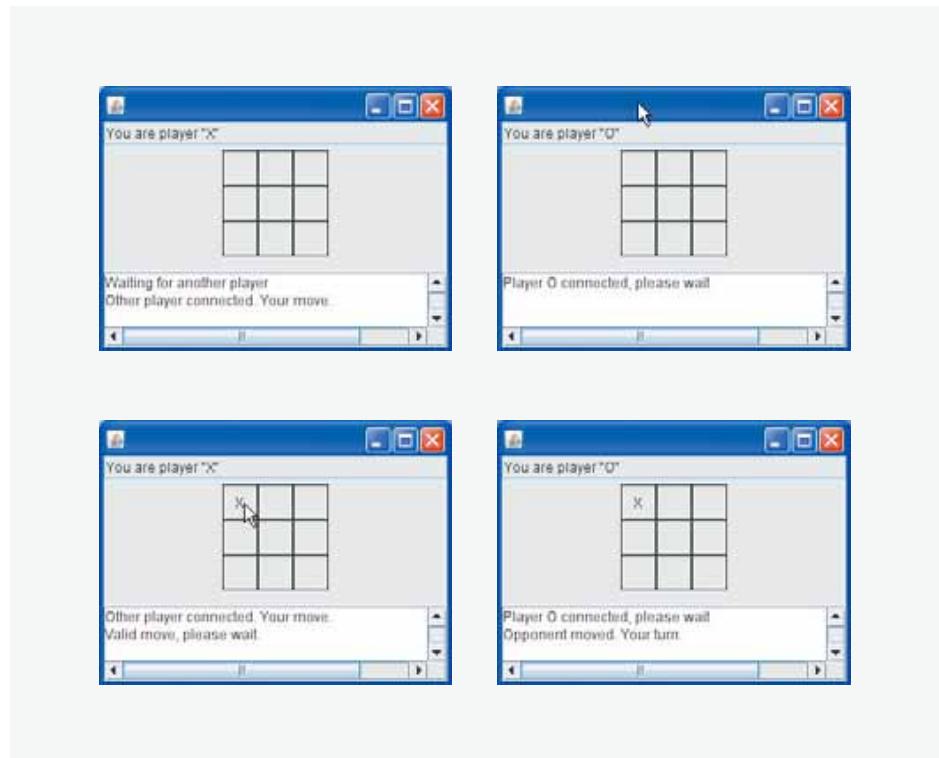

## 24.8 Client/Server Tic-Tac-Toe Using a Multithreaded Server

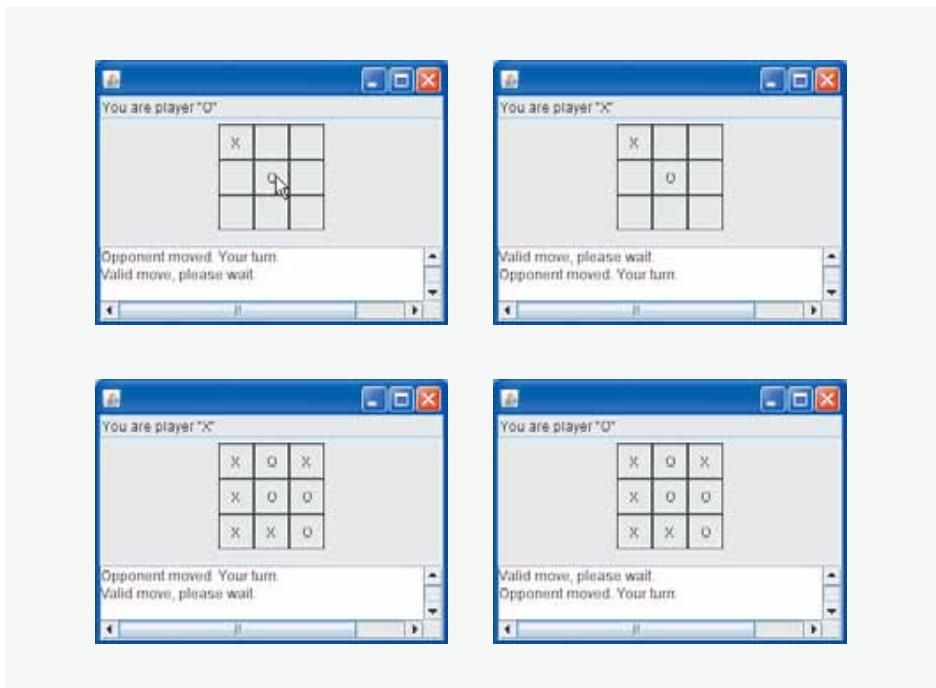

1165

```

1 // Fig. 24.16: TicTacToeClientTest.java
2 // Tests the TicTacToeClient class.
3 import javax.swing.JFrame;
4
5 public class TicTacToeClientTest
6 {
7 public static void main(String args[])
8 {
9 TicTacToeClient application; // declare client application
10
11 // if no command line args
12 if (args.length == 0)
13 application = new TicTacToeClient("127.0.0.1"); // LocalHost
14 else
15 application = new TicTacToeClient(args[0]); // use args
16
17 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
18 } // end main
19 } // end class TicTacToeClientTest

```

## 24.9 Security and the Network

As much as we look forward to writing a great variety of powerful network-based applications, our efforts may be limited because of security concerns. Many web browsers, such as Mozilla and Microsoft Internet Explorer, by default prohibit Java applets from doing file processing on the machines on which they execute. Think about it. A Java applet is designed to be sent to your browser via an HTML document that could be downloaded from any web server in the world. Often you will know very little about the sources of Java applets that will execute on your system. To allow these applets free rein with your files could be disastrous.

A more subtle situation occurs with limiting the machines to which executing applets can make network connections. To build truly collaborative applications, we would ideally like to have our applets communicate with machines almost anywhere. The Java security manager in a web browser often restricts an applet so that it can communicate only with the machine from which it was originally downloaded.

These restrictions may seem too strict. However, the Java Security API now provides capabilities for digitally signed applets that will enable browsers to determine whether an applet is downloaded from a **trusted source**. A trusted applet can be given additional access to the computer on which it is executing. The features of the Java Security API and additional networking capabilities are discussed in our text *Advanced Java 2 Platform How to Program*.

24.10 [Web Bonus] Case Study: DeitelMessenger Server and Client **1167**

## 24.10 [Web Bonus] Case Study: DeitelMessenger Server and Client

*[Note:* This case study is available at [www.deitel.com/books/jhtp7/](http://www.deitel.com/books/jhtp7/).] Chat rooms have become common on the Internet. They provide a central location where users can chat with each other via short text messages. Each participant can see all messages that the other users post, and each user can post messages. This case study integrates many of the Java networking, multithreading and Swing GUI features you have learned thus far to build an online chat system. We also introduce **multicasting**, which enables an application to send **DatagramPackets** to groups of clients.

The DeitelMessenger case study is a significant application that uses many intermediate Java features, such as networking with Sockets, **DatagramPackets** and **MulticastSockets**, multithreading and Swing GUI. The case study also demonstrates good software engineering practices by separating interface from implementation, enabling developers to support different network protocols and provide different user interfaces. After reading this case study, you will be able to build more significant networking applications.

## 24.11 Wrap-Up

In this chapter, you have learned the basics of network programming in Java. You learned two different methods of sending data over a network: streams-based networking using TCP/IP and datagrams-based networking using UDP. In the next chapter, you will learn basic database concepts, how to interact with data in a database using SQL and how to use JDBC to allow Java applications to manipulate database data.

### Summary

#### Section 24.1 Introduction

- Java provides stream sockets and datagram sockets. With stream sockets, a process establishes a connection to another process. While the connection is in place, data flows between the processes in streams. Stream sockets are said to provide a connection-oriented service. The protocol used for transmission is the popular TCP (Transmission Control Protocol).
- With datagram sockets, individual packets of information are transmitted. UDP (User Datagram Protocol) is a connectionless service that does not guarantee that packets will not be lost, duplicated or arrive out of sequence. Extra programming is required on your part to deal with these problems.

#### Section 24.2 Manipulating URLs

- The HTTP protocol (Hypertext Transfer Protocol) that forms the basis of the web uses URIs (Uniform Resource Identifiers) to locate data on the Internet. Common URIs represent files or directories and can represent complex tasks such as database lookups and Internet searches. A URI that represents a document is called a URL (Uniform Resource Locator).
- Applet method `getAppletContext` returns a reference to an `AppletContext` object that represents the applet's environment (i.e., the browser in which the applet is executing). `AppletContext` method `showDocument` receives a URL as an argument and passes it to the `AppletContext` (i.e., the browser), which displays the web resource associated with that URL. A second version of `showDocument` enables an applet to specify the target frame in which to display a web resource. Special

## 1168 Chapter 24 Networking

target frames include `_blank` (display in a new web browser window), `_self` (display in the same frame as the applet) and `_top` (remove the current frames, then display in the current window).

### *Section 24.3 Reading a File on a Web Server*

- `JEditorPane` method `setPage` downloads the document specified by its argument and displays it in the `JEditorPane`.
- Typically, an HTML document contains hyperlinks—text, images or GUI components that, when clicked, link to another document on the web. If an HTML document is displayed in a `JEditorPane` and the user clicks a hyperlink, the `JEditorPane` generates a `HyperlinkEvent` and notifies all registered `HyperlinkListeners` of the event.
- `HyperlinkEvent` method `getEventType` determines the event type. `HyperlinkEvent` contains nested class `EventType`, which declares three hyperlink event types: `ACTIVATED` (hyperlink clicked), `ENTERED` (mouse over a hyperlink) and `EXITED` (mouse moved away from a hyperlink). `HyperlinkEvent` method `getURL` obtains the URL represented by the hyperlink.

### *Section 24.4 Establishing a Simple Server Using Stream Sockets*

- Stream-based connections are managed with `Socket` objects.
- A `ServerSocket` object establishes the port where a server waits for connections from clients. The second argument to the `ServerSocket` constructor is the number of connections that can wait in a queue to connect to the server. If the queue of clients is full, client connections are refused. The `ServerSocket` method `accept` waits indefinitely (i.e., blocks) for a connection from a client and returns a `Socket` object when a connection is established.
- `Socket` methods `getOutputStream` and `getInputStream` get references to a `Socket`'s `OutputStream` and `InputStream`, respectively. `Socket` method `close` terminates a connection.

### *Section 24.5 Establishing a Simple Client Using Stream Sockets*

- A server name and port number are specified when creating a `Socket` object to enable it to connect a client to the server. A failed connection attempt throws an `IOException`.
- `InetAddress` method `getByName` returns an `InetAddress` object containing the host name of the computer for which the host name or IP address is specified as an argument. `InetAddress` method `getLocalHost` returns an `InetAddress` object containing the host name of the local computer executing the program.

### *Section 24.7 Connectionless Client/Server Interaction with Datagrams*

- Connection-oriented transmission is like the telephone system—you dial and are given a connection to the telephone of the person with whom you wish to communicate. The connection is maintained for the duration of your phone call, even when you are not talking.
- Connectionless transmission with datagrams is similar to mail carried via the postal service. A large message that will not fit in one envelope can be broken into separate message pieces that are placed in separate, sequentially numbered envelopes. All the letters are then mailed at once. They could arrive in order, out of order or not at all.
- `DatagramPacket` objects store packets of data that are to be sent or that are received by an application. `DatagramSockets` send and receive `DatagramPackets`.
- The `DatagramSocket` constructor that takes no arguments binds the application to a port chosen by the computer on which the program executes. The `DatagramSocket` constructor that takes an integer port number argument binds the application to the specified port. If a `DatagramSocket` constructor fails to bind the application to a port, a `SocketException` occurs. `DatagramSocket` method `receive` blocks (waits) until a packet arrives, then stores the packet in its argument.

## Terminology 1169

- `DatagramPacket` method `getAddress` returns an `InetAddress` object containing information about the host computer from which the packet was sent. Method `getPort` returns an integer specifying the port number through which the host computer sent the `DatagramPacket`. Method `getLength` returns an integer representing the number of bytes of data in a `DatagramPacket`. Method `getData` returns a byte array containing the data in a `DatagramPacket`.
- The `DatagramPacket` constructor for a packet to be sent takes four arguments—the byte array to be sent, the number of bytes to be sent, the client address to which the packet will be sent and the port number where the client is waiting to receive packets.
- `DatagramSocket` method `send` sends a `DatagramPacket` out over the network.
- If an error occurs when receiving or sending a `DatagramPacket`, an `IOException` occurs.

**Section 24.9 Security and the Network**

- Web browsers often restrict an applet so that it can communicate only with the machine from which it was originally downloaded.

**Terminology**

|                                                                       |                                                                                    |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------|
| accept method of class <code>ServerSocket</code>                      | <code>getLength</code> method of class <code>DatagramPacket</code>                 |
| ACTIVATED constant of nested class <code>EventType</code>             | <code>getLocalHost</code> method of class <code>InetAddress</code>                 |
| applet parameter                                                      | <code>getOutputStream</code> method of class <code>Socket</code>                   |
| <code>AppletContext</code> interface                                  | <code>getParameter</code> method of class <code>Applet</code>                      |
| binding the server to the port                                        | <code>getPort</code> method of class <code>DatagramPacket</code>                   |
| <code>_blank</code> target frame                                      | <code>getResource</code> method of class <code>Class</code>                        |
| block to listen for a connection                                      | <code>getURL</code> method of class <code>HyperlinkEvent</code>                    |
| class loader                                                          | handshake point                                                                    |
| client                                                                | HTML frame                                                                         |
| client/server relationship                                            | hyperlink                                                                          |
| <code>close</code> method of class <code>Socket</code>                | <code>HyperlinkEvent</code> class                                                  |

**1170 Chapter 24 Networking**

|                                            |                                     |
|--------------------------------------------|-------------------------------------|
| showDocument method of class AppletContext | target frame                        |
| socket                                     | TCP (Transmission Control Protocol) |
| socket-based communication                 | _top target frame                   |
| Socket class                               | trusted source                      |
| SocketException class                      | UDP (User Datagram Protocol)        |
| stream header                              | Uniform Resource Identifier (URI)   |
| stream socket                              | UnknownHostException class          |
| stream-based communication                 | User Datagram Protocol (UDP)        |
| stream-based transmission                  | World Wide Web Consortium (W3C)     |

**Self-Review Exercises****24.1** Fill in the blanks in each of the following statements:

- a) Exception \_\_\_\_\_ occurs when an input/output error occurs when closing a socket.
- b) Exception \_\_\_\_\_ occurs when a host name indicated by a client cannot be resolved to an address.
- c) If a DatagramSocket constructor fails to set up a DatagramSocket properly, an exception of type \_\_\_\_\_ occurs.
- d) Many of Java's networking classes are contained in package \_\_\_\_\_.
- e) Class \_\_\_\_\_ binds the application to a port for datagram transmission.
- f) An object of class \_\_\_\_\_ contains an IP address.
- g) The two types of sockets we discussed in this chapter are \_\_\_\_\_ and \_\_\_\_\_.
- h) The acronym URL stands for \_\_\_\_\_.
- i) The acronym URI stands for \_\_\_\_\_.
- j) The key protocol that forms the basis of the World Wide Web is \_\_\_\_\_.
- k) AppletContext method \_\_\_\_\_ receives a URL object as an argument and displays in a browser the World Wide Web resource associated with that URL.
- l) Method getLocalHost returns a(n) \_\_\_\_\_ object containing the local host name of the computer on which the program is executing.
- m) The URL constructor determines whether its string argument is a valid URL. If so, the URL object is initialized with that location. If not, a(n) \_\_\_\_\_ exception occurs.

**24.2** State whether each of the following is *true or false*. If *false*, explain why.

- a) UDP is a connection-oriented protocol.
- b) With stream sockets a process establishes a connection to another process.
- c) A server waits at a port for connections from a client.
- d) Datagram packet transmission over a network is reliable—packets are guaranteed to arrive in sequence.
- e) For security reasons, many web browsers, such as Mozilla, allow Java applets to do file processing only on the machines on which they execute.
- f) Web browsers often restrict an applet so that it can communicate only with the machine from which it was originally downloaded.

**Answers to Self-Review Exercises**

**24.1** a) IOException. b) UnknownHostException. c) SocketException. d) java.net.  
 e) DatagramSocket. f) InetAddress. g) stream sockets, datagram sockets. h) Uniform Resource Locator. i) Uniform Resource Identifier. j) HTTP. k) showDocument. l) InetAddress. m) MalformedURLException.

**24.2** a) False; UDP is a connectionless protocol and TCP is a connection-oriented protocol.  
 b) True. c) True. d) False; packets can be lost, arrive out of order or be duplicated. e) False; most browsers prevent applets from doing file processing on the client machine. f) True.

## Exercises 1171

## Exercises

- 24.3** Distinguish between connection-oriented and connectionless network services.
- 24.4** How does a client determine the host name of the client computer?
- 24.5** Under what circumstances would a `SocketException` be thrown?
- 24.6** How can a client get a line of text from a server?
- 24.7** Describe how a client connects to a server.
- 24.8** Describe how a server sends data to a client.
- 24.9** Describe how to prepare a server to receive a stream-based connection request from a single client.
- 24.10** How does a server listen for streams-based socket connections at a port?
- 24.11** What determines how many connect requests from clients can wait in a queue to connect to a server?
- 24.12** As described in the text, what reasons might cause a server to refuse a connection request from a client?
- 24.13** Use a socket connection to allow a client to specify a file name and have the server send the contents of the file or indicate that the file does not exist.
- 24.14** Modify Exercise 24.13 to allow the client to modify the contents of the file and send the file back to the server for storage. The user can edit the file in a `JTextArea`, then click a *save changes* button to send the file back to the server.
- 24.15** Modify the program in Fig. 24.2 to allow users to add their own sites to the list and remove sites from the list.
- 24.16** Multithreaded servers are quite popular today, especially because of the increasing use of multiprocessing servers. Modify the simple server application presented in Section 24.6 to be a multithreaded server. Then use several client applications and have each of them connect to the server simultaneously. Use an `ArrayList` to store the client threads. `ArrayList` provides several methods of use in this exercise. Method `size` determines the number of elements in an `ArrayList`. Method `get` returns the element in the location specified by its argument. Method `add` places its argument at the end of the `ArrayList`. Method `remove` deletes its argument from the `ArrayList`.
- 24.17** (*Checkers Game*) In the text, we presented a Tic-Tac-Toe program controlled by a multi-threaded server. Develop a checkers program modeled after the Tic-Tac-Toe program. The two users should alternate making moves. Your program should mediate the players' moves, determining whose turn it is and allowing only valid moves. The players themselves will determine when the game is over.
- 24.18** (*Chess Game*) Develop a chess-playing program modeled after the checkers program in the Exercise 24.17.
- 24.19** (*Blackjack Game*) Develop a blackjack card game program in which the server application deals cards to each of the client applets. The server should deal additional cards (as per the rules of the game) to each player as requested.
- 24.20** (*Poker Game*) Develop a poker card game in which the server application deals cards to each of the client applets. The server should deal additional cards (as per the rules of the game) to each player as requested.

## 1172 Chapter 24 Networking

**24.21** (*Modifications to the Multithreaded Tic-Tac-Toe Program*) The programs in Figs. 24.13 and 24.15 implemented a multithreaded, client/server version of the game of Tic-Tac-Toe. Our goal in developing this game was to demonstrate a multithreaded server that could process multiple connections from clients at the same time. The server in the example is really a mediator between the two client applets—it makes sure that each move is valid and that each client moves in the proper order. The server does not determine who won or lost or whether there was a draw. Also, there is no capability to allow a new game to be played or to terminate an existing game.

The following is a list of suggested modifications to Figs. 24.13 and 24.15:

- Modify the `TicTacToeServer` class to test for a win, loss or draw on each move in the game. Send a message to each client applet that indicates the result of the game when the game is over.
- Modify the `TicTacToeClient` class to display a button that when clicked allows the client to play another game. The button should be enabled only when a game completes. Note that both class `TicTacToeClient` and class `TicTacToeServer` must be modified to reset the board and all state information. Also, the other `TicTacToeClient` should be notified that a new game is about to begin so that its board and state can be reset.
- Modify the `TicTacToeClient` class to provide a button that allows a client to terminate the program at any time. When the user clicks the button, the server and the other client should be notified. The server should then wait for a connection from another client so that a new game can begin.
- Modify the `TicTacToeClient` class and the `TicTacToeServer` class so that the winner of a game can choose game piece X or O for the next game. Remember: X always goes first.
- If you would like to be ambitious, allow a client to play against the server while the server waits for a connection from another client.

**24.22** (*3-D Multithreaded Tic-Tac-Toe*) Modify the multithreaded, client/server Tic-Tac-Toe program to implement a three-dimensional 4-by-4-by-4 version of the game. Implement the server application to mediate between the two clients. Display the three-dimensional board as four boards containing four rows and four columns each. If you would like to be ambitious, try the following modifications:

- Draw the board in a three-dimensional manner.
- Allow the server to test for a win, loss or draw. Beware! There are many possible ways to win on a 4-by-4-by-4 board!

**24.23** (*Networked Morse Code*) Perhaps the most famous of all coding schemes is the Morse code, developed by Samuel Morse in 1832 for use with the telegraph system. The Morse code assigns a series of dots and dashes to each letter of the alphabet, each digit, and a few special characters (e.g., period, comma, colon and semicolon). In sound-oriented systems, the dot represents a short sound and the dash represents a long sound. Other representations of dots and dashes are used with light-oriented systems and signal-flag systems. Separation between words is indicated by a space or, simply, the absence of a dot or dash. In a sound-oriented system, a space is indicated by a short time during which no sound is transmitted. The international version of the Morse code appears in Fig. 24.18.

Write a client/server application in which two clients can send Morse-code messages to each other through a multithreaded server application. The client application should allow the user to type English-language phrases in a `JTextArea`. When the user sends the message, the client application encodes the text into Morse code and sends the coded message through the server to the other client. Use one blank between each Morse-coded letter and three blanks between each Morse-coded word. When messages are received, they should be decoded and displayed as normal characters and as Morse code. The client should have one `JTextField` for typing and one `JTextArea` for displaying the other client's messages.

Exercises    **1173**

| Character | Code  | Character     | Code      |
|-----------|-------|---------------|-----------|
| A         | .-    | T             | -         |

# Accessing Databases with JDBC

## OBJECTIVES

In this chapter you will learn:

- Relational database concepts.
- To use Structured Query Language (SQL) to retrieve data from and manipulate data in a database.
- To use the JDBC™ API of package `java.sql` to access databases.
- To use the `RowSet` interface from package `javax.sql` to manipulate databases.
- To use JDBC 4.0's automatic JDBC driver discovery.
- To use `PreparedStatement`s to create precompiled SQL statements with parameters.
- How transaction processing makes database applications more robust.

*It is a capital mistake to theorize before one has data.  
—Arthur Conan Doyle*

*Now go, write it before them in a table, and note it in a book, that it may be for the time to come for ever and ever.*

—The Holy Bible, Isaiah 30:8

*Get your facts first, and then you can distort them as much as you please.*

—Mark Twain

*I like two kinds of men: domestic and foreign.*

—Mae West

## 25.1 Introduction

A **database** is an organized collection of data. There are many different strategies for organizing data to facilitate easy access and manipulation. A **database management system (DBMS)** provides mechanisms for storing, organizing, retrieving and modifying data for many users. Database management systems allow for the access and storage of data without concern for the internal representation of data.

Today's most popular database systems are relational databases, where the data is stored without consideration of its physical structure (Section 25.2). A language called **SQL**—pronounced “sequel,” or as its individual letters—is the international standard language used almost universally with relational databases to perform **queries** (i.e., to request information that satisfies given criteria) and to manipulate data. [Note: As you learn about SQL, you will see some authors writing “a SQL statement” (which assumes the pronunciation “sequel”) and others writing “an SQL statement” (which assumes that the individual letters are pronounced). In this book we pronounce SQL as “sequel.”]

## 1176 Chapter 25 Accessing Databases with JDBC

Some popular **relational database management systems (RDBMSs)** are Microsoft SQL Server, Oracle, Sybase, IBM DB2, Informix, PostgreSQL and MySQL. The JDK now comes with a pure-Java RDBMS called Java DB—Sun's version of Apache Derby. In this chapter, we present examples using MySQL and Java DB.<sup>1</sup>

Java programs communicate with databases and manipulate their data using the **JDBC™ API**. A **JDBC driver** enables Java applications to connect to a database in a particular DBMS and allows you to manipulate that database using the JDBC API.

### Software Engineering Observation 25.1

*Using the JDBC API enables developers to change the underlying DBMS without modifying the Java code that accesses the database.*

Most popular database management systems now provide JDBC drivers. There are also many third-party JDBC drivers available. In this chapter, we introduce JDBC and use it to manipulate MySQL and Java DB databases. The techniques demonstrated here can also be used to manipulate other databases that have JDBC drivers. Check your DBMS's documentation to determine whether your DBMS comes with a JDBC driver. If not, third-party vendors provide JDBC drivers for many DBMSs.

For more information on JDBC, visit

[java.sun.com/javase/technologies/database/index.jsp](http://java.sun.com/javase/technologies/database/index.jsp)

This site contains JDBC information including the JDBC specification, FAQs, a learning resource center and software downloads to search for JDBC drivers for your DBMS,

[developers.sun.com/product/jdbc/drivers/](http://developers.sun.com/product/jdbc/drivers/)

This site provides a search engine to help you locate drivers appropriate for your DBMS.

## 25.2 Relational Databases

A **relational database** is a logical representation of data that allows the data to be accessed without consideration of its physical structure. A relational database stores data in **tables**. Figure 25.1 illustrates a sample table that might be used in a personnel system. The table name is **Employee**, and its primary purpose is to store the attributes of an employee. Tables are composed of **rows**, and rows are composed of **columns** in which values are stored. This table consists of six rows. The **Number** column of each row in this table is the table's **primary key**—a column (or group of columns) in a table with a unique value that cannot be duplicated in other rows. This guarantees that each row can be identified by its primary key. Good examples of primary key columns are a social security number, an employee ID number and a part number in an inventory system, as values in each of these columns are guaranteed to be unique. The rows in Fig. 25.1 are displayed in order by primary key. In this case, the rows are listed in increasing order, but we could also use decreasing order.

- 
1. MySQL is one of the most popular open-source database management systems in use today. As of this writing, it does not yet support JDBC 4, which is part of Java SE 6 (Mustang). However, Sun's Java DB, which is based on the open-source Apache Derby database management system and bundled with Sun's JDK 1.6.0, does support JDBC 4. We use MySQL and JDBC 3 in Sections 25.8–25.10, and we use Java DB and JDBC 4 in Section 25.11.

## 25.3 Relational Database Overview: The books Database

1177

|     | Number | Name     | Department | Salary | Location    |
|-----|--------|----------|------------|--------|-------------|
| Row | 23603  | Jones    | 413        | 1100   | New Jersey  |
|     | 24568  | Kerwin   | 413        | 2000   | New Jersey  |
|     | 34589  | Larson   | 642        | 1800   | Los Angeles |
|     | 35761  | Myers    | 611        | 1400   | Orlando     |
|     | 47132  | Neumann  | 413        | 9000   | New Jersey  |
|     | 78321  | Stephens | 611        | 8500   | Orlando     |

**Fig. 25.1** | Employee table sample data.

Rows in tables are not guaranteed to be stored in any particular order. As we will demonstrate in an upcoming example, programs can specify ordering criteria when requesting data from a database.

Each column represents a different data attribute. Rows are normally unique (by primary key) within a table, but particular column values may be duplicated between rows. For example, three different rows in the Employee table's Department column contain number 413.

Different users of a database are often interested in different data and different relationships among the data. Most users require only subsets of the rows and columns. To obtain these subsets, we use queries to specify which data to select from a table. You use SQL to define complex queries that select data from a table. For example, you might select data from the Employee table to create a result that shows where each department is located, and present the data sorted in increasing order by department number. This result is shown in Fig. 25.2. SQL queries are discussed in Section 25.4.

| Department | Location    |
|------------|-------------|
| 413        | New Jersey  |
| 611        | Orlando     |
| 642        | Los Angeles |

**Fig. 25.2** | Result of selecting distinct Department and Location data from table Employee.

## 25.3 Relational Database Overview: The books Database

We now overview relational databases in the context of a sample books database we created for this chapter. Before we discuss SQL, we overview the tables of the books database. We use this database to introduce various database concepts, including how to use SQL to obtain information from the database and to manipulate the data. We provide a script to create the database. You can find the script in the examples directory for this chapter on the CD that accompanies this book. Section 25.5 explains how to use this script.

The database consists of three tables: authors, authorISBN and titles. The authors table (described in Fig. 25.3) consists of three columns that maintain each author's unique ID number, first name and last name. Figure 25.4 contains sample data from the authors table of the books database.

**1178 Chapter 25 Accessing Databases with JDBC**

| Column    | Description                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| authorID  | Author's ID number in the database. In the books database, this integer column is defined as <b>autoincremented</b> —for each row inserted in this table, the authorID value is increased by 1 automatically to ensure that each row has a unique authorID. This column represents the table's primary key. |
| firstName | Author's first name (a string).                                                                                                                                                                                                                                                                             |
| lastName  | Author's last name (a string).                                                                                                                                                                                                                                                                              |

**Fig. 25.3** | authors table from the books database.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Andrew    | Goldberg |
| 4        | David     | Choffnes |

**Fig. 25.4** | Sample data from the authors table.

The authorISBN table (described in Fig. 25.5) consists of two columns that maintain each ISBN and the corresponding author's ID number. This table associates authors with their books. Both columns are foreign keys that represent the relationship between the tables authors and titles—one row in table authors may be associated with many rows in table titles, and vice versa. Figure 25.6 contains sample data from the authorISBN

| Column   | Description                                                 |
|----------|-------------------------------------------------------------|
| authorID | The author's ID number, a foreign key to the authors table. |
| isbn     | The ISBN for a book, a foreign key to the titles table.     |

**Fig. 25.5** | authorISBN table from the books database.

| authorID | isbn       | authorID | isbn       |
|----------|------------|----------|------------|
| 1        | 0131869000 | 2        | 0131450913 |
| 2        | 0131869000 | 1        | 0131828274 |

### 25.3 Relational Database Overview: The books Database 1179

table of the books database. [Note: To save space, we have split the contents of this table into two columns, each containing the `authorID` and `isbn` columns.] The `authorID` column is a **foreign key**—a column in this table that matches the primary key column in another table (i.e., `authorID` in the `authors` table). Foreign keys are specified when creating a table. The foreign key helps maintain the **Rule of Referential Integrity**: Every foreign-key value must appear as another table's primary-key value. This enables the DBMS to determine whether the `authorID` value for a particular book is valid. Foreign keys also allow related data in multiple tables to be selected from those tables for analytic purposes—this is known as **joining** the data.

The `titles` table described in Fig. 25.7 consists of four columns that stand for the ISBN, the title, the edition number and the copyright year. The table is in Fig. 25.8.

There is a one-to-many relationship between a primary key and a corresponding foreign key (e.g., one publisher can publish many books). A foreign key can appear many times in its own table, but can appear only once (as the primary key) in another table. Figure 25.9 is an **entity-relationship (ER) diagram** for the `books` database. This diagram shows the database tables and the relationships among them. The first compartment in each box contains the table's name. The names in italic are primary keys. A table's primary key uniquely identifies each row in the table. Every row must have a primary-key value, and that value must be unique in the table. This is known as the **Rule of Entity Integrity**.

| Column                     | Description                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>isbn</code>          | ISBN of the book (a string). The table's primary key. ISBN is an abbreviation for “International Standard Book Number”—a numbering scheme that publishers use to give every book a unique identification number. |
| <code>title</code>         | Title of the book (a string).                                                                                                                                                                                    |
| <code>editionNumber</code> | Edition number of the book (an integer).                                                                                                                                                                         |
| <code>copyright</code>     | Copyright year of the book (a string).                                                                                                                                                                           |

### Common Programming Error 25.1

*Not providing a value for every column in a primary key breaks the Rule of Entity Integrity and causes the DBMS to report an error.*

### Common Programming Error 25.2

*Providing the same value for the primary key in multiple rows causes the DBMS to report an error.*

The lines connecting the tables in Fig. 25.9 represent the relationships between the tables. Consider the line between the `authorISBN` and `authors` tables. On the `authors` end of the line, there is a 1, and on the `authorISBN` end, there is an infinity symbol ( $\infty$ ), indicating a **one-to-many relationship** in which every author in the `authors` table can have an arbitrary number of books in the `authorISBN` table. Note that the relationship line links the `authorID` column in the table `authors` (i.e., its primary key) to the `authorID` column in table `authorISBN` (i.e., its foreign key). The `authorID` column in the `authorISBN` table is a foreign key.

### Common Programming Error 25.3

*Providing a foreign-key value that does not appear as a primary-key value in another table breaks the Rule of Referential Integrity and causes the DBMS to report an error.*

The line between the `titles` and `authorISBN` tables illustrates another one-to-many relationship; a title can be written by any number of authors. In fact, the sole purpose of the `authorISBN` table is to provide a many-to-many relationship between the `authors` and `titles` tables—an author can write any number of books and a book can have any number of authors.

## 25.4 SQL

We now provide an overview of SQL in the context of our books database. You will be able to use the SQL discussed here in the examples later in the chapter and in examples in Chapters 26–28.

The next several subsections discuss the SQL keywords listed in Fig. 25.10 in the context of SQL queries and statements. Other SQL keywords are beyond this text's scope. To learn other keywords, refer to the SQL reference guide supplied by the vendor of the RDBMS you are using. [Note: For more information on SQL, refer to the web resources in Section 25.15 and the recommended readings listed at the end of this chapter.]

25.4 SQL **1181**

| SQL keyword | Description                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| SELECT      | Retrieves data from one or more tables.                                                                                         |
| FROM        | Tables involved in the query. Required in every SELECT.                                                                         |
| WHERE       | Criteria for selection that determine the rows to be retrieved, deleted or updated. Optional in a SQL query or a SQL statement. |
| GROUP BY    | Criteria for grouping rows. Optional in a SELECT query.                                                                         |
| ORDER BY    | Criteria for ordering rows. Optional in a SELECT query.                                                                         |
| INNER JOIN  | Merge rows from multiple tables.                                                                                                |
| INSERT      | Insert rows into a specified table.                                                                                             |
| UPDATE      | Update rows in a specified table.                                                                                               |
| DELETE      | Delete rows from a specified table.                                                                                             |

**Fig. 25.10** | SQL query keywords.**25.4.1 Basic SELECT Query**

Let us consider several SQL queries that extract information from database books. A SQL query “selects” rows and columns from one or more tables in a database. Such selections are performed by queries with the `SELECT` keyword. The basic form of a `SELECT` query is

```
SELECT * FROM tableName
```

in which the `asterisk (*)` indicates that all columns from the `tableName` table should be retrieved. For example, to retrieve all the data in the `authors` table, use

```
SELECT * FROM authors
```

Most programs do not require all the data in a table. To retrieve only specific columns from a table, replace the asterisk (\*) with a comma-separated list of the column names. For example, to retrieve only the columns `authorID` and `lastName` for all rows in the `authors` table, use the query

```
SELECT authorID, lastName FROM authors
```

This query returns the data listed in Fig. 25.11.

| authorID | lastName |
|----------|----------|
| 1        | Deitel   |
| 2        | Deitel   |
| 3        | Goldberg |
| 4        | Choffnes |

**Fig. 25.11** | Sample `authorID` and `lastName` data from the `authors` table.

**1182 Chapter 25 Accessing Databases with JDBC****Software Engineering Observation 25.2**

*For most queries, the asterisk (\*) should not be used to specify column names. In general, you process results by knowing in advance the order of the columns in the result—for example, selecting authorID and lastName from table authors ensures that the columns will appear in the result with authorID as the first column and lastName as the second column. Programs typically process result columns by specifying the column number in the result (starting from number 1 for the first column). Selecting columns by name also avoids returning unneeded columns and protects against changes in the actual order of the columns in the table(s).*

**Common Programming Error 25.4**

*If you assume that the columns are always returned in the same order from a query that uses the asterisk (\*), the program may process the results incorrectly. If the column order in the table(s) changes or if additional columns are added at a later time, the order of the columns in the result would change accordingly.*

**25.4.2 WHERE Clause**

In most cases, it is necessary to locate rows in a database that satisfy certain **selection criteria**. Only rows that satisfy the selection criteria (formally called **predicates**) are selected. SQL uses the optional **WHERE clause** in a query to specify the selection criteria for the query. The basic form of a query with selection criteria is

```
SELECT columnName1, columnName2, ... FROM tableName WHERE criteria
```

For example, to select the **title**, **editionNumber** and **copyright** columns from table **titles** for which the **copyright** date is greater than 2005, use the query

```
SELECT title, editionNumber, copyright
 FROM titles
 WHERE copyright > '2005'
```

Figure 25.12 shows the result of the preceding query. The **WHERE** clause criteria can contain the operators **<**, **>**, **<=**, **>=**, **=**, **<>** and **LIKE**. Operator **LIKE** is used for **pattern matching** with wildcard characters **percent (%)** and **underscore (\_)**. Pattern matching allows SQL to search for strings that match a given pattern.

A pattern that contains a percent character (%) searches for strings that have zero or more characters at the percent character's position in the pattern. For example, the next query locates the rows of all the authors whose last name starts with the letter D:

```
SELECT authorID, firstName, lastName
 FROM authors
 WHERE lastName LIKE 'D%'
```

This query selects the two rows shown in Fig. 25.13—two of the four authors have a last name starting with the letter D (followed by zero or more characters). The % in the **WHERE** clause's **LIKE** pattern indicates that any number of characters can appear after the letter D in the **lastName**. Note that the pattern string is surrounded by single-quote characters.

**Portability Tip 25.1**

*See the documentation for your database system to determine whether SQL is case sensitive on your system and to determine the syntax for SQL keywords (i.e., should they be all uppercase letters, all lowercase letters or some combination of the two?).*

| title                            | editionNumber | copyright |
|----------------------------------|---------------|-----------|
| Visual C# How to Program         | 2             | 2006      |
| Visual Basic 2005 How to Program | 3             | 2006      |
| Java How to Program              | 7             | 2007      |
| C How to Program                 | 5             | 2007      |

**Fig. 25.12** | Sampling of titles with copyrights after 2005 from table `titles`.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |

**Fig. 25.13** | Authors whose last name starts with D from the `authors` table.

### Portability Tip 25.2

Read your database system's documentation carefully to determine whether your system supports the `LIKE` operator. The SQL we discuss is supported by most RDBMSs, but it is always a good idea to check the features of SQL that are supported by your RDBMS.

An underscore (`_`) in the pattern string indicates a single wildcard character at that position in the pattern. For example, the following query locates the rows of all the authors whose last names start with any character (specified by `_`), followed by the letter o, followed by any number of additional characters (specified by `%`):

```
SELECT authorID, firstName, lastName
 FROM authors
 WHERE lastName LIKE '_o%'
```

The preceding query produces the row shown in Fig. 25.14, because only one author in our database has a last name that contains the letter o as its second letter.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 3        | Andrew    | Goldberg |

**Fig. 25.14** | The only author from the `authors` table whose last name contains o as the second letter.

### 25.4.3 ORDER BY Clause

The rows in the result of a query can be sorted into ascending or descending order by using the optional `ORDER BY` clause. The basic form of a query with an `ORDER BY` clause is

**1184** Chapter 25 Accessing Databases with JDBC

```
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column ASC
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column DESC
```

where `ASC` specifies ascending order (lowest to highest), `DESC` specifies descending order (highest to lowest) and `column` specifies the column on which the sort is based. For example, to obtain the list of authors in ascending order by last name (Fig. 25.15), use the query

```
SELECT authorID, firstName, lastName
FROM authors
ORDER BY lastName ASC
```

Note that the default sorting order is ascending, so `ASC` is optional. To obtain the same list of authors in descending order by last name (Fig. 25.16), use the query

```
SELECT authorID, firstName, lastName
FROM authors
ORDER BY lastName DESC
```

Multiple columns can be used for sorting with an `ORDER BY` clause of the form

```
ORDER BY column1 sortOrder, column2 sortOrder, ...
```

where `sortOrder` is either `ASC` or `DESC`. Note that the `sortOrder` does not have to be identical for each column. The query

```
SELECT authorID, firstName, lastName
FROM authors
ORDER BY lastName, firstName
```

| authorID | firstName | lastName |
|----------|-----------|----------|
| 4        | David     | Choffnes |
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Andrew    | Goldberg |

**Fig. 25.15** | Sample data from table authors in ascending order by lastName.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 3        | Andrew    | Goldberg |
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 4        | David     | Choffnes |

**Fig. 25.16** | Sample data from table authors in descending order by lastName.

## 25.4 SQL 1185

sorts all the rows in ascending order by last name, then by first name. If any rows have the same last name value, they are returned sorted by first name (Fig. 25.17).

The WHERE and ORDER BY clauses can be combined in one query, as in

```
SELECT isbn, title, editionNumber, copyright
 FROM titles
 WHERE title LIKE '%How to Program'
 ORDER BY title ASC
```

which returns the isbn, title, editionNumber and copyright of each book in the titles table that has a title ending with "How to Program" and sorts them in ascending order by title. A portion of the query results are shown in Fig. 25.18.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 4        | David     | Choffnes |
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 4        | Andrew    | Goldberg |

**Fig. 25.17** | Sample data from authors in ascending order by LastName and firstName.

| isbn       | title                                      | edition<br>-Number | copy-<br>right |
|------------|--------------------------------------------|--------------------|----------------|
| 0132404168 | C How to Program                           | 5                  | 2007           |
| 0131857576 | C++ How to Program                         | 5                  | 2005           |
| 0131450913 | Internet and World Wide Web How to Program | 3                  | 2004           |
| 0132222205 | Java How to Program                        | 7                  | 2007           |
| 0131869000 | Visual Basic 2005 How to Program           | 3                  | 2006           |
| 013152539  | Visual C# How to Program                   | 2                  | 2006           |

**Fig. 25.18** | Sampling of books from table titles whose titles end with How to Program in ascending order by title.

#### 25.4.4 Merging Data from Multiple Tables: INNER JOIN

Database designers often split related data into separate tables to ensure that a database does not store data redundantly. For example, the books database has tables authors and titles. We use an authorISBN table to store the relationship data between authors and their corresponding titles. If we did not separate this information into individual tables, we would need to include author information with each entry in the titles table. This

**1186** Chapter 25 Accessing Databases with JDBC

would result in the database storing duplicate author information for authors who wrote multiple books. Often, it is necessary to merge data from multiple tables into a single result. Referred to as joining the tables, this is specified by an `INNER JOIN` operator in the query. An `INNER JOIN` merges rows from two tables by matching values in columns that are common to the tables. The basic form of an `INNER JOIN` is:

```
SELECT columnName1, columnName2, ...
 FROM table1
 INNER JOIN table2
 ON table1.columnName = table2.columnName
```

The `ON clause` of the `INNER JOIN` specifies the columns from each table that are compared to determine which rows are merged. For example, the following query produces a list of authors accompanied by the ISBNs for books written by each author:

```
SELECT firstName, lastName, isbn
 FROM authors
 INNER JOIN authorISBN
 ON authors.authorID = authorISBN.authorID
 ORDER BY lastName, firstName
```

The query merges the `firstName` and `lastName` columns from table `authors` with the `isbn` column from table `authorISBN`, sorting the result in ascending order by `lastName` and `firstName`. Note the use of the syntax `tableName.columnName` in the `ON` clause. This syntax, called a `qualified name`, specifies the columns from each table that should be compared to join the tables. The “`tableName.`” syntax is required if the columns have the same name in both tables. The same syntax can be used in any query to distinguish columns in different tables that have the same name. In some systems, table names qualified with the database name can be used to perform cross-database queries. As always, the query can contain an `ORDER BY` clause. Figure 25.19 depicts a portion of the results of the preceding query, ordered by `lastName` and `firstName`. [Note: To save space, we split the result of the query into two columns, each containing the `firstName`, `lastName` and `isbn` columns.]

| firstName | lastName | isbn       | firstName | lastName | isbn       |
|-----------|----------|------------|-----------|----------|------------|
| David     | Choffnes | 0131828274 | Paul      | Deitel   | 0131525239 |
| Harvey    | Deitel   | 0131525239 | Paul      | Deitel   | 0132404168 |
| Harvey    | Deitel   | 0132404168 | Paul      | Deitel   | 0131869000 |
| Harvey    | Deitel   | 0131869000 | Paul      | Deitel   | 0132222205 |
| Harvey    | Deitel   | 0132222205 | Paul      | Deitel   | 0131450913 |
| Harvey    | Deitel   | 0131450913 | Paul      | Deitel   | 0131525239 |
| Harvey    | Deitel   | 0131525239 | Paul      | Deitel   | 0131857576 |
| Harvey    | Deitel   | 0131857576 | Paul      | Deitel   | 0131828274 |
| Harvey    | Deitel   | 0131828274 | Andrew    | Goldberg | 0131450913 |

**Fig. 25.19** | Sampling of authors and ISBNs for the books they have written in ascending order by `lastName` and `firstName`.

### Software Engineering Observation 25.3

If a SQL statement includes columns with the same name from multiple tables, the statement must precede those column names with their table names and a dot (e.g., `authors.authorID`).

### Common Programming Error 25.5

Failure to qualify names for columns that have the same name in two or more tables is an error.

#### 25.4.5 INSERT Statement

The INSERT statement inserts a row into a table. The basic form of this statement is

```
INSERT INTO tableName (columnName1, columnName2, ..., columnNameN)
VALUES (value1, value2, ..., valueN)
```

where `tableName` is the table in which to insert the row. The `tableName` is followed by a comma-separated list of column names in parentheses (this list is not required if the INSERT operation specifies a value for every column of the table in the correct order). The list of column names is followed by the SQL keyword `VALUES` and a comma-separated list of values in parentheses. The values specified here must match the columns specified after the table name in both order and type (e.g., if `columnName1` is supposed to be the `firstName` column, then `value1` should be a string in single quotes representing the first name). Always explicitly list the columns when inserting rows. If the table's column order changes or a new column is added, using only `VALUES` may cause an error. The `INSERT` statement

```
INSERT INTO authors (firstName, lastName)
VALUES ('Sue', 'Smith')
```

inserts a row into the `authors` table. The statement indicates that values are provided for the `firstName` and `lastName` columns. The corresponding values are 'Sue' and 'Smith'. We do not specify an `authorID` in this example because `authorID` is an autoincremented column in the `authors` table. For every row added to this table, MySQL assigns a unique `authorID` value that is the next value in the autoincremented sequence (i.e., 1, 2, 3 and so on). In this case, Sue Smith would be assigned `authorID` number 5. Figure 25.20 shows the `authors` table after the `INSERT` operation. [Note: Not every database management system supports autoincremented columns. Check the documentation for your DBMS for alternatives to autoincremented columns.]

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Andrew    | Goldberg |
| 4        | David     | Choffnes |
| 5        | Sue       | Smith    |

**Fig. 25.20** | Sample data from table Authors after an INSERT operation.

**1188** Chapter 25 Accessing Databases with JDBC**Common Programming Error 25.6**

*It is normally an error to specify a value for an autoincrement column.*

**Common Programming Error 25.7**

*SQL uses the single-quote (' ) character as a delimiter for strings. To specify a string containing a single quote (e.g., O'Malley) in a SQL statement, the string must have two single quotes in the position where the single-quote character appears in the string (e.g., 'O''Malley'). The first of the two single-quote characters acts as an escape character for the second. Not escaping single-quote characters in a string that is part of a SQL statement is a SQL syntax error.*

**25.4.6 UPDATE Statement**

An UPDATE statement modifies data in a table. The basic form of the UPDATE statement is

```
UPDATE tableName
 SET columnName1 = value1, columnName2 = value2, ..., columnNameN = valueN
 WHERE criteria
```

where *tableName* is the table to update. The *tableName* is followed by keyword **SET** and a comma-separated list of column name/value pairs in the format *columnName* = *value*. The optional **WHERE** clause provides criteria that determine which rows to update. Though not required, the **WHERE** clause is typically used, unless a change is to be made to every row. The UPDATE statement

```
UPDATE authors
 SET lastName = 'Jones'
 WHERE lastName = 'Smith' AND firstName = 'Sue'
```

updates a row in the *authors* table. The statement indicates that *lastName* will be assigned the value *Jones* for the row in which *lastName* is equal to *Smith* and *firstName* is equal to *Sue*. [Note: If there are multiple rows with the first name “*Sue*” and the last name “*Smith*,” this statement will modify all such rows to have the last name “*Jones*.”] If we know the *authorID* in advance of the UPDATE operation (possibly because we searched for it previously), the **WHERE** clause can be simplified as follows:

```
WHERE AuthorID = 5
```

Figure 25.21 shows the *authors* table after the UPDATE operation has taken place.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Andrew    | Goldberg |
| 4        | David     | Choffnes |
| 5        | Sue       | Jones    |

**Fig. 25.21** | Sample data from table *authors* after an UPDATE operation.

## 25.5 Instructions for installing MySQL and MySQL Connector/J

1189

**25.4.7 DELETE Statement**

A SQL DELETE statement removes rows from a table. The basic form of a DELETE is

```
DELETE FROM tableName WHERE criteria
```

where *tableName* is the table from which to delete. The optional WHERE clause specifies the criteria used to determine which rows to delete. If this clause is omitted, all the table's rows are deleted. The DELETE statement

```
DELETE FROM authors
WHERE lastName = 'Jones' AND firstName = 'Sue'
```

deletes the row for Sue Jones in the authors table. If we know the authorID in advance of the DELETE operation, the WHERE clause can be simplified as follows:

```
WHERE authorID = 5
```

Figure 25.22 shows the authors table after the DELETE operation has taken place.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Andrew    | Goldberg |
| 4        | David     | Choffnes |

**Fig. 25.22** | Sample data from table authors after a DELETE operation.

**25.5 Instructions for installing MySQL and MySQL Connector/J**

**MySQL 5.0 Community Edition** is an open-source database management system that executes on many platforms, including Windows, Solaris, Linux, and Macintosh. Complete information about MySQL is available from [www.mysql.com](http://www.mysql.com). The examples in Section 25.8 and Section 25.9 manipulate MySQL databases.

*Installing MySQL*

To install MySQL Community Edition:

1. To learn about the installation requirements for your platform, visit the site [dev.mysql.com/doc/refman/5.0/en/general-installation-issues.html](http://dev.mysql.com/doc/refman/5.0/en/general-installation-issues.html).
2. Visit [dev.mysql.com/downloads/mysql/5.0.html](http://dev.mysql.com/downloads/mysql/5.0.html) and download the installer for your platform. For the MySQL examples in this chapter, you need only the Windows Essentials package on Microsoft Windows, or the Standard package on most other platforms. [Note: For these instructions, we assume you are running Microsoft Windows. Complete installation instructions for other platforms are available at [dev.mysql.com/doc/refman/5.0/en/installing.html](http://dev.mysql.com/doc/refman/5.0/en/installing.html).]
3. Double click `mysql-essential-5.0.27-win32.msi` to start the installer. [Note: This file name may differ based on the current version of MySQL 5.0.]

**1190 Chapter 25 Accessing Databases with JDBC**

- 4.** Choose **Typical** for the **Setup Type** and click **Next >**. Then click **Install**.

When the installation completes, you will be asked to set up an account on MySQL.com. If you do not wish to do this, select **Skip Sign-up** and click **Next >**. After completing the sign-up process or skipping it, you can configure the MySQL Server. Click **Finish** to start the **MySQL Server Instance Configuration Wizard**. To configure the server:

- 1.** Click **Next >** then select **Standard Configuration** and click **Next >** again.
- 2.** You have the option of installing MySQL as a Windows service, which enables the MySQL server to begin executing automatically each time your system starts. For our examples, this is unnecessary, so uncheck **Install as a Windows Service**, then check **Include Bin Directory in Windows PATH**. This will enable you to use the MySQL commands in the Windows Command Prompt.
- 3.** Click **Next >** then click **Execute** to perform the server configuration.
- 4.** Click **Finish** to close the wizard.

***Installing MySQL Connector/J***

To use MySQL with JDBC, you also need to install **MySQL Connector/J** (the J stands for Java)—a JDBC driver that allows programs to use JDBC to interact with MySQL. MySQL Connector/J can be downloaded from

```
dev.mysql.com/downloads/connector/j/5.0.html
```

The documentation for Connector/J is located at [dev.mysql.com/doc/connector/j/en/connector-j.html](http://dev.mysql.com/doc/connector/j/en/connector-j.html). At the time of this writing, the current generally available release of MySQL Connector/J is 5.0.4. To install MySQL Connector/J:

- 1.** Download `mysql-connector-java-5.0.4.zip`.
- 2.** Open `mysql-connector-java-5.0.4.zip` with a file extractor, such as WinZip ([www.winzip.com](http://www.winzip.com)). Extract its contents to the C:\ drive. This will create a directory named `mysql-connector-java-5.0.4`. The documentation for MySQL Connector/J is in `connector-j.pdf` in the `docs` subdirectory of `mysql-connector-java-5.0.4` or you can view it online at [dev.mysql.com/doc/connector/j/en/connector-j.html](http://dev.mysql.com/doc/connector/j/en/connector-j.html).

**25.6 Instructions for Setting Up a MySQL User Account**

For the MySQL examples to execute correctly, you need to set up a user account that allows users to create, delete and modify a database. After MySQL is installed, follow the steps below to set up a user account (these steps assume MySQL is installed in its default installation directory):

- 1.** Open a Command Prompt and start the database server by executing the command `mysqld-nt.exe`. Note that this command has no output—it simply starts the MySQL server. Do not close this window—doing so terminates the server.
- 2.** Next, you'll start the MySQL monitor so you can set up a user account, open another Command Prompt and execute the command

```
mysql -h localhost -u root
```

## 25.7 Creating Database books in MySQL 1191

The `-h` option indicates the host (i.e., computer) on which the MySQL server is running—in this case your local computer (`localhost`). The `-u` option indicates the user account that will be used to log in to the server—`root` is the default user account that is created during installation to allow you to configure the server. Once you've logged in, you'll see a `mysql>` prompt at which you can type commands to interact with the MySQL server.

3. At the `mysql>` prompt, type

```
USE mysql;
```

to select the built-in database named `mysql`, which stores server information, such as user accounts and their privileges for interacting with the server. Note that each command must end with a semicolon. To confirm the command, MySQL issues the message “Database changed.”

4. Next, you'll add the `jhttp7` user account to the `mysql` built-in database. The `mysql` database contains a table called `user` with columns that represent the user's name, password and various privileges. To create the `jhttp7` user account with the password `jhttp7`, execute the following commands from the `mysql>` prompt:

```
create user 'jhttp7'@'localhost' identified by 'jhttp7';
grant select, insert, update, delete, create, drop, references,
execute on *.* to 'jhttp7'@'localhost';
```

This creates the `jhttp7` user with the privileges needed to create the databases used in this chapter and manipulate those databases. Next, type

5. Type the command

```
exit;
```

to terminate the MySQL monitor.

## 25.7 Creating Database books in MySQL

For each MySQL database we discuss in this book, we provide a SQL script in a file with the `.sql` extension that sets up the database and its tables. You can execute these scripts in the MySQL monitor. In the examples directory for this chapter, you'll find the SQL script `books.sql` to create the `books` database. For the following steps, we assume that the MySQL server (`mysqld-nt.exe`) is still running. To execute the `books.sql` script:

1. Open a Command Prompt and use the `cd` command to change directories to the location that contains the `books.sql` script.
2. Start the MySQL monitor by typing

```
mysql -h localhost -u jhttp7 -p
```

The `-p` option prompts you for the password for the `jhttp7` user account. When prompted, enter the password `jhttp7`.

3. Execute the script by typing

```
source books.sql;
```

**1192** Chapter 25 Accessing Databases with JDBC

This creates a new directory named *books* in the server's data directory—located on Windows at `C:\Program Files\MySQL\MySQL Server 5.0\data` by default. This new directory contains the *books* database.

4. Type the command

```
exit;
```

to terminate the MySQL monitor. You are now ready to proceed to the first JDBC example.

## 25.8 Manipulating Databases with JDBC

In this section, we present two examples. The first example introduces how to connect to a database and query the database. The second example demonstrates how to display the result of the query in a `JTable`.

### 25.8.1 Connecting to and Querying a Database

The example of Fig. 25.23 performs a simple query on the *books* database that retrieves the entire *authors* table and displays the data. The program illustrates connecting to the database, querying the database and processing the result. The following discussion presents the key JDBC aspects of the program. [Note: Sections 25.5—25.7 demonstrate how to start the MySQL server, configure a user account and create the *books* database. These steps *must* be performed before executing the program of Fig. 25.23.]

```

1 // Fig. 25.23: DisplayAuthors.java
2 // Displaying the contents of the authors table.
3 import java.sql.Connection;
4 import java.sql.Statement;
5 import java.sql.DriverManager;
6 import java.sql.ResultSet;
7 import java.sql.ResultSetMetaData;
8 import java.sql.SQLException;
9
10 public class DisplayAuthors
11 {
12 // JDBC driver name and database URL
13 static final String DRIVER = "com.mysql.jdbc.Driver";
14 static final String DATABASE_URL = "jdbc:mysql://localhost/books";
15
16 // launch the application
17 public static void main(String args[])
18 {
19 Connection connection = null; // manages connection
20 Statement statement = null; // query statement
21 ResultSet resultSet = null; // manages results
22
23 // connect to database books and query database
24 try
25 {

```

**Fig. 25.23** | Displaying the contents of the *authors* table. (Part I of 3.)

## 25.8 Manipulating Databases with JDBC 1193

```

26 // load the driver class
27 Class.forName(DRIVER);
28
29 // establish connection to database
30 connection =
31 DriverManager.getConnection(DATABASE_URL, "jhttp7", "jhttp7");
32
33 // create Statement for querying database
34 statement = connection.createStatement();
35
36 // query database
37 resultSet = statement.executeQuery(
38 "SELECT authorID, firstName, lastName FROM authors");
39
40 // process query results
41 ResultSetMetaData metaData = resultSet.getMetaData();
42 int numberofColumns = metaData.getColumnCount();
43 System.out.println("Authors Table of Books Database:\n");
44
45 for (int i = 1; i <= numberofColumns; i++)
46 System.out.printf("%-8s\t", metaData.getColumnName(i));
47 System.out.println();
48
49 while (resultSet.next())
50 {
51 for (int i = 1; i <= numberofColumns; i++)
52 System.out.printf("%-8s\t", resultSet.getObject(i));
53 System.out.println();
54 } // end while
55 } // end try
56 catch (SQLException sqlException)
57 {
58 sqlException.printStackTrace();
59 } // end catch
60 catch (ClassNotFoundException classNotFound)
61 {
62 classNotFound.printStackTrace();
63 } // end catch
64 finally // ensure resultSet, statement and connection are closed
65 {
66 try
67 {
68 resultSet.close();
69 statement.close();
70 connection.close();
71 } // end try
72 catch (Exception exception)
73 {
74 exception.printStackTrace();
75 } // end catch
76 } // end finally
77 } // end main
78 } // end class DisplayAuthors

```

**Fig. 25.23** | Displaying the contents of the authors table. (Part 2 of 3.)

**1194 Chapter 25 Accessing Databases with JDBC**

| Authors Table of Books Database: |           |          |
|----------------------------------|-----------|----------|
| authorID                         | firstName | lastName |
| 1                                | Harvey    | Deitel   |
| 2                                | Paul      | Deitel   |
| 3                                | Andrew    | Goldberg |
| 4                                | David     | Choffnes |

**Fig. 25.23** | Displaying the contents of the authors table. (Part 3 of 3.)

Lines 3–8 import the JDBC interfaces and classes from package `java.sql` used in this program. Line 13 declares a string constant for the database driver, and line 14 declares a string constant for the database URL. This identifies the name of the database to connect to, as well as information about the protocol used by the JDBC driver (discussed shortly). Method `main` (lines 17–77) connects to the books database, queries the database, displays the result of the query and closes the database connection.

The program must load the database driver before connecting to the database. Line 27 uses the `static` method `forName` of class `Class` to load the class for the database driver. This line throws a checked exception of type `java.lang.ClassNotFoundException` if the class loader cannot locate the driver class. To avoid this exception, you need to include the `mysql-connector-java-5.0.4-bin.jar` (in the `C:\mysql-connector-java-5.0.4` directory) in your program's classpath when you execute the program, as in:

```
java -classpath
 .;c:\mysql-connector-java-5.0.4\mysql-connector-java-5.0.4-bin.jar
DisplayAuthors
```

In the classpath of the preceding command, notice the period (.) at the beginning of the classpath information. If this period is missing, the JVM will not look for classes in the current directory and thus will not find the `DisplayAuthors` class file. You may also copy the `mysql-connector-java-5.0.4-bin.jar` file to the directory `C:\Program Files\Java\jdk1.6.0\jre\lib\ext`. After doing so, you can run the application simply using the command `java DisplayAuthors`.

**Software Engineering Observation 25.4**

*Most major database vendors provide their own JDBC database drivers, and many third-party vendors provide JDBC drivers as well. For more information on JDBC drivers, visit the Sun Microsystems JDBC Web site, [servlet.java.sun.com/products/jdbc/drivers](http://servlet.java.sun.com/products/jdbc/drivers).*

Lines 30–31 of Fig. 25.23 create a `Connection` object (package `java.sql`) referenced by `connection`. An object that implements interface `Connection` manages the connection between the Java program and the database. `Connection` objects enable programs to create SQL statements that manipulate databases. The program initializes `connection` with the result of a call to `static` method `getConnection` of class `DriverManager` (package `java.sql`), which attempts to connect to the database specified by its URL. Method `get Connection` takes three arguments—a `String` that specifies the database URL, a `String` that specifies the username and a `String` that specifies the password. The username and password are set in Section 25.6. If you used a different username and password, you need

## 25.8 Manipulating Databases with JDBC 1195

to replace the username (second argument) and password (third argument) passed to method `getConnectio`n in line 31. The URL locates the database (possibly on a network or in the local file system of the computer). The URL `jdbc:mysql://localhost/books` specifies the protocol for communication (`jdbc`), the `subprotocol` for communication (`mysql`) and the location of the database (`//localhost/books`, where `localhost` is the host running the MySQL server and `books` is the database name). The subprotocol `mysql` indicates that the program uses a MySQL-specific subprotocol to connect to the MySQL database. If the `DriverManager` cannot connect to the database, method `getConnectio`n throws a `SQLException` (package `java.sql`). Figure 25.24 lists the JDBC driver names and database URL formats of several popular RDBMSs.

**Software Engineering Observation 25.5**

*Most database management systems require the user to log in before accessing the database contents. `DriverManager` method `getConnectio`n is overloaded with versions that enable the program to supply the user name and password to gain access.*

Line 34 invokes `Connection` method `createStatement` to obtain an object that implements interface `Statement` (package `java.sql`). The program uses the `Statement` object to submit SQL to the database.

Lines 37–38 use the `Statement` object's `executeQuery` method to submit a query that selects all the author information from table `authors`. This method returns an object that implements interface `ResultSet` and contains the query results. The `ResultSet` methods enable the program to manipulate the query result.

Lines 41–54 process the `ResultSet`. Line 41 obtains the metadata for the `ResultSet` as a `ResultSetMetaData` (package `java.sql`) object. The `metadata` describes the `ResultSet`'s contents. Programs can use metadata programmatically to obtain information about the `ResultSet`'s column names and types. Line 42 uses `ResultSetMetaData` method `getColumnCount` to retrieve the number of columns in the `ResultSet`. Lines 45–46 display the column names.

| RDBMS                | Database URL format                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------|

| Microsoft SQL Server | <code>jdbc:sqlserver://hostname:portNumber;databaseName=dataBaseName</code>                                             |
| Sybase               | <code>jdbc:sybase:Tds:hostname:portNumber/databaseName</code>                                                           |

**Fig. 25.24** | Popular JDBC database URL formats.

**1196** Chapter 25 Accessing Databases with JDBC**Software Engineering Observation 25.6**

*Metadata enables programs to process ResultSet contents dynamically when detailed information about the ResultSet is not known in advance.*

Lines 49–54 display the data in each ResultSet row. First, the program positions the ResultSet cursor (which points to the row being processed) to the first row in the ResultSet with method next (line 49). Method next returns boolean value true if it is able to position to the next row; otherwise, the method returns false.

**Common Programming Error 25.8**

*Initially, a ResultSet cursor is positioned before the first row. Attempting to access a ResultSet's contents before positioning the ResultSet cursor to the first row with method next causes a SQLException.*

If there are rows in the ResultSet, line 52 extracts the contents of one column in the current row. When processing a ResultSet, it is possible to extract each column of the ResultSet as a specific Java type. In fact, ResultSetMetaData method getColumnType returns a constant integer from class Types (package java.sql) indicating the type of a specified column. Programs can use these values in a switch statement to invoke ResultSet methods that return the column values as appropriate Java types. If the type of a column is Types.INTEGER, ResultSet method getInt returns the column value as an int. ResultSet get methods typically receive as an argument either a column number (as an int) or a column name (as a String) indicating which column's value to obtain. Visit

[java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/GettingStartedTOC.fm.html](http://java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/GettingStartedTOC.fm.html)

for detailed mappings of SQL data types to Java types and to determine the appropriate ResultSet method to call for each SQL data type.

**Performance Tip 25.1**

*If a query specifies the exact columns to select from the database, the ResultSet contains the columns in the specified order. In this case, using the column number to obtain the column's value is more efficient than using the column name. The column number provides direct access to the specified column. Using the column name requires a search of the column names to locate the appropriate column.*

For simplicity, this example treats each value as an Object. The program retrieves each column value with ResultSet method getObject (line 52) and prints the String representation of the Object. Note that, unlike array indices, which start at 0, ResultSet column numbers start at 1. The finally block (lines 64–76) closes the ResultSet (line 68), the Statement (line 69) and the database Connection (line 70). [Note: Lines 68–70 will throw NullPointerExceptions if the ResultSet, Statement or Connection objects were not created properly. In production code, you should check the variables that refer to these objects to see if they are null before you call close.]

**Common Programming Error 25.9**

*Specifying column 0 when obtaining values from a ResultSet causes a SQLException.*

**Common Programming Error 25.10**

*Attempting to manipulate a ResultSet after closing the Statement that created the ResultSet causes a SQLException. The program discards the ResultSet when the corresponding Statement is closed.*

**Software Engineering Observation 25.7**

*Each Statement object can open only one ResultSet object at a time. When a Statement returns a new ResultSet, the Statement closes the prior ResultSet. To use multiple ResultSets in parallel, separate Statement objects must return the ResultSets.*

**25.8.2 Querying the books Database**

The next example (Fig. 25.25 and Fig. 25.28) allows the user to enter any query into the program. The example displays the result of a query in a JTable, using a TableModel object to provide the ResultSet data to the JTable. A JTable is a swing GUI component that can be bound to a database to display the results of a query. Class ResultSetTableModel (Fig. 25.25) performs the connection to the database via a TableModel and maintains the ResultSet. Class DisplayQueryResults (Fig. 25.28) creates the GUI and specifies an instance of class ResultSetTableModel to provide data for the JTable.

**ResultSetTableModel Class**

Class ResultSetTableModel (Fig. 25.25) extends class AbstractTableModel (package javax.swing.table), which implements interface TableModel. Class ResultSetTableModel overrides TableModel methods getColumnClass, getColumnCount, getColumnName, getRowCount and getValueAt. The default implementations of TableModel methods isCellEditable and setValueAt (provided by AbstractTableModel) are not overridden, because this example does not support editing the JTable cells. The default implementations of TableModel methods addTableModelListener and removeTableModelListener (provided by AbstractTableModel) are not overridden, because the implementations of these methods in AbstractTableModel properly add and remove event listeners.

```

1 // Fig. 25.25: ResultSetTableModel.java
2 // A TableModel that supplies ResultSet data to a JTable.
3 import java.sql.Connection;
4 import java.sql.Statement;
5 import java.sql.DriverManager;
6 import java.sql.ResultSet;
7 import java.sql.ResultSetMetaData;
8 import java.sql.SQLException;
9 import javax.swing.table.AbstractTableModel;
10
11 // ResultSet rows and columns are counted from 1 and JTable
12 // rows and columns are counted from 0. When processing
13 // ResultSet rows or columns for use in a JTable, it is
14 // necessary to add 1 to the row or column number to manipulate
15 // the appropriate ResultSet column (i.e., JTable column 0 is
16 // ResultSet column 1 and JTable row 0 is ResultSet row 1).

```

171 {
172 // close Statement and Connection
173 try
174 {

```

**Fig. 25.25** | A TableModel that supplies ResultSet data to a JTable. (Part 4 of 5.)

## 25.8 Manipulating Databases with JDBC

1201

```

175 resultSet.close();
176 statement.close();
177 connection.close();
178 } // end try
179 catch (SQLException sqlException)
180 {
181 sqlException.printStackTrace();
182 } // end catch
183 finally // update database connection status
184 {
185 connectedToDatabase = false;
186 } // end finally
187 } // end if
188 } // end method disconnectFromDatabase
189 } // end class ResultSetTableModel

```

**Fig. 25.25** | A TableModel that supplies ResultSet data to a JTable. (Part 5 of 5.)

The `ResultSetTableModel` constructor (lines 30–48) accepts five `String` arguments—the name of the MySQL driver, the URL of the database, the username, the password and the default query to perform. The constructor throws any exceptions that occur in its body back to the application that created the `ResultSetTableModel` object, so that the application can determine how to handle the exception (e.g., report an error and terminate the application). Line 34 loads the driver. Line 36 establishes a connection to the database. Lines 39–41 invoke `Connection` method `createStatement` to create a `Statement` object. This example uses a version of method `createStatement` that takes two arguments—the result set type and the result set concurrency. The **result set type** (Fig. 25.26) specifies whether the `ResultSet`'s cursor is able to scroll in both directions or forward only and whether the `ResultSet` is sensitive to changes. `ResultSets` that are sensitive to changes reflect those changes immediately after they are made with methods of interface `ResultSet`. If a `ResultSet` is insensitive to changes, the query that produced the `ResultSet` must be

| ResultSet static type constant       | Description                                                                                                                                                                                                                                                                      |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TYPE_FORWARD_ONLY</code>       | Specifies that a <code>ResultSet</code> 's cursor can move only in the forward direction (i.e., from the first row to the last row in the <code>ResultSet</code> ).                                                                                                              |
| <code>TYPE_SCROLL_INSENSITIVE</code> | Specifies that a <code>ResultSet</code> 's cursor can scroll in either direction and that the changes made to the <code>ResultSet</code> during <code>ResultSet</code> processing are not reflected in the <code>ResultSet</code> unless the program queries the database again. |
| <code>TYPE_SCROLL_SENSITIVE</code>   | Specifies that a <code>ResultSet</code> 's cursor can scroll in either direction and that the changes made to the <code>ResultSet</code> during <code>ResultSet</code> processing are reflected immediately in the <code>ResultSet</code> .                                      |

**Fig. 25.26** | ResultSet constants for specifying ResultSet type.

**1202 Chapter 25 Accessing Databases with JDBC**

executed again to reflect any changes made. The **result set concurrency** (Fig. 25.27) specifies whether the `ResultSet` can be updated with `ResultSet`'s update methods. This example uses a `ResultSet` that is scrollable, insensitive to changes and read only. Line 47 invokes our method `setQuery` (lines 146–165) to perform the default query.

**Portability Tip 25.3**

*Some JDBC drivers do not support scrollable ResultSets. In such cases, the driver typically returns a ResultSet in which the cursor can move only forward. For more information, see your database driver documentation.*

**Portability Tip 25.4**

*Some JDBC drivers do not support updatable ResultSets. In such cases, the driver typically returns a read-only ResultSet. For more information, see your database driver documentation.*

**Common Programming Error 25.11**

*Attempting to update a ResultSet when the database driver does not support updatable ResultSets causes SQLFeatureNotSupportedExceptions.*

**Common Programming Error 25.12**

*Attempting to move the cursor backward through a ResultSet when the database driver does not support backward scrolling causes a SQLException.*

Method `getColumnClass` (lines 51–71) returns a `Class` object that represents the superclass of all objects in a particular column. The `JTable` uses this information to configure the default cell renderer and cell editor for that column in the `JTable`. Line 60 uses `ResultSetMetaData` method `getColumnName` to obtain the fully qualified class name for the specified column. Line 63 loads the class and returns the corresponding `Class` object. If an exception occurs, the catch in lines 65–68 prints a stack trace and line 70 returns `Object.class`—the `Class` instance that represents class `Object`—as the default type. [Note: Line 60 uses the argument `column + 1`. Like arrays, `JTable` row and column numbers are counted from 0. However, `ResultSet` row and column numbers are counted from 1. Thus, when processing `ResultSet` rows or columns for use in a `JTable`, it is necessary to add 1 to the row or column number to manipulate the appropriate `ResultSet` row or column.]

| ResultSet static concurrency constant | Description                                                                                                                                                                                         |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CONCUR_READ_ONLY</code>         | Specifies that a <code>ResultSet</code> cannot be updated (i.e., changes to the <code>ResultSet</code> contents cannot be reflected in the database with <code>ResultSet</code> 's update methods). |
| <code>CONCUR_UPDATABLE</code>         | Specifies that a <code>ResultSet</code> can be updated (i.e., changes to the <code>ResultSet</code> contents can be reflected in the database with <code>ResultSet</code> 's update methods).       |

**Fig. 25.27** | `ResultSet` constants for specifying result properties.

## 25.8 Manipulating Databases with JDBC 1203

Method `getColumnNameCount` (lines 74–91) returns the number of columns in the model's underlying `ResultSet`. Line 83 uses `ResultSetMetaData` method `getColumnCount` to obtain the number of columns in the `ResultSet`. If an exception occurs, the catch in lines 85–88 prints a stack trace and line 93 returns 0 as the default number of columns.

Method `getColumnName` (lines 94–111) returns the name of the column in the model's underlying `ResultSet`. Line 103 uses `ResultSetMetaData` method `getColumnName` to obtain the column name from the `ResultSet`. If an exception occurs, the catch in lines 105–108 prints a stack trace and line 110 returns the empty string as the default column name.

Method `getRowCount` (lines 114–121) returns the number of rows in the model's underlying `ResultSet`. When method `setQuery` (lines 146–165) performs a query, it stores the number of rows in variable `numberOfRows`.

Method `getValueAt` (lines 124–143) returns the `Object` in a particular row and column of the model's underlying `ResultSet`. Line 134 uses `ResultSet` method `absolute` to position the `ResultSet` cursor at a specific row. Line 135 uses `ResultSet` method `getObject` to obtain the `Object` in a specific column of the current row. If an exception occurs, the catch in lines 137–140 prints a stack trace and line 142 returns an empty string as the default value.

Method `setQuery` (lines 146–165) executes the query it receives as an argument to obtain a new `ResultSet` (line 154). Line 157 gets the `ResultSetMetaData` for the new `ResultSet`. Line 160 uses `ResultSet` method `last` to position the `ResultSet` cursor at the last row in the `ResultSet`. [Note: This can be slow if the table contains many rows.] Line 161 uses `ResultSet` method `getRow` to obtain the row number for the current row in the `ResultSet`. Line 164 invokes method `fireTableStructureChanged` (inherited from class `AbstractTableModel`) to notify any `JTable` using this `ResultSetTableModel` object as its model that the structure of the model has changed. This causes the `JTable` to repopulate its rows and columns with the new `ResultSet` data. Method `setQuery` throws any exceptions that occur in its body back to the application that invoked `setQuery`.

Method `disconnectFromDatabase` (lines 168–188) implements an appropriate termination method for class `ResultSetTableModel`. A class designer should provide a `public` method that clients of the class must invoke explicitly to free resources that an object has used. In this case, method `disconnectFromDatabase` closes the `ResultSet`, `Statement` and `Connection` (lines 175–177), which are considered limited resources. Clients of the `ResultSetTableModel` class should always invoke this method when the instance of this class is no longer needed. Before releasing resources, line 170 verifies whether the connection is already terminated. If not, the method proceeds. Note that the other methods in class `ResultSetTableModel` each throw an `IllegalStateException` if `connectedToDatabase` is `false`. Method `disconnectFromDatabase` sets `connectedToDatabase` to `false` (line 185) to ensure that clients do not use an instance of `ResultSetTableModel` after that instance has already been terminated. `IllegalStateException` is an exception from the Java libraries that is appropriate for indicating this error condition.

### ***DisplayQueryResults Class***

Class `DisplayQueryResults` (Fig. 25.28) implements the application's GUI and interacts with the `ResultSetTableModel` via a `JTable` object. This application also demonstrates the new `JTable` sorting and filtering capabilities introduced in Java SE 6.

**1204** Chapter 25 Accessing Databases with JDBC

Lines 27–30 and 33 declare the database driver, URL, username, password and default query that are passed to the `ResultSetTableModel` constructor to make the initial connection to the database and perform the default query. The `DisplayQueryResults` constructor (lines 39–198) creates a `ResultSetTableModel` object and the GUI for the application. Line 69 creates the `JTable` object and passes a `ResultSetTableModel` object to the `JTable` constructor, which then registers the `JTable` as a listener for `TableModelEvents` generated by the `ResultSetTableModel`.

```

**Fig. 25.28** | Displays contents of the database books. (Part 5 of 5.)

Lines 86–125 register an event handler for the submitButton that the user clicks to submit a query to the database. When the user clicks the button, method actionPerformed (lines 91–123) invokes method setQuery from the class ResultSetTableModel to execute the new query. If the user's query fails (e.g., because of a syntax error in the user's input), lines 108–109 execute the default query. If the default query also fails, there could be a more serious error, so line 118 ensures that the database connection is closed and line

## 25.9 RowSet Interface 1209

120 exits the program. The screen captures in Fig. 25.28 show the results of two queries. The first screen capture shows the default query that retrieves all the data from table `authors` of database `books`. The second screen capture shows a query that selects each author's first name and last name from the `authors` table and combines that information with the title and edition number from the `titles` table. Try entering your own queries in the text area and clicking the **Submit Query** button to execute the query.

As of Java SE 6, `JTables` now allow users to sort rows by the data in a specific column. Lines 127–128 use the `TableRowSorter` class (from package `javax.swing.table`) to create an object that uses our `ResultSetTableModel` to sort rows in the `JTable` that displays query results. When the user clicks the title of a particular `JTable` column, the `TableRowSorter` interacts with the underlying `TableModel` to reorder the rows based on the data in that column. Line 129 uses `JTable` method `setRowSorter` to specify the `TableRowSorter` for `resultTable`.

Another new feature of `JTables` is the ability to view subsets of the data from the underlying `TableModel`. This is known as filtering the data. Lines 134–160 register an event handler for the `filterButton` that the user clicks to filter the data. In method `actionPerformed` (lines 138–158), line 140 obtains the filter text. If the user did not specify filter text, line 143 uses `JTable` method `setRowFilter` to remove any prior filter by setting the filter to `null`. Otherwise, lines 148–149, use `setRowFilter` to specify a `RowFilter` (from package `javax.swing`) based on the user's input. Class `RowFilter` provides several methods for creating filters. The `static` method `regexFilter` receives a `String` containing a regular expression pattern as its argument and an optional set of indices that specify which columns to filter. If no indices are specified, then all the columns are searched. In this example, the regular expression pattern is the text the user typed. Once the filter is set, the data displayed in the `JTable` is updated based on the filtered `TableModel`.

### 25.9 RowSet Interface

In the previous examples, you learned how to query a database by explicitly establishing a `Connection` to the database, preparing a `Statement` for querying the database and executing the query. In this section, we demonstrate the `RowSet` interface, which configures the database connection and prepares query statements automatically. The interface `RowSet` provides several `set` methods that allow you to specify the properties needed to establish a connection (such as the database URL, user name and password of the database) and create a `Statement` (such as a query). `RowSet` also provides several `get` methods that return these properties.

There are two types of `RowSet` objects—connected and disconnected. A `connected RowSet` object connects to the database once and remains connected until the application terminates. A `disconnected RowSet` object connects to the database, executes a query to retrieve the data from the database and then closes the connection. A program may change the data in a disconnected `RowSet` while it is disconnected. Modified data can be updated in the database after a disconnected `RowSet` reestablishes the connection with the database.

Package `javax.sql.rowset` contains two subinterfaces of `RowSet`—`JdbcRowSet` and `CachedRowSet`. `JdbcRowSet`, a connected `RowSet`, acts as a wrapper around a `ResultSet` object, and allows you to scroll through and update the rows in the `ResultSet`. Recall that by default, a `ResultSet` object is non-scrollable and read only—you must explicitly set the result set type constant to `TYPE_SCROLL_INSENSITIVE` and set the result set concurrency

## 1210 Chapter 25 Accessing Databases with JDBC

constant to CONCUR\_UPDATABLE to make a ResultSet object scrollable and updatable. A JdbcRowSet object is scrollable and updatable by default. [CachedRowSet](#), a disconnected RowSet, caches the data of a ResultSet in memory and disconnects from the database. Like JdbcRowSet, a CachedRowSet object is scrollable and updatable by default. A CachedRowSet object is also serializable, so it can be passed between Java applications through a network, such as the Internet. However, CachedRowSet has a limitation—the amount of data that can be stored in memory is limited. Package javax.sql.rowset contains three other subinterfaces of RowSet. For details of these interfaces, visit [java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/rowsetImpl.html](http://java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/rowsetImpl.html).

### Portability Tip 25.5

*A RowSet can provide scrolling capability for drivers that do not support scrollable ResultSets.*

Figure 25.29 reimplements the example of Fig. 25.23 using a RowSet. Rather than establish the connection and create a Statement explicitly, Fig. 25.29 uses a JdbcRowSet object to create a Connection and a Statement automatically.

```

71 } // end class JdbcRowSetTest

```

Authors Table of Books Database:

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Andrew    | Goldberg |
| 4        | David     | Choffnes |

**Fig. 25.29** | Displaying the authors table using `JdbcRowSet`. (Part 2 of 2.)

The package `com.sun.rowset` provides Sun's reference implementations of the interfaces in package `javax.sql.rowset`. Line 26 uses Sun's reference implementation of the `JdbcRowSet` interface—`JdbcRowSetImpl`—to create a `JdbcRowSet` object. We used class

## 1212 Chapter 25 Accessing Databases with JDBC

`JdbcRowSetImpl` here to demonstrate the capability of the `JdbcRowSet` interface. Other databases may provide their own `RowSet` implementations.

Lines 27–29 set the `RowSet` properties that are used by the `DriverManager` to establish a connection to the database. Line 27 invokes `JdbcRowSet` method `setUrl` to specify the database URL. Line 28 invokes `JdbcRowSet` method `setUsername` to specify the username. Line 29 invokes `JdbcRowSet` method `setPassword` to specify the password. Line 30 invokes `JdbcRowSet` method `setCommand` to specify the SQL query that will be used to populate the `RowSet`. Line 31 invokes `JdbcRowSet` method `execute` to execute the SQL query. Method `execute` performs four actions—it establishes a `Connection`, prepares the `query Statement`, executes the query and stores the `ResultSet` returned by `query`. The `Connection`, `Statement` and `ResultSet` are encapsulated in the `JdbcRowSet` object.

The remaining code is almost identical to Fig. 25.23, except that line 34 obtains a `ResultSetMetaData` object from the `JdbcRowSet`, line 44 uses the `JdbcRowSet`'s `next` method to get the next row of the result and line 47 uses the `JdbcRowSet`'s `getObject` method to obtain a column's value. Line 52 invokes `JdbcRowSet` method `close`, which closes the `RowSet`'s encapsulated `ResultSet`, `Statement` and `Connection`. In a `CachedRowSet`, invoking `close` also releases the memory held by that `RowSet`. Note that the output of this application is the same as that of Fig. 25.23.

## 25.10 Java DB/Apache Derby

As of JDK 6, Sun Microsystems now bundles the open-source, pure Java database **Java DB** (the Sun branded version of Apache Derby) with the JDK. In Section 25.11, we use Java DB to demonstrate a new JDBC 4.0 feature and to demonstrate so called `PreparedStatement`s. Before you can execute the application in the next section, you must set up the `AddressBook` database in Java DB. In Section 25.11, we use the embedded version of Java DB. There is also a network version that executes similarly to the MySQL DBMS introduced earlier in the chapter. For the purpose of the following steps, we assume you are running Microsoft Windows with Java installed in its default location.

1. Java DB comes with several batch files to configure and run it. Before executing these batch files from a command prompt, you must set the environment variable `JAVA_HOME` to refer to the JDK's `C:\Program Files\Java\jdk1.6.0` installation directory. For information on setting an environment variable's value, see the *Before You Begin* section of this book.
2. Open the batch file `setEmbeddedCP.bat` (located in `C:\Program Files\Java\jdk1.6.0\db\frameworks\embedded\bin`) in a text editor such as Notepad. Locate the line

```
rem set DERBY_INSTALL=
```

and change it to

```
set DERBY_INSTALL=C:\Program Files\Java\jdk1.6.0\db
```

Also, comment out the line

```
@FOR %%X in ("%DERBY_HOME%") DO SET DERBY_HOME=%~SX
```

by preceding it with `REM` as in

25.11 **PreparedStatement** 1215

Our address book application consists of three classes—**Person** (Fig. 25.30), **PersonQueries** (Fig. 25.31) and **AddressBookDisplay** (Fig. 25.32). Class **Person** is a simple class that represents one person in the address book. The class contains fields for the address ID, first name, last name, email address and phone number, as well as *set* and *get* methods for manipulating these fields.

```

1 // Fig. 25.30: Person.java
2 // Person class that represents an entry in an address book.
3 public class Person
4 {
5 private int addressID;
6 private String firstName;
7 private String lastName;
8 private String email;
9 private String phoneNumber;
10
11 // no-argument constructor
12 public Person()
13 {
14 // end no-argument Person constructor
15
16 // constructor
17 public Person(int id, String first, String last,
18 String emailAddress, String phone)
19 {
20 setAddressID(id);
21 setFirstName(first);
22 setLastName(last);
23 setEmail(emailAddress);
24 setPhoneNumber(phone);
25 } // end five-argument Person constructor
26
27 // sets the addressID
28 public void setAddressID(int id)
29 {
30 addressID = id;
31 } // end method setAddressID
32
33 // returns the addressID
34 public int getAddressID()
35 {
36 return addressID;
37 } // end method getAddressID
38
39 // sets the firstName
40 public void setFirstName(String first)
41 {
42 firstName = first;
43 } // end method setFirstName
44

```

**Fig. 25.30** | Person class that represents an entry in an AddressBook. (Part I of 2.)

**1216 Chapter 25 Accessing Databases with JDBC**

```

45 // returns the first name
46 public String getFirstName()
47 {
48 return firstName;
49 } // end method getFirstName
50
51 // sets the lastName
52 public void setLastName(String last)
53 {
54 lastName = last;
55 } // end method setLastName
56
57 // returns the first name
58 public String getLastname()
59 {
60 return lastName;
61 } // end method getLastname
62
63 // sets the email address
64 public void setEmail(String emailAddress)
65 {
66 email = emailAddress;
67 } // end method setEmail
68
69 // returns the email address
70 public String getEmail()
71 {
72 return email;
73 } // end method getEmail
74
75 // sets the phone number
76 public void setPhoneNumber(String phone)
77 {
78 phoneNumber = phone;
79 } // end method setPhoneNumber
80
81 // returns the email address
82 public String getPhoneNumber()
83 {
84 return phoneNumber;
85 } // end method getPhoneNumber
86 } // end class Person

```

**Fig. 25.30** | Person class that represents an entry in an AddressBook. (Part 2 of 2.)***Class PersonQueries***

Class PersonQueries (Fig. 25.31) manages the address book application's database connection and creates the `PreparedStatement`s that the application uses to interact with the database. Lines 18–20 declare three `PreparedStatement` variables. The constructor (lines 23–49) connects to the database at lines 27–28. Notice that we do not use `Class.forName` to load the database driver for Java DB as we did in the examples that use MySQL earlier in the chapter. JDBC 4.0, part of Java SE 6, supports **automatic driver discovery**—you

25.11 **PreparedStatement** 1217

are no longer required to load the database driver in advance. At the time of this writing, this feature in the process of being implemented in MySQL.

```

25.11 **PreparedStatement** 1219

```

103 // executeQuery returns ResultSet containing matching entries
104 resultSet = selectPeopleByLastName.executeQuery();
105
106 results = new ArrayList< Person >();
107
108 while (resultSet.next())
109 {
110 results.add(new Person(
111 resultSet.getInt("addressID"),
112 resultSet.getString("firstName"),
113 resultSet.getString("lastName"),
114 resultSet.getString("email"),
115 resultSet.getString("phoneNumber")));
116 } // end while
117 } // end try
118 catch (SQLException sqlException)
119 {
120 sqlException.printStackTrace();
121 } // end catch
122 finally
123 {
124 try
125 {
126 resultSet.close();
127 } // end try
128 catch (SQLException sqlException)
129 {
130 sqlException.printStackTrace();
131 close();
132 } // end catch
133 } // end finally
134 } // end finally
135
136 return results;
137 } // end method getPeopleByName
138
139 // add an entry
140 public int addPerson(
141 String fname, String lname, String email, String num)
142 {
143 int result = 0;
144
145 // set parameters, then execute insertNewPerson
146 try
147 {
148 insertNewPerson.setString(1, fname);
149 insertNewPerson.setString(2, lname);
150 insertNewPerson.setString(3, email);
151 insertNewPerson.setString(4, num);
152
153 // insert the new entry; returns # of rows updated
154 result = insertNewPerson.executeUpdate();
155 } // end try

```

**Fig. 25.31** | An interface that stores all the queries to be used by AddressBook. (Part 3 of 4.)

**1220** Chapter 25 Accessing Databases with JDBC

```

156 catch (SQLException sqlException)
157 {
158 sqlException.printStackTrace();
159 close();
160 } // end catch
161
162 return result;
163 } // end method addPerson
164
165 // close the database connection
166 public void close()
167 {
168 try
169 {
170 connection.close();
171 } // end try
172 catch (SQLException sqlException)
173 {
174 sqlException.printStackTrace();
175 } // end catch
176 } // end method close
177 } // end interface PersonQueries

```

**Fig. 25.31** | An interface that stores all the queries to be used by AddressBook. (Part 4 of 4.)

Lines 31–32 invoke `Connection` method `prepareStatement` to create the `PreparedStatement` named `selectAllPeople` that selects all the rows in the `Addresses` table. Lines 35–36 create the `PreparedStatement` named `selectPeopleByLastName` with a parameter. This statement selects all the rows in the `Addresses` table that match a particular last name. Notice the `?` character that is used to specify the last name parameter. Lines 39–42 create the `PreparedStatement` named `insertNewPerson` with four parameters that represent the first name, last name, email address and phone number for a new entry. Again, notice the `?` characters used to represent these parameters.

Method `getAllPeople` (lines 52–91) executes `PreparedStatement` `selectAllPeople` (line 60) by calling method `executeQuery`, which returns a `ResultSet` containing the rows that match the query (in this case, all the rows in the `Addresses` table). Lines 61–71 place the query results in an `ArrayList` of `Person` objects, which is returned to the caller at line 90. Method `getPeopleByLastName` (lines 95–137) uses `PreparedStatement` method `setString` to set the parameter to `selectPeopleByLastName`. Then, line 105 executes the query and lines 107–117 place the query results in an `ArrayList` of `Person` objects. Line 136 returns the `ArrayList` to the caller.

Method `addPerson` (lines 140–163) uses `PreparedStatement` method `setString` (lines 148–151) to set the parameters for the `insertNewPerson` `PreparedStatement`. Line 154 uses `PreparedStatement` method `executeUpdate` to insert the new record. This method returns an integer indicating the number of rows that were updated (or inserted) in the database. Method `close` (lines 166–176) simply closes the database connection.

***Class AddressBookDisplay***

The `AddressBookDisplay` (Fig. 25.32) application uses an object of class `PersonQueries` to interact with the database. Line 59 creates the `PersonQueries` object used throughout

25.11 **PreparedStatement** 1221

class `AddressBookDisplay`. When the user presses the `Browse All Entries` JButton, the `browseButtonActionPerformed` handler (lines 309–335) is called. Line 313 calls the method `getAllPeople` on the `PersonQueries` object to obtain all the entries in the database. The user can then scroll through the entries using the `Previous` and `Next` JButtons. When the user presses the `Find` JButton, the `queryButtonActionPerformed` handler (lines 265–287) is called. Lines 267–268 call method `getPeopleByLastName` on the `PersonQueries` object to obtain the entries in the database that match the specified last name. If there are several such entries, the user can then scroll through them using the `Previous` and `Next` JButtons.

To add a new entry into the `AddressBook` database, the user can enter the first name, last name, email and phone number (the `AddressID` will autoincrement) in the JTextFields and press the `Insert New Entry` JButton. When the user presses `Insert New Entry`, the `insertButtonActionPerformed` handler (lines 338–352) is called. Lines 340–342 call the method `addPerson` on the `PersonQueries` object to add a new entry to the database.

The user can then view different entries by pressing the `Previous` JButton or `Next` JButton, which results in calls to methods `previousButtonActionPerformed` (lines 241–250) or `nextButtonActionPerformed` (lines 253–262), respectively. Alternatively, the user can enter a number in the `indexTextField` and press *Enter* to view a particular entry.

358 } // end class AddressBookDisplay

```

**Fig. 25.32** | A simple address book. (Part 8 of 8.)

## 25.11 PreparedStatements 1213

```
REM @FOR %%X in ("%DERBY_HOME%") DO SET DERBY_HOME=%~sX
```

Save your changes and close this file.

3. Open a Command Prompt and change directories to C:\Program Files\Java\jdk1.6.0\db\frameworks\embedded\bin\. Then, type setEmbeddedCP.bat and press *Enter* to set the environment variables required by Java DB.
4. An embedded Java DB database must reside in the same location as the application that manipulates the database. For this reason, change to the directory that contains the code for Figs. 25.30–25.32. This directory contains a SQL script address.sql that builds the AddressBook database.
5. Execute the command

```
"C:\Program Files\Java\jdk1.6.0\db\frameworks\embedded\bin\ij"
```

to start the command-line tool for interacting with Java DB. The double quotes are necessary because the path contains a space. This will display the ij> prompt

6. At the ij> prompt type

```
connect 'jdbc:derby:AddressBook;create=true;user=jhttp7;
password=jhttp7';
```

to create the AddressBook database in the current directory. This command also creates the user jhttp7 with the password jhttp7 for accessing the database.

7. To create the database table and insert sample data in the database type

```
run 'address.sql';
```

8. To terminate the Java DB command-line tool, type

```
exit;
```

You are now ready to execute the AddressBook application in Section 25.12.

## 25.11 PreparedStatements

Interface **PreparedStatement** enables you to create compiled SQL statements that execute more efficiently than **Statement** objects. **PreparedStatement**s also can specify parameters, making them more flexible than **Statements**. Programs can execute the same query repeatedly with different parameter values. For example, in the books database, you might want to locate all book titles for an author with a specific last name and first name, and you might want to execute that query for several authors. With a **PreparedStatement**, that query is defined as follows:

```
PreparedStatement authorBooks = connection.prepareStatement(
 "SELECT lastName, firstName, title " +
 "FROM authors INNER JOIN authorISBN " +
 "ON authors.authorID=authorISBN.authorID " +
 "INNER JOIN titles " +
 "ON authorISBN.isbn=titles.isbn " +
 "WHERE lastName = ? AND firstName = ?");
```

The two question marks (?) in the preceding SQL statement's last line are placeholders for values that will be passed as part of the query to the database. Before executing a **Pre-**

## 1214 Chapter 25 Accessing Databases with JDBC

`paredStatement`, the program must specify the parameter values by using the `PreparedStatement` interface's `set` methods.

For the preceding query, both parameters are strings that can be set with `PreparedStatement` method `setString` as follows:

```
authorBooks.setString(1, "Deitel");
authorBooks.setString(2, "Paul");
```

Method `setString`'s first argument represents the number of the parameter being set and the second argument is that parameter's value. Parameter numbers are counted from 1, starting with the first question mark (?). When the program executes the preceding `PreparedStatement` with the parameter values shown here, the SQL statement passed to the database is

```
SELECT lastName, firstName, title
FROM authors INNER JOIN authorISBN
 ON authors.authorID=authorISBN.authorID
INNER JOIN titles
 ON authorISBN.isbn=titles.isbn
WHERE lastName = 'Deitel' AND firstName = 'Paul'
```

Method `setString` automatically escapes String parameter values as necessary. For example, if the last name is O'Brien, the statement

```
authorBooks.setString(1, "O'Brien");
```

escapes the ' character in O'Brien by replacing it with two single-quote characters.

### Performance Tip 25.2

*PreparedStatements are more efficient than Statements when executing SQL statements multiple times and with different parameter values.*

### Error-Prevention Tip 25.1

*Use PreparedStatements with parameters for queries that receive String values as arguments to ensure that the Strings are quoted properly in the SQL statement.*

Interface `PreparedStatement` provides `set` methods for each supported SQL type. It is important to use the `set` method that is appropriate for the parameter's SQL type in the database—`SQLExceptions` occur when a program attempts to convert a parameter value to an incorrect type. For a complete list of interface `PreparedStatement`'s `set` methods, see [java.sun.com/javase/6/docs/api/java/sql/PreparedStatement.html](http://java.sun.com/javase/6/docs/api/java/sql/PreparedStatement.html).

### Address Book Application that Uses `PreparedStatement`

We now present an address book application that enables you to browse existing entries, add new entries and search for entries with a specific last name. Our `AddressBook` Java DB database contains an `Addresses` table with the columns `addressID`, `firstName`, `lastName`, `email` and `phoneNumber`. The column `addressID` is a so-called identity column. This is the SQL standard way to represent an autoincremented column. The SQL script we provide for this database uses the SQL `IDENTITY` keyword to mark the `addressID` column as an identity column. For more information on using the `IDENTITY` keyword and creating databases, see the Java DB Developer's Guide at [developers.sun.com/prodtech/javadb/reference/docs/10.2.1.6/devguide/index.html](http://developers.sun.com/prodtech/javadb/reference/docs/10.2.1.6/devguide/index.html).

## 25.12 Stored Procedures

Many database management systems can store individual SQL statements or sets of SQL statements in a database, so that programs accessing that database can invoke them. Such named collections of SQL statements are called **stored procedures**. JDBC enables programs to invoke stored procedures using objects that implement the interface **CallableStatement**. CallableStatements can receive arguments specified with the methods inherited from interface **PreparedStatement**. In addition, CallableStatements can specify **output parameters** in which a stored procedure can place return values. Interface **CallableStatement** includes methods to specify which parameters in a stored procedure are output parameters. The interface also includes methods to obtain the values of output parameters returned from a stored procedure.

### Portability Tip 25.6

*Although the syntax for creating stored procedures differs across database management systems, the interface CallableStatement provides a uniform interface for specifying input and output parameters for stored procedures and for invoking stored procedures.*

### Portability Tip 25.7

*According to the Java API documentation for interface CallableStatement, for maximum portability between database systems, programs should process the update counts or ResultSets returned from a CallableStatement before obtaining the values of any output parameters.*

## 25.13 Transaction Processing

Many database applications require guarantees that a series of database insertions, updates and deletions executes properly before the applications continue processing the next database operation. For example, when you transfer money electronically between bank accounts, several factors determine if the transaction is successful. You begin by specifying the source account and the amount you wish to transfer from that account to a destination account. Next, you specify the destination account. The bank checks the source account to determine if there are sufficient funds in the account to complete the transfer. If so, the bank withdraws the specified amount from the source account and, if all goes well, deposits the money into the destination account to complete the transfer. What happens if the transfer fails after the bank withdraws the money from the source account? In a proper banking system, the bank redeposits the money in the source account. How would you feel if the money was subtracted from your source account and the bank *did not* deposit the money in the destination account?

**Transaction processing** enables a program that interacts with a database to treat a database operation (or set of operations) as a single operation. Such an operation also is known as an **atomic operation** or a **transaction**. At the end of a transaction, a decision can be made either to **commit the transaction** or **roll back the transaction**. Committing the transaction finalizes the database operation(s); all insertions, updates and deletions performed as part of the transaction cannot be reversed without performing a new database operation. Rolling back the transaction leaves the database in its state prior to the database operation. This is useful when a portion of a transaction fails to complete properly. In our bank-account-transfer discussion, the transaction would be rolled back if the deposit could not be made into the destination account.

**1230** Chapter 25 Accessing Databases with JDBC

Java provides transaction processing via methods of interface `Connection`. Method `setAutoCommit` specifies whether each SQL statement commits after it completes (a `true` argument) or if several SQL statements should be grouped as a transaction (a `false` argument). If the argument to `setAutoCommit` is `false`, the program must follow the last SQL statement in the transaction with a call to `Connection` method `commit` (to commit the changes to the database) or `Connection` method `rollback` (to return the database to its state prior to the transaction). Interface `Connection` also provides method `getAutoCommit` to determine the autocommit state for the `Connection`.

### 25.14 Wrap-Up

In this chapter, you learned basic database concepts, how to interact with data in a database using SQL and how to use JDBC to allow Java applications to manipulate MySQL and Java DB databases. You learned about the SQL commands `SELECT`, `INSERT`, `UPDATE` and `DELETE`, as well as clauses such as `WHERE`, `ORDER BY` and `INNER JOIN`. You learned the explicit steps for obtaining a `Connection` to the database, creating a `Statement` to interact with the database's data, executing the statement and processing the results. Then you saw how to use a `RowSet` to simplify the process of connecting to a database and creating statements. You used `PreparedStatement`s to create precompiled SQL statements. You also learned how to create and configure databases in both MySQL and Java DB. We also provided overviews of `CallableStatements` and transaction processing. In the next chapter, you will learn about web application development with JavaServer Faces. Web-based applications create content that is typically displayed in web browser clients. As you'll see in Chapter 27, web applications can also use the JDBC API to access databases to create more dynamic web content.

## Summary

### Section 25.1 Introduction

- A database is an integrated collection of data. A database management system (DBMS) provides mechanisms for storing, organizing, retrieving and modifying data for many users.
- Today's most popular database management systems are relational database systems.
- SQL is the international standard language used almost universally with relational database systems to perform queries and manipulate data.
- Programs connect to, and interact with, relational databases via an interface—software that facilitates communications between a database management system and a program.
- Java programs communicate with databases and manipulate their data using the JDBC API. A JDBC driver enables Java applications to connect to a database in a particular DBMS and allows you to retrieve and manipulate database data.

### Section 25.2 Relational Databases

- A relational database stores data in tables. Tables are composed of rows, and rows are composed of columns in which values are stored.
- A primary key provides a unique value that cannot be duplicated in other rows of the same table.
- Each column of a table represents a different attribute.
- The primary key can be composed of more than one column.
- SQL provides a rich set of language constructs that enable you to define complex queries to retrieve data from a database.
- Every column in a primary key must have a value, and the value of the primary key must be unique. This is known as the Rule of Entity Integrity.
- A one-to-many relationship between tables indicates that a row in one table can have many related rows in a separate table.
- A foreign key is a column in a table that matches the primary-key column in another table.
- The foreign key helps maintain the Rule of Referential Integrity: Every foreign-key value must appear as another table's primary-key value. Foreign keys enable information from multiple tables to be joined together. There is a one-to-many relationship between a primary key and its corresponding foreign key.

[Summary](#)**I233**

#### **Section 25.4.1 Basic SELECT Query**

- The basic form of a query is

```
SELECT * FROM tableName
```

where the asterisk (\*) indicates that all columns from *tableName* should be selected, and *tableName* specifies the table in the database from which rows will be retrieved.

- To retrieve specific columns from a table, replace the asterisk (\*) with a comma-separated list of column names.
- You process query results by knowing in advance the order of the columns in the result. Specifying columns explicitly guarantees that they are always returned in the specified order, even if the actual order in the table(s) is different.

#### **Section 25.4.2 WHERE Clause**

- The optional WHERE clause in a query specifies the selection criteria for the query. The basic form of a query with selection criteria is

```
SELECT columnName1, columnName2, ... FROM tableName WHERE criteria
```

- The WHERE clause can contain operators <, >, <=, >=, =, <> and LIKE. Operator LIKE is used for string pattern matching with wildcard characters percent (%) and underscore (\_).
- A percent character (%) in a pattern indicates that a string matching the pattern can have zero or more characters at the percent character's location in the pattern.
- An underscore (\_) in the pattern string indicates a single character at that position in the pattern.

#### **Section 25.4.3 ORDER BY Clause**

- The result of a query can be sorted in ascending or descending order using the optional ORDER BY clause. The simplest form of an ORDER BY clause is

```
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column ASC
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column DESC
```

where ASC specifies ascending order, DESC specifies descending order and *column* specifies the column on which the sort is based. The default sorting order is ascending, so ASC is optional.

- Multiple columns can be used for ordering purposes with an ORDER BY clause of the form

```
ORDER BY column1 sortingOrder, column2 sortingOrder, ...
```

- The WHERE and ORDER BY clauses can be combined in one query. If used, ORDER BY must be the last clause in the query.

#### **Section 25.4.4 Merging Data from Multiple Tables: INNER JOIN**

- An INNER JOIN merges rows from two tables by matching values in columns that are common to the tables. The basic form for the INNER JOIN operator is:

```
SELECT columnName1, columnName2, ...
FROM tableName1
INNER JOIN tableName2
ON tableName1.columnName = tableName2.columnName
```

The ON clause specifies the columns from each table that are compared to determine which rows are joined. If a SQL statement uses columns with the same name from multiple tables, the column names must be fully qualified by prefixing them with their table names and a dot (.).

**I234** Chapter 25 Accessing Databases with JDBC**Section 25.4.5 INSERT Statement**

- An INSERT statement inserts a new row into a table. The basic form of this statement is

```
INSERT INTO tableName (columnName1, columnName2, ..., columnNameN)
VALUES (value1, value2, ..., valueN)
```

where *tableName* is the table in which to insert the row. The *tableName* is followed by a comma-separated list of column names in parentheses. The list of column names is followed by the SQL keyword VALUES and a comma-separated list of values in parentheses.

- SQL uses single quotes ('') as the delimiter for strings. To specify a string containing a single quote in SQL, the single quote must be escaped with another single quote.

**Section 25.4.6 UPDATE Statement**

- An UPDATE statement modifies data in a table. The basic form of an UPDATE statement is

```
UPDATE tableName
SET columnName1 = value1, columnName2 = value2, ..., columnNameN = valueN
WHERE criteria
```

where *tableName* is the table in which to update data. The *tableName* is followed by keyword SET and a comma-separated list of column name/value pairs in the format *columnName = value*. The optional WHERE clause *criteria* determines which rows to update.

**Section 25.4.7 DELETE Statement**

- A DELETE statement removes rows from a table. The simplest form for a DELETE statement is

```
DELETE FROM tableName WHERE criteria
```

where *tableName* is the table from which to delete a row (or rows). The optional WHERE *criteria* determines which rows to delete. If this clause is omitted, all the table's rows are deleted.

**Section 25.8.1 Connecting to and Querying a Database**

- Package `java.sql` contains classes and interfaces for accessing relational databases in Java.
- An object that implements interface `Connection` manages the connection between a Java program and a database. `Connection` objects enable programs to create SQL statements that access data.
- Method `getConnection` of class `DriverManager` attempts to connect to a database specified by its URL argument. The URL helps the program locate the database. The URL includes the protocol for communication, the subprotocol for communication and the name of the database.
- `Connection` method `createStatement` creates an object of type `Statement`. The program uses the `Statement` object to submit SQL statements to the database.
- `Statement` method `executeQuery` executes a query and returns an object that implements interface `ResultSet` containing the query result. `ResultSet` methods enable a program to manipulate query results.
- A `ResultSetMetaData` object describes a `ResultSet`'s contents. Programs can use metadata programmatically to obtain information about the `ResultSet` column names and types.
- `ResultSetMetaData` method `getColumnCount` retrieves the number of `ResultSet` columns.
- `ResultSet` method `next` positions the `ResultSet` cursor to the next row in the `ResultSet`. The cursor points to the current row. Method `next` returns boolean value `true` if it is able to position to the next row; otherwise, the method returns `false`. This method must be called to begin processing a `ResultSet`.

**Summary    1235**

- When processing `ResultSets`, it is possible to extract each column of the `ResultSet` as a specific Java type. `ResultSetMetaData` method `getColumnType` returns a constant integer from class `Types` (package `java.sql`) indicating the type of the data for a specific column.
- `ResultSet` `get` methods typically receive as an argument either a column number (as an `int`) or a column name (as a `String`) indicating which column's value to obtain.
- `ResultSet` row and column numbers start at 1.
- Each `Statement` object can open only one `ResultSet` object at a time. When a `Statement` returns a new `ResultSet`, the `Statement` closes the prior `ResultSet`.
- `Connection` method `createStatement` has an overloaded version that takes two arguments: the result type and the result concurrency. The result type specifies whether the `ResultSet`'s cursor is able to scroll in both directions or forward only and whether the `ResultSet` is sensitive to changes. The result concurrency specifies whether the `ResultSet` can be updated with `ResultSet`'s update methods.
- Some JDBC drivers do not support scrollable or updatable `ResultSets`.

***Section 25.8.2 Querying the books Database***

- `TableModel` method `getColumnClass` returns a `Class` object that represents the superclass of all objects in a particular column. `JTable` uses this information to set up the default cell renderer and cell editor for that column in a `JTable`.
- `ResultSetMetaData` method `getColumnClassName` obtains the fully qualified class name of the specified column.
- `TableModel` method `getColumnCount` returns the number of columns in the model's underlying `ResultSet`.
- `TableModel` method `getColumnName` returns the name of the column in the model's underlying `ResultSet`.
- `ResultSetMetaData` method `getColumnName` obtains the column name from the `ResultSet`.
- `TableModel` method `getRowCount` returns the number of rows in the model's `ResultSet`.
- `TableModel` method `getValueAt` returns the `Object` at a particular row and column of the model's underlying `ResultSet`.
- `ResultSet` method `absolute` positions the `ResultSet` cursor at a specific row.
- `AbstractTableModel` method `fireTableStructureChanged` notifies any `JTable` using a particular `TableModel` object as its model that the data in the model has changed.

***Section 25.9 RowSet Interface***

- Interface `RowSet` configures the database connection and executes the query automatically.
- There are two types of `RowSets`—connected and disconnected.
- A connected `RowSet` connects to the database once and remains connected until the application terminates.
- A disconnected `RowSet` connects to the database, executes a query to retrieve the data from the database and then closes the connection.
- `JdbcRowSet`, a connected `RowSet`, acts as a wrapper for a `ResultSet` object and allows you to scroll and update the rows in the `ResultSet`. Unlike a `ResultSet` object, a `JdbcRowSet` object is scrollable and updatable by default.
- `CachedRowSet`, a disconnected `RowSet`, caches the data of a `ResultSet` in memory. Like `JdbcRowSet`, a `CachedRowSet` object is scrollable and updatable. A `CachedRowSet` object is also serializable, so it can be passed between Java applications through a network, such as the Internet.

**1236**    [Chapter 25](#)   Accessing Databases with JDBC**Section 25.10 Java DB/Apache Derby**

- As of JDK 6, Sun Microsystems now bundles the open-source, pure Java database Java DB (the Sun branded version of Apache Derby) with the JDK.
- Java DB has both an embedded version and a network version.

**Section 25.11 PreparedStatements**

- Interface `PreparedStatement` enables you to create compiled SQL statements that execute more efficiently than `Statement` objects.
- `PreparedStatement`s also can specify parameters, making them more flexible than `Statements`. Programs can execute the same query repeatedly with different parameter values.
- A parameter is specified with a question mark (?) in the SQL statement. Before executing a `PreparedStatement`, the program must specify the parameter values by using the `PreparedStatement` interface's `set` methods.
- `PreparedStatement` method `setString`'s first argument represents the number of the parameter being set and the second argument is that parameter's value.
- Parameter numbers are counted from 1, starting with the first question mark (?).
- Method `setString` automatically escapes `String` parameter values as necessary.
- Interface `PreparedStatement` provides `set` methods for each supported SQL type.
- An identity column is the SQL standard way to represent an autoincremented column. The SQL `IDENTITY` keyword to mark a column as an identity column.

**Section 25.12 Stored Procedures**

- JDBC enables programs to invoke stored procedures using objects that implement interface `CallableStatement`.
- `CallableStatement` can specify input parameters, like `PreparedStatement`. In addition, `CallableStatement` can specify output parameters in which a stored procedure can place return values.

**Section 25.13 Transaction Processing**

- Transaction processing enables a program that interacts with a database to treat a database operation (or set of operations) as a single operation. Such an operation is also known as an atomic operation or a transaction.
- At the end of a transaction, a decision can be made either to commit the transaction or roll back the transaction.
- Committing the transaction finalizes the database operation(s); all insertions, updates and deletions performed as part of the transaction cannot be reversed without performing a new database operation.
- Rolling back a transaction leaves the database in its state prior to the database operation. This is useful when a portion of a transaction fails to complete properly.
- Java provides transaction processing via methods of interface `Connection`.
- Method `setAutoCommit` specifies whether each SQL statement commits after it completes (a `true` argument) or if several SQL statements should be grouped as a transaction (a `false` argument).
- If the argument to `setAutoCommit` is `false`, the program must follow the last SQL statement in the transaction with a call to `Connection` method `commit` (to commit the changes to the database) or `Connection` method `rollback` (to return the database to its state prior to the transaction).
- Method `getAutoCommit` determines the autocommit state for the `Connection`.

## Terminology

% SQL wildcard character  
 \_ SQL wildcard character  
 \* SQL wildcard character  
 absolute method of ResultSet

**Self-Review Exercise**

- 25.1** Fill in the blanks in each of the following statements:
- The international standard database language is \_\_\_\_\_.
  - A table in a database consists of \_\_\_\_\_ and \_\_\_\_\_.
  - Statement objects return SQL query results as \_\_\_\_\_ objects.
  - The \_\_\_\_\_ uniquely identifies each row in a table.
  - SQL keyword \_\_\_\_\_ is followed by the selection criteria that specify the rows to select in a query.
  - SQL keywords \_\_\_\_\_ specify the order in which rows are sorted in a query.
  - Merging rows from multiple database tables is called \_\_\_\_\_ the tables.
  - A(n) \_\_\_\_\_ is an organized collection of data.
  - A(n) \_\_\_\_\_ is a set of columns whose values match the primary key values of another table.
  - A(n) \_\_\_\_\_ object is used to obtain a Connection to a database.
  - Interface \_\_\_\_\_ helps manage the connection between a Java program and a database.
  - A(n) \_\_\_\_\_ object is used to submit a query to a database.
  - Unlike a ResultSet object, \_\_\_\_\_ and \_\_\_\_\_ objects are scrollable and updatable by default.
  - \_\_\_\_\_, a disconnected RowSet, caches the data of a ResultSet in memory.

**Answers to Self-Review Exercise**

- 25.1** a) SQL. b) rows, columns. c) ResultSet. d) primary key. e) WHERE. f) ORDER BY. g) joining. h) database. i) foreign key. j) DriverManager. k) Connection. l) Statement. m) JdbcRowSet, CachedRowSet n) CachedRowSet.

**Exercises**

- 25.2** Using the techniques shown in this chapter, define a complete query application for the books database. Provide the following predefined queries:

- Select all authors from the authors table.
- Select a specific author and list all books for that author. Include each book's title, year and ISBN. Order the information alphabetically by the author's last then first name.
- Select a specific publisher and list all books published by that publisher. Include the title, year and ISBN. Order the information alphabetically by title.
- Provide any other queries you feel are appropriate.

Display a JComboBox with appropriate names for each predefined query. Also allow users to supply their own queries.

Exercises **1239**

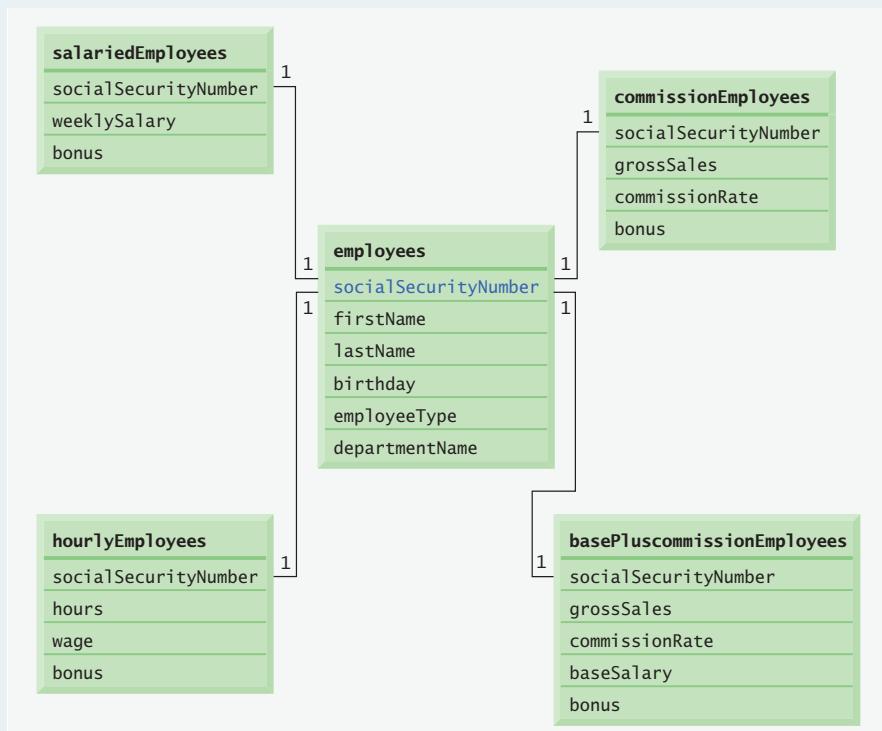

**25.3** Define a data-manipulation application for the books database. The user should be able to edit existing data and add new data to the database (obeying referential and entity integrity constraints). Allow the user to edit the database in the following ways:

- Add a new author.
- Edit the existing information for an author.
- Add a new title for an author. (Remember that the book must have an entry in the `authorISBN` table.).
- Add a new entry in the `authorISBN` table to link authors with titles.

**25.4** In Section 10.7, we introduced an employee-payroll hierarchy to calculate each employee's payroll. In this exercise, we provide a database of employees that corresponds to the employee payroll hierarchy. (A SQL script to create the `employees` database is provided with the examples for this chapter on the CD that accompanies this text and on our website, [www.deitel.com](http://www.deitel.com).) Write an application that allows the user to:

- Add employees to the `employee` table.
- Add payroll information to the appropriate table for each new employee. For example, for a salaried employee add the payroll information to the `salariedEmployees` table.

Figure 25.33 is the entity-relationship diagram for the `employees` database.

**Fig. 25.33** | Table relationships in `employees`.

**1240** Chapter 25 Accessing Databases with JDBC

**25.5** Modify Exercise 25.4 to provide a JComboBox and a JTextArea to allow the user to perform a query that is either selected from the JComboBox or defined in the JTextArea. Sample predefined queries are:

- a) Select all employees working in Department SALES.
- b) Select hourly employees working over 30 hours.
- c) Select all commission employees in descending order of the commission rate.

**25.6** Modify Exercise 25.5 to perform the following tasks:

- a) Increase base salary by 10% for all base-plus-commission employees.
- b) If the employee's birthday is in the current month, add a \$100 bonus.
- c) For all commission employees with gross sales over \$10,000, add a \$100 bonus.

**25.7** Modify the program in Figs. 25.31–25.33 to provide a JButton that allows the user to call a method named updatePerson in PersonQueries interface to update the current entry in the AddressBook database.

*If any man will draw up his case, and put his name at the foot of the first page, I will give him an immediate reply. Where he compels me to turn over the sheet, he must wait my leisure.*

—Lord Sandwich

*Rule One: Our client is always right*

*Rule Two: If you think our client is wrong, see Rule One.*

—Anonymous

*A fair question should be followed by a deed in silence.*

—Dante Alighieri

*You will come here and get books that will open your eyes, and your ears, and your curiosity, and turn you inside out or outside in.*

—Ralph Waldo Emerson

# 26

## Web Applications: Part I

### OBJECTIVES

In this chapter you will learn:

- Web application development using Java Technologies and Java Studio Creator 2.0.
- To create JavaServer Pages with JavaServer Faces components.
- To create web applications consisting of multiple pages.
- To validate user input on a web page.
- To maintain state information about a user with session tracking and cookies.

**1242    Chapter 26  Web Applications: Part I****Outline**

- 26.1** Introduction
- 26.2** Simple HTTP Transactions
- 26.3** Multitier Application Architecture
- 26.4** Java Web Technologies
  - 26.4.1** Servlets
  - 26.4.2** JavaServer Pages
  - 26.4.3** JavaServer Faces
  - 26.4.4** Web Technologies in Java Studio Creator 2
- 26.5** Creating and Running a Simple Application in Java Studio Creator 2

  - 26.6.1** Text and Graphics Components
  - 26.6.2** Validation Using Validator Components and Custom Validators
- 26.7** Session Tracking
  - 26.7.1** Cookies
  - 26.7.2** Session Tracking with the SessionBean Object
- 26.8** Wrap-Up
- 26.9** Web Resources

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 26.1 Introduction

In this chapter, we introduce [web application development](#) with Java-based technology. Web-based applications create web content for web browser clients. This web content includes Extensible HyperText Markup Language (XHTML), client-side scripting, images and binary data. For those who are not familiar with XHTML, we've provided on the CD that accompanies this book three chapters from our book *Internet & World Wide Web How to Program, 3/e*—Introduction to XHTML: Part 1, Introduction to XHTML: Part 2 and Cascading Style Sheets (CSS). In Chapters 26–28, we assume you already know XHTML.

This chapter begins with an overview of multitier application architecture and Java's web technologies for implementing multitier applications. We then present several examples that demonstrate web application development. The first example introduces you to Java web development. In the second example, we build a web application that simply shows the look-and-feel of several web-application GUI components. Next, we demonstrate how to use validation components and custom validation methods to ensure that user input is valid before it is submitted for processing on the server. The chapter finishes with two examples of customizing a user's experience with session tracking.

26.2 Simple HTTP Transactions **1243**

In Chapter 27, we continue our discussion of web application development with more advanced concepts, including the AJAX-enabled components from Sun's Java BluePrints. AJAX helps web-based applications provide the interactivity and responsiveness that users typically expect of desktop applications.

Throughout this chapter and Chapter 27, we use [Sun Java Studio Creator 2.0](#)—an IDE that helps you build web applications using Java technologies such as JavaServer Pages and JavaServer Faces. To implement the examples presented in this chapter, you must install Java Studio Creator 2.0, which is available for download at [developers.sun.com/prodtech/javatools/jscreator/downloads/index.jsp](http://developers.sun.com/prodtech/javatools/jscreator/downloads/index.jsp). The features of Java Studio Creator 2.0 are being incorporated into Netbeans 5.5 via an add-on called the Netbeans Visual Web Pack 5.5 ([www.netbeans.org/products/visualweb/](http://www.netbeans.org/products/visualweb/)).

## 26.2 Simple HTTP Transactions

Web application development requires a basic understanding of networking and the World Wide Web. In this section, we discuss the Hypertext Transfer Protocol (HTTP) and what occurs behind the scenes when a user requests a web page in a browser. HTTP specifies a set of methods and headers that allow clients and servers to interact and exchange information in a uniform and reliable manner.

In its simplest form, a web page is nothing more than an XHTML document—a plain text file containing [markup](#) (i.e., [tags](#)) that describe to a web browser how to display and format the document's information. For example, the XHTML markup

```
<title>My Web Page</title>
```

indicates that the browser should display the text between the [start tag](#) and the [end tag](#) in the browser's title bar. XHTML documents also can contain [hyper-text](#) data (usually called [hyperlinks](#)) that link to different pages or to other parts of the same page. When the user activates a hyperlink (usually by clicking it with the mouse), the requested web page loads into the user's web browser.

HTTP uses [URIs \(Uniform Resource Identifiers\)](#) to identify data on the Internet. URIs that specify document locations are called [URLs \(Uniform Resource Locators\)](#). Common URLs refer to files, directories or objects that perform complex tasks, such as database lookups and Internet searches. If you know the HTTP URL of a publicly available XHTML document anywhere on the web, you can access it through HTTP.

A URL contains information that directs a browser to the resource that the user wishes to access. Computers that run [web server](#) software make such resources available. Let's examine the components of the URL

```
http://www.deitel.com/books/downloads.html
```

The [http://](#) indicates that the resource is to be obtained using the HTTP protocol. The middle portion, [www.deitel.com](#), is the server's fully qualified [hostname](#)—the name of the server on which the resource resides. This computer usually is referred to as the [host](#), because it houses and maintains resources. The hostname [www.deitel.com](#) is translated into an [IP address](#) (68.236.123.125), which identifies the server in a manner similar to how a telephone number uniquely defines a particular phone line. This translation is performed by a [domain name system \(DNS\) server](#)—a computer that maintains a database of hostnames and their corresponding IP addresses—and the process is called a [DNS lookup](#).

**1244** Chapter 26 Web Applications: Part I

The remainder of the URL (i.e., `/books/downloads.html`) specifies both the name of the requested resource (the XHTML document `downloads.html`) and its path, or location (`/books`), on the web server. The path could specify the location of an actual directory on the web server's file system. However, for security reasons, the path normally specifies the location of a **virtual directory**. The server translates the virtual directory into a real location on the server (or on another computer on the server's network), thus hiding the true location of the resource. Some resources are created dynamically and do not reside anywhere on the server. The hostname in the URL for such a resource specifies the correct server; the path and resource information identify the location of the resource with which to respond to the client's request.

When given a URL, a web browser performs a simple HTTP transaction to retrieve and display the web page found at that address. Figure 26.1 illustrates the transaction in detail, showing the interaction between the web browser (the client side) and the web server application (the server side).

In Fig. 26.1, the web browser sends an HTTP request to the server. The request (in its simplest form) is

```
GET /books/downloads.html HTTP/1.1
```

The word **GET** is an **HTTP method** indicating that the client wishes to obtain a resource from the server. The remainder of the request provides the path name of the resource (an XHTML document) and the protocol's name and version number (HTTP/1.1).

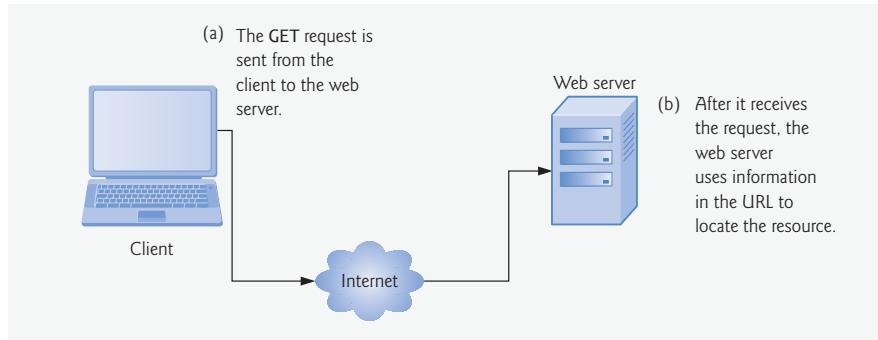

Any server that understands HTTP (version 1.1) can translate this request and respond appropriately. Figure 26.2 depicts the results of a successful request. The server first responds by sending a line of text that indicates the HTTP version, followed by a numeric code and a phrase describing the status of the transaction. For example,

```
HTTP/1.1 200 OK
```

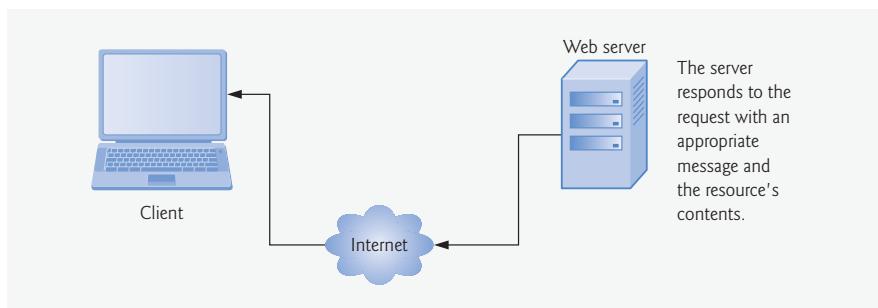

indicates success, whereas

```
HTTP/1.1 404 Not found
```

informs the client that the web server could not locate the requested resource. A complete list of numeric codes indicating the status of an HTTP transaction can be found at [www.w3.org/Protocols/HTTP/HTRESP.html](http://www.w3.org/Protocols/HTTP/HTRESP.html).

**Fig. 26.1** | Client interacting with web server. *Step 1: The GET request.*

26.3 Multitier Application Architecture **1245**

**Fig. 26.2** | Client interacting with web server. Step 2: The HTTP response.

The server then sends one or more **HTTP headers**, which provide additional information about the data that will be sent. In this case, the server is sending an XHTML text document, so the HTTP header for this example reads:

```
Content-type: text/html
```

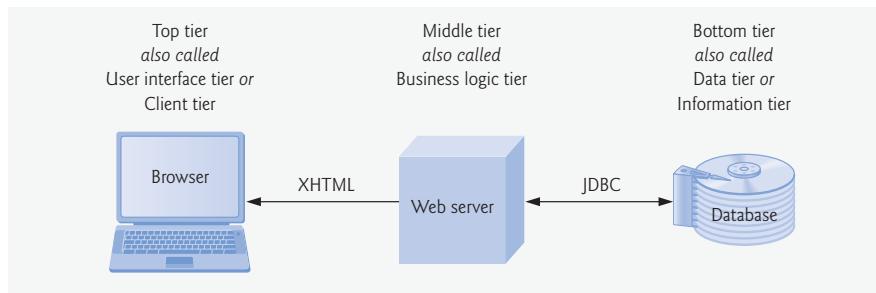

The information provided in this header specifies the **Multipurpose Internet Mail Extensions (MIME)** type of the content that the server is transmitting to the browser. MIME is an Internet standard that specifies data formats so that programs can interpret data correctly. For example, the MIME type `text/plain` indicates that the sent information is text that can be displayed directly, without any interpretation of the content as XHTML markup. Similarly, the MIME type `image/jpeg` indicates that the content is a JPEG image. When the browser receives this MIME type, it attempts to display the image.

The header or set of headers is followed by a blank line, which indicates to the client that the server is finished sending HTTP headers. The server then sends the contents of the requested XHTML document (`downloads.html`). The server terminates the connection when the resource transfer is complete. The client-side browser parses the XHTML markup it receives and **renders** (or displays) the results.

### 26.3 Multitier Application Architecture

Web-based applications are **multitier applications** (sometimes referred to as **n-tier applications**) that divide functionality into separate **tiers** (i.e., logical groupings of functionality). Although tiers can be located on the same computer, the tiers of web-based applications typically reside on separate computers. Figure 26.3 presents the basic structure of a **three-tier web-based application**.

The **bottom tier** (also called the data tier or the information tier) maintains the application's data. This tier typically stores data in a relational database management system (RDBMS). We discussed RDBMSs in Chapter 25. For example, a retail store might have an inventory information database containing product descriptions, prices and quantities in stock. The same database also might contain customer information, such as user names, billing addresses and credit card numbers. There could be multiple databases residing on one or more computers, which together comprise the application's data.

**1246**    [Chapter 26](#) [Web Applications: Part I](#)

**Fig. 26.3** | Three-tier architecture.

The **middle tier** implements business logic, controller logic and presentation logic to control interactions between the application's clients and its data. The middle tier acts as an intermediary between data in the information tier and the application's clients. The middle-tier **controller logic** processes client requests (such as requests to view a product catalog) and retrieves data from the database. The middle-tier **presentation logic** then processes data from the information tier and presents the content to the client. Web applications typically present data to clients as XHTML documents.

**Business logic** in the middle tier enforces **business rules** and ensures that data is reliable before the server application updates the database or presents the data to users. Business rules dictate how clients can and cannot access application data, and how applications process data. For example, a business rule in the middle tier of a retail store's web-based application might ensure that all product quantities remain positive. A client request to set a negative quantity in the bottom tier's product information database would be rejected by the middle tier's business logic.

The **top tier**, or client tier, is the application's user interface, which gathers input and displays output. Users interact directly with the application through the user interface, which is typically a web browser, keyboard and mouse. In response to user actions (e.g., clicking a hyperlink), the client tier interacts with the middle tier to make requests and to retrieve data from the information tier. The client tier then displays the data retrieved for the user. The client tier never directly interacts with the information tier.

Java multitier applications are typically implemented using the features of Java Enterprise Edition (Java EE). The technologies we use to develop web applications in Chapters 26–28 are part of Java EE 5 ([java.sun.com/javaee](http://java.sun.com/javaee)).

## 26.4 Java Web Technologies

Java web technologies continually evolve to provide developers with higher levels of abstraction and greater separation of the application's tiers. This separation makes web applications more maintainable and extensible. It also allows for an effective division of labor. A graphic designer can build the application's user interface without concern for the underlying page logic, which will be handled by a programmer. Meanwhile, the programmer is free to focus on the application's business logic, leaving the details of building an attractive and easy-to-use application to the designer. Java Studio Creator 2 is the latest step in this evolution, allowing you to develop a web application's GUI in a drag-and-drop design tool, while handling the business logic in separate Java classes.

### 26.4.1 Servlets

Servlets are the lowest-level view of web development technologies in Java that we will discuss in this chapter. They use the HTTP request-response model of communication between client and server.

**Servlets** extend a server's functionality by allowing the server to generate dynamic content. For instance, servlets can dynamically generate custom XHTML documents, help provide secure access to a website, interact with databases on behalf of a client and maintain unique session information for each client. A web server component called the **Servlet container** executes and interacts with servlets. Packages `javax.servlet` and `javax.servlet.http` provide the classes and interfaces to define servlets. The servlet container receives HTTP requests from a client and directs each request to the appropriate servlet. The servlet processes the request and returns an appropriate response to the client—usually in the form of an XHTML or **XML (Extensible Markup Language)** document to display in the browser. XML is a language used to exchange structured data on the web.

Architecturally, all servlets must implement the `Servlet` interface of package `javax.servlet`, which ensures that each servlet can execute in the framework provided by the servlet container. Interface `Servlet` declares methods used by the servlet container to manage the servlet's life cycle. A servlet's life cycle begins when the servlet container loads it into memory—usually in response to the first request for the servlet. Before the servlet can handle that request, the container invokes the servlet's `init` method, which is called only once during a servlet's life-cycle to initialize the servlet. After `init` completes execution, the servlet is ready to respond to its first request. All requests are handled by a servlet's `service` method, which is the key method in defining a servlet's functionality. The `service` method receives the request, processes it and sends a response to the client. During a servlet's life cycle, `service` is called once per request. Each new request is typically handled in a separate thread of execution (managed by the servlet container), so each servlet must be thread safe. When the servlet container terminates the servlet (e.g. when the servlet container needs more memory or when it is shut down), the servlet's `destroy` method is called to release any resources held by the servlet.

### 26.4.2 JavaServer Pages

**JavaServer Pages (JSP)** technology is an extension of servlet technology. Each JSP is translated by the JSP container into a servlet. Unlike servlets, JSPs help you separate presentation from content. JavaServer Pages enable web application programmers to create dynamic content by reusing predefined components and by interacting with components using server-side scripting. JSP programmers can use special software components called JavaBeans and custom tag libraries that encapsulate complex, dynamic functionality. A **JavaBean** is a reusable component that follows certain conventions for class design. For example, JavaBeans classes that allow reading and writing of instance variables must provide appropriate `get` and `set` methods. The complete set of class design conventions is discussed in the JavaBeans specification ([java.sun.com/products/javabeans/glasgow/index.html](http://java.sun.com/products/javabeans/glasgow/index.html)).

#### *Custom Tag Libraries*

**Custom tag libraries** are a powerful feature of JSP that allows Java developers to hide code for database access and other complex operations in **custom tags**. To use such capabilities,

**1248**    [Chapter 26](#)   [Web Applications: Part I](#)

you simply add the custom tags to the page. This simplicity enables web-page designers who are not familiar with Java to enhance web pages with powerful dynamic content and processing capabilities. The JSP classes and interfaces are located in packages `javax.servlet.jsp` and `javax.servlet.jsp.tagext`.

***JSP Components***

There are four key components to JSPs—directives, actions, scripting elements and tag libraries. **Directives** are messages to the **JSP container**—the web server component that executes JSPs. Directives enable you to specify page settings, to include content from other resources and to specify custom tag libraries for use in JSPs. **Actions** encapsulate functionality in predefined tags that programmers can embed in JSPs. Actions often are performed based on the information sent to the server as part of a particular client request. They also can create Java objects for use in JSPs. **Scripting elements** enable you to insert Java code that interacts with components in a JSP (and possibly other web application components) to perform request processing. **Tag libraries** are part of the **tag extension mechanism** that enables programmers to create custom tags. Such tags enable web-page designers to manipulate JSP content without prior Java knowledge. The **JavaServer Pages Standard Tag Library (JSTL)** provides the functionality for many common web application tasks, such as iterating over a collection of objects and executing SQL statements.

***Static Content***

JSPs can contain other static content. For example JSPs normally include XHTML or XML markup. Such markup is known as **fixed-template data** or **fixed-template text**. Any literal text in a JSP is translated to a `String` literal in the servlet representation of the JSP.

***Processing a JSP Request***

When a JSP-enabled server receives the first request for a JSP, the JSP container translates the JSP into a servlet that handles the current request and future requests to the JSP. JSPs thus rely on the same request-response mechanism as servlets to process requests from and send responses to clients.

**Performance Tip 26.1**

*Some JSP containers translate JSPs into servlets at the JSP's deployment time (i.e., when the application is placed on a web server). This eliminates the translation overhead for the first client that requests each JSP, as the JSP will be translated before it is ever requested by a client.*

**26.4.3 JavaServer Faces**

**JavaServer Faces (JSF)** is a web application framework that simplifies the design of an application's user interface and further separates a web application's presentation from its business logic. A **framework** simplifies application development by providing libraries and sometimes software tools to help you organize and build your applications. Though the JSF framework can use many technologies to define the pages in web applications, this chapter focuses on JSF applications that use JavaServer Pages. JSF provides a set of user interface components, or **JSF components** that simplify web-page design. These components are similar to the Swing components used to build GUI applications. JSF provides two JSP custom tag libraries for adding these components to a JSP page. JSF also includes APIs for handling component events (such as processing component state changes and val-

## 26.5 Creating and Running a Simple Application in Java Studio Creator 2 1249

idating user input), navigating between web application pages and more. You design the look-and-feel of a page with JSF by adding tags to a JSP file and manipulating their attributes. You define the page's behavior separately in a related Java source-code file.

Though the standard JSF components are sufficient for most basic web applications, you can also write custom component libraries. Additional component libraries are available through the [Java BluePrints](#) project—which shows best practices for developing Java applications. Many other vendors provide JSF component libraries. For example, Oracle provides almost 100 components in its ADF Faces library. We discuss one such component library, the BluePrints AJAX components library ([blueprints.dev.java.net/ajax-components.html](http://blueprints.dev.java.net/ajax-components.html)). We discuss the Java BluePrints components for building AJAX-enabled JSF applications in the next chapter.

### 26.4.4 Web Technologies in Java Studio Creator 2

Java Studio Creator 2 web applications consist of one or more JSP web pages built in the JavaServer Faces framework. These JSP files have the file-name extension `.jsp` and contain the web page's GUI elements. The JSPs can also contain JavaScript to add functionality to the page. JSPs can be customized in Java Studio Creator 2 by adding JSF components, including labels, text fields, images, buttons and other GUI components. The IDE allows you to design pages visually by dragging and dropping these components onto a page; you can also customize a web page by editing the `.jsp` file manually.

Every JSP file created in Java Studio Creator 2 represents a web page and has a corresponding JavaBean class called the [page bean](#). A JavaBean class must have a default (or no-argument) constructor, and `get` and `set` methods for all of the bean's properties (i.e., instance variables). The page bean defines properties for each of the page's elements. The page bean also contains event handlers and page life-cycle methods for managing tasks such as page initialization and rendering, and other supporting code for the web application.

Every web application built with Java Studio Creator 2 has three other JavaBeans. The [RequestBean](#) object is maintained in [request scope](#)—this object exists only for the duration of an HTTP request. A [SessionBean](#) object has [session scope](#)—the object exists throughout a user's browsing session or until the session times out. There is a unique [SessionBean](#) object for each user. Finally, the [ApplicationBean](#) object has [application scope](#)—this object is shared by all instances of an application and exists as long as the application remains deployed on a web server. This object is used for application-wide data storage or processing; only one instance exists for the application, regardless of the number of open sessions.

## 26.5 Creating and Running a Simple Application in Java Studio Creator 2

Our first example displays the web server's time of day in a browser window. When run, this program displays the text "Current Time on the Web Server", followed by the web server's time. The application contains a single web page and, as mentioned previously, consists of two related files—a JSP file (Fig. 26.4) and a supporting page bean file (Fig. 26.6). The application also has the three scoped data beans for request, session, and application scopes. Since this application does not store data, these beans are not used in

**1250** Chapter 26 Web Applications: Part I

this example. We first discuss the markup in the JSP file, the code in the page bean file and the application output, then we provide step-by-step instructions for creating the program. [Note: The markup in Fig. 26.4 and other JSP file listings in this chapter is the same as the markup that appears in Java Studio Creator 2, but we have reformatted these listings for presentation purposes to make the code more readable.]

Java Studio Creator 2 generates all the markup shown in Fig. 26.4 when you set the web page's title, drag two **Static Text** components onto the page and set the properties of the **Static Text** components. **Static Text** components display text that cannot be edited by the user. We show these steps shortly.

```

## 26.5 Creating and Running a Simple Application in Java Studio Creator 2

1251

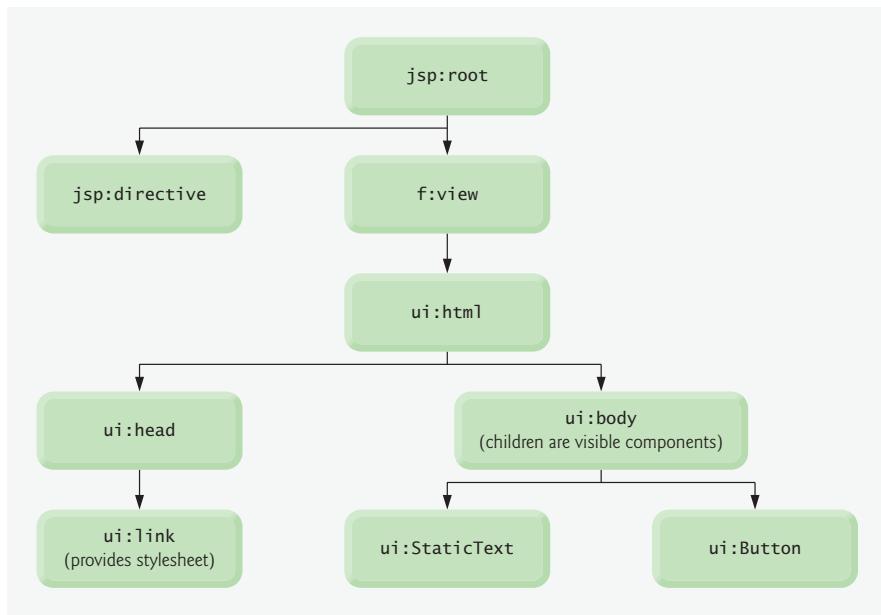

## 26.5.1 Examining a JSP File

The JSP files used in this and the following examples are generated almost entirely by Java Studio Creator 2, which provides a Visual Editor that allows you to build a page's GUI by dragging and dropping components onto a design area. The IDE generates a JSP file in response to your interactions. Line 1 of Fig. 26.4 is the XML declaration, indicating that the JSP is expressed in XML syntax and the version of XML that is used. Lines 3–5 are comments that we added to the JSP to indicate its figure number, file name and purpose.

Line 6 begins the root element for the JSP. All JSPs must have this `jsp:root` element, which has a `version` attribute to indicate the version of JSP being used (line 6) and one or more `xmlns` attributes (lines 7–10). Each `xmlns` attribute specifies a prefix and a URL for a tag library, allowing the page to use tags specified in that library. For example, line 9 allows the page to use the standard JSP elements. To use these elements, each element's tag must be preceded by the `jsp` prefix. All JSPs generated by Java Studio Creator 2 include the tag libraries specified in lines 7–10 (the JSF core components library, the JSF HTML components library, the JSP standard components library and the JSF user interface components library).

Lines 11–12 are the `jsp:directive.page` element. Its `contentType` attribute specifies the MIME type (`text/html`) and the character set (`UTF-8`) the page uses. The `pageEncoding` attribute specifies the character encoding used by the page source. These attributes help the client (typically a web browser) determine how to render the content.

All pages containing JSF components are represented in a `component tree` (Fig. 26.5) with the root JSF element `f:view`, which is of type `UIViewRoot`. This component tree

**Fig. 26.5** | Sample JSF component tree.

## 1252 Chapter 26 Web Applications: Part I

structure is represented in a JSP by enclosing all JSF component tags inside the `f:view` element (lines 13–37).

Lines 14–20 begin the definition of the JSP with the `ui:page`, `ui:html`, and `ui:head` tags, all from the `ui` (JSF user interface components) tag library. These, and many other `ui` page elements, have a `binding` attribute. For example, the `ui:head` element (line 16) has the attribute `binding = "#{Time.head}"`. This attribute uses **JSF Expression Language** notation (i.e., `#{Time.head}`) to reference the `head` property in the `Time` class that represents the page bean (you'll see this class in Fig. 26.6). It is possible to bind a single attribute of a JSP element to a property in any of the web application's JavaBeans. For instance, the `text` attribute of a `ui:label` component can be bound to a `String` property in the application's `SessionBean`. We will see an example of this in Section 26.7.2.

The `ui:head` element (lines 16–20) has a `title` attribute that specifies the page's title. This element also contains a `ui:link` element (lines 18–19) that specifies the CSS stylesheet used by the page. The `ui:body` element (lines 22–34) contains a `ui:form` element (lines 24–33), which contains two `ui:staticText` components (lines 25–28 and 29–32). These components display the page's text. The `timeHeader` component (lines 25–28) has a `text` attribute (lines 27–28) that specifies the text to display (i.e., "Current Time on the Web Server"). The `clockText` component (lines 29–32) does not specify a `text` attribute because this component's text will be set programmatically.

For the markup in this file to be displayed in a web browser, all of the JSP's elements are automatically mapped to XHTML elements that the browser recognizes. The same web component can map to different XHTML elements, depending on the client browser and the component's property settings. In this example, the `ui:staticText` components (lines 25–28, 29–32) map to XHTML `span` elements. A `span` element contains text that is displayed on a web page and is typically used to control the formatting of the text. The `style` attributes of a JSP's `ui:staticText` element will be represented as part of the corresponding `span` element's `style` attribute when the browser renders the page. We show momentarily the XHTML document that results when `Time.jsp` is requested by a browser.

### 26.5.2 Examining a Page Bean File

Figure 26.6 presents the page bean file. Line 3 indicates that this class belongs to package `webtime`. This line is autogenerated and specifies the project's name as the package name. Line 17 begins class `Time`'s declaration and indicates that it inherits from class `AbstractPageBean` (from package `com.sun.rave.web.ui.appbase`). All page bean classes that support JSP files with JSF components must inherit from the abstract class `AbstractPageBean`, which provides page life-cycle methods. Note that the IDE makes the class name match the page name. Package `com.sun.rave.web.ui.component` includes classes for many of the basic JSF components (see the `import` statements at lines 6–11 and 13).

```

1 // Fig. 26.6: Time.java
2 // Page bean file that sets clockText to the time on the web server.
3 package webtime;
4
5 import com.sun.rave.web.ui.appbase.AbstractPageBean;
6 import com.sun.rave.web.ui.component.Body;
```

101 public StaticText getTimeHeader()
102 {
103 return timeHeader;
104 } // end method getStaticText
105
106 public void setTimeHeader(StaticText st)
107 {
108 this.timeHeader = st;
109 } // end method setTimeHeader
110
111 private StaticText clockText = new StaticText();
112

```

**Fig. 26.6** | Page bean file that sets `clockText` to the time on the web server. (Part 3 of 5.)

26.5 Creating and Running a Simple Application in Java Studio Creator 2 **1255**

```

113 public StaticText getClockText()
114 {
115 return clockText;
116 } // end method getClockText
117
118 public void setClockText(StaticText st)
119 {
120 this.clockText = st;
121 } // end method setClockText
122
123 // Construct a new page bean instance.
124 public Time()
125 {
126 // empty constructor
127 } // end constructor
128
129 // Return a reference to the scoped data bean.
130 protected RequestBean getRequestBean()
131 {
132 return (RequestBean) getBean("RequestBean");
133 } // end method getRequestBean
134
135 // Return a reference to the scoped data bean.
136 protected ApplicationBean getApplicationBean()
137 {
138 return (ApplicationBean) getBean("ApplicationBean");
139 } // end method getApplicationBean
140
141 // Return a reference to the scoped data bean.
142 protected SessionBean getSessionBean()
143 {
144 return (SessionBean) getBean("SessionBean");
145 } // end method getSessionBean
146
147 // initializes page content
148 public void init()
149 {
150 super.init();
151 try
152 {
153 _init();
154 } // end try
155 catch (Exception e)
156 {
157 log("Time Initialization Failure", e);
158 throw e instanceof FacesException ? (FacesException) e:
159 new FacesException(e);
160 } // end catch
161 } // end method init
162
163 // method called when a postback occurs.
164 public void preprocess()
165 {

```

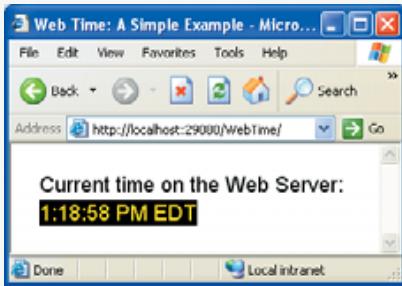

**Fig. 26.6** | Page bean file that sets `clockText` to the time on the web server. (Part 4 of 5.)

**1256**    Chapter 26  Web Applications: Part I

```

166 // empty body
167 } // end method preprocess
168
169 // method called before the page is rendered.
170 public void prerender()
171 {
172 clockText.setValue(DateFormat.getTimeInstance(
173 DateFormat.LONG).format(new Date()));
174 } // end method prerender
175
176 // method called after rendering completes, if init was called.
177 public void destroy()
178 {
179 // empty body
180 } // end method destroy
181 } // end class Time

```

**Fig. 26.6** | Page bean file that sets `clockText` to the time on the web server. (Part 5 of 5.)

This page bean file provides `get` and `set` methods for every element of the JSP file of Fig. 26.4. These methods are generated automatically by the IDE. We included the complete page bean file in this first example, but in future examples these properties and their `get` and `set` methods will be omitted to save space. Lines 99–109 and 111–121 of the page bean file define the two **Static Text** components that we dropped onto the page and their `get` and `set` methods. These components are objects of class `StaticText` in package `com.sun.rave.web.ui.component`.

The only logic required in this page is to set the `clockText` component's text to read the current time on the server. We do this in the `prerender` method (lines 170–174). The meaning of this and other page bean methods will be discussed shortly. Lines 172–173 fetch and format the time on the server and set the value of `clockText` to that time.

### 26.5.3 Event-Processing Life Cycle

Java Studio Creator 2's application model places several methods in the page bean that tie into the JSF **event-processing life cycle**. These methods represent four major stages—initialization, preprocessing, prerendering and destruction. Each corresponds to a method in the page bean class—`init`, `preprocess`, `prerender` and `destroy`, respectively. Java Studio Creator 2 automatically creates these methods, but you can customize them to handle life-cycle processing tasks, such as rendering an element on a page only if a user clicks a button.

## 26.5 Creating and Running a Simple Application in Java Studio Creator 2 1257

The **`init`** method (Fig. 26.6, lines 148–161) is called by the JSP container the first time the page is requested and on postbacks. A **`postback`** occurs when form data is submitted, and the page and its contents are sent to the server to be processed. Method `init` invokes its superclass version (line 150) then tries to call the method `_init` (declared in lines 22–25). The `_init` method is also automatically generated and handles component initialization tasks (if there are any), such as setting the options for a group of radio buttons.

The **`preprocess`** method (lines 164–167) is called after `init`, but only if the page is processing a postback. The **`prerender`** method (lines 170–174) is called just before a page is rendered (i.e., displayed) by the browser. This method should be used to set component properties; properties that are set sooner (such as in method `init`) may be overwritten before the page is actually rendered by the browser. For this reason, we set the value of `clockText` in the `prerender` method.

Finally, the **`destroy`** method (lines 177–180) is called after the page has been rendered, but only if the `init` method was called. This method handles tasks such as freeing resources used to render the page.

### 26.5.4 Relationship Between the JSP and Page Bean Files

The page bean has a property for every element that appears in the JSP file of Fig. 26.4, from the `html` element to the two `Static Text` components. Recall that the elements in the JSP file were explicitly bound to these properties by each element's `binding` attribute using a JSF Expression Language statement. Because this is a JavaBean class, `get` and `set` methods for each of these properties are also included (lines 27–121). This code is automatically generated by the IDE for every web application project.

### 26.5.5 Examining the XHTML Generated by a Java Web Application

Figure 26.7 shows the XHTML generated when `Time.jsp` (Fig. 26.4) is requested by a client web browser. To view this XHTML, select **View > Source** in Internet Explorer. [Note: We added the XHTML comments in lines 3–4 and reformatted the XHTML to conform to our coding conventions.]

The XHTML document in Fig. 26.7 is similar in structure to the JSP file of Fig. 26.4. Lines 5–6 are the document type declaration, which declares this document to be an `XHTML 1.0 Transitional` document. The `ui:meta` tags in lines 9–13 are equivalent to HTTP headers and are used to control browser behavior.

```

1 <?xml version = "1.0"?>
2
3 <!-- Fig. 26.7: Time.html -->
4 <!-- The XHTML response generated when the browser requests Time.jsp. -->
5 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
6 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
7 <html xmlns = "http://www.w3.org/1999/xhtml">
8 <head>
9 <meta content = "no-cache" http-equiv = "Pragma" />
10 <meta content = "no-cache" http-equiv = "Cache-Control" />
11 <meta content = "no-store" http-equiv = "Cache-Control" />
```

```

12 <meta content = "max-age=0" http-equiv = "Cache-Control" />
13 <meta content = "1" http-equiv = "Expires" />
14 <title>Web Time: A Simple Example</title>
15 <script type = "text/javascript"
16 src = "/WebTime/theme/com/sun/rave/web/ui/defaulttheme/
17 javascript/formElements.js"></script>
18 <link rel = "stylesheet" type = "text/css" href = "/WebTime/theme/
19 com/sun/rave/web/ui/defaulttheme/css/css_master.css" />
20 <link rel = "stylesheet" type = "text/css" href = "/WebTime/theme/
21 com/sun/rave/web/ui/defaulttheme/css/css_ie55up.css" />
22 <script type = "text/javascript">
23 var sjwuic_ScrollCookie = new sjwuic_ScrollCookie(
24 '/Time.jsp', '/WebTime/faces/Time.jsp');
25 </script>
26 <link id = "link" rel = "stylesheet" type = "text/css"
27 href = "/WebTime/resources/styleSheet.css" />
28 </head>
29 <meta id = "_id0" http-equiv = "refresh" content = "5" />
30 <body id = "body" style = "-rave-layout: grid">
31 <form id = "form" class = "form" method = "post"
32 action = "/WebTime/faces/Time.jsp"
33 enctype = "application/x-www-form-urlencoded">
34 <span id = "form:timeHeader" style = "font-size: 18px; left: 24px;
35 top: 24px; position: absolute">Current time on the Web Server:
36
37 <span id = "form:clockText" style = "background-color: black;
38 color: yellow; font-size: 18px; left: 24px; top: 48px; position:
39 absolute">1:18:58 AM EDT
40 <input id = "form_hidden" name = "form_hidden"
41 value = "form_hidden" type = "hidden" />
42 </form>
43 </body>
44 </html>
```

**Fig. 26.7** | XHTML response generated when the browser requests *Time.jsp*. (Part 2 of 2.)

Lines 30–43 define the body of the document. Line 31 begins the **form**, a mechanism for collecting user information and sending it to the web server. In this particular program, the user does not submit data to the web server for processing; however, processing user data is a crucial part of many web applications that is facilitated by forms. We demonstrate how to submit data to the server in later examples.

XHTML forms can contain visual and nonvisual components. Visual components include clickable buttons and other GUI components with which users interact. Nonvisual components, called **hidden form elements**, store data, such as e-mail addresses, that the document author specifies. One of these hidden inputs is defined in lines 40–41. We discuss the precise meaning of this hidden input later in the chapter. Attribute **method** of the **form** element (line 31) specifies the method by which the web browser submits the form to the server. By default, JSPs use the **post** method. The two most common **HTTP request types** (also known as **request methods**) are **get** and **post**. A **get** request gets (or retrieves) information from a server. Such requests often retrieve an HTML document or an image. A **post** request posts (or sends) data to a server, such as authentication informa-

## 26.5 Creating and Running a Simple Application in Java Studio Creator 2 1259

tion or data from a form that gathers user input. Usually, post requests are used to post a message to a news group or a discussion forum, pass user input to a data-handling process on the server and store or update the data on a server. The form's `action` attribute (line 32) identifies the resource that will be requested when this form is submitted—in this case, `/WebTime/faces/Time.jsp`.

Note that the two **Static Text** components (i.e., `timeHeader` and `clockText`) are represented by two span elements in the XHTML document (lines 34–36, 37–39) as previously discussed. The formatting options that were specified as properties of `timeHeader` and `clockText`, such as the font size and text color in the components, are now specified in each span element's `style` attribute.

### 26.5.6 Building a Web Application in Java Studio Creator 2

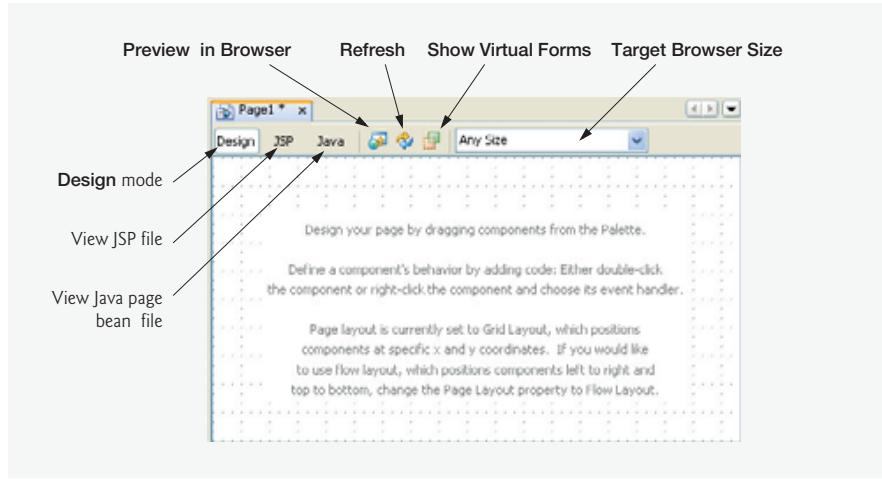

Now that we have presented the JSP file, the page bean file and the resulting XHTML web page sent to the web browser, we discuss the steps to create this application. To build the `WebTime` application, perform the following steps in Java Studio Creator 2:

#### *Step 1: Creating the Web Application Project*

Select **File > New Project...** to display the **New Project** dialog. In this dialog, select **Web** in the **Categories** pane, **JSF Web Application** in the **Projects** pane and click **Next**. Change the project name to `WebTime` and use the default project location and Java package. These settings will create a `WebTime` directory in your `My Documents\Creator\Projects` directory to store the project's files. Click **Finish** to create the web application project.

#### *Step 2: Examining the Visual Editor Window of the New Project*

The next several figures describe important features of the IDE, beginning with the **Visual Editor** window (Fig. 26.8). Java Studio Creator 2 creates a single web page named `Page1` when a new project is created. This page is open by default in the Visual Editor in **Design mode** when the project first loads. As you drag and drop new components onto the page,

**Fig. 26.8** | Visual Editor window in **Design mode**.

**1260**    Chapter 26 Web Applications: Part I

**Design** mode allows you to see how your page will be rendered in the browser. The JSP file for this page, named `Page1.jsp`, can be viewed by clicking the **JSP** button at the top of the Visual Editor or by right clicking anywhere in the Visual Editor and selecting **Edit JSP Source**. As mentioned previously, each web page is supported by a page bean file. Java Studio Creator 2 creates a file named `Page1.java` when a new project is created. To open this file, click the **Java** button at the top of the Visual Editor or right click anywhere in the Visual Editor and select **Edit Page1 Java Source**.

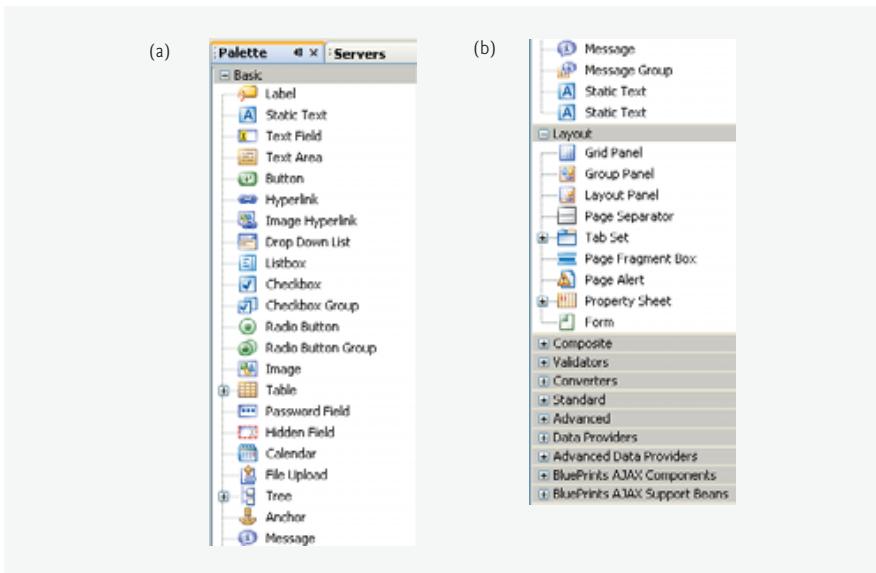

The **Preview in Browser** button at the top of the Visual Editor window allows you to view your pages in a browser without having to build and run the application. The **Refresh** button redraws the page in the Visual Editor. The **Show Virtual Forms** button allows you to see which form elements are participating in virtual forms (we discuss this concept in Chapter 27). The **Target Browser Size** drop-down list lets you specify the optimal browser resolution for viewing the page and lets you see what the page will look like in different screen resolutions.

#### *Step 3: Examining the Palette in Java Studio Creator 2*

Figure 26.9 shows the **Palette** displayed in the IDE when the project loads. Part (a) displays the beginning of the **Basic** list of web components, and part (b) displays the remaining **Basic** components, as well as the list of **Layout** components. We discuss specific components in Fig. 26.9 as they are used throughout the chapter.

#### *Step 4: Examining the Projects Window*

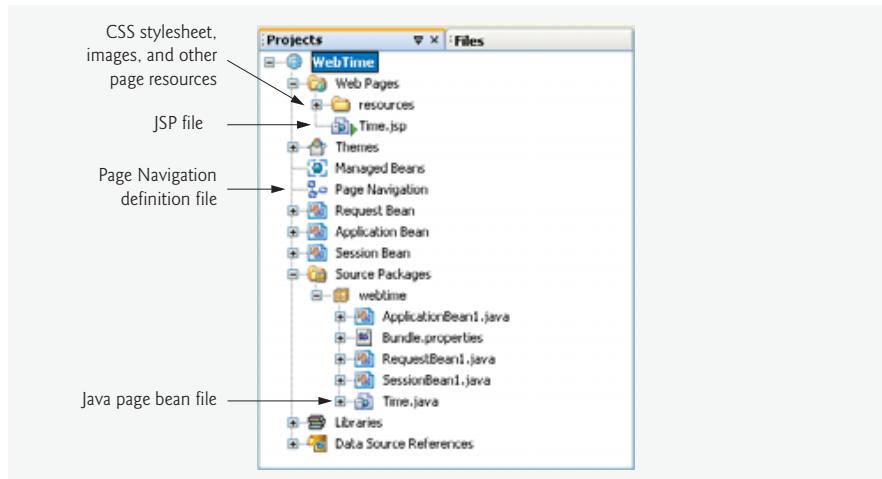

Figure 26.10 displays the **Projects** window, which appears in the lower-right corner of the IDE. This window displays the hierarchy of all files included in the project. The JSP files for each page are listed under the **Web Pages** node. This node also includes the **resources**

**Fig. 26.9** | **Palette** in Java Studio Creator 2.

## 26.5 Creating and Running a Simple Application in Java Studio Creator 2

1261

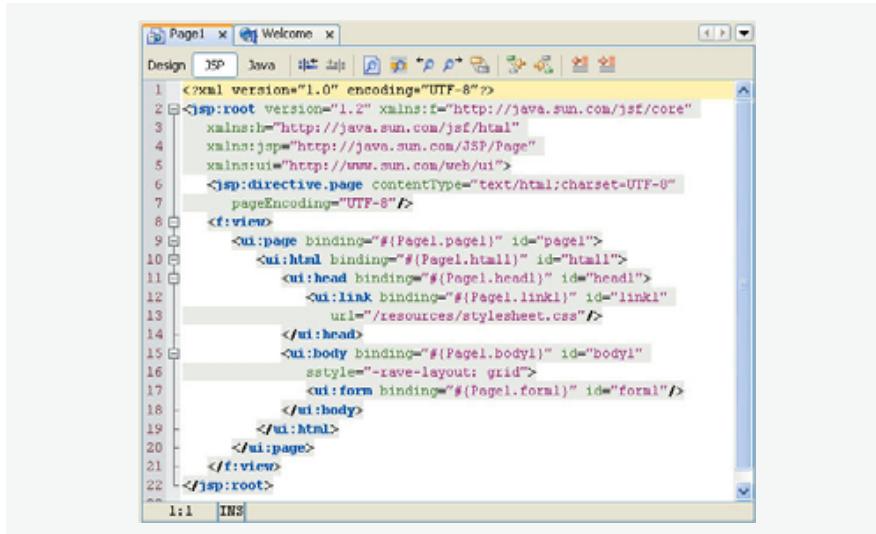

**Fig. 26.10** | Projects window for the WebTime project.

folder, which contains the CSS stylesheet for the project and any other files the pages may need to display properly, such as image files. All of the Java source code, including the page bean file for each web page and the application, session and request scope beans, can be found under the **Source Packages** node. Another useful file displayed in the project window is the **Page Navigation** file, which defines rules for navigating the project's pages based on the outcome of some user-initiated event, such as clicking a button or a link. The **Page Navigation** file can also be accessed by right clicking in the Visual Editor while in **Design** mode and selecting **Page Navigation....**

#### Step 5: Examining the JSP and Java Files in the IDE

Figure 26.11 displays `Page1.jsp`—the JSP file generated by Java Studio Creator 2 for `Page1`. [Note: We reformatted the code to match our coding conventions.] Click the **JSP** button at the top of the Visual Editor to open the JSP file. When it is first created, this file contains some tags for setting up the page, including linking to the page's stylesheet and defining the necessary JSF libraries. Otherwise, the JSP file's tags are empty, as no components have been added to the page yet.

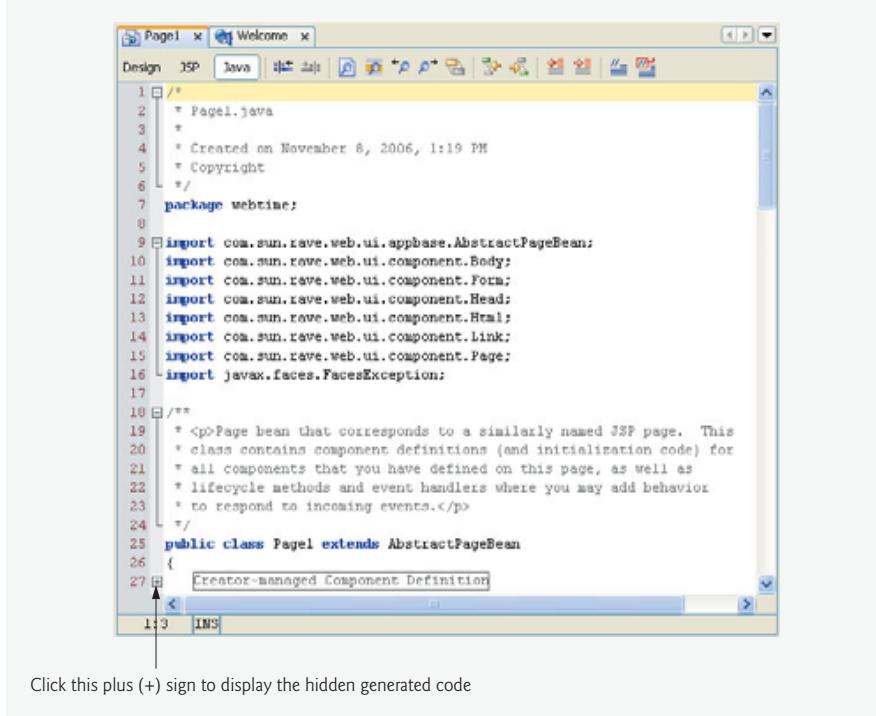

Figure 26.12 displays part of `Page1.java`—the page bean file generated by Java Studio Creator 2 for `Page1`. Click the **Java** button at the top of the Visual Editor to open the page bean file. This file contains a Java class with the same name as the page (i.e., `Page1`), which extends the class `AbstractPageBean`. As previously mentioned, `AbstractPageBean` has several methods that manage the page's life cycle. Four of these methods—`init`, `preprocess`, `prerender` and `destroy`—are overridden by `Page1.java`. Other than method `init`, these methods are initially empty. They serve as placeholders for you to customize the behavior of your web application. The page bean file also includes `get` and `set` methods for all of the page's elements—`page`, `html`, `head`, `body` and `link` to start. You can view these `get` and `set` methods by clicking the plus (+) sign on the line that says **Creator-managed Component Definition**.

**Fig. 26.12** | Page bean file for Page1.jsp generated by Java Studio Creator 2.

26.5 Creating and Running a Simple Application in Java Studio Creator 2 **1263****Step 6: Renaming the JSP and JSF Files**

Typically, you'll want to rename the JSP and Java files in your project, so that their names are relevant to your application. Right click the `Page1.jsp` file in the **Projects Window** and select **Rename** to display the **Rename** dialog. Enter the new file name `Time`. If **Preview All Changes** is checked, the **Refactoring Window** will appear at the bottom of the IDE when you click **Next >**. **Refactoring** is the process of modifying source code to improve its readability and reusability without changing its behavior—for example, by renaming methods or variables, or breaking long methods into shorter ones. Java Studio Creator 2 has built-in refactoring tools that automate some refactoring tasks. Using these tools to rename the project files updates the name of both the JSP file and the page bean file. The refactoring tool also changes the class name in the page bean file and all of the attribute bindings in the JSP file to reflect the new class name. Note that none of these changes will be made until you click **Do Refactoring** in the **Refactoring Window**. If you do not preview the changes, refactoring occurs when you click **Next >** in the **Rename** dialog.

**Step 7: Changing the Title of the Page**

Before designing the content of the web page, we give it the title "Web Time: A Simple Example". By default, the page does not have a title when it is generated by the IDE. To add a title, open the JSP file in **Design** mode. In the **Properties** window, enter the new title next to the **Title** property and press *Enter*. View the JSP to see that the attribute `title = "Web Time: A Simple Example"` was automatically added to the `ui:head` tag.

**Step 8: Designing the Page**

Designing a web page is simple in Java Studio Creator 2. To add components to the page, you can drag and drop them from the **Palette** onto the page in **Design** mode. Like the web page itself, each component is an object that has properties, methods and events. You can set these properties and events visually using the **Properties** window or programmatically in the page bean file. *Get* and *set* methods are automatically added to the page bean file for each component you add to the page.

The IDE generates the JSP tags for the components you drag and drop using a grid layout, as specified in the `ui:body` tag. This means that components will be rendered to the browser using **absolute positioning**, so that they appear exactly where they are dropped on the page. As you add components to the page, the `style` attribute in each component's JSP element will include the number of pixels from the top and left margins of the page at which the component is positioned.

In this example, we use two **Static Text** components. To add the first one to the web page, drag and drop it from the **Palette**'s **Basic** components list to the page in **Design** mode. Edit the component's text by typing "Current time on the Web Server:" directly into the component. The text can also be edited by changing the component's `text` property in the **Properties** window. Java Studio Creator 2 is a **WYSIWYG (What You See Is What You Get)** editor—whenever you make a change to a web page in **Design** mode, the IDE creates the markup (visible in **JSP** mode) necessary to achieve the desired visual effects seen in **Design** mode. After adding the text to the web page, switch to **JSP** mode. You should see that the IDE added a `ui:staticText` element to the page body, which is bound to the object `staticText1`, in the page bean file and whose `text` attribute matches the text you just entered. Back in **Design** mode, click the **Static Text** component to select it. In the **Properties** window, click the ellipsis button next to the `style` property to open a dialog box

**1264** Chapter 26 Web Applications: Part I

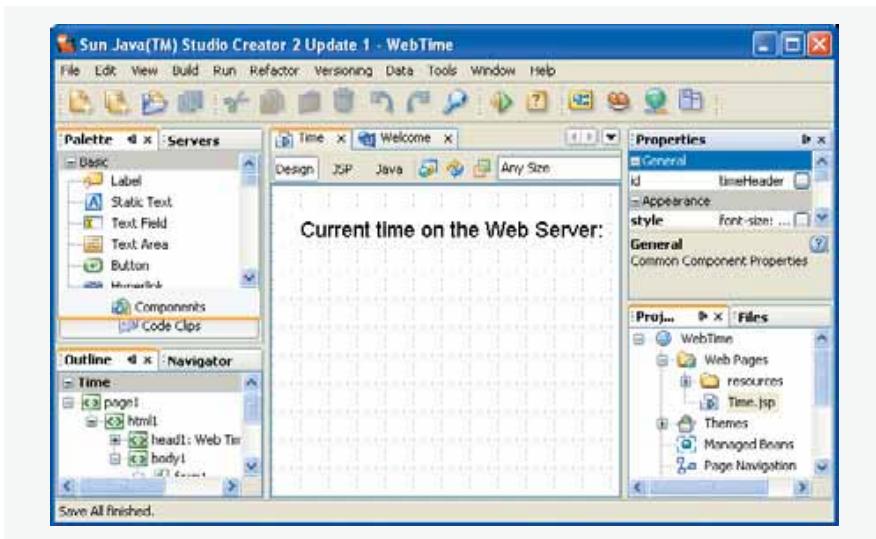

to edit the text's style. Select 18 px for the font size and click **OK**. Again in the **Properties** window, change the **id** property to **timeHeader**. Setting the **id** property also changes the name of the component's corresponding property in the page bean and updates its **binding** attribute in the JSP accordingly. Notice that **font-size: 18 px** has been added to **style** attribute and the **id** attribute has been changed to **timeHeader** in the component's tag in the JSP file. The IDE should now appear as in Fig. 26.13.

Drop a second **Static Text** component onto the page and set its **id** to **clockText**. Edit its **style** property so that the font size is 18 px, the text color is yellow, and the background color is black. Do not edit the component's text, as this will be set programmatically in the page bean file. The component will display with the text **Static Text** in the IDE, but will not display any text at runtime unless the text is set programmatically. Figure 26.14 shows the IDE after the second component is added.

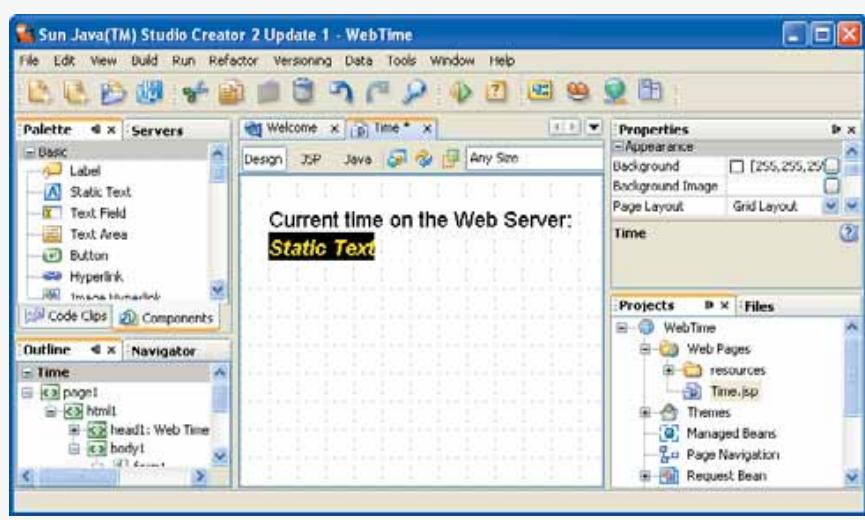

**Step 9: Adding Page Logic**

After designing the user interface, you can modify the page bean file to set the text of the **clockText** element. In this example, we add a statement to method **prerender** (lines 170–174 of Fig. 26.6). Recall that we use method **prerender** to ensure that **clockText** will be updated each time the page is refreshed. Lines 172–173 of Fig. 26.6 programmatically set the text of **clockText** to the current time on the server.

We would like this page to refresh automatically to display an up-to-date time. To accomplish this, add the empty tag `<ui:meta content = "60" httpEquiv = "refresh" />` to the JSP file, between the end of the **ui:head** tag and the beginning of the **ui:body** tag. This tag tells browser to reload the page automatically every 60 seconds. You can also add this tag by dragging a **Meta** component from the **Advanced** section of the **Palette** to your page, then setting the component's **content** attribute to 60 and its **httpEquiv** attribute to **refresh**.

**Fig. 26.13** | Time.jsp after inserting the first **Static Text** component.

26.5 Creating and Running a Simple Application in Java Studio Creator 2 **1265**

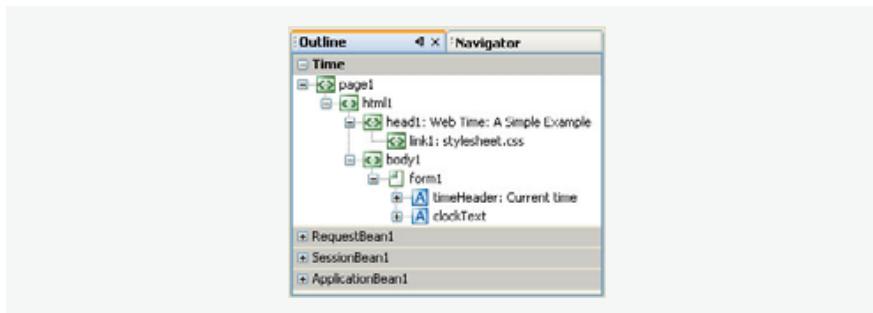

**Fig. 26.14** | Time.jsp after adding the second Static Text component.

#### Step 10: Examining the Outline Window

Figure 26.15 displays the **Outline window** in Java Studio Creator 2. The project's four Java files are displayed as gray nodes. The **Time** node representing the page bean file is expanded and shows the contents of the component tree. The request, session and application scope beans are collapsed by default, as we have not added any properties to these beans in this example. Clicking an item in the page's component tree selects the item in the Visual Editor.

#### Step 11: Running the Application

After creating the web page, you can view it several ways. First, you can select **Build > Build Main Project**, and after the build completes, select **Run > Run Main Project**, to run the application in a browser window. You can run a project that has already been built by pressing the **Run Main Project** icon ( ) in the toolbar at the top of the IDE. Note that if changes

**Fig. 26.15** | Outline window in Java Studio Creator 2.

**1266** Chapter 26 Web Applications: Part I

are made to a project, the project must be rebuilt before they will be reflected when the application is viewed in a browser. Because this application was built on the local file system, the URL displayed in the address bar of the browser when the application is run will be `http://localhost:29080/WebTime/` (Fig. 26.6), where 29080 is the port number on which Java Studio Creator 2's built-in test server—**Sun Application Server 8**—runs by default. When you run a program on the test server, a tray icon appears near the bottom-right of your screen to show that the Sun Application Server is running. To shut down the server after you exit Java Studio Creator 2, right click the tray icon and select **Stop Domain creator**.

Alternatively, you can press **F5** to build the application, then run it in debug mode—the Java Studio Creator 2 built-in debugger can help you troubleshoot applications. If you type `<Ctrl> F5`, the program executes without debugging enabled.

**Error-Prevention Tip 26.1**

*If you have trouble building your project due to errors in the Java Studio Creator-generated XML files used for building, try cleaning the project and building again. You can do this by selecting Build > Clean and Build Main Project or by pressing <Alt> B.*

Finally, you can run your built application by opening a browser window and typing the web page's URL in the **Address** field. Since your application resides on the local file system, you must first start the Sun Application Server. If you have previously run the application using one of the methods above, the server will already be started. Otherwise, you can start the server from the IDE by opening the **Servers** tab (located in the same panel as the **Palette**), right clicking the **Deployment Server**, selecting **Start/Stop Server**, and clicking **Start** in the dialog that appears. Then you can type the URL (including the port number for the application server, 29080) in the browser to execute the application. For this example it is not necessary to type the entire URL, `http://localhost:29080/WebTime/faces/Time.jsp`. The path to the file `Time.jsp` (i.e., `faces/Time.jsp`) can be omitted, because this file was set by default as the project's start page. For projects with multiple pages, you can change the start page by right clicking the desired page in the **Projects** window and selecting **Set As Start Page**. The start page is indicated by a green arrow next to the page's name in the **Projects** window. [Note: If you use the Netbeans Visual Web Pack 5.5, the port number will depend on the server to which you deploy your web application. Also, the **Servers** tab is called **Runtime** in Netbeans.]

## 26.6 JSF Components

This section introduces some of the JSF components featured in the **Palette** (Fig. 26.9). Figure 26.16 summarizes some of the JSF components used in the chapter examples.

JSF Components	Description
<b>Label</b>	Displays text that can be associated with an input element.
<b>Static Text</b>	Displays text that the user cannot edit.
<b>Text Field</b>	Gathers user input and displays text.

**Fig. 26.16** | Commonly used JSF components. (Part I of 2.)

26.6 JSF Components **1267**

JSF Components	Description
Button	Triggers an event when clicked.
Hyperlink	Displays a hyperlink.
Drop Down List	Displays a drop-down list of choices.
Radio Button Group	Groups radio buttons.
Image	Displays images (e.g., GIF and JPG).

**Fig. 26.16** | Commonly used JSF components. (Part 2 of 2.)**26.6.1 Text and Graphics Components**

Figure 26.17 displays a simple form for gathering user input. This example uses all the components listed in Fig. 26.16, except Label, which you will see in later examples. All the code in Fig. 26.17 was generated by Java Studio Creator 2 in response to actions performed in Design mode. This example does not perform any tasks when the user clicks Register. We ask you to add functionality to this example as an exercise. In successive examples, we demonstrate how to add functionality to many of these JSF components.

**Fig. 26.17** | Registration form that demonstrates JSF components. (Part 3 of 3.)

**1270** Chapter 26 Web Applications: Part I

Before discussing the JSF components used in this JSP file, we explain the XHTML that creates the layout in Fig. 26.17. As discussed previously, Java Studio Creator 2 uses absolute positioning, so components are rendered wherever they were dropped in the Visual Editor. In this example, in addition to absolute positioning, we use a **Grid Panel** component (lines 31–52) from the **Palette's Layout** component group. The **h:** prefix indicates that it can be found in the JSF HTML tag library. This component, an object of class **HtmlPanelGrid** in package **javax.faces.component.html**, controls the positioning of the components it contains. The **Grid Panel** component allows the designer to specify the number of columns the grid should contain. Components may then be dropped anywhere inside the panel, and they will automatically be repositioned into evenly spaced columns in the order in which they are dropped. When the number of components exceeds the number of columns, the panel moves the additional components to a new row. In this way, the **Grid Panel** behaves like an XHTML table, and is in fact rendered to the browser as an XHTML table. In this example, we use the **Grid Panel** to control the positions of the **Image** and **Text Field** components in the user information section of the page.

#### *Adding a Formatting Component to a Web Page*

To create the layout for the **User Information** section of the form shown in Fig. 26.17, drag a **Grid Panel** component onto the page. In the **Properties** window, set the component's **columns** property to 4. The component also has properties to control the cell padding, cell spacing and other elements of the component's appearance. In this case, accept the defaults for these properties. Now you can simply drag the **Images** and **Text Fields** for user information into the **Grid Panel**. The **Grid Panel** will manage their spacing and their organization into rows and columns.

#### *Examining Web Components on a Sample Registration Form*

Lines 28–30 of Fig. 26.17 define an **Image** component, an object of class **Image** which inserts an image into a web page. The images used in this example are located in this chapter's examples directory. Images to be displayed on a web page must be placed in the project's resources folder. To add images to the project, drop an **Image** component onto the page and click the ellipsis button next to the **url** property in the **Properties** window. This opens a dialog in which you can select the image to display. Since no images have been added to the resources folder yet, click the **Add File** button, locate the image on your computer's file system and click **Add File**. This copies the file you selected into the project's resources directory. Now you can select the image from the list of files in the resources folder and click **OK** to insert the image into the page.

Lines 31–52 contain an **h:panelGrid** element representing the **Grid Panel** component. Within this element, there are eight **Image** and **Text Field** components. **Text Fields** allow you to obtain text input from the user. For example, lines 37–38 define a **Text Field** control used to collect the user's first name. Lines 49–51 define a **Text Field** with the **label** property set to "Must be in the form (555) 555-5555". Setting the **label** property of a **Text Field** places text directly above the **Text Field**. Alternatively, you can label a **Text Field** by dragging and dropping a **Label** component onto the page, which allows you to customize the **Label**'s position and style.

The order in which **Text Fields** are dragged to the page is important, because their JSP tags are added to the JSP file in that order. When a user presses the *Tab* key to navigate between input fields, they will navigate the fields in the order in which the JSP tags occur

26.6 JSF Components **1271**

in the JSP file. To specify the navigation order, you should drag components onto the page in that order. Alternatively, you can set each input field's **Tab Index** property in the **Properties** window to control the order in which the user will tab through the fields. A component with a tab index of 1 will be the first in the tab sequence.

Lines 62–65 define a **Drop Down List**. When a user clicks the drop-down list, it expands and displays a list from which the user can make a selection. This component is an object of class `DropDownList` and is bound to the object `booksDropDown`, a `SingleSelectOptionsList` object that controls the list of options. This object can be configured automatically by right clicking the drop-down list in **Design** mode and selecting **Configure Default Options**, which opens the **Options Customizer** dialog box to add options to the list. Each option consists of a display `String` that will represent the option in the browser and a value `String` that will be returned when programmatically retrieving the user's selection from the drop-down list. Java Studio Creator 2 constructs the `SingleSelectOptionsList` object in the page bean file based on the display-value pairs entered in the **Options Customizer** dialog box. To view the code that constructs the object, close the dialog box by clicking **OK**, open the page bean file, and expand the **Creator-managed Component Definition** node near the top of the file. The object is constructed in the `_init` method, which is called from method `init` the first time the page loads.

The **Hyperlink** component (lines 66–70) of class `Hyperlink` adds a link to a web page. The `url` property of this component specifies the resource (`http://www.deitel.com` in this case) that is requested when a user clicks the hyperlink. Setting the `target` property to `_blank` specifies that the requested web page should open in a new browser window. By default, **Hyperlink** components cause pages to open in the same browser window.

Lines 78–82 define a **Radio Button Group** component of class `RadioButtonGroup`, which provides a series of radio buttons from which the user can select only one. Like **Drop Down List**, a **Radio Button Group** is bound to a `SingleSelectOptionList` object. The options can be edited by right clicking the component and selecting **Configure Default Options**. Also like the drop-down list, the `SingleSelectOptionsList` constructor is automatically generated by the IDE and placed in the `_init` method of the page bean class.

The final web control in Fig. 26.17 is a **Button** (lines 83–85), a JSF component of class `Button` that triggers an action when clicked. A **Button** component typically maps to an `input` XHTML element with attribute `type` set to `submit`. As stated earlier, clicking the **Register** button in this example does not do anything.

### 26.6.2 Validation Using Validator Components and Custom Validators

This section introduces form **validation**. Validating user input is an important step in collecting information from users. Validation helps prevent processing errors due to incomplete or improperly formatted user input. For example, you may perform validation to ensure that all required fields have been filled out or that a ZIP-code field contains exactly five digits. Java Studio Creator 2 provides three validator components. A **Length Validator** determines whether a field contains an acceptable number of characters. **Double Range Validators** and **Long Range Validators** determine whether numeric input falls within acceptable ranges. Package `javax.faces.validators` contains the classes for these validators. Studio Creator 2 also allows custom validation with validator methods in the page bean file. The following example demonstrates validation using both a validator component and custom validation.

**1272**    [Chapter 26](#) [Web Applications: Part I](#)***Validating Form Data in a Web Application***

The example in this section prompts the user to enter a name, e-mail address and phone number. After the user enters any data, but before the data is sent to the web server, validation ensures that the user entered a value in each field, that the entered name does not exceed 30 characters, and that the e-mail address and phone number values are in an acceptable format. In this example, (555) 123-4567, 555-123-4567 and 123-4567 are all considered valid phone numbers. Once the data is submitted, the web server responds by displaying an appropriate message and a **Grid Panel** component repeating the submitted information. Note that a real business application would typically store the submitted data in a database or in a file on the server. We simply send the data back to the page to demonstrate that the server received the data.

***Building the Web Page***

This web application introduces two additional JSF components—**Label** and **Message** from the **Basic** section of the **Palette**. Each of the page's three text fields should have its own label and message. **Label** components describe other components and can be associated with user input fields by setting their **for** property. **Message** components display error messages when validation fails. This page requires three **Text Fields**, three **Labels** and three **Messages**, as well as a submit **Button**. To associate the **Label** components and **Message** components with their corresponding **Text Field** components, hold the *Ctrl* and *Shift* keys, then drag the label or message to the appropriate **Text Field**. In the **Properties** window, notice that each **Label** and **Message** component's **for** property is set to the appropriate **Text Field**.

You should also add a **Static Text** component to display a validation success message at the bottom of the page. Set the text to "Thank you for your submission. <br/>We received the following information:" and change the component's id to **resultText**. In the **Properties** window, unset the component's **rendered** and **escaped** properties. The **rendered** property controls whether the component will be displayed the first time the page loads. Setting **escaped** to **false** enables the browser to recognize the **<br/>** tag so it can start a new line of text rather than display the characters "**<br/>**" in the web page.

Finally, add a **Grid Panel** component below the **resultText** component. The panel should have two columns, one for displaying **Static Text** components that label the user's validated data, and one for displaying **Static Text** components that echo back that data.

The JSP file for this page is displayed in Fig. 26.18. Lines 30–34, 35–39 and 40–44 define **ui:textFields** for retrieving the user's name, e-mail address and phone number, respectively. Lines 45–48, 49–53, and 54–58 define **ui:labels** for each of these text fields. Lines 63–74 define the text fields' **ui:message** elements. Lines 59–62 define a **Submit ui:button**. Lines 75–80 create a **ui:staticText** named **resultText** that displays the response from the server when the user successfully submits the form, and lines 81–101 define a **ui:panelGrid** that contains components for echoing validated user input to the browser.

***Setting the Required Property of an Input Component***

Ensuring that the user has made a selection or entered some text in a required input element is a basic type of validation. This is accomplished by checking the **required** box in the element's **Properties** window. If you add a validator component or custom validator method to an input field, the field's **required** property must be set to **true** for validation

26.6 JSF Components **1273**

to occur. Notice that the three input `ui:textFields` in this example (Fig. 26.18, lines 30–44) all have their `required` property set to `true`. Also note in the Visual Editor that the label for a required field is automatically marked by a red asterisk. If a user submits this form with empty text fields, the default error message for a required field will be displayed in the empty field's associated `ui:message` component.

Validation - Microsoft Internet Explorer

Please fill out the following form.  
All fields are required and must contain valid information.

* Name:	<input type="text" value="Mr. Robert William Charles White, Sr."/>	Validation Error: Value is greater than allowable maximum of '30'
* Email address:	<input type="text" value="bwhite"/>	Enter a valid email address, e.g. user@domain.com
* Phone number:	<input type="text" value="55-1234"/>	Enter a valid phone number, e.g. (555) 555-1234
<input type="button" value="Submit"/>		

(d)

Validation - Microsoft Internet Explorer

Please fill out the following form.  
All fields are required and must contain valid information.

* Name:	<input type="text" value="Bob White"/>
* Email address:	<input type="text" value="bwhite@email.com"/>
* Phone number:	<input type="text" value="(555) 555-1234"/>
<input type="button" value="Submit"/>	

Thank you for your submission.  
We received the following information:

Name:	E-mail address:
Phone number:	Bob White
bwhite@email.com	(555) 555-1234

**Fig. 26.18** | JSP that demonstrates validation of user input. (Part 4 of 4.)

### ***Using the LengthValidator Component***

In this example, we use the **Length Validator** component (found in the **Validators** section of the **Palette**) to ensure that the length of the user's name does not exceed 30 characters. This might be useful to ensure that a value will fit in a particular database field.

To add a **Length Validator** to a component, simply drag the validator from the **Palette** and drop it onto the field to validate. A **lengthValidator** node will appear in the **Validation** section of the **Outline** window. To edit the validation component's properties, click this node and set the **maximum** and **minimum** properties to the desired number of characters in the **Properties** window. Here, we set only the **maximum** property to 30. We also changed the component's **id** to **nameLengthValidator**. Notice that the **nameTF** input field in the JSP file has been bound to the **validate** method of the property **nameLengthValidator** in the page bean file (lines 33–34).

This validator allows users to type as much text in the field as they wish, and if they exceed the limit, the default length validation error message will be displayed in the field's **ui:message** component after the user clicks the **Submit** button. It is possible to limit the length of user input without using validation. By setting a **Text Field**'s **maxLength** property, the **Text Field**'s cursor will not advance beyond the maximum allowable number of characters, so the user cannot submit data that exceeds the length limit.

### ***Using Regular Expressions to Perform Custom Validation***

Some of the most common validation tasks involve checking user input for appropriate formatting. For instance, it may be necessary to check user-entered email addresses and telephone numbers to ensure that they conform to the standard formatting for valid email addresses and phone numbers. Matching user input against a regular expression is an effective way to ensure that the input is properly formatted. (We discuss regular expressions in Section 30.7.) Java Studio Creator 2 does not provide components for validation using regular expressions, so we will add our own custom validator methods to the page bean file. To add a custom validator to an input component, right-click the component and select **Edit Event Handler > validate**. This creates a validation method for the component with an empty body in the page bean file. We'll add code to this method shortly. Note that both **emailTF** and **phoneTF**'s **validate** attributes are bound to their respective custom validation methods in the page bean file (lines 38–39 and 43–44).

### ***Examining the Page Bean File for a Form That Receives User Input***

Figure 26.19 contains the page bean file for the JSP file in Fig. 26.18. Line 33 sets the maximum length for the **nameLengthValidator**, which is a property of this page bean. Recall that the **name** text field was bound to this property in the JSP file. Method **emailTF\_validate** (lines 398–410) and **phoneTF\_validate** (lines 414–426) are the custom validator methods that verify the user-entered email address and phone number, respectively. The **submitButton\_action** method (lines 429–440) echoes the entered data back to the user if validation is successful. The validator methods are called before the event handler, so if validation fails, **submitButton\_action** will not be called and the user input will not be echoed.

The two custom validator methods in this page bean file validate a text field's contents against a regular expression using the **String** method **match**, which takes a regular expression as an argument and returns **true** if the **String** conforms to the specified format.

433 String phone = String.valueOf(phoneTF.getValue());
434 nameResult.setValue(name);
435 emailResult.setValue(email);
436 phoneResult.setValue(phone);
437 gridPanel.setRendered(true);
438 resultText.setRendered(true);
439 return null;
440 } // end method submitButton_action
441 } // end class Validation

```

**Fig. 26.19** | Page bean for validating user input and redisplaying that input if valid. (Part 3 of 3.)

For the `emailTF_validate` method, we use the validation expression

`\w+([-.\']\w+)*@\w+([-.\']\w+)*\.\w+([-.\']\w+)*`

Note that each backslash in the regular expression `String` (line 405) must be escaped with another backslash (as in `\\`), because the backslash character normally represents the beginning of an escape sequence. This regular expression indicates that an e-mail address is valid if the part before the @ symbol contains one or more word characters (i.e., alphanumeric characters or underscores), followed by zero or more strings comprised of a hyphen, plus sign, period or apostrophe and additional word characters. After the @ symbol, a valid e-mail address must contain one or more groups of word characters potentially separated by hyphens or periods, followed by a required period and another group of one or more word characters potentially separated by hyphens or periods. For example, the e-mail addresses `bob's-personal.email@white.email.com`, `bob-white@my-email.com` and `bob.white@email.com` are all valid. If the user enters text in `emailTF` that does not have the correct format and attempts to submit the form, lines 408–408 throw a `ValidatorException`. The `emailMessage` component will catch this exception and display the message in red.

The regular expression in `phoneTF_validate` ensures that the `phoneTextBox` contains a valid phone number before the form is submitted. The user input is matched against the regular expression

26.7 Session Tracking **I28I**

```
((\\d{3}\\) ?|\\d{3}-)\\d{3}-\\d{4}
```

(Again, each backslash is escaped in the regular expression `String` in line 421.) This expression indicates that a phone number can contain a three-digit area code either in parentheses and followed by an optional space or without parentheses and followed by required hyphen. After an optional area code, a phone number must contain three digits, a hyphen and another four digits. For example, (555) 123-4567, 555-123-4567 and 123-4567 are all valid phone numbers. If a user enters an invalid phone number, lines 423–424 throw a `ValidatorException`. The `emailMessage` component catches this exception and displays the error message in red.

If all six validators are successful (i.e., each `TextField` contains data, the name is less than 30 characters and the e-mail address and phone number are valid), clicking the `Submit` button sends the form's data to the server. As shown in Fig. 26.18(d), the `submitButton_action` method displays the submitted data in a `gridPanel` (lines 434–437) and a success message in `resultsText` (line 128).

## 26.7 Session Tracking

In the early days of the internet, e-businesses could not provide the kind of customized service typically experienced in “brick-and-mortar” stores. To address this problem, e-businesses began to establish mechanisms by which they could personalize users' browsing experiences, tailoring content to individual users while enabling them to bypass irrelevant information. Businesses achieve this level of service by tracking each customer's movement through their websites and combining the collected data with information provided by the consumer, including billing information, personal preferences, interests and hobbies.

### *Personalization*

**Personalization** makes it possible for e-businesses to communicate effectively with their customers and also improves the user's ability to locate desired products and services. Companies that provide content of particular interest to users can establish relationships with customers and build on those relationships over time. Furthermore, by targeting consumers with personal offers, recommendations, advertisements, promotions and services, e-businesses create customer loyalty. Websites can use sophisticated technology to allow visitors to customize home pages to suit their individual needs and preferences. Similarly, online shopping sites often store personal information for customers, tailoring notifications and special offers to their interests. Such services encourage customers to visit sites and make purchases more frequently.

### *Privacy*

A trade-off exists, however, between personalized e-business service and protection of privacy. Some consumers embrace the idea of tailored content, but others fear the possible adverse consequences if the info they provide to e-businesses is released or collected by tracking technologies. Consumers and privacy advocates ask: What if the e-business to which we give personal data sells or gives that information to another organization without our knowledge? What if we do not want our actions on the Internet—a supposedly anonymous medium—to be tracked and recorded by unknown parties? What if unauthorized parties gain access to sensitive private data, such as credit-card numbers or medical history?

**1282**    [Chapter 26](#) [Web Applications: Part I](#)

All of these are questions that must be debated and addressed by programmers, consumers, e-businesses and lawmakers alike.

### *Recognizing Clients*

To provide personalized services to consumers, e-businesses must be able to recognize clients when they request information from a site. As we have discussed, the request/response system on which the web operates is facilitated by HTTP. Unfortunately, HTTP is a stateless protocol—it does not support persistent connections that would enable web servers to maintain state information regarding particular clients. So, web servers cannot determine whether a request comes from a particular client or whether a series of requests comes from one or several clients. To circumvent this problem, sites can provide mechanisms to identify individual clients. A session represents a unique client on a website. If the client leaves a site and then returns later, the client will still be recognized as the same user. To help the server distinguish among clients, each client must identify itself to the server. Tracking individual clients, known as [session tracking](#), can be achieved in a number of ways. One popular technique uses cookies (Section 26.7.1); another uses the `SessionBean` object (Section 26.7.2). Additional session-tracking techniques include using `input` form elements of type "hidden" and URL rewriting. With "hidden" form elements, a web form can write session-tracking data into a form in the web page that it returns to the client in response to a prior request. When the user submits the form in the new web page, all the form data, including the "hidden" fields, is sent to the form handler on the web server. With URL rewriting, the web server embeds session-tracking information directly in the URLs of hyperlinks that the user clicks to send subsequent requests to the web server.

#### [26.7.1 Cookies](#)

[Cookies](#) provide web developers with a tool for personalizing web pages. A cookie is a piece of data typically stored in a text file on the user's computer. A cookie maintains information about the client during and between browser sessions. The first time a user visits the website, the user's computer might receive a cookie; this cookie is then reactivated each time the user revisits that site. The collected information is intended to be an anonymous record containing data that is used to personalize the user's future visits to the site. For example, cookies in a shopping application might store unique identifiers for users. When a user adds items to an online shopping cart or performs another task resulting in a request to the web server, the server receives a cookie from the client containing the user's unique identifier. The server then uses the unique identifier to locate the shopping cart and perform any necessary processing.

In addition to identifying users, cookies also can indicate clients' shopping preferences. When a web server receives a request from a client, the server can examine the cookie(s) it sent to the client during previous communications, identify the client's preferences and immediately display products of interest to the client.

Every HTTP-based interaction between a client and a server includes a header containing information either about the request (when the communication is from the client to the server) or about the response (when the communication is from the server to the client). When a page receives a request, the header includes information such as the request type (e.g., GET or POST) and any cookies that have been sent previously from the server to be stored on the client machine. When the server formulates its response, the header infor-

mation contains any cookies the server wants to store on the client computer and other information, such as the MIME type of the response.

The **expiration date** of a cookie determines how long the cookie remains on the client's computer. If you do not set an expiration date for a cookie, the web browser maintains the cookie for the duration of the browsing session. Otherwise, the web browser maintains the cookie until the expiration date occurs. When the browser requests a resource from a web server, cookies previously sent to the client by that web server are returned to the web server as part of the request formulated by the browser. Cookies are deleted when they **expire**.

### Portability Tip 26.1

*Clients may disable cookies in their web browsers for more privacy. When such clients use web applications that depend on cookies to maintain state information, the applications will not execute correctly.*

#### Using Cookies to Provide Book Recommendations

The next web application shows how to use cookies. The example contains two pages. In the first page (Figs. 26.20 and 26.22), users select a favorite programming language from a group of radio buttons and submit the form to the web server for processing. The web server responds by creating a cookie that stores the selected language and the ISBN number for a recommended book on that topic. The server then renders new components in the browser that allow the user either to select another favorite programming language or to view the second page in our application (Figs. 26.23–26.24), which lists recommended books pertaining to the programming language(s) that the user selected. When the user clicks the hyperlink, the cookies previously stored on the client are read and used to form the list of book recommendations.

The JSP file in Fig. 26.20 contains a **Radio Button Group** (lines 26–39) with the options Java, C, C++, Visual Basic 2005, and Visual C# 2005. Recall that you can set the display and value Strings of radio buttons by right clicking the **Radio Button Group** and selecting **Configure Default Options**. The user selects a programming language by clicking one of the radio buttons. When the user presses the **Submit** button, the web application creates a cookie containing the selected language. This cookie is added to the HTTP response header and sent to the client as part of the response.

When **Submit** is clicked, the **ui:label**, **ui:radioButtonGroup** and **ui:button** elements used to select a language are hidden, and a **ui:staticText** and two **ui:hyperlink** elements are displayed. Each **ui:staticText** and **ui:hyperlink** initially has its **rendered** property set to **false** (lines 31, 37, and 43). This indicates that these components are not visible the first time the page loads, as we want the user's first view of the page to include only the components for selecting a programming language and submitting the selection.

**Fig. 26.20** | JSP file that allows the user to select a programming language. (Part 3 of 4.)

**1286** Chapter 26 Web Applications: Part I

**Fig. 26.20** | JSP file that allows the user to select a programming language. (Part 4 of 4.)

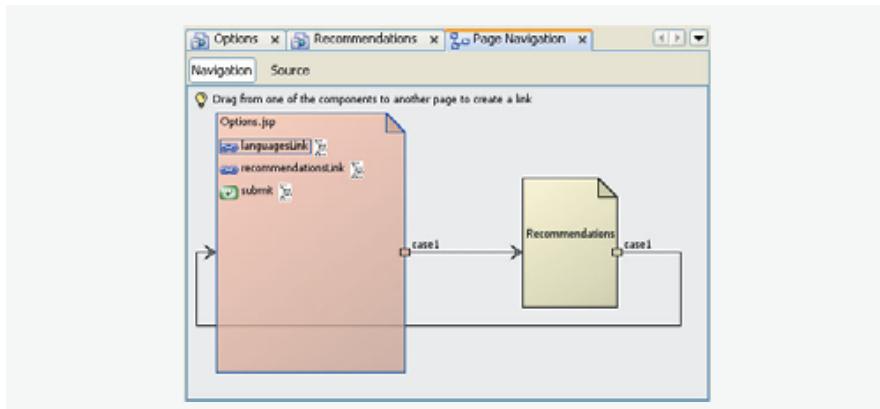

The first hyperlink (lines 35–39) requests this page, and the second (lines 40–47) requests `Recommendations.jsp`. The `url` property is not set for the first link; we discuss this momentarily. The second link's `url` property is set to `/faces/Recommendations.jsp`. Recall that earlier in the chapter, we set a `url` property to a remote website (`http://www.deitel.com`). To set this property to a page within the current application, click the ellipsis button next to the `url` property in the **Properties** window to open a dialog. Use this dialog to select a page within your project as the destination for the link.

#### *Adding and Linking to a New Web Page*

Setting the `url` property to a page in the current application requires that the destination page already exists. To set the `url` property of a link to `Recommendations.jsp`, you must first create this page. Right click the **Web Pages** node in the **Projects** window and select **New > Page** from the menu that appears. In the **New Page** dialog, change the name of the page to `Recommendations` and click **Finish** to create the files `Recommendations.jsp` and `Recommendations.java`. (We discuss the contents of these files shortly.) Once the `Recommendations.jsp` file exists, you can select it as the `url` value for `recommendationsLink`.

For `Options.jsp`, rather than setting the `languagesLink`'s `url` property, we will add an action handler for this component to the page bean. The action handler will enable us to show and hide components of the page without redirecting the user to another page. Specifying a destination `url` would override the component's action handler and redirect the user to the specified page, so it is important that we do not set the `url` property in this case. Since we use this link to reload the current page, we simply return `null` from the action handler, causing `Options.jsp` to reload.

To add an action handler to a hyperlink that should also direct the user to another page, you must add a rule to the **Page Navigation** file (Fig. 26.21). To edit this file, right click anywhere in the Visual Designer and select **Page Navigation....** Locate the link whose navigation rule you would like to set and drag it to the destination page. Now the link can direct the user to a new page without overriding its action handler. Editing the **Page Navigation** file is also useful when you would like action elements that cannot specify a `url` property, such as buttons, to direct users to another page.

26.7 Session Tracking **1287**

**Fig. 26.21** | Editing the Page Navigation file.

Figure 26.22 contains the code that writes a cookie to the client machine when the user selects a programming language. The file also determines which components appear on the page, displaying either the components for choosing a language or the links for navigating the application, depending on the user's actions.

315 } // end class Options

```

**Fig. 26.22** | Page bean that stores the user's language selection in a cookie on the client. (Part 4 of 4.)

As mentioned previously, the `_init` method handles component initialization. Since this page contains a `RadioButtonGroup` object that requires initialization, method `_init` (lines 30–44) constructs an array of `Option` objects to be displayed by the buttons. The option's names contain slashes rather than spaces in lines 38 and 40, because we later use these names as cookie names and Java does not allow cookie names to contain spaces.

Lines 212–216 in the constructor initialize a `Properties` object—a data structure that stores `String` key-value pairs. The application uses the key to store and retrieve the associated value in the `Properties` object. In this example, the keys are `Strings` containing the programming language names, and the values are `Strings` containing the ISBN numbers for the recommended books. Class `Properties` provides method `setProperty`, which takes as arguments a key and a value. A value that is added via method `setProperty` is placed in the `Properties` at a location determined by the key. The value for a specific `Properties` entry can be determined by invoking the method `getProperty` on the `Properties` object with that value's key as an argument.

### Software Engineering Observation 26.1

*Java Studio Creator 2 can automatically import any missing packages your Java file needs. For example, after adding the Properties object to Options.java, you can right click in the Java editor window and select Fix Imports to automatically import java.util.Properties.*

Clicking **Submit** invokes the event handler `submit_action` (lines 267–301), which display a message indicating the selected language in the `responseLabel` element and adds a new cookie to the response. If a language was selected (line 272), the selected value is retrieved (line 274). Line 275 converts the selection to a `String` that can be displayed in the `responseLabel`, replacing the slashes with spaces. Line 276 adds the selected language to the results message.

Line 279 retrieves the ISBN for the selected language from the books `Properties`. Then line 282 creates a new cookie object (of class `Cookie` in package `javax.servlet.http`), using the selected language as the cookie's name and a corresponding ISBN number as the cookie's value. This cookie is added to the HTTP response header in lines 286–288. An object of class `HttpServletResponse` (from package `javax.servlet.http`) represents the response. This object can be accessed by invoking the method `getExternalContext` on the page bean then invoking `getResponse` on the resulting object. If a language was not selected, line 291 sets the results message to indicate that no selection was made.

Lines 293–299 control the appearance of the page after the user clicks **Submit**. Line 293 sets the `responseLabel` to display the `String msg`. Since the user has just submitted a language selection, the components used to collect the selection are hidden (lines 294–296) and `responseLabel` and the links used to navigate the application are displayed (lines 297–299). The action handler returns `null` at line 300, which reloads `Options.jsp`.

Lines 305–311 contain the `languagesLink`'s event handler. When the user clicks this link, `responseLabel` and the two links are hidden (lines 307–309), and the components that allow the user to select a language are redisplayed (lines 310–312). The method returns `null` at line 313, causing `Options.jsp` to reload.

#### Displaying Book Recommendations Based on Cookie Values

After clicking **Submit**, the user may request a book recommendation. The book recommendations hyperlink forwards the user to `Recommendations.jsp` (Fig. 26.23) to display recommendations based on the user's language selections.

```

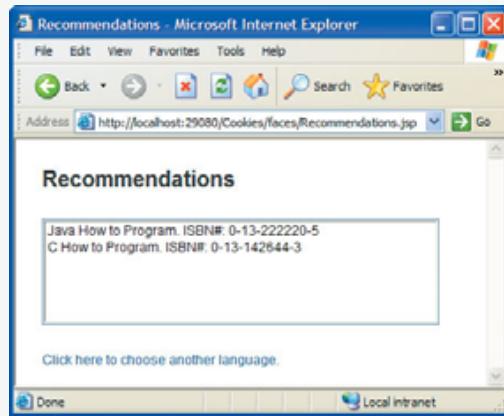

1 <?xml version = "1.0" encoding = "UTF-8"?>
2

29 width: 360px"/>
30 <ui:hyperlink action = "case1" binding =
31 "#{Recommendations.optionsLink}" id = "optionsLink"
32 style = "left: 24px; top: 192px; position: absolute"
33 text = "Click here to choose another language." />
34 </ui:form>
35 </ui:body>
36 </ui:html>
37 </ui:page>
38 </f:view>
39 </jsp:root>
```

**Fig. 26.23** | JSP file that displays book recommendations based on cookies. (Part 2 of 2.)

Recommendations.jsp contains a **Label** (lines 21–24), a **List Box** (lines 25–29) and a **Hyperlink** (lines 30–33). The **Label** displays the text Recommendations at the top of the page. A **List Box** component displays a list of options from which a user can make multiple selections. The **List Box** in this example displays the recommendations created by the Recommendation.java page bean (Fig. 26.24), or the text "No Recommendations. Please

26.7 Session Tracking **1293**

select a language." The **Hyperlink** allows the user to return to **Options.jsp** to select additional languages.

*Page Bean That Creates Book Recommendations from Cookies*

In **Recommendations.java** (Fig. 26.24), method **prerender** (lines 192–223) retrieves the cookies from the client, using the request object's **getCookies** method (lines 195–197). An object of class **HttpServletRequest** (from package **javax.servlet.http**) represents the request. This object can be obtained by invoking method **getExternalContext** on the page bean, then invoking **getRequest** on the resulting object. The call to **getCookies** returns an array of the cookies previously written to the client. Cookies can be read by an application only if they were created by a server in the domain in which the application is running—a web server cannot access cookies created by servers in other domains. For example, a cookie created by a web server in the **deitel.com** domain cannot be read by a web server in any other domain.

**Fig. 26.24** | Page bean that displays book recommendations based on cookies storing user's selected languages. (Part 3 of 3.)

Line 203 determines whether at least one cookie exists. (We ignore the first cookie in the array which contains information that is not specific to our application.) Lines 205–213 add the information in the cookie(s) to an `Option` array. Arrays of `Option` objects can be displayed as a list of items in a `List Box` component. The loop retrieves the name and value of each cookie using the control variable to determine the current value in the cookie array. If no language was selected, lines 215–220 add to an `Options` array a message instructing the user to select a language. Line 222 sets `booksListBox` to display the resulting `Options` array. We summarize commonly used `Cookie` methods in Fig. 26.25.

Methods	Description
<code>getDomain</code>	Returns a <code>String</code> containing the cookie's domain (i.e., the domain from which the cookie was written). This determines which web servers can receive the cookie. By default, cookies are sent to the web server that originally sent the cookie to the client. Changing the <code>Domain</code> property causes the cookie to be returned to a web server other than the one that originally wrote it.

**Fig. 26.25** | `javax.servlet.http.Cookie` methods. (Part 1 of 2.)

**1296** Chapter 26 Web Applications: Part I

Methods	Description
getMaxAge	Returns an int indicating how many seconds the cookie will persist on the browser. This is -1 by default, meaning the cookie will persist until the browser is shut down.
getName	Returns a String containing the cookie's name.
getPath	Returns a String containing the path to a directory on the server to which the cookie applies. Cookies can be "targeted" to specific directories on the web server. By default, a cookie is returned only to applications operating in the same directory as the application that sent the cookie or a subdirectory of that directory. Changing the Path property causes the cookie to be returned to a directory other than the one from which it was originally written.
getSecure	Returns a bool value indicating whether the cookie should be transmitted through a secure protocol. The value true causes a secure protocol to be used.
getValue	Returns a String containing the cookie's value.

**Fig. 26.25** | javax.servlet.http.Cookie methods. (Part 2 of 2.)**26.7.2 Session Tracking with the SessionBean Object**

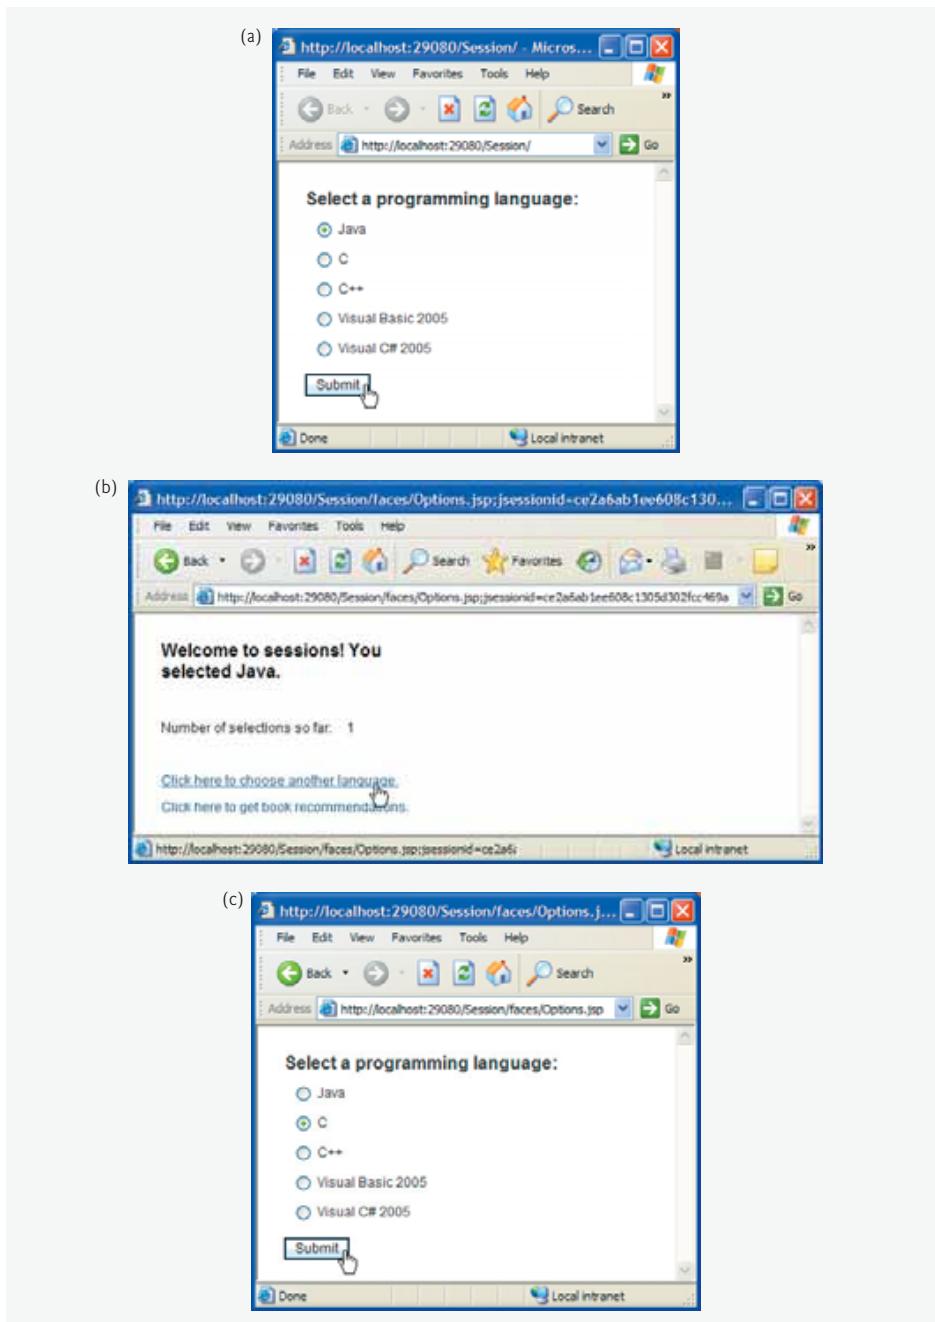

You can also perform session tracking with the `SessionBean` class that is provided in each web application created with Java Studio Creator 2. When a web page in the project is requested, a `SessionBean` object is created. Properties of this object can be accessed throughout a browser session by invoking the method `getSessionBean` on the page bean. To demonstrate session-tracking techniques using the `SessionBean`, we modified the page bean files in Figs. 26.22 and 26.24 so that they use the `SessionBean` to store the user's selected languages. We begin with the updated `Options.jsp` file (Fig. 26.27). Figure 26.29 presents the `SessionBean.java` file, and Fig. 26.30 presents the modified page bean file for `Options.jsp`.

The `Options.jsp` file in Fig. 26.26 is similar to that presented in Fig. 26.20 for the cookies example. Lines 38–45 define two `ui:staticText` elements that were not present in the cookies example. The first element displays the text "Number of selections so far:". The second element's `text` attribute is bound to property `numSelections` in the `SessionBean` (lines 44–45). We discuss how to bind the `text` attribute to a `SessionBean` property momentarily.

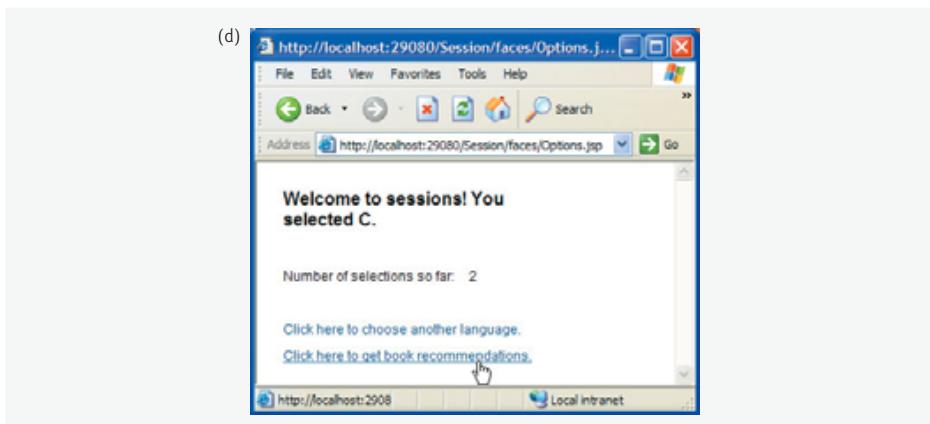

```

1 <?xml version = "1.0" encoding = "UTF-8"?>

#### *Adding Properties to the SessionBean*

In this example, we use session tracking to store not only the user's selected languages, but also the number of selections made. To store this information in the SessionBean, we add properties to the SessionBean class.

To add a property that will store the number of selections so far, right click the SessionBean node in the Outline window and select **Add > Property** to display the **New Property Pattern** dialog (Fig. 26.27). This dialog allows you to add primitive, String or primitive type-wrapper properties to the SessionBean. Add an int property named numSelections and click **OK** to accept the default settings for this property. Open the SessionBean file and you will see a new property definition, a *get* and *set* method for numSelections.

**Fig. 26.27** | New Property dialog for adding a property to the SessionBean.

26.7 Session Tracking **1297**

```

55 "/faces/Recommendations.jsp"/>
56 </ui:form>
57 </ui:body>
58 </ui:html>
59 </ui:page>
60 </f:view>
61 </jsp:root>
```

**Fig. 26.26** | JSP file that allows the user to select a programming language. (Part 2 of 4.)

**1300 Chapter 26 Web Applications: Part I**

Property `numSelections` will be manipulated in the page bean file to store the number of languages the user selected. To display the value of this property in the `numSelected` **Static Text** element in the JSP file, right click the **Static Text** component in the Outline window in Design mode and select **Bind to Data....** In the **Bind to Data** dialog (Fig. 26.28), select the **Bind to an Object** tab, locate property `numSelections` under the `SessionBean` node and click **OK**. The **Static Text** element will now always display the value of `SessionBean`'s `numSelections` property. If the property's value changes, the text changes as well, so that you need not programmatically set the text in the page bean file.

Now that we have added a property to store the number of selections in the `SessionBean`, we must add a second property to store the selections themselves. We would like to store selections as key-value pairs of the selected language and the ISBN number of a related book, similar to the way selections were stored using cookies. To do this, we add a `Properties` object named `selectedLanguages` to the `SessionBean`. We manually added this property to the `SessionBean` file, but you can add it using the **New Property** dialog in Fig. 26.27. Simply type `java.util.Properties` in the **Type** drop down list's field, configure the property and click **OK**. The final `SessionBean` file after the two properties have been added is displayed in Fig. 26.29.

**Fig. 26.28** | Bind to Data dialog

```

1 // Fig. 26.29: SessionBean.java
2 // SessionBean file for storing language selections.
3 package session;
4
5 import com.sun.rave.web.ui.appbase.AbstractSessionBean;
6 import java.util.Properties;
7 import javax.faces.FacesException;
8

```

**Fig. 26.29** | SessionBean file for storing language selections. (Part I of 3.)

26.7 Session Tracking **I30I**

```

9 public class SessionBean extends AbstractSessionBean
10 {
11 private int __placeholder;
12
13 private void _init() throws Exception
14 {
15 // empty body
16 } // end method _init
17
18 public SessionBean()
19 {
20 // empty constructor
21 } // end constructor
22
23 protected ApplicationBean getApplicationBean()
24 {
25 return (ApplicationBean1) getBean("ApplicationBean");
26 } // end method getApplicationBean
27
28 public void init()
29 {
30 super.init();
31 try
32 {
33 _init();
34 } // end try
35 catch (Exception e)
36 {
37 log("SessionBean Initialization Failure", e);
38 throw e instanceof FacesException ? (FacesException) e:
39 new FacesException(e);
40 } // end catch
41 } // end method init
42
43 public void passivate()
44 {
45 // empty body
46 } // end method passivate
47
48 public void activate()
49 {
50 // empty body
51 } // end method activate
52
53 public void destroy()
54 {
55 // empty body
56 } // end method destroy
57
58 private int numSelections = 0; // stores number of unique selections
59
60 public int getNumSelections()
61 {

```

**Fig. 26.29** | SessionBean file for storing language selections. (Part 2 of 3.)

**1302** Chapter 26 Web Applications: Part I

```

62 return this.numSelections;
63 } // end method getNumSelections
64
65 public void setNumSelections(int numSelections)
66 {
67 this.numSelections = numSelections;
68 } // end method setNumSelections
69
70 // Stores key-value pairs of selected languages
71 private Properties selectedLanguages = new Properties();
72
73 public Properties getSelectedLanguages()
74 {
75 return this.selectedLanguages;
76 } // end method getSelectedLanguages
77
78 public void setSelectedLanguages(Properties selectedLanguages)
79 {
80 this.selectedLanguages = selectedLanguages;
81 } // end method setSelectedLanguages
82 } // end class SessionBean

```

**Fig. 26.29** | SessionBean file for storing language selections. (Part 3 of 3.)

Line 58 declares the `numSelections` property, and lines 60–63 and 65–68 declare its *get* and *set* methods, respectively. This portion of the code was generated automatically when we used the **New Property** dialog. Line 71 defines the `Properties` object `selectedLanguages` that will store user selections. Lines 73–76 and 78–81 are the *get* and *set* methods for this property.

***Manipulating SessionBean Properties in a Page Bean File***

The page bean file for the `Options.jsp` page is displayed in Fig. 26.30. Because much of this example is identical to the preceding one, we concentrate on the new features.

```

1 // Fig. 26.30: Options.java
2 // Page bean that stores language selections in a SessionBean property.
3 package session;
4
5 import com.sun.rave.web.ui.appbase.AbstractPageBean;
6 import com.sun.rave.web.ui.component.Body;
7 import com.sun.rave.web.ui.component.Form;
8 import com.sun.rave.web.ui.component.Head;
9 import com.sun.rave.web.ui.component.Html;
10 import com.sun.rave.web.ui.component.Link;
11 import com.sun.rave.web.ui.component.Page;
12 import javax.faces.FacesException;
13 import com.sun.rave.web.ui.component.RadioButtonGroup;
14 import com.sun.rave.web.ui.component.Hyperlink;
15 import com.sun.rave.web.ui.component.Button;
16 import com.sun.rave.web.ui.component.Label;

328 recommendationsLink.setRendered(false);
329 languageList.setRendered(true);
330 languageLabel.setRendered(true);
331 submit.setRendered(true);
332 return null;
333 } // end method languagesLink_action
334 } // end class Options

```

**Fig. 26.30** | Page bean that stores language selections in a SessionBean property. (Part 4 of 4.)

The submit Button's action handler (lines 280–319) stores the user's selections in the SessionBean and increments the number of selections made, if necessary. Line 294 retrieves from the SessionBean the Properties object that contains the user's selections. Line 295 adds the current selection to the Properties object. Method `setProperty` returns the value previously associated with the new key, or `null` if this key was not already stored in the Properties object. If adding the new property returns `null`, then the user has made a new selection. In this case, lines 302–303 increment the `numSelections` property in the SessionBean. Lines 309–317 and the `languagesLink` action handler (lines 323–334) control the components that will be displayed on the page, just as in the cookies examples.

## 1306 Chapter 26 Web Applications: Part I

**Software Engineering Observation 26.2**

*A benefit of using SessionBean properties (rather than cookies) is that they can store any type of object (not just Strings) as attribute values. This provides you with increased flexibility in maintaining client state information.*

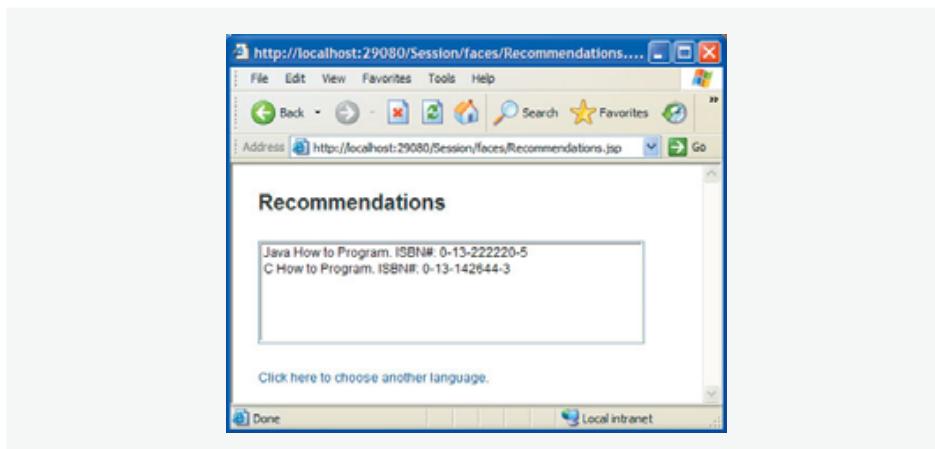

**Displaying Recommendations Based on Session Values**

As in the cookies example, this application provides a link to `Recommendations.jsp` (Fig. 26.31), which displays a list of book recommendations based on the user's language selections. It is identical to `recommendation.jsp` from the cookies example (Fig. 26.23).

```

1 <?xml version = "1.0" encoding = "UTF-8"?>
2
3 <!-- Fig. 26.31: Recommendations.jsp -->
4 <!-- JSP file that displays book recommendations based on language
5 selections stored in session scope. -->
6 <jsp:root version = "1.2" xmlns:f = "http://java.sun.com/jsf/core"
7 xmlns:h = "http://java.sun.com/jsf/html" xmlns:jsp =
8 "http://java.sun.com/JSP/Page" xmlns:ui = "http://www.sun.com/web/ui">
9 <jsp:directive.page contentType = "text/html; charset = UTF-8"
10 pageEncoding = "UTF-8"/>
11 <f:view>
12 <ui:page binding = "#{Recommendations.page}" id = "page">
13 <ui:html binding = "#{Recommendations.html}" id = "html">
14 <ui:head binding = "#{Recommendations.head}" id = "head">
15 <ui:link binding = "#{Recommendations.link}" id = "link"
16 url = "/resources/stylesheets.css"/>
17 </ui:head>
18 <ui:body binding = "#{Recommendations.body}" id = "body"
19 style = "-rave-layout: grid">
20 <ui:form binding = "#{Recommendations.form}" id = "form">
21 <ui:label binding = "#{Recommendations.languageLabel}"
22 for = "booksListBox" id = "languageLabel" style =
23 "font-size: 20px; font-weight: bold; left: 24px; top:
24 24px; position: absolute" text = "Recommendations"/>
25 <ui:listbox binding = "#{Recommendations.booksListBox}"
26 id = "booksListBox" items = "#{Recommendations.
27 booksListBoxDefaultOptions.options}" rows = "6"
28 style = "left: 24px; top: 72px; position: absolute;
29 width: 360px"/>
30 <ui:hyperlink action = "case1" binding =
31 "#{Recommendations.optionsLink}" id = "optionsLink"
32 style = "left: 24px; top: 192px; position: absolute"
33 text = "Click here to choose another language."/>
34 </ui:form>
35 </ui:body>
36 </ui:html>
37 </ui:page>
38 </f:view>
39 </jsp:root>
```

26.8 Wrap-Up **1309**

```

193 //retrieve user's selections and number of selections made
194 Properties languages = getSessionBean().getSelectedLanguages();
195 Enumeration selectionsEnum = languages.propertyNames();
196 int numSelected = getSessionBean().getNumSelections();
197
198 Option [] recommendations;
199
200 // if at least one selection was made
201 if (numSelected > 0)
202 {
203 recommendations = new Option[numSelected];
204
205 for (int i = 0; i < numSelected; i++)
206 {
207 String language = (String) selectionsEnum.nextElement() ;
208 recommendations[i] = new Option(language +
209 "How to Program. ISBN#:" +
210 languages.getProperty(language));
211 } // end for
212 } // end if
213 else
214 {
215 recommendations = new Option[1];
216 recommendations[0] = new Option("No recommendations. " +
217 "Please select a language.");
218 } // end else
219
220 booksListBox.setItems(recommendations);
221 } // end method prerender
222
223 public void destroy()
224 {
225 // empty body
226 } // end method destroy
227 } // end class Recommendations

```

**Fig. 26.32** | Page bean that displays book recommendations based on a SessionBean property.  
(Part 3 of 3.)

Line 194 retrieves the `Properties` object containing the user's selections from the `SessionBean`, and line 195 gets an enumeration of all of the keys in that `Properties` object. Line 196 retrieves the number of selections made from the `SessionBean`. If any selections were made, line 208 constructs an appropriately sized `Option` array to display the selections in the `ui:listBox` element of `Recommendations.jsp`. Lines 205–211 add each of the user's selections to this `Option` array. Line 207 gets the next key from the enumeration of keys, and lines 208–210 add a recommendation to the `Option` array.

## 26.8 Wrap-Up

In this chapter, we introduced web application development using JavaServer Pages and JavaServer Faces in Java Studio Creator 2. We began by discussing the simple HTTP transactions that take place when you request and receive a web page through a web brows-

**1310**    [Chapter 26](#) [Web Applications: Part I](#)

er. We then discussed the three tiers (i.e., the client or top tier, the business logic or middle tier and the information or bottom tier) that comprise most web applications.

You learned the role of JSP files and page bean files, and the relationship between them. You learned how to use Java Studio Creator 2 to compile and execute web applications. You also learned how to build web applications visually using Java Studio Creator 2's drag-and-drop capabilities.

We demonstrated several common JSF components used for displaying text and images on web pages. We also discussed validation components and custom validator methods, which allow you to ensure that user input satisfies certain requirements.

We discussed the benefits of maintaining user information across multiple pages of a website. We then demonstrated how you can include such functionality in a web application using either cookies or properties in the `SessionBean` class. In the next chapter, we continue our discussion of web application development. You'll learn how to access a database from a web application, how to use several of the AJAX-enabled JSF components from Sun's Java Blueprints and how to use virtual forms.

The Java BluePrints solution catalog contains reusable code examples for designing web applications using JavaServer Faces and AJAX.

[Summary](#)

1311

## Summary

### Section 26.1 Introduction

- Web-based applications create web content for web browser clients.
- AJAX helps web-based applications provide the interactivity and responsiveness that users typically expect of desktop applications.

### Section 26.2 Simple HTTP Transactions

- Hypertext Transfer Protocol (HTTP) specifies a set of methods and headers that allow clients and servers to interact and exchange information in a uniform and reliable manner.
- In its simplest form, a web page is nothing more than an XHTML document containing markup that describes to a web browser how to display and format the document's information.
- XHTML documents can contain hypertext data (hyperlinks) that link to different pages or to other parts of the same page when the user clicks the link.
- HTTP uses URIs (Uniform Resource Identifiers) to identify data on the Internet.
- URIs that specify the locations of documents are called URLs (Uniform Resource Locators). Common URLs refer to files or directories and can reference objects that perform complex tasks.
- A URL contains information that directs a browser to the resource that the user wishes to access. Computers that run web server software make such resources available.
- When given a URL, a web browser performs a simple HTTP transaction to retrieve and display the web page found at that address.
- The HTTP GET method indicates that the client wishes to obtain a resource from the server.
- HTTP headers provide information about the data sent to a client, such as the MIME type.
- Multipurpose Internet Mail Extensions (MIME) is an Internet standard that specifies data formats so that programs can interpret data correctly.

### Section 26.3 Multitier Application Architecture

- Web-based applications are multitier (or *n*-tier) applications that divide functionality into separate tiers that typically reside on separate computers.
- The bottom tier (also called the data tier or the information tier) maintains the application's data. This tier typically stores data in a relational database management system (RDBMS).
- The middle tier implements business logic, controller logic and presentation logic to control interactions between the application's clients and the its data. The middle tier acts as an intermediary between data in the information tier and the application's clients.
- The middle-tier controller logic processes client requests and retrieves data from the database.
- The middle-tier presentation logic processes data from the information tier and presents the content to the client.
- Web applications typically present data to clients as XHTML documents.
- Business logic in the middle tier enforces business rules and ensures that data is reliable before the server application updates the database or presents the data to users.
- Business rules dictate how clients can and cannot access application data, and how applications process data.
- The top tier, or client tier, is the application's user interface, which gathers input and displays output. Users interact with the application through the user interface, typically in a web browser.

**1312 Chapter 26 Web Applications: Part I**

- In response to user actions, the client tier interacts with the middle tier to make requests and to retrieve data from the information tier. The client tier then displays the data retrieved for the user. The client tier never directly interacts with the information tier.

**Section 26.4 Java Web Technologies**

- Java web technologies continually evolve to provide developers with higher levels of abstraction and greater separation of the application's tiers. This separation makes web applications more maintainable and extensible.
- Java Studio Creator 2 allows you to develop a web application's GUI in a drag-and-drop design tool, while handling the business logic in separate Java classes.

**Section 26.4.1 Servlets**

- Servlets use the HTTP request-response model of communication between client and server.
- Servlets extend a server's functionality by allowing the server to generate dynamic content. A servlet container executes and interacts with servlets.
- Packages `javax.servlet` and `javax.servlet.http` contain the servlet classes and interfaces.
- The servlet container receives HTTP requests from a client and directs each request to the appropriate servlet. The servlet processes the request and returns an appropriate response to the client—usually in the form of an XHTML or XML document.
- All servlets implement the `Servlet` interface of package `javax.servlet`, which ensures that each servlet can execute in the framework provided by the servlet container. Interface `Servlet` declares methods used by the servlet container to manage the servlet's life cycle.
- A servlet's life cycle begins when the servlet container loads it into memory—usually in response to the first request for the servlet. The container invokes the servlet's `init` method, which is called only once during a servlet's life-cycle to initialize the servlet. After `init` completes execution, the servlet is ready to respond to its first request. All requests are handled by a servlet's `service` method, which receives the request, processes it and sends a response to the client. Method `service` is called once per request. When the servlet container terminates the servlet, the servlet's `destroy` method is called to release any resources held by the servlet.

**Section 26.4.2 JavaServer Pages**

- JavaServer Pages (JSP) are an extension of servlet technology. Each JSP is translated by the JSP container into a servlet.
- Unlike servlets, JSPs help you separate presentation from content.
- JavaServer Pages enable web application programmers to create dynamic content by reusing pre-defined components and by interacting with components using server-side scripting.
- JSP programmers can use special software components called JavaBeans and custom tag libraries that encapsulate complex, dynamic functionality.
- Custom tag libraries allow Java developers to hide code for database access and other complex operations in custom tags. To use such capabilities, you simply add the custom tags to the page. This simplicity enables web-page designers who are not familiar with Java to enhance web pages with powerful dynamic content and processing capabilities.
- The JSP classes and interfaces are located in packages `javax.servlet.jsp` and `javax.servlet.jsp.tagext`.
- There are four key components to JSPs—directives, actions, scripting elements and tag libraries.
- Directives are messages to the JSP container that enable you to specify page settings, to include content from other resources and to specify custom tag libraries for use in JSPs.

**Summary 1313**

- Actions encapsulate functionality in predefined tags that programmers can embed in JSPs. Actions often are performed based on the information sent to the server as part of a particular client request. They also can create Java objects for use in JSPs.
- Scripting elements enable you to insert Java code that interacts with components in a JSP to perform request processing.
- Tag libraries enable programmers to create custom tags and web-page designers to manipulate JSP content without prior Java knowledge.
- The JavaServer Pages Standard Tag Library (JSTL) provides the functionality for many common web application tasks.
- JSPs can contain static content such as XHTML or XML markup, which is known as fixed-template data or fixed-template text. Any literal text in a JSP is translated to a `String` literal in the servlet representation of the JSP.
- When a JSP-enabled server receives the first request for a JSP, the JSP container translates the JSP into a servlet that handles the current request and future requests to the JSP.
- JSPs rely on the same request/response mechanism as servlets to process requests from and send responses to clients.

**Section 26.4.3 JavaServer Faces**

- JavaServer Faces (JSF) is a web application framework that simplifies the design of an application's user interface and further separates a web application's presentation from its business logic.
- A framework simplifies application development by providing libraries and sometimes software tools to help you organize and build your applications.
- JSF provides custom tag libraries containing user interface components that simplify web-page design. JSF also includes a set of APIs for handling component events.
- You design the look-and-feel of a page with JSF by adding custom tags to a JSP file and manipulating their attributes. You define the page's behavior in a separate Java source-code file.

**Section 26.4.4 Web Technologies in Java Studio Creator 2**

- Java Studio Creator 2 web applications consist of one or more JSPs built in the JavaServer Faces framework. Each has the file-name extension `.jsp` and contains the web page's GUI elements.
- Java Studio Creator 2 allows you to design pages visually by dragging and dropping JSF components onto a page; you can also customize a web page by editing its `.jsp` file manually.
- Every JSP file created in Java Studio Creator 2 represents a web page and has a corresponding JavaBean class called the page bean.
- A JavaBean class must have a default (or no-argument) constructor, and `get` and `set` methods for all of its properties.
- The page bean defines properties for each of the page's elements, and contains event handlers, page life-cycle methods and other supporting code for the web application.
- Every web application built with Java Studio Creator 2 has a page bean, a `RequestBean`, a `SessionBean` and an `ApplicationBean`.
- The `RequestBean` object is maintained in request scope—this object exists only for the duration of an HTTP request.
- A `SessionBean` object has session scope—the object exists throughout a user's browsing session or until the session times out. There is a unique `SessionBean` object for each user.
- The `ApplicationBean` object has application scope—this object is shared by all instances of an application and exists as long as the application remains deployed on a web server. This object is

## 1314 Chapter 26 Web Applications: Part I

used for application-wide data storage or processing; only one instance exists for the application, regardless of the number of open sessions.

### *Section 26.5.1 Examining a JSP File*

- Java Studio Creator 2 generates a JSP file in response to your interactions with the Visual Editor.
- All JSPs have a `jsp:root` element with a `version` attribute to indicate the version of JSP being used and one or more `xmllns` attributes. Each `xmllns` attribute specifies a prefix and a URL for a tag library, allowing the page to use tags specified in that library.
- All JSPs generated by Java Studio Creator 2 include the tag libraries for the JSF core components library, the JSF HTML components library, the JSP standard components library and the JSP user interface components library.
- The `jsp:directive.page` element's `contentType` attribute specifies the MIME type and the character set the page uses. The `pageEncoding` attribute specifies the character encoding used by the page source. These attributes help the client determine how to render the content.
- All pages containing JSF components are represented in a component tree with the root JSF element `f:view` (of type `UIViewRoot`). All JSF component elements are placed in this element.
- Many `ui` page elements have a `binding` attribute to bind their values to properties in the web application's JavaBeans. JSF Expression Language is used to perform these bindings.
- The `ui:head` element has a `title` attribute that specifies the page's title.
- A `ui:link` element can be used to specify the CSS stylesheet used by a page.
- A `ui:body` element defines the body of the page.
- A `ui:form` element defines a form in a page.
- A `ui:staticText` component displays text that does not change.
- JSP elements are mapped to XHTML elements for rendering in a browser. The same JSP element can map to different XHTML elements, depending on the client browser and the component's property settings.
- A `ui:staticText` component typically maps to an XHTML `span` element. A `span` element contains text that is displayed on a web page and is used to control the formatting of the text. The `style` attribute of a `ui:staticText` element will be represented as part of the corresponding `span` element's `style` attribute when the browser renders the page.

### *Section 26.5.2 Examining a Page Bean File*

- Page bean classes inherit from class `AbstractPageBean` (package `com.sun.rave.web.ui.appbase`), which provides page life-cycle methods.
- Package `com.sun.rave.web.ui.component` includes classes for many basic JSF components.
- A `ui:staticText` component is a `StaticText` object (package `com.sun.rave.web.ui.component`).

### *Section 26.5.3 Event-Processing Life Cycle*

- Java Studio Creator 2's application model places several methods (`init`, `preprocess`, `prerender` and `destroy`) in the page bean that tie into the JSF event-processing life cycle. These methods represent four major stages—initialization, preprocessing, prerendering and destruction.
- The `init` method is called by the JSP container the first time the page is requested and on postbacks. A postback occurs when form data is submitted, and the page and its contents are sent to the server to be processed.
- Method `init` invokes its superclass version, then tries to call the method `_init`, which handles component initialization tasks.

- The `preprocess` method is called after `init`, but only if the page is processing a postback. The `prerender` method is called just before a page is rendered by the browser. This method should be used to set component properties; properties that are set sooner (such as in method `init`) may be overwritten before the page is actually rendered by the browser.
- The `destroy` method is called after the page has been rendered, but only if the `init` method was called. This method handles tasks such as freeing resources used to render the page.

#### **Section 26.5.4 Relationship Between the JSP and Page Bean Files**

- The page bean has a property for every element that appears in the JSP file.

#### **Section 26.5.5 Examining the XHTML Generated by a Java Web Application**

- To create a new web application, select **File > New Project...** to display the **New Project** dialog. In this dialog, select **Web** in the **Categories** pane, **JSF Web Application** in the **Projects** pane and click **Next**. Specify the project name and location. Click **Finish** to create the web application project.
- Java Studio Creator 2 creates a single web page named `Page1` when you create a new project. This page is open by default in the Visual Editor in **Design** mode when the project first loads. As you drag and drop new components onto the page, **Design** mode allows you to see how your page will be rendered in the browser. The JSP file for this page, named `Page1.jsp`, can be viewed by clicking the **JSP** button at the top of the Visual Editor or by right clicking anywhere in the Visual Editor and selecting **Edit JSP Source**.
- To open the corresponding page bean file, click the **Java** button at the top of the Visual Editor or right click anywhere in the Visual Editor and select **Edit Page1 Java Source**.
- The **Preview in Browser** button at the top of the Visual Editor window allows you to view your pages in a browser without having to build and run the application.
- The **Refresh** button redraws the page in the Visual Editor.
- The **Target Browser Size** drop-down list allows you to specify the optimal browser resolution for viewing the page and allows you to see what the page will look like in different screen resolutions.
- The **Projects** window in the lower-right corner of the IDE displays the hierarchy of all the project's files. The **Web Pages** node contains the JSP files and includes the **resources** folder, which contains the project's CSS stylesheet and any other files the pages may need to display properly (e.g., images). The Java source code, including the page bean file for each web page and the application, session and request scope beans, can be found under the **Source Packages** node.
- The **Page Navigation** file defines rules for navigating the project's pages based on the outcome of user-initiated events, such as clicking a button or a link. This file can also be accessed by right clicking in the Visual Editor while in **Design** mode and selecting **Page Navigation....**
- Methods `init`, `preprocess`, `prerender` and `destroy` are overridden in each page bean. Other than method `init`, these methods are initially empty. They serve as placeholders for you to customize the behavior of your web application.
- Typically, you'll want to rename the JSP and Java files in your project, so that their names are relevant to your application. To do so, right click the JSP file in the **Projects Window** and select **Rename** to display the **Rename** dialog. Enter the new file name. If **Preview All Changes** is checked, the **Refactoring Window** will appear at the bottom of the IDE when you click **Next >**. No changes will be made until you click **Do Refactoring** in the **Refactoring Window**. If you do not preview the changes, refactoring occurs when you click **Next >** in the **Rename** dialog.
- Refactoring is the process of modifying source code to improve its readability and reusability without changing its behavior—for example, by renaming methods or variables, or breaking long methods into shorter ones. Java Studio Creator 2 has built-in refactoring tools that automate some refactoring tasks.

## 1316 Chapter 26 Web Applications: Part I

- To add a title, open the JSP file in **Design** mode. In the **Properties** window, enter the new title next to the **Title** property and press *Enter*.
- To add components to a page, drag and drop them from the **Palette** onto the page in **Design** mode. Each component is an object that has properties, methods and events. You can set these properties and events in the **Properties** window or programmatically in the page bean file. *Get* and *set* methods are added to the page bean file for each component you add to the page.
- Components are rendered using absolute positioning, so that they appear exactly where they are dropped on the page.
- Java Studio Creator 2 is a WYSIWYG (What You See Is What You Get) editor—whenever you make a change to a web page in **Design** mode, the IDE creates the markup (visible in **JSP** mode) necessary to achieve the desired visual effects seen in **Design** mode.
- After designing the user interface, you can modify the page bean to add your business logic.
- The **Outline** window displays the page bean and the request, session and application scope beans. Clicking an item in the page bean's component tree selects the item in the Visual Editor.
- Select **Build > Build Main Project** then **Run > Run Main Project** to run the application.
- You can run a project that has already been built by pressing the **Run Main Project** icon () in the toolbar at the top of the IDE.
- If changes are made to a project, the project must be rebuilt before the changes will be reflected when the application is viewed in a browser.
- Press **F5** to build the application, then run it in debug mode. If you type **<Ctrl> F5**, the program executes without debugging enabled.

### Section 26.5.6 Building a Web Application in Java Studio Creator 2

- The **Grid Panel** component allows the designer to specify the number of columns the grid should contain. Components may then be dropped anywhere inside the panel, and they will automatically be repositioned into evenly spaced columns in the order in which they are dropped. When the number of components exceeds the number of columns, the panel moves the additional components to a new row.
- An **Image** component (of class `Image`) inserts an image into a web page. Images to be displayed on a web page must be placed in the project's resources folder. To add images to the project, drop an **Image** component onto the page and click the ellipsis button next to the **url** property in the **Properties** window. This opens a dialog in which you can select the image to display.
- **Text Fields** allow you to obtain text input from the user.
- Note that the order in which components are dragged to the page is important, because their JSP tags will be added to the JSP file in that order. Tabbing between components navigates the components in the order in which the JSP tags occur in the JSP file. If you would like the user to navigate the components in a certain order, you should drag them onto the page in that order. Alternatively, you can set each input field's **Tab Index** property in the **Properties** window. A component with a tab index of 1 will be the first in the tab sequence.
- A **Drop Down List** displays a list from which the user can make a selection. This object can be configured by right clicking the drop-down list in **Design** mode and selecting **Configure Default Options**, which opens the **Options Customizer** dialog box to add options to the list.
- A **Hyperlink** component of class `Hyperlink` adds a link to a web page. The **url** property of this component specifies the resource that is requested when a user clicks the hyperlink.
- A **Radio Button Group** component of class `RadioButtonGroup` provides a series of radio buttons from which the user can select only one. The options can be edited by right clicking the component and selecting **Configure Default Options**.

[Summary](#)

1317

- A **Button** is a JSF component of class `Button` that triggers an action when clicked. A **Button** component typically maps to an `input` XHTML element with attribute `type` set to `submit`.

#### *Section 26.6.2 Validation Using Validator Components and Custom Validators*

- Validation helps prevent processing errors due to incomplete or improperly formatted user input.
- A **Length Validator** determines whether a field contains an acceptable number of characters.
- **Double Range Validators** and **Long Range Validators** determine whether numeric input falls within acceptable ranges.
- Package `javax.faces.validators` contains the classes for these validators.
- **Label** components describe other components and can be associated with user input fields by setting their `for` property.
- **Message** components display error messages when validation fails.
- To associate a **Label** or **Message** component with another component, hold the *Ctrl* and *Shift* keys, then drag the label or message to the appropriate component.
- Set the `required` property of a component to ensure that the user enters data for it.
- If you add a validator component or custom validator method to an input field, the field's `required` property must be set to `true` for validation to occur.
- In the Visual Editor the label for a required field is automatically marked by a red asterisk.
- If a user submits a form with an empty text field for which a value is required, the default error message for that field will be displayed in its associated `ui:message` component.
- To edit a **Double Range Validator**'s or a **Long Range Validator**'s properties, click its node in the **Outline** window in **Design** mode and set the `maximum` and `minimum` properties in the **Properties** window.
- It is possible to limit the length of user input without using validation by setting a **Text Field**'s `maxLength` property.
- Matching user input against a regular expression is an effective way to ensure that the input is properly formatted.
- Java Studio Creator 2 does not provide components for validation using regular expressions, but you can add your own custom validator methods to the page bean file.
- To add a custom validator method to an input component, right click the component and select **Edit Event Handler > validate** to create a validation method for the component in the page bean file.

#### *Section 26.7 Session Tracking*

- Personalization makes it possible for e-businesses to communicate effectively with their customers and also improves the user's ability to locate desired products and services.
- A trade-off exists between personalized e-business service and protection of privacy. Some consumers embrace the idea of tailored content, but others fear the possible adverse consequences if the information they provide to e-businesses is released or collected by tracking technologies.
- To provide personalized services to consumers, e-businesses must be able to recognize clients when they request information from a site. Unfortunately, HTTP is a stateless protocol—it does not support persistent connections that would enable web servers to maintain state information regarding particular clients. So, web servers cannot determine whether a request comes from a particular client or whether a series of requests comes from one or several clients.
- To help the server distinguish among clients, each client must identify itself to the server. Tracking individual clients, known as session tracking, can be achieved in a number of ways. One popular technique uses cookies; another uses the `SessionBean` object.

## 1318 Chapter 26 Web Applications: Part I

- With "hidden" form elements, a web form can write session-tracking data into a form in the web page that it returns to the client in response to a prior request. When the user submits the form in the new web page, all the form data, including the "hidden" fields, is sent to the form handler on the web server. With URL rewriting, the web server embeds session-tracking information directly in the URLs of hyperlinks that the user clicks to send subsequent requests.

### *Section 26.7.1 Cookies*

- A cookie is a piece of data typically stored in a text file on the user's computer. A cookie maintains information about the client during and between browser sessions.
- The first time a user visits the website, the user's computer might receive a cookie; this cookie is then reactivated each time the user revisits that site. The collected information is intended to be an anonymous record containing data that is used to personalize the user's future visits to the site.
- Every HTTP-based interaction between a client and a server includes a header containing information either about the request (when the communication is from the client to the server) or about the response (when the communication is from the server to the client).
- When a page receives a request, the header includes information such as the request type and any cookies that have been sent previously from the server to be stored on the client machine. When the server formulates its response, the header information contains any cookies the server wants to store on the client computer and other information, such as the MIME type of the response.
- A cookie's expiration date determines how long the cookie remains on the client's computer. If you do not set a cookie's expiration date, the web browser maintains the cookie for the browsing session's duration. Otherwise, it maintains the cookie until the expiration date.
- Setting the action handler for a **Hyperlink** enables you to respond to a click without redirecting the user to another page.
- To add an action handler to a **Hyperlink** that should also direct the user to another page, you must add a rule to the **Page Navigation** file. To edit this file, right click in the Visual Designer and select **Page Navigation...**, then drag the appropriate **Hyperlink** to the destination page.
- A cookie object is an instance of class **Cookie** in package **javax.servlet.http**.
- An object of class **HttpServletResponse** (from package **javax.servlet.http**) represents the response. This object can be accessed by invoking the method **getExternalContext** on the page bean, then invoking **getResponse** on the resulting object.
- An object of class **HttpServletRequest** (from package **javax.servlet.http**) represents the request. This object can be obtained by invoking method **getExternalContext** on the page bean, then invoking **getRequest** on the resulting object.
- HttpServletRequest** method **getCookies** returns an array of the cookies previously written to the client.
- A web server cannot access cookies created by servers in other domains.

### *Section 26.7.2 Session Tracking with the **SessionBean** Object*

- You can perform session tracking with the **SessionBean** class that is provided in each web application created with Java Studio Creator 2. When a new client requests a web page in the project, a **SessionBean** object is created.
- The **SessionBean** can be accessed throughout a session by invoking the method **getSessionBean** on the page bean. You can then use the **SessionBean** object to access stored session properties.
- To store information in the **SessionBean**, add properties to the **SessionBean** class. To add a property, right click the **SessionBean** node in the **Outline** window and select **Add > Property** to display the **New Property Pattern** dialog. Configure the property and click **OK** to create it.

**Self-Review Exercises**

**26.1** State whether each of the following is *true* or *false*. If *false*, explain why.

- a) Every JSP web page created in Java Studio Creator 2 has its own `ApplicationBean`, `SessionBean`, and `RequestBean` files.
- b) Event-processing life-cycle method `init` is invoked every time a page loads.
- c) Every component on a JSP web page is bound to a property in the Java page bean file.
- d) A single JSF component may have multiple validation components placed on it.
- e) If no expiration date is set for a cookie, that cookie will be destroyed at the end of the browser session.
- f) Each JSF component maps to exactly one corresponding XHTML element.
- g) Expressions in the JSF Expression Language syntax are delimited by `<!--` and `-->`.
- h) The `SessionBean` can store only primitive properties and properties of type `String`.

**26.2** Fill in the blanks in each of the following statements:

- a) Web applications contain three basic tiers: \_\_\_\_\_, \_\_\_\_\_, and \_\_\_\_\_.
- b) The \_\_\_\_\_ JSF component is used to display error messages if validation fails.
- c) A component that checks the input in another component before submitting that input to the server is called a(n) \_\_\_\_\_.
- d) Every page bean class inherits from class \_\_\_\_\_.
- e) When a page loads the first time, the \_\_\_\_\_ event occurs first, followed by the \_\_\_\_\_ event.
- f) The \_\_\_\_\_ file contains the functionality for a JSP.
- g) A(n) \_\_\_\_\_ can be used in a custom validator method to validate the format of user input.
- h) The array of `Cookie` objects stored on the client can be obtained by calling `getCookies` on the \_\_\_\_\_ object.
- i) In a multitier application, the \_\_\_\_\_ tier controls interactions between the application's clients and the application's data.

**Answers to Self-Review Exercises**

**26.1** a) False. If an application contains multiple JSPs, those JSPs will share the scoped data beans. b) False. `init` is invoked the first time the page is requested, but not on page refreshes. c) True. d) True. e) True. f) False. A web component can map to a group of XHTML elements—JSPs can generate complex XHTML markup from simple components. g) False. `#`{ and } delimit JSF Expression Language statements. h) False. The scoped data beans may store any type of property.

**26.2** a) bottom (information), middle (business logic), top (client). b) `Message`. c) validator. d) `AbstractPageBean`. e) `init`, `prerender`. f) page bean. g) regular expression. h) Request (`HttpServletRequest`). i) middle.

**Exercises      1321**

## Exercises

**26.3** (*WebTime Modification*) Modify the `WebTime` example to contain drop-down lists that allow the user to modify such **Static Text** component properties as `background-color`, `color` and `font-size`. Configure these drop-down lists so that the page refreshes whenever the user makes a selection. When the page reloads, it should reflect the specified changes to the properties of the **Static Text** displaying the time.

**26.4** (*Registration Form Modification*) Modify the `WebComponents` application to add functionality to the **Register** button. When the user clicks **Submit**, validate all input fields to make sure the user has filled out the form completely and entered a valid email address and phone number. Then, direct the user to another page that displays a message indicating successful registration and echoes back the user's registration information.

**26.5** (*Page Hit Counter with Cookies*) Create a JSP that uses a persistent cookie (i.e., a cookie with an expiration date in the future) to keep track of how many times the client computer has visited the page. Use the `setMaxAge` method to cause the cookie to remain on the client's computer for one month. Display the number of page hits (i.e., the cookie's value) every time the page loads.

**26.6** (*Page Hit Counter with ApplicationBean*) Create a JSP that uses the `ApplicationBean` to keep track of how many times a page has been visited. [Note: if you were to deploy this page on the web, it would count the number of times that any computer requested the page, unlike in the previous exercise.] Display the number of page hits (i.e., the value of an `int` property in the `ApplicationBean`) every time the page loads.

# 27

# Web Applications: Part 2

## OBJECTIVES

In this chapter you will learn:

- To use data providers to access databases from web applications built in Java Studio Creator 2.
- The basic principles and advantages of Ajax technology.
- To include Ajax-enabled JSF components in a Java Studio Creator 2 web application project.
- To configure virtual forms that enable subsets of a form's input components to be submitted to the server.

*Whatever is in any way  
beautiful hath its source of  
beauty in itself, and is  
complete in itself; praise  
forms no part of it.*

—Marcus Aurelius Antoninus

*There is something in a face,  
An air, and a peculiar grace,  
Which boldest painters  
cannot trace.*

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 27.1 Introduction

This chapter continues our discussion of web application development with several advanced concepts. We discuss accessing, updating and searching databases in a web application, adding virtual forms to web pages to enable subsets of a form's input components to be submitted to the server, and using Ajax-enabled component libraries to improve application performance and component responsiveness.

We present a single address book application developed in three stages to illustrate these concepts. The application is backed by a Java DB database for storing the contact names and their addresses.

The address book application presents a form that allows the user to enter a new name and address to store in the address book and displays the contents of the address book in table format. It also provides a search form that allows the user to search for a contact and, if found, display the contact's address on a map. The first version of this application demonstrates how to add contacts to the database and how to display the list of contacts in a **JSF Table** component. In the second version, we add an Ajax-enabled **Auto Complete Text Field** component and enable it to suggest a list of contact names as the user types. The last version allows you to search the address book for a contact and display the corresponding address on a map using the Ajax-enabled **MapView** component that is powered by Google Maps ([maps.google.com](http://maps.google.com)).

As in Chapter 26, the examples in this chapter were developed in Java Studio Creator 2.0. We installed a supplementary component library—the [Java BluePrints Ajax component library](#)—which provides the Ajax-enabled components used in the address book application. Instructions for installing this library are included in Section 27.3.1.

## 27.2 Accessing Databases in Web Applications

Many web applications access databases to store and retrieve persistent data. In this section, we build a web application that uses a Java DB database to store contacts in the address book and display contacts from the address book on a web page.

The web page enables the user to enter new contacts in a form. This form consists of **Text Field** components for the contact's first name, last name, street address, city, state and zip code. The form also has a **Submit** button to send the data to the server and a **Clear** button to reset the form's fields. The application stores the address book information in a database named **AddressBook**, which has a single table named **Addresses**. (We provide this database in the examples directory for this chapter. You can download the examples from [www.deitel.com/books/jhttp7](http://www.deitel.com/books/jhttp7)). This example also introduces the **Table** JSF component, which displays the addresses from the database in tabular format. We show how to configure the **Table** component shortly.

### 27.2.1 Building a Web Application That Displays Data from a Database

We now explain how to build the **AddressBook** application's GUI and set up a data binding that allows the **Table** component to display information from the database. We present the generated JSP file later in the section, and we discuss the related page bean file in Section 27.2.2. To build the **AddressBook** application, perform the following steps:

#### *Step 1: Creating the Project*

In Java Studio Creator 2, create a **JSF Web Application** project named **AddressBook**. Rename the JSP and page bean files to **AddressBook** using the refactoring tools.

#### *Step 2: Creating the Form for User Input*

In **Design** mode, add a **Static Text** component to the top of the page that reads "Add a contact to the address book:" and use the component's **style** property to set the font size to 18px. Add six **Text Field** components to the page and rename them **fnameTextField**, **lnameTextField**, **streetTextField**, **cityTextField**, **stateTextField** and **zipTextField**. Set each **Text Field**'s **required** property to **true** by selecting the **Text Field**, then clicking the required property's checkbox. Label each **Text Field** with a **Label** component and associate the **Label** with its corresponding **Text Field**. Finally, add a **Submit** and a **Clear** button. Set the **Submit** button's **primary** property to **true** to make it stand out more on the page than the **Clear** button and to allow the user to submit a new contact by pressing **Enter** rather than by clicking the **Submit** button. Set the **Clear** button's **reset** property to **true** to prevent validation when the user clicks the **Clear** button. Since we are clearing the fields, we don't want to ensure that they contain information. We discuss the action handler for the **Submit** button after we present the page bean file. The **Clear** button does not need an action handler method, because setting the **reset** property to **true** automatically configures the button to reset all of the page's input fields. When you have finished these steps, your form should look like Fig. 27.1.

#### *Step 3: Adding a Table Component to the Page*

Drag a **Table** component from the **Basic** section of the **Palette** to the page and place it just below the two **Button** components. Name it **addressesTable**. The **Table** component formats and displays data from database tables. In the **Properties** window, change the **Table**'s

## 27.2 Accessing Databases in Web Applications

1325

The screenshot shows a web-based form titled "Add a contact to the AddressBook:". The form contains fields for "First Name", "Last Name", "Street", "City", "State", and "Zip". Each field is preceded by an asterisk (\*) indicating it is required. Below the fields are two buttons: "Submit" and "Clear".

**Fig. 27.1** | AddressBook application form for adding a contact.

title property to `Contacts`. We show how to configure the `Table` to interact with the `AddressBook` database shortly.

#### Step 4: Adding a Database to a Java Studio Creator 2 Web Application

For this example, we use a Java DB database named `AddressBook` with a single database table named `Addresses`. To make this database available in your projects, copy the `AddressBook` folder from the chapter's examples folder into your Java Studio Creator 2 installation folder's `SunAppServer8\derby\databases` folder.

To use a database in a Java Studio Creator 2 web application, you must first start the IDE's **bundled database server**, which allows database connections to be used in Java Studio Creator 2 projects. The server includes drivers for many databases, including Java DB. Click the **Servers** tab below the **File** menu, right click **Bundled Database Server** at the bottom of the **Servers** window and select **Start Bundled Database Server**. You can now use databases that run on this server in your applications.

To add the `AddressBook` database to this project, right click the **Data Sources** node at the top of the **Servers** window and select **Add Data Source....** In the **Add Data Source** dialog (Fig. 27.2), enter `AddressBook` for the data source name and select **Derby** for the server type. (Recall from Chapter 25 that Java DB is the Sun-branded version of Apache Derby.) The user ID and password for this database are both `jhttp7`. For the database

**Fig. 27.2** | Dialog to add a data source.

**1326** Chapter 27 Web Applications: Part 2

URL, enter `jdbc:derby://localhost:21527/AddressBook`. This URL indicates that the database resides on the local machine and accepts connections on port 21527. Click the **Select** button to choose a table that will be used to validate the database. In the dialog that appears, choose the **JHTP7.ADDRESSES** table, as this is the only table in the database. Click **Select** to close this dialog, then click **Add** to add the database as a data source for the project and close the dialog. [Note: Java Studio Creator 2 displays database and table names in capital letters.]

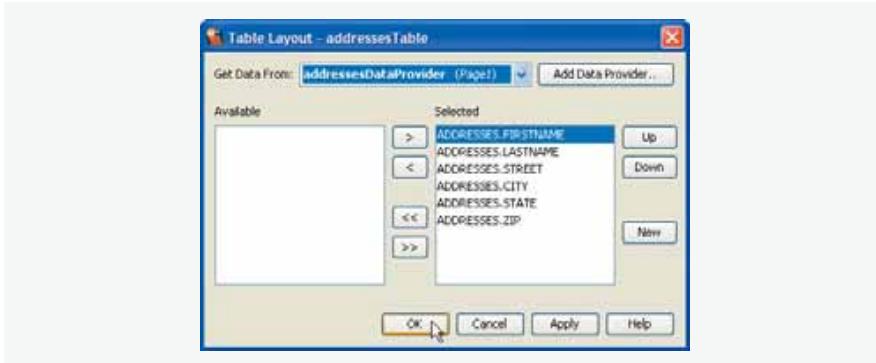

**Step 5: Binding the Table Component to the Addresses Table of the AddressBook Database**

Now that we've configured a data source for the Addresses database table, we can configure the **Table** component to display the AddressBook data. Simply drag the database table from the Servers tab and drop it on the **Table** component to create the binding.

If you need more precise control over the columns to display, you can bind to a database table as follows: Right click the **Table** component and select **Bind to Data** to display the **Table Layout** dialog. Click the **Add Data Provider...** button to display the **Add Data Provider** dialog, which contains a list of the available data sources. Expand the **AddressBook** node, expand the **Tables** node, select **ADDRESSES** and click **Add**. The **Table Layout** dialog now displays a list of the columns in the Addresses database table (Fig. 27.3). All of the items under the **Selected** heading will be displayed in the **Table**. To remove a column from the **Table**, you can select it and click the < button. Since we want to display all of these columns in our **Table**, simply click **OK** to exit the dialog.

By default, the **Table** uses the database table's column names in all uppercase letters as headings. To change these headings, select a column and edit its **headerText** property in the **Properties** window. To select a column, expand the **addressesTable** node in the **Outline** window (while in **Design** mode), then select the appropriate column object. We also changed the **id** property of each column to make the variable names in the code more readable. In **Design** mode, your **Table**'s column heads should appear as in Fig. 27.4.

An address book might contain many contacts, so we'd like to display only a few at a time. Clicking the checkbox next to the table's **paginationControls** property in the **Properties** window configures this **Table** for automatic pagination. Five rows will be displayed at a time, and buttons for moving forward and backward between groups of five contacts

**Fig. 27.3** | Dialog for binding to the Addresses table.

## 27.2 Accessing Databases in Web Applications

1327

First Name	Last Name	Street	City	State	Zip
abc	abc	abc	abc	abc	abc
abc	abc	abc	abc	abc	abc
abc	abc	abc	abc	abc	abc

**Fig. 27.4** | Table component after binding it to a database table and editing its column names for display purposes.

will be added to the bottom of the **Table**. (You may also use the **Table Layout** dialog's **Options** tab to select the pagination and number of rows. To view this tab, right click the **Table**, select **Table Layout...**, then click the **Options** tab.) Next, set the **addressesTable**'s **internalVirtualForm** property. Virtual forms allow subsets of a form's input components to be submitted to the server. Setting this property prevents the pagination control buttons on the **Table** from submitting the **Text Fields** on the form every time the user wishes to view the next group of contacts. Virtual forms are discussed in Section 27.4.1.

Notice that binding the **Table** to a data provider added a new **addressesDataProvider** object (an instance of class **CachedRowSetDataProvider**) to the **AddressBook** node in the **Outline** window. A **CachedRowSetDataProvider** provides a scrollable **RowSet** that can be bound to a **Table** component to display the **RowSet**'s data. This data provider is a wrapper for a **CachedRowSet** object. If you click the **addressesDataProvider** element in the **Outline** window, you will see in the **Properties** window that its **CachedRowSet** property is set to **addressesRowSet**, an object that implements interface **CachedRowSet**.

#### Step 6: Modifying **addressesRowSet**'s SQL Statement

The **CachedRowSet** object wrapped by our **addressesDataProvider** is configured by default to execute a SQL query that selects all the data in the **Addresses** table of the **AddressBook** database. You can edit this SQL query by expanding the **SessionBean** node in the **Outline** window and double clicking the **addressesRowSet** element to open the query editor window (Fig. 27.5). We'd like to edit the SQL statement so that records with duplicate last names are sorted by last name, then by first name. To do this, click in the **Sort Type** column next to the **LASTNAME** row and select **Ascending**. Then, repeat this for the **FIRSTNAME** row. Notice that the expression

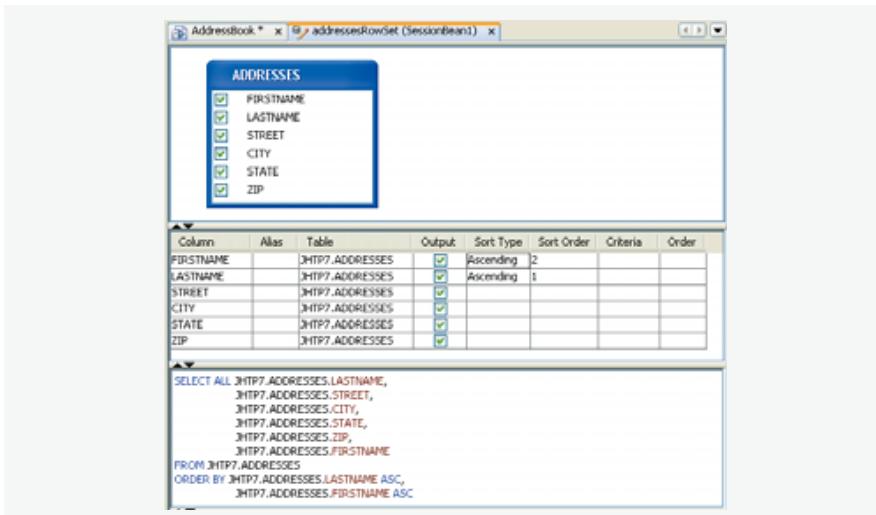

```
ORDER BY JHTP7.ADDRESSES.LASTNAME ASC,
JHTP7.ADDRESSES.FIRSTNAME ASC
```

was added to the SQL statement at the bottom of the editor.

#### Step 7: Adding Validation

It is important to validate the form data on this page to ensure that the data can be successfully inserted into the **AddressBook** database. All of the database's columns are of type **varchar** and have length restrictions. For this reason, you should either add a **Length Validator** to each **Text Field** component or set each **Text Field** component's **maxLength** property. We chose to set the **maxLength** property of each. The first name, last name, street, city, state and zip code **Text Field** components may not exceed 20, 30, 100, 30, 2 and 5 characters, respectively.

## 1328 Chapter 27 Web Applications: Part 2

**Fig. 27.5** | Editing addressesRowSet's SQL statement.

Finally, drag a **Message Group** component onto your page to the right of the **Table**. A **Message Group** component displays system messages. We use this component to display an error message when an attempt to add a contact to the database fails. Set the **Message Group**'s `showGlobalOnly` property to true to prevent component-level validation error messages from being displayed here.

#### *JSP File for a Web Page that Interacts with a Database*

The JSP file for the application is shown in Fig. 27.6. This file contains a large amount of generated markup for components you learned in Chapter 26. We discuss the markup for only the components that are new in this example.

```

1 <?xml version="1.0" encoding="UTF-8"?>
2
3 <!-- Fig. 27.6: AddressBook.jsp -->
4 <!-- AddressBook JSP with an add form and a Table JSF component. -->
5
6 <jsp:root version="1.2" xmlns:f="http://java.sun.com/jsf/core"
7 xmlns:h="http://java.sun.com/jsf/html" xmlns:jsf=
8 "http://java.sun.com/JSP/Page" xmlns:ui="http://www.sun.com/web/ui">
9 <jsp:directive.page contentType="text/html;charset = UTF-8"
10 pageEncoding="UTF-8"/>
11 <f:view>
12 <ui:page binding="#{AddressBook.page1}" id="page1">
13 <ui:html binding="#{AddressBook.html1}" id="html1">
14 <ui:head binding="#{AddressBook.head1}" id="head1">
15 <ui:link binding="#{AddressBook.link1}" id="link1"
16 url="/resources/stylesheets.css"/>
```

208 </jsp:root>
```

**Fig. 27.6** | AddressBook JSP with an add form and a Table JSF component (Part 4 of 5.)

## 1332 Chapter 27 Web Applications: Part 2

**Fig. 27.6** | AddressBook JSP with an add form and a **Table** JSF component (Part 5 of 5.)

Lines 21–72 contain the JSF components that comprise the form that gathers user input. Lines 73–199 define the **Table** element (`ui:table`) that displays address information from the database. Lines 79–140 (not shown here) contain JavaScript functions generated by the IDE to handle **Table** actions, such as a change in the current row's state. JSF **Tables** may have multiple groups of rows displaying different data. This **Table** has a single `ui:tableRowGroup` with a start tag in lines 142–146. The row group's `sourceData` attribute is bound to our `addressesDataProvider` and given the variable name `currentRow`. The row group also defines the **Table**'s columns. Each `ui:tableColumn` element contains a `ui:staticText` element with its `text` attribute bound to a column in the data provider `currentRow`. These `ui:staticText` elements enable the **Table** to display each row's data.

#### Session Bean for the AddressBook Application

Figure 27.7 displays the `SessionBean1.java` file generated by Java Studio Creator 2 for the AddressBook application. The `CachedRowSet` that the **Table** component's data provider uses to access the AddressBook database is a property of this class (lines 31–41).

```

1 // Fig. 27.7: SessionBean1.java
2 // Session bean that initializes the data source for the
3 // AddressBook database.

```

**Fig. 27.7** | Session Bean that initializes the data source for the AddressBook database. (Part 1 of 2.)

27.2 Accessing Databases in Web Applications **1333**

```

4 package addressbook;
5
6 import com.sun.rave.web.ui.appbase.AbstractSessionBean;
7 import javax.faces.FacesException;
8 import com.sun.sql.rowset.CachedRowSetXImpl;
9
10 public class SessionBean1 extends AbstractSessionBean
11 {
12 private int __placeholder;
13
14 private void _init() throws Exception
15 {
16 addressesRowSet.setDataSourceName(
17 "java:comp/env/jdbc/AddressBook");
18 addressesRowSet.setCommand(
19 "SELECT ALL JHTTP7.ADDRESSES.FIRSTNAME," +
20 "\nJHTTP7.ADDRESSES.LASTNAME," +
21 "\nJHTTP7.ADDRESSES.STREET," +
22 "\nJHTTP7.ADDRESSES.CITY," +
23 "\nJHTTP7.ADDRESSES.STATE," +
24 "\nJHTTP7.ADDRESSES.ZIP" +
25 "\nFROM JHTTP7.ADDRESSES" +
26 "\nORDER BY JHTTP7.ADDRESSES.LASTNAME ASC," +
27 "\nJHTTP7.ADDRESSES.FIRSTNAME ASC");
28 addressesRowSet.setTableName("ADDRESSES");
29 } // end method _init
30
31 private CachedRowSetXImpl addressesRowSet = new CachedRowSetXImpl();
32
33 public CachedRowSetXImpl getAddressesRowSet()
34 {
35 return addressesRowSet;
36 }
37
38 public void setAddressesRowSet(CachedRowSetXImpl crsxi)
39 {
40 this.addressesRowSet = crsxi;
41 }
42
43 // Lines 43-76 of the autogenerated code were removed to save space.
44 // The complete source code is provided in this example's folder.
45 } // end class SessionBean1

```

**Fig. 27.7** | Session Bean that initializes the data source for the AddressBook database. (Part 2 of 2.)

The `_init` method (lines 14–29) configures `addressesRowSet` to interact with the `AddressBook` database (lines 16–27). Lines 16–17 connect the row set to the database. Lines 18–27 set `addressesRowSet`'s SQL command to the query configured in Fig. 27.5.

### 27.2.2 Modifying the Page Bean File for the AddressBook Application

After building the web page and configuring the components used in this example, double click the `Submit` button to create an action event handler for this button in the page bean

**1334**    [Chapter 27](#)   [Web Applications: Part 2](#)

file. The code to insert a contact into the database will be placed in this method. The page bean with the completed event handler is shown in Fig. 27.8 below.

```

1 // Fig. 27.8: AddressBook.java
2 // Page bean for adding a contact to the address book.
3 package addressbook;
4
5 import com.sun.data.provider.RowKey;
6 import com.sun.rave.web.ui.appbase.AbstractPageBean;
7 import com.sun.rave.web.ui.component.Body;
8 import com.sun.rave.web.ui.component.Form;
9 import com.sun.rave.web.ui.component.Head;
10 import com.sun.rave.web.ui.component.Html;
11 import com.sun.rave.web.ui.component.Link;
12 import com.sun.rave.web.ui.component.Page;
13 import javax.faces.FacesException;
14 import com.sun.rave.web.ui.component.StaticText;
15 import com.sun.rave.web.ui.component.TextField;
16 import com.sun.rave.web.ui.component.Label;
17 import com.sun.rave.web.ui.component.Button;
18 import com.sun.rave.web.ui.component.Table;
19 import com.sun.rave.web.ui.component.TableRowGroup;
20 import com.sun.rave.web.ui.component.TableColumn;
21 import com.sun.data.provider.impl.CachedRowSetDataProvider;
22 import com.sun.rave.web.ui.component.MessageGroup;
23
24 public class AddressBook extends AbstractPageBean
25 {
26 private int __placeholder;
27
28 private void _init() throws Exception
29 {
30 addressesDataProvider.setCachedRowSet(
31 (javax.sql.rowset.CachedRowSet)
32 .getValue("#{"SessionBean1.addressesRowSet}"));
33 addressesTable.setInternalVirtualForm(true);
34 }
35
36 // Lines 36-521 of the autogenerated code were removed to save space.
37 // The complete source code is provided in this example's folder.
38
522 public void prerender()
523 {
524 addressesDataProvider.refresh();
525 } // end method prerender
526
527 public void destroy()
528 {
529 addressesDataProvider.close();
530 } // end method destroy
531

```

**Fig. 27.8** | Page bean for adding a contact to the address book. (Part I of 2.)

27.2 Accessing Databases in Web Applications **1335**

```

532 // action handler that adds a contact to the AddressBook database
533 // when the user clicks submit
534 public String submitButton_action()
535 {
536 if (addressesDataProvider.canAppendRow())
537 {
538 try
539 {
540 RowKey rk = addressesDataProvider.appendRow();
541 addressesDataProvider.setCursorRow(rk);
542
543 addressesDataProvider.setValue("ADDRESSES.FIRSTNAME",
544 fnameTextField.getValue());
545 addressesDataProvider.setValue("ADDRESSES.LASTNAME",
546 lnameTextField.getValue());
547 addressesDataProvider.setValue("ADDRESSES.STREET",
548 streetTextField.getValue());
549 addressesDataProvider.setValue("ADDRESSES.CITY",
550 cityTextField.getValue());
551 addressesDataProvider.setValue("ADDRESSES.STATE",
552 stateTextField.getValue());
553 addressesDataProvider.setValue("ADDRESSES.ZIP",
554 zipTextField.getValue());
555 addressesDataProvider.commitChanges();
556
557 // reset text fields
558 lnameTextField.setValue("");
559 fnameTextField.setValue("");
560 streetTextField.setValue("");
561 cityTextField.setValue("");
562 stateTextField.setValue("");
563 zipTextField.setValue("");
564 } // end try
565 catch (Exception ex)
566 {
567 error("The address book was not updated. " +
568 ex.getMessage());
569 } // end catch
570 } // end if
571
572 return null;
573 } // end method submitButton_action
574 } // end class AddressBook

```

**Fig. 27.8** | Page bean for adding a contact to the address book. (Part 2 of 2.)

Lines 534–573 contain the event-handling code for the **Submit** button. Line 536 determines whether a new row can be appended to the data provider. If so, a new row is appended at line 540. Every row in a `CachedRowSetDataProvider` has its own key; method `appendRow` returns the key for the new row. Line 541 sets the data provider's cursor to the new row, so that any changes we make to the data provider affect that row. Lines 543–554 set each of the row's columns to the values entered by the user in the cor-

**1336**    [Chapter 27](#) [Web Applications: Part 2](#)

responding **Text Fields**. Line 555 stores the new contact by calling method `commitChanges` of class `CachedRowSetDataProvider` to insert the new row into the `AddressBook` database.

Lines 558–563 clear all of the form's **Text Fields**. If these lines are omitted, the fields will retain their current values after the database is updated and the page reloads. Also, the **Clear** button will not work properly if the **Text Fields** are not cleared. Rather than emptying the **Text Fields**, it will reset them to the values they held the last time form was submitted.

Lines 565–569 catch any exceptions that might occur while updating the `AddressBook` database. Lines 567–568 display a message indicating that the database was not updated as well as the exception's error message in the page's `MessageGroup` component.

In method `prerender`, line 524 calls `CachedRowSetDataProvider` method `refresh`. This re-executes the wrapped `CachedRowSet`'s SQL statement and re-sorts the `Table`'s rows so that the new row is displayed in the proper order. If you do not call `refresh`, the new address is displayed at the end of the `Table` (since we appended the new row to the end of the data provider). The IDE automatically generated code to free resources used by the data provider (line 529) in the `destroy` method.

### 27.3 Ajax-Enabled JSF Components

The term **Ajax**—short for **Asynchronous JavaScript and XML**—was coined by Jesse James Garrett of Adaptive Path, Inc. in February 2005 to describe a range of technologies for developing highly responsive, dynamic web applications. Ajax applications include Google Maps, Yahoo's Flickr and many more. Ajax separates the user interaction portion of an application from its server interaction, enabling both to proceed asynchronously in parallel. This enables Ajax web-based applications to perform at speeds approaching those of desktop applications, reducing or even eliminating the performance advantage that desktop applications have traditionally had over web-based applications. This has huge ramifications for the desktop applications industry—the applications platform of choice is starting to shift from the desktop to the web. Many people believe that the web—especially in the context of abundant open-source software, inexpensive computers and exploding Internet bandwidth—will create the next major growth phase for Internet companies.

Ajax makes asynchronous calls to the server to exchange small amounts of data with each call. Where normally the entire page would be submitted and reloaded with every user interaction on a web page, Ajax allows only the necessary portions of the page to reload, saving time and resources.

Ajax applications are marked up in XHTML and CSS as any other web page and make use of client-side scripting technologies such as JavaScript to interact with page elements. The `XMLHttpRequestObject` enables the asynchronous exchanges with the web server that make Ajax applications so responsive. This object can be used by most scripting languages to pass XML data from the client to the server and to process XML data sent from the server back to the client.

While using Ajax technologies in web applications can dramatically improve performance, programming in Ajax is complex and error prone. It requires page designers to know both scripting and markup languages. **Ajax libraries** make it possible to reap Ajax's benefits in web applications without the labor of writing "raw" Ajax. These libraries provide Ajax-enabled page elements that can be included in web pages simply by adding library-defined tags to the page's markup. We limit our discussion of building Ajax applications to the use of one such library in Java Studio Creator 2.

### 27.3.1 Java BluePrints Component Library

The **Java BluePrints** Ajax component library provides **Ajax-enabled JSF components**. These components rely on Ajax technology to deliver the feel and responsiveness of a desktop application over the web. Figure 27.9 summarizes the current set of components that you can download and use with Java Studio Creator 2. We demonstrate the **AutoComplete Text Field** and **Map Viewer** components in the next two sections.

To use the Java BluePrints Ajax-enabled components in Java Studio Creator 2, you must download and import them. The IDE provides a wizard for installing this group of components. To access it, choose **Tools > Update Center** to display the **Update Center Wizard** dialog. Click **Next >** to search for available updates. In the **Available Updates** and **New Modules** area of the dialog, select **BluePrints AJAX Components** and click the right arrow (**>**) button to add it to the list of items you'd like to install. Click **Next >** and follow the prompts to accept the terms of use and download the components. When the download completes, click **Next >** then click **Finish**. Click **OK** to restart the IDE.

Next, you must import the components into the **Palette**. Select **Tools > Component Library Manager**, then click **Import....** Click **Browse...** in the **Import Component Library** dialog that appears. Select the **ui.complib** file and click **Open**. Click **OK** to import both the **BluePrints AJAX Components** and the **BluePrints AJAX SupportBeans**. Close the **Component Library Manager** to return to the IDE.

You should now see two new nodes at the bottom of the **Palette**. The first, **BluePrints AJAX Components**, provides the eight components listed in Fig. 27.9. The second, **Blue-**

Component	Description
AutoComplete Text Field	Makes Ajax requests to display a list of suggestions as the user types in the text field.
Buy Now Button	Initiates a transaction through the PayPal web site.
Map Viewer	Uses the Google Maps API to display a map that pans, zooms, and can display markers for locations of interest.
Popup Calendar	Provides a calendar that enables a user to scroll between months and years. Fills a <b>Text Field</b> with a formatted date when the user selects a day.
Progress Bar	Visually displays the progress of a long-running operation. Uses a programmer-supplied calculation to determine the progress percentage.
Rating	Provides a customizable five-star rating bar that can display messages as the user moves the mouse over the ratings.
Rich Textarea Editor	Provides an editable text area that allows the user to format text with fonts, colors, hyperlinks and backgrounds.
Select Value Text Field	Displays a list of suggestions in a drop-down list as the user types, similar to the <b>AutoComplete Text Field</b> .

**Fig. 27.9** | Ajax-enabled components provided by the Java BluePrints Ajax component library.

**1338**    [Chapter 27](#) [Web Applications: Part 2](#)

**Prints AJAX Support Beans**, includes components that support the Ajax components. You can now build high-performance Ajax web applications by dragging, dropping and configuring the component's properties, just as you do with other components in the **Palette**.

## 27.4 AutoComplete Text Field and Virtual Forms

We demonstrate the **AutoComplete Text Field** component from the BluePrints catalog by adding a new form to our **AddressBook** application. The **AutoComplete Text Field** provides a list of suggestions as the user types. It obtains the suggestions from a data source, such as a database or web service. Eventually, the new form will allow users to search the address book by last name, then first name. If the user selects a contact, the application will display the contact's name and address on a map of the neighborhood. We build this form in two stages. First, we'll add the **AutoComplete Text Field** that will display suggestions as the user types a contact's last name. Then we'll add the search functionality and map display in the next step.

### *Adding Search Components to the AddressBook.jsp Page*

Using the **AddressBook** application from Section 27.2, drop a **Static Text** component named **searchHeader** below **addressesTable**. Change its text to "Search the address book by last name:" and change its font size to 18 px. Now drag an **AutoComplete Text Field** component to the page and name it **name.AutoComplete**. Set this field's required property to **true**. Add a **Label** named **nameSearchLabel** containing the text "Last Name:" to the left of the **AutoComplete Text Field**. Finally, add a button called **lookUpButton** with the text **Look Up** to the right of the **AutoComplete Text Field**.

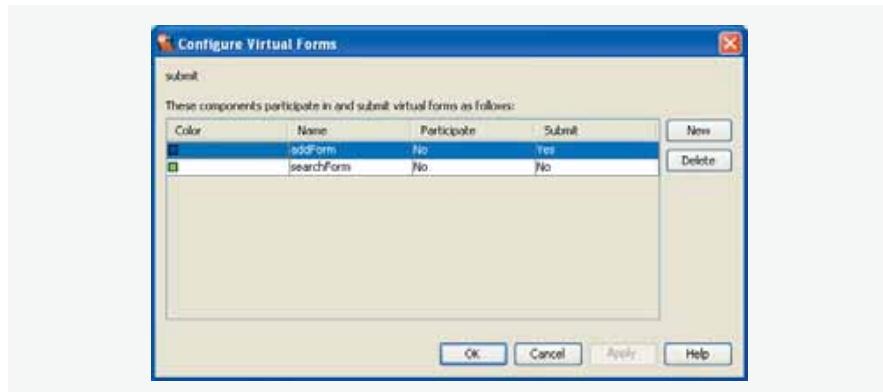

### 27.4.1 Configuring Virtual Forms

**Virtual forms** are used when you would like a button to submit a subset of the page's input fields to the server. Recall that the **Table**'s internal virtual forms were enabled so that clicking the pagination buttons would not submit any of the data in the **Text Fields** used to add a contact to the **AddressBook** database. Virtual forms are particularly useful for displaying multiple forms on the same page. They allow you to specify a **submitter** and one or more **participants** for a form. When the virtual form's submitter component is clicked, only the values of its participant components will be submitted to the server. We use virtual forms in our **AddressBook** application to separate the form for adding a contact to the **AddressBook** database from the form for searching the database.

To add virtual forms to the page, right click the **Submit** button on the upper form and choose **Configure Virtual Forms...** from the popup menu to display the **Configure Virtual Forms** dialog. Click **New** to add a virtual form, then click in the **Name** column and change the new form's name to **addForm**. Double click the **Submit** column and change the option to **Yes** to indicate that this button should be used to submit the **addForm** virtual form. Click **OK** to exit the dialog. Next, select all the **Text Fields** used to enter a contact's information in the upper form. You can do this by holding the **Ctrl** key while you click each **Text Field**. Right click one of the selected **Text Fields** and choose **Configure Virtual Forms....** In the **Participate** column of the **addForm**, change the option to **Yes** to indicate that the values in these **Text Fields** should be submitted to the server when the form is submitted. Figure 27.10 shows the **Configure Virtual Forms** dialog after both virtual forms have been added. Click **OK** to exit.

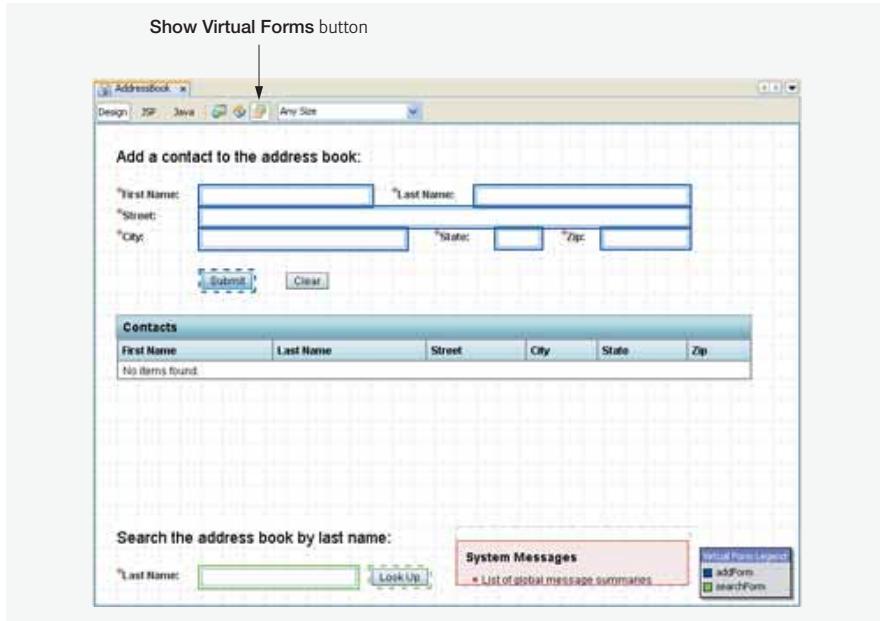

## 27.4 AutoComplete Text Field and Virtual Forms

1339

**Fig. 27.10** | Configure Virtual Forms dialog.

Repeat the process described above to create a second virtual form named `searchForm` for the lower form. The **Look Up** Button should submit the `searchForm`, and **name.AutoComplete** should participate in the `searchForm`. Next, return to **Design** mode and click the **Show Virtual Forms** button ( at the top of the Visual Designer panel to display a legend of the virtual forms on the page. Your virtual forms should be configured as in Fig. 27.11. The **Text Fields** outlined in blue participate in the virtual form `addForm`. Those outlined in green participate in the virtual form `searchForm`. The components outlined with a

**Fig. 27.11** | Virtual forms legend.

**1340** Chapter 27 Web Applications: Part 2

dashed line submit their respective forms. A color key is provided at the bottom right of the **Design** area so that you know which components belong to each virtual form.

### 27.4.2 JSP File with Virtual Forms and an AutoComplete Text Field

Figure 27.12 presents the JSP file generated by Java Studio Creator 2 for this stage of the AddressBook application. Notice that a new tag library is specified in the root element (`xmlns:bp="http://java.sun.com/blueprints/ui/14"; line 6`). This is the BluePrints catalog library that provides Ajax-enabled components such as the **AutoComplete Text Field** component. We focus only on the new features of this JSP.

```

230 </jsp:root>
```

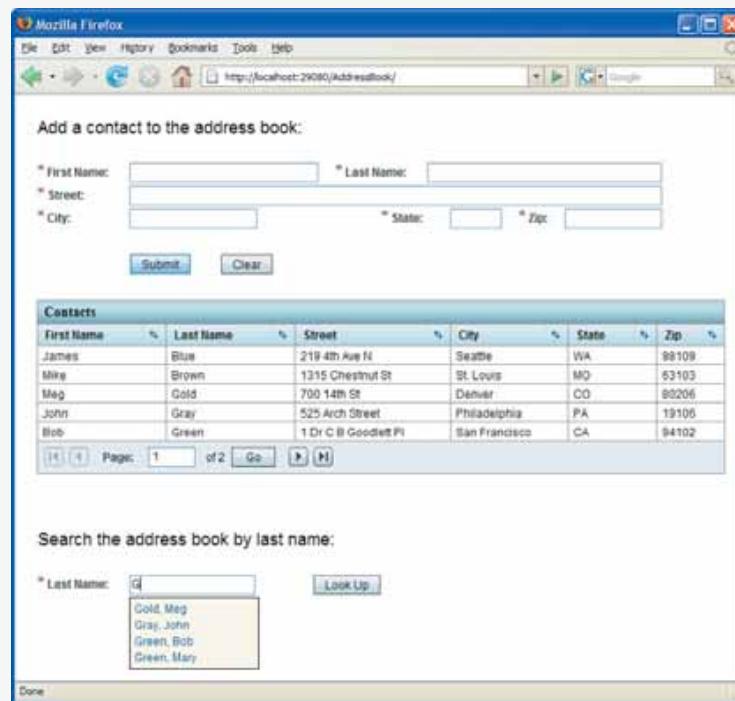

Fig. 27.12 | AddressBook JSP with an AutoComplete Text Field component. (Part 4 of 4.)

**1344 Chapter 27 Web Applications: Part 2**

Lines 21–25 configure the virtual forms for this page. Lines 217–221 define the **AutoComplete Text Field** component. This component's `completionMethod` attribute is bound to the page bean's `name.AutoComplete_complete` method (discussed in Section 27.4.3), which provides the list of options the **AutoComplete Text Field** component should suggest. To create this method, right click the `name.AutoComplete` component in **Design** view and select **Edit Event Handler > complete**. Notice that the **Look Up** button (lines 222–224) does not specify an action handler method binding; we'll add this in Section 27.5.

#### 27.4.3 Providing Suggestions for an AutoComplete Text Field

Figure 27.13 displays the page bean file for the JSP in Fig. 27.12. It includes the method `name.AutoComplete_complete`, which provides the functionality for the **AutoComplete Text Field**. Otherwise, this page bean is identical to the one in Fig. 27.8.

```

655 // alphabetically less than the prefix
656 if (prefix.compareTo(name) < 0)
657 {
658 break;
659 } // end if
660 } // end else
661
662 // move cursor to next row of database
663 hasNext = addressesDataProvider.cursorNext();
664 } // end while
665 } // end try
666 catch (Exception ex)
667 {
668 result.addItem("Exception getting matching names.");
669 } // end catch
670 } // end method nameAutoComplete_complete
671 } // end class AddressBook

```

**Fig. 27.13** | Page bean that suggests names in the AutoComplete Text Field. (Part 3 of 3.)

## 27.5 Google Maps Map Viewer Component 1347

Method `nameAutoComplete_complete` (lines 630–670) is invoked after every key-stroke in the **AutoComplete Text Field** to update the list of suggestions based on the text the user has typed so far. The method receives a string (`prefix`) containing the text the user has entered and a `CompletionResult` object (`result`) that is used to display suggestions to the user. The method loops through the rows of the `addressesDataProvider`, retrieves the name from each row, checks whether the name begins with the letters typed so far and, if so, adds the name to `result`. Line 635 sets the cursor to the first row in the data provider. Line 637 determines whether there are more rows in the data provider. If so, lines 640–644 retrieve the last name and first name from the current row and create a `String` in the format *last name, first name*. Line 648 compares the lowercase versions of `name` and `prefix` to determine whether the name starts with the characters typed so far. If so, the name is a match and line 650 adds it to `result`.

Recall that the data provider wraps a `CachedRowSet` object that contains a SQL query which returns the rows in the database sorted by last name, then first name. This allows us to stop iterating through the data provider once we reach a row whose name comes alphabetically after the text entered by the user—names in the rows beyond this will all be alphabetically greater and thus are not potential matches. If the name does not match the text entered so far, line 656 tests whether the current name is alphabetically greater than the `prefix`. If so, line 658 terminates the loop.

### Performance Tip 27.1

*When using database columns to provide suggestions in an AutoComplete Text Field, sorting the columns eliminates the need to check every row in the database for potential matches. This significantly improves performance when dealing with a large database.*

If the name is neither a match nor alphabetically greater than `prefix`, then line 663 moves the cursor to the next row in the data provider. If there is another row, the loop iterates again, checking whether the name in the next row matches the `prefix` and should be added to `results`.

Lines 666–669 catch any exceptions generated while searching the database. Line 668 adds text to the suggestion box indicating the error to the user.

## 27.5 Google Maps Map Viewer Component

We now complete the `AddressBook` application by adding functionality to the **Look Up Button**. When the user clicks this **Button**, the name in the **AutoComplete Text Field** is used to search the `AddressBook` database. We also add a **Map Viewer** Ajax-enabled JSF component to the page to display a map of the area for the address. A **Map Viewer** uses the **Google Maps API** web service to find and display maps. (The details of web services are covered in Chapter 28.) In this example, using the Google Maps API is analogous to making ordinary method calls on a **Map Viewer** object and its supporting bean in the page bean file. When a contact is found, we display a map of the neighborhood with a **Map Marker** that points to the location and indicates the contact’s name and address.

### 27.5.1 Obtaining a Google Maps API Key

To use the **Map Viewer** component, you must have an account with Google. Visit the site <https://www.google.com/accounts/ManageAccount> to register for a free account if you

## 1348 Chapter 27 Web Applications: Part 2

do not have one. Once you have logged in to your account, you must obtain a key to use the Google Maps API from [www.google.com/apis/maps](http://www.google.com/apis/maps). The key you receive will be specific to this web application and will limit the number of maps the application can display per day. When you sign up for the key, you will be asked to enter the URL for the application that will be using the Google Maps API. If you are deploying the application only on Java Studio Creator 2's built-in Sun Application Server 8 test server, enter `http://localhost:29080/` as the URL.

After you accept Google's terms and conditions, you'll be redirected to a page containing your new Google Maps API key. Save this key in a text file in a convenient location for future reference.

### 27.5.2 Adding a Map Viewer Component to a Page

Now that you have a key to use the Google Maps API, you are ready to complete the AddressBook application. With `AddressBook.jsp` open in **Design** mode, add a **Map Viewer** component named `mapViewer` below the `nameAutoComplete`. In the **Properties** window, set the **Map Viewer**'s **key** property to the key you obtained for accessing the Google Maps API. Set the **rendered** property to `false` so that the map will not be displayed when the user has not yet searched for an address. Set the **zoomLevel** property to 1 (`In`) so the user can see the street names on the map.

Drop a **Map Marker** (named `mapMarker`) from the **AJAX Support Beans** section of the **Palette** anywhere on the page. This component (which is not visible in **Design** view) marks the contact's location on the map. You must bind the marker to the map so that the marker will display on the map. To do so, right click the **Map Viewer** in **Design** mode component and choose **Property Bindings...** to display the **Property Bindings** dialog. Select `info` from the **Select bindable property** column of the dialog, then select `mapMarker` from the **Select binding target** column. Click **Apply**, then **Close**.

Finally, drop a **Geocoding Service Object** (named `geoCoder`) from the **AJAX Support Beans** section of the **Palette** anywhere on the page. This object (which is not visible in **Design** view) converts street addresses into latitudes and longitudes that the **Map Viewer** component uses to display an appropriate map.

#### *Adding a Data Provider to the Page*

To complete this application, you need a second data provider to search the `AddressBook` database based on the first and last name entered in the **AutoComplete Text Field**. Open the **Servers** window and expand the `AddressBook` node and its `Tables` node to reveal the `Addresses` table. Right click the table's node and select **Add To Page** to display the **Add New Data Provider with RowSet** dialog (Fig. 27.14). We want to create a new data source rather than reuse the existing one, because the query to search for contacts is different from the query to display all the contacts. Select the **Create** option for the `SessionBean` and enter the name `addressesSearch` for the data provider. Click **OK** to create the new data provider. In the **Outline** window, a new node named `addressesSearchDataProvider` has been added to the `AddressBook` node, and a node named `addressesSearch` has been added to the `SessionBean` node.

Double click the `addressesSearch` node to edit the SQL statement for this RowSet. Since we will use this row set to search the database for a given last and first name, we need to add search parameters to the `SELECT` statement the RowSet will execute. To do this,

## 27.5 Google Maps Map Viewer Component

1349

**Fig. 27.14** | Dialog to create a new data provider.

enter the text "= ?" in the **Criteria** column of both the first-name and last-name rows in the SQL statement editor table. The number 1 should appear in the **Order** column for first name and 2 should appear for last name. Notice that the lines

```
WHERE JHTP7.ADDRESSES.FIRSTNAME = ?
AND JHTP7.ADDRESSES.LASTNAME = ?
```

have been added to the SQL statement. This indicates that the RowSet now executes a parameterized SQL statement. The parameters can be set programmatically, with the first name as the first parameter and the last name as the second.

### 27.5.3 JSP File with a Map Viewer Component

Figure 27.15 presents the JSP file for the completed address book application. It is nearly identical to the JSP for the previous two versions of this application. The new feature is the **Map Viewer** component (and its supporting components) used to display a map with the contact's location. We discuss only the new elements of this file. [Note: This code will not run until you have specified your own Google Maps key in lines 227–229. You can paste your key into the **Map Viewer** component's key property in the **Properties** window.]

**Fig. 27.15** | AddressBook JSP with a **Map Viewer** component. (Part 5 of 5.)

Lines 242–247 define the `mapViewer` component that displays a map of the area surrounding the address. The component's `center` attribute is bound to the page bean property `mapViewer_center`. This property is manipulated in the page bean file to center the map on the desired address.

**1354 Chapter 27 Web Applications: Part 2**

The **Look Up** Button's action attribute is now bound to method `lookUp_action` in the page bean (line 226). This action handler searches the `AddressBook` database for the name entered in the **AutoComplete Text Field** and displays the contact's name and address on a map of the contact's location. We discuss this method in Section 27.5.3.

#### 27.5.4 Page Bean that Displays a Map in the Map Viewer Component

Figure 27.16 presents the page bean for the completed `AddressBook` application. Most of this file is identical to the page beans for the first two versions of this application. We discuss only the new action-handler method, `lookUpButton_action`.

Method `lookUpButton_action` (lines 646–704) is invoked when the user clicks the **Look Up** button in the lower form on the page. Lines 649–652 retrieve the name from the **AutoComplete Text Field** and split it into `Strings` for the first and last name. Lines 662–669 each obtain the `addressesSearchDataProvider`'s `CachedRowSet`, then use its method `setObject` to set the parameters for the query to the first and last name. The `setObject` method replaces a parameter in the SQL query with a specified string. Line 661 refreshes the data provider, which executes the wrapped `RowSet`'s query with the new parameters. The result set now contains only rows that match the first and last name from the **AutoComplete Text Field**. Lines 662–669 fetch the street address, city, state and zip code for this contact from the database. Note that in this example, we assume there are not multiple entries in the address book for the same first and last name, as we fetch only the address information for the first row in the data provider. Any additional rows that match the first and last name are ignored.

704 } // end method lookUpButton_action
705 } // end class AddressBook

```

**Fig. 27.16** | Page bean that gets a map to display in the MapViewer component. (Part 5 of 5.)

Lines 672–673 format the address as a `String` for use with the Google Maps API. Line 219 calls the `Geocoding Service Object`'s `geoCode` method with the address as an argument. This method returns an array of `GeoPoint` objects representing locations that match the address parameter. `GeoPoint` objects provide the latitude and longitude of a given location. We supply a complete address with a street, city, state and zip code as an argument to `geoCode`, so the returned array will contain just one `GeoPoint` object. Line 679 determines whether the array of `GeoPoint` objects is `null`. If so, the address could not be found, and lines 681–683 display a message in the `Message Group` informing the user of the search error, hide the `Map Viewer` and return `null` to terminate the processing.

Lines 687–688 set the latitude and longitude of the `Map Viewer`'s center to the latitude and longitude of the `GeoPoint` that represents the selected address. Lines 691–694 set the `Map Marker`'s latitude and longitude, and set the text to display on the marker. Line 696 displays the recentered map containing the `Map Marker` that indicates the contact's location.

Lines 698–701 catch any exceptions generated throughout the method body and display an error message in the `Message Group`. If the user has simply selected a name from the list of selections in the `AutoComplete Text Field`, there will be no errors in searching the database, as the name is guaranteed to be in the proper *last name, first name* format and included in the `AddressBook` database. We did not include any special error-handling code for cases in which the user types a name that cannot be found in the `AddressBook` or for improperly formatted names.

## 27.6 Wrap-Up

In this chapter, we presented a three-part case study on building a web application that interacts with a database and provides rich user interaction using Ajax-enabled JSF components. We first showed how to build an `AddressBook` application that allows a user to add addresses to the `AddressBook` and browse its contents. Through this example, you learned how to insert user input into a Java DB database and how to display the contents of a database on a web page using a `Table` JSF component.

You learned how to download and import the Java BluePrints Ajax-enabled component library. We then extended the `AddressBook` application to include an `AutoComplete Text Field` component. We showed how to use a database to display suggestions in the `AutoComplete Text Field`. You also learned how to use virtual forms to submit subsets of a form's input components to the server for processing.

Finally, we completed the third part of the `AddressBook` application by adding functionality to the search form. You learned how to use a Map Viewer, a Map Marker and a Geocoding Service Object from the Java BluePrints Ajax-enabled component library to display a Google map that shows a contact's location.

In the next chapter, you'll learn how to create and consume web services with Java. You'll use the Netbeans 5.5 IDE to create web services and consume them from desktop applications, and you'll use the Java Studio Creator IDE to consume a web service from a web application. If you would prefer to perform all these tasks in one IDE, you can download the Netbeans Visual Web Pack 5.5 ([www.netbeans.org/products/visualweb/](http://www.netbeans.org/products/visualweb/)) for Netbeans 5.5.

## Summary

### Section 27.2 Accessing Databases in Web Applications

- Many web applications access databases to store and retrieve persistent data. In this section, we build a web application that uses a Java DB database to store contacts in the address book and display contacts from the address book on a web page.
- The web page enables the user to enter new contacts in a form. This form consists of **Text Field** components for the contact's first name, last name, street address, city, state and zip code. The form also has a **Submit** button to send the data to the server and a **Clear** button to reset the form's fields. The application stores the address book information in a database named **AddressBook**, which has a single table named **Addresses**. (We provide this database in the examples directory for this chapter. You can download the examples from [www.deitel.com/books/jhttp7](http://www.deitel.com/books/jhttp7).) This example also introduces the **Table** JSF component, which displays the addresses from the database in tabular format. We show how to configure the **Table** component shortly.
- The **Table** component formats and displays data from database tables.
- Change the **Table**'s **title** property to specify the text displayed at the top of the **Table**.
- To use a database in a Java Studio Creator 2 web application, you must first start the IDE's bundled database server, which includes drivers for many types of databases, including Java DB.
- To start the server, click the **Servers** tab below the **File** menu, right click **Bundled Database Server** at the bottom of the **Servers** window and select **Start Bundled Database Server**.
- To add a Java DB database to a project, right click the **Data Sources** node at the top of the **Servers** window and select **Add Data Source....** In the **Add Data Source** dialog, enter the data source name and select **Derby** for the server type. Specify the user ID and password for the database. For the database URL, enter `jdbc:derby://localhost:21527/YourDatabaseNameHere`. This URL indicates that the database resides on the local machine and accepts connections on port 21527. Click the **Select** button to choose a table that will be used to validate the database. Click **Select** to close this dialog, then click **Add** to add the database as a data source for the project and close the dialog.
- To configure a **Table** component to display database data, right click the **Table** and select **Bind to Data** to display the **Table Layout** dialog. Click the **Add Data Provider...** button to display the **Add Data Provider** dialog, which contains a list of the available data sources. Expand the database's node, expand the **Tables** node, select a table and click **Add**. The **Table Layout** dialog displays a list of the columns in the database table. All of the items under the **Selected** heading will be displayed in the **Table**. To remove a column from the **Table**, you can select it and click the < button.
- By default, the **Table**'s column headings are the column names in the database table displayed in all capital letters. You can change these headings by selecting a column and editing its **headerText** property in the **Properties** window. To select a column, expand the table's node in the **Outline** window (while in **Design** mode), then select the appropriate column object.
- Clicking the checkbox next to a **Table**'s **paginationControls** property in the **Properties** window configures a **Table** for automatic pagination. Five rows will be displayed at a time, and buttons for moving forward and backward between groups of five contacts will be added to the bottom of the **Table**.
- Binding a **Table** to a data provider adds a new **CachedRowSetDataProvider** to the application's node in the **Outline** window. A **CachedRowSetDataProvider** provides a scrollable **RowSet** that can be bound to a **Table** component to display the **RowSet**'s data.
- The **CachedRowSet** object wrapped by our **addressesDataProvider** is configured by default to execute a SQL query that selects all the data in the database table. You can edit this SQL query by expanding the **SessionBean** node in the **Outline** window and double clicking the **RowSet** element to open the query editor window.

[Summary](#)

1361

- Every row in a `CachedRowSetDataProvider` has its own key; method `appendRow`, which adds a new row to the `CachedRowSet`, returns the key for the new row.
- Method `commitChanges` of class `CachedRowSetDataProvider` applies any changes to the `CachedRowSet` to the database.
- `CachedRowSetDataProvider` method `refresh` re-executes the wrapped `CachedRowSet`'s SQL statement.

***Section 27.3 Ajax-Enabled JSF Components***

- The term Ajax—short for Asynchronous JavaScript and XML—was coined by Jesse James Garrett of Adaptive Path, Inc. in February 2005 to describe a range of technologies for developing highly responsive, dynamic web applications.
- Ajax separates the user interaction portion of an application from its server interaction, enabling both to proceed asynchronously in parallel. This enables Ajax web-based applications to perform at speeds approaching those of desktop applications.
- Ajax makes asynchronous calls to the server to exchange small amounts of data with each call.
- Ajax allows only the necessary portions of the page to reload, saving time and resources.
- Ajax applications are marked up in XHTML and CSS as any other web page and make use of client-side scripting technologies such as JavaScript to interact with page elements.
- The `XMLHttpRequestObject` enables the asynchronous exchanges with the web server that make Ajax applications so responsive. This object can be used by most scripting languages to pass XML data from the client to the server and to process XML data sent from the server to the client.
- Ajax libraries make it possible to reap Ajax's benefits in web applications without the labor of writing "raw" Ajax.
- The Java BluePrints Ajax component library provides Ajax-enabled JSF components.
- To use the Java BluePrints Ajax-enabled components in Java Studio Creator 2, you must download and import them. Choose **Tools > Update Center** to display the **Update Center Wizard** dialog. Click **Next >** to search for available updates. In the **Available Updates and New Modules** area of the dialog, select **BluePrints AJAX Components** and click the right arrow (>) button to add it to the list of items you'd like to install. Click **Next >** and follow the prompts to accept the terms of use and download the components. When the download completes, click **Next >** then click **Finish**. Click **OK** to restart the IDE.
- Next, you must import the components into the **Palette**. Select **Tools > Component Library Manager**, then click **Import....** Click **Browse...** in the **Import Component Library** dialog that appears. Select the `ui.complib` file and click **Open**. Click **OK** to import both the **BluePrints AJAX Components** and the **BluePrints AJAX SupportBeans**.

***Section 27.4 AutoComplete Text Field and Virtual Forms***

- The **AutoComplete Text Field** provides a list of suggestions from a data source (such as a database or web service) as the user types.
- **Virtual forms** are used when you would like a button to submit a subset of the page's input fields to the server.
- **Virtual forms** enable you to display multiple forms on the same page. They allow you to specify a submitter and one or more participants for each form. When the virtual form's submitter component is clicked, only the values of its participant components will be submitted to the server.
- To add virtual forms to a page, right click the submitter component on the form and choose **Configure Virtual Forms...** from the pop-up menu to display the **Configure Virtual Forms** dialog. Click **New** to add a virtual form, then click in the **Name** column and specify the new form's name. Dou-

## 1362 Chapter 27 Web Applications: Part 2

ble click the **Submit** column and change the option to **Yes** to indicate that this button should be used to submit the virtual form. Click **OK** to exit the dialog. Next, select all the input components that will participate in the virtual form. Right click one of the selected components and choose **Configure Virtual Forms...**. In the **Participate** column of the appropriate virtual form, change the option to **Yes** to indicate that the values in these components should be submitted to the server when the form is submitted.

- To see the virtual forms in the **Design** mode, click the **Show Virtual Forms** button () at the top of the Visual Designer panel to display a legend of the virtual forms on the page.
- An **AutoComplete Text Field** component's `completionMethod` attribute is bound to a page bean's `complete` event handler. To create this method, right click the **AutoComplete Text Field** component in **Design** view and select **Edit Event Handler > complete**.
- The `complete` event handler is invoked after every keystroke in an **AutoComplete Text Field** to update the list of suggestions based on the text the user has typed so far. The method receives a string containing the text the user has entered and a `CompletionResult` object that is used to display suggestions to the user.

### Section 27.5 Google Maps Map Viewer Component

- A **Map Viewer** Ajax-enabled JSF component uses the Google Maps API web service to find and display maps. A **Map Marker** points to a location on a map.
- To use the **Map Viewer** component, you must have an account with Google. Register for a free account at <https://www.google.com/accounts/ManageAccount>. You must obtain a key to use the Google Maps API from [www.google.com/apis/maps](https://www.google.com/apis/maps). The key you receive will be specific to your web application and will limit the number of maps the application can display per day. When you sign up for the key, you will be asked to enter the URL for the application that will be using the Google Maps API. If you are deploying the application only on Java Studio Creator 2's built-in test server, enter the URL <http://localhost:29080/>.
- To use a **Map Viewer**, set its `key` property to the Google Maps API key you obtained.
- A **Map Marker** (from the **AJAX Support Beans** section of the **Palette**) marks a location on a map. You must bind the marker to the map so that the marker will display on the map. To do so, right click the **Map Viewer** in **Design** mode component and choose **Property Bindings...** to display the **Property Bindings** dialog. Select `info` from the **Select bindable property** column of the dialog, then select the **Map Marker** from the **Select binding target** column. Click **Apply**, then **Close**.
- A **Geocoding Service Object** (from the **AJAX Support Beans** section of the **Palette**) converts street addresses into latitudes and longitudes that the **Map Viewer** component uses to display an appropriate map.
- The **Map Viewer**'s `center` attribute is bound to the page bean property `mapViewer_center`. This property is manipulated in the page bean file to center the map on the desired address.
- The **Geocoding Service Object**'s `geoCode` method receives an address as an argument and returns an array of **GeoPoint** objects representing locations that match the address parameter. **GeoPoint** objects provide the latitude and longitude of a given location.

### Terminology

Ajax (Asynchronous JavaScript and XML)	binding a JSF <b>Table</b> to a database table
Ajax-enabled component libraries	bundled database server
Ajax-enabled JSF components	<b>Button</b> JSF component
Apache Derby	<b>Buy Now Button</b> JSF component
<b>AutoComplete Text Field</b> JSF component	CachedRowSet interface

**Self-Review Exercises    1363**

CachedRowSetDataProvider class	participant in a virtual form
commitChanges method of class CachedRowSet-	<b>Popup Calendar</b> JSF component
DataProvider	primary property of a JSF <b>Button</b>
data provider	<b>Progress Bar</b> JSF component
event-processing life cycle	<b>Rating</b> JSF component
<b>Geocoding Service Object</b>	refresh method of
geoCode method of a <b>Geocoding Service Object</b>	class CachedRowSetDataProvider
Google Maps	reset property of a JSF <b>Button</b>
Google Maps API	<b>Rich Textarea Editor</b> JSF component
Java BluePrints	<b>Select Value Text Field</b> JSF component
Java BluePrints Ajax component library	<b>Servers</b> tab in Java Studio Creator 2
Java DB	submitter in a virtual form
JavaServer Faces (JSF)	<b>Table</b> JSF component
Jesse James Garrett	ui:staticText JSF element
JSF element	ui:table JSF element
<b>Map Marker</b> JSF component	ui:tableRowGroup JSF element
<b>Map Viewer</b> JSF component	virtual form
Message Group JSF component	XMLHttpRequestObject

**Self-Review Exercises**

- 27.1** State whether each of the following is *true* or *false*. If *false*, explain why.
- The **Table** JSF component allows you to lay out other components and text in tabular format.
  - Virtual forms allow multiple forms, each with its own **Submit** button, to be displayed on the same web page.
  - A **CachedRowSetDataProvider** is stored in the **SessionBean** and executes SQL queries to provide **Table** components with data to display.
  - The **XMLHttpRequestObject** provides access to a page's request object.
  - The **complete** event handler for an **AutoComplete Text Field** is called after every key-stroke in the text field to provide a list of suggestions based on what has already been typed.
  - A data provider automatically re-executes its SQL command to provide updated database information at every page refresh.
  - To recenter a **Map Viewer** component, you must set the longitude and latitude of the map's center.
- 27.2** Fill in the blanks in each of the following statements.
- Ajax is an acronym for \_\_\_\_\_.
  - Method \_\_\_\_\_ of class \_\_\_\_\_ updates a database to reflect any changes made in the database's data provider.
  - A(n) \_\_\_\_\_ is a supporting component used to translate addresses into latitudes and longitudes for display in a **Map Viewer** component.
  - A virtual form specifies that certain JSF components are \_\_\_\_\_ whose data will be submitted when the submitter component is clicked.
  - Ajax components for Java Studio Creator 2 such as the **AutoComplete Text Field** and **Map Viewer** are provided by the \_\_\_\_\_.

**Answers to Self-Review Exercises**

- 27.1** a) False. **Table** components are used to display data from databases. b) True. c) False. The **CachedRowSetDataProvider** is a property of the page bean. It wraps a **CachedRowSet**, which is stored

**1364**    [Chapter 27](#) [Web Applications: Part 2](#)

in the `SessionBean` and executes SQL queries. d) False. The `XMLHttpRequestObject` is an object that allows asynchronous exchanges with a web server. e) True. f) False. You must call method `refresh` on the data provider to re-execute the SQL command. g) True.

- 27.2** a) Asynchronous JavaScript and XML. b) `commitChanges`, `CachedRowSetDataProvider`. c) **Geocoding Service Object**. d) participants. e) Java BluePrints Ajax component library.

### Exercises

**27.3** (*Guestbook Application*) Create a JSF web page that allows users to sign and view a guestbook. Use the Guestbook database (provided in the examples directory for this chapter) to store guestbook entries. The Guestbook database has a single table, `Messages`, which has four columns: `date`, `name`, `email` and `message`. The database already contains a few sample entries. On the web page, provide **Text Fields** for the user's name and email address and a **Text Area** for the message. Add a **Submit Button** and a **Table** component and configure the **Table** to display guestbook entries. Use the **Submit Button**'s action-handler method to insert a new row containing the user's input and today's date into the Guestbook database.

**27.4** (*AddressBook Application Modification*) Modify the `AddressBook` application so that users enter searches in the **AutoComplete Text Field** in the format *first name last name*. You will need to add a new data provider (or modify the existing one) to sort the rows in the `AddressBook` database by first name, then last name.

**27.5** (*Map Search Application*) Create a JSF web page that allows users to obtain a map of any address. Recall that a search for a location using the Google Maps API returns an array of `GeoPoint` objects. Search for locations a user enters in a **Text Field** and display a map of the first location in the resulting `GeoPoint` array. To handle multiple search results, display all results in a **Listbox** component. You can obtain a string representation of each result by invoking method `toString` on a `GeoPoint` object. Add a **Button** that allows users to select a result from the **Listbox** and displays a map for that result with a **Map Marker** showing the location on the map. Finally, use a **Message Group** to display messages regarding search errors. In case of an error, and when the page loads for the first time, recenter the map on a default location of your choosing.

*A client is to me a mere unit,  
a factor in a problem.*

—Sir Arthur Conan Doyle

*They also serve who only  
stand and wait.*

—John Milton

*...if the simplest things of  
nature have a message that  
you understand, rejoice, for  
your soul is alive.*

—Eleonora Duse

*Protocol is everything.*

—Francoise Giuliani

## JAX-WS Web Services, Web 2.0 and Mash-Ups

### OBJECTIVES

In this chapter you will learn:

- What a web service is.
- How to publish and consume web services in Netbeans.
- The elements that comprise web services, such as service descriptions and classes that implement web services.
- How to create client desktop and web applications that invoke web service methods.
- The important part that XML and the Simple Object Access Protocol (SOAP) play in enabling web services.
- How to use session tracking in web services to maintain client state information.
- How to use JDBC with web services to connect to databases.
- How to pass objects of user-defined types to and return them from a web service.

**1366 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups****Outline**

- 28.1** Introduction
  - 28.1.1** Downloading, Installing and Configuring Netbeans 5.5 and the Sun Java System Application Server
  - 28.1.2** Web Services Resource Center and Java Resource Centers at [www.deitel.com](http://www.deitel.com)
- 28.2** Java Web Services Basics
- 28.3** Creating, Publishing, Testing and Describing a Web Service
  - 28.3.1** Creating a Web Application Project and Adding a Web Service Class in Netbeans
  - 28.3.2** Defining the HugeInteger Web Service in Netbeans
  - 28.3.3** Publishing the HugeInteger Web Service from Netbeans
  - 28.3.4** Testing the HugeInteger Web Service with Sun Java System Application Server's Tester Web Page
  - 28.3.5** Describing a Web Service with the Web Service Description Language (WSDL)
- 28.4** Consuming a Web Service
  - 28.4.1** Creating a Client to Consume the HugeInteger Web Service
  - 28.4.2** Consuming the HugeInteger Web Service
- 28.5** SOAP
- 28.6** Session Tracking in Web Services
  - 28.6.1** Creating a Blackjack Web Service
  - 28.6.2** Consuming the Blackjack Web Service
- 28.7** Consuming a Database-Driven Web Service from a Web Application
  - 28.7.1** Configuring Java DB in Netbeans and Creating the Reservation Database
  - 28.7.2** Creating a Web Application to Interact with the Reservation Web Service
- 28.8** Passing an Object of a User-Defined Type to a Web Service
- 28.9** Wrap-Up
- 28.10** Web Resources

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 28.1 Introduction

This chapter introduces web services, which promote software portability and reusability in applications that operate over the Internet. A **web service** is a software component stored on one computer that can be accessed via method calls by an application (or other software component) on another computer over a network. Web services communicate using such technologies as XML and HTTP. Several Java APIs facilitate web services. In this chapter, we'll be dealing with APIs that are based on the **Simple Object Access Protocol (SOAP)**—an XML-based protocol that allows web services and clients to communicate, even if the client and the web service are written in different languages. There are other web services technologies, such as Representational State Transfer (REST), which

we do not cover in this chapter. For information on REST, see the web resources in Section 28.10 and visit our Web Services Resource Center at

[www.deitel.com/WebServices](http://www.deitel.com/WebServices)

The Deitel Free Content Library includes the following tutorials that introduce XML:

[www.deitel.com/articles/xml\\_tutorials/20060401/XMLBasics/](http://www.deitel.com/articles/xml_tutorials/20060401/XMLBasics/)  
[www.deitel.com/articles/xml\\_tutorials/20060401/XMLStructuringData/](http://www.deitel.com/articles/xml_tutorials/20060401/XMLStructuringData/)

Web services have important implications for **business-to-business (B2B) transactions**. They enable businesses to conduct transactions via standardized, widely available web services rather than relying on proprietary applications. Web services and SOAP are platform and language independent, so companies can collaborate via web services without worrying about the compatibility of their hardware, software and communications technologies. Companies such as Amazon, Google, eBay, PayPal and many others are using web services to their advantage by making their server-side applications available to partners via web services.

By purchasing web services and using extensive free web services that are relevant to their businesses, companies can spend less time developing new applications and can create innovative new applications. E-businesses can use web services to provide their customers with enhanced shopping experiences. Consider an online music store. The store's website links to information about various CDs, enabling users to purchase the CDs, to learn about the artists, to find more titles by those artists, to find other artists' music the users may enjoy, and more. Another company that sells concert tickets provides a web service that displays upcoming concert dates for various artists, and allows users to buy tickets. By consuming the concert-ticket web service on its site, the online music store can provide an additional service to its customers and increase its site traffic and perhaps earn a commission on concert-ticket sales. The company that sells concert tickets also benefits from the business relationship by selling more tickets and possibly by receiving revenue from the online music store for the use of the web service.

Any Java programmer with a knowledge of web services can write applications that can "consume" web services. The resulting applications would call web service methods of objects running on servers which could be thousands of miles away. To learn more about Java web services read the Java Technology and Web Services Overview at [java.sun.com/webservices/overview.html](http://java.sun.com/webservices/overview.html).

#### *Netbeans 5.5 and Sun Java Studio Creator 2*

**Netbeans 5.5** and Sun Java Studio Creator 2—both developed by Sun—are two of the many tools that enable programmers to "publish" and/or "consume" web services. We demonstrate how to use these tools to implement web services and invoke them from client applications. For each example, we provide the code for the web service, then present a client application that uses the web service. Our first examples build web services and client applications in Netbeans. Then we demonstrate web services that use more sophisticated features, such as manipulating databases with JDBC (which was introduced in Chapter 25, Accessing Databases with JDBC) and manipulating class objects.

Sun Java Studio Creator 2 facilitates web application development and consuming web services. Netbeans provides broader capabilities, including the ability to create, publish and consume web services. We use Netbeans to create and publish web services, and

## 1368 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

to build desktop applications that consume them. We use Sun Java Studio Creator 2 to build web applications that consume web services. The capabilities of Sun Java Studio Creator 2 can be added to Netbeans via the Netbeans Visual Web Pack. For more information on this Netbeans add-on, visit [www.netbeans.org/products/visualweb/](http://www.netbeans.org/products/visualweb/).

### 28.1.1 Downloading, Installing and Configuring Netbeans 5.5 and the Sun Java System Application Server

To develop the web services in this chapter, we use Netbeans 5.5 and the Sun Java System Application Server with the default installation options. The Netbeans website provides a bundled installer for both of these products. To download the installer, go to

[www.netbeans.org/products/ide/](http://www.netbeans.org/products/ide/)

then click the **Download Netbeans IDE** button. On the next page, select your operating system and language, then click the **Next** button. Download the installer with the title **NetBeans IDE 5.5 with Java EE Application Server 9.0 U1 bundle**.

Once you've downloaded and installed these tools, run the Netbeans IDE. On Windows XP, the installer will place an entry for Netbeans in **Start > All Programs**. Before proceeding with the rest of the chapter, perform the following steps to configure Netbeans to allow testing with the Sun Java System Application Server:

1. Select **Tools > Server Manager** to display the **Server Manager** dialog. If Sun Java System Application Server already appears in the list of servers, skip *Steps 2–6*.
2. Click the **Add Server...** button in the lower-left corner of the dialog to display the **Add Server Instance** dialog.
3. Choose **Sun Java System Application Server** from the **Server** drop-down list, then click **Next >**.
4. In the **Platform Location** field, specify the install location of Sun Java System Application Server—by default, **C:\Sun\AppServer** on Windows. Click **Next >**.
5. Specify the username and password for the server—by default, these are set to **admin** and **adminadmin**, respectively. Click **Finish**.
6. Click **Close** to close the **Server Manager** dialog.

### 28.1.2 Web Services Resource Center and Java Resource Centers at [www.deitel.com](http://www.deitel.com)

Visit our Web Services Resource Center at [www.deitel.com/WebServices/](http://www.deitel.com/WebServices/) for information on designing and implementing web services in many languages, and information about web services offered by companies such as Google, Amazon and eBay. You'll also find many additional Java tools for publishing and consuming web services.

Our Java Resource Centers at

[www.deitel.com/java/](http://www.deitel.com/java/)  
[www.deitel.com/JavaSE6/](http://www.deitel.com/JavaSE6/)  
[www.deitel.com/JavaEE5/](http://www.deitel.com/JavaEE5/)

provide additional Java-specific information, such as books, papers, articles, journals, websites and blogs that cover a broad range of Java topics (including Java web services).

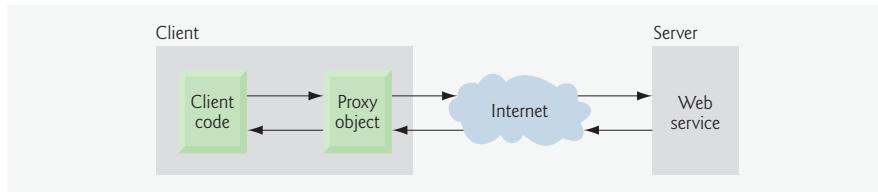

## 28.2 Java Web Services Basics

The computer on which a web service resides is referred to as a **remote machine** or **server**. The application (i.e., the client) that accesses the web service sends a method call over a network to the remote machine, which processes the call and returns a response over the network to the application. This kind of distributed computing is beneficial in many applications. For example, a client application without direct access to a database on a remote server might be able to retrieve the data via a web service. Similarly, an application lacking the processing power to perform specific computations could use a web service to take advantage of another system's superior resources.

In Java, a web service is implemented as a class. In previous chapters, all the pieces of an application resided on one machine. The class that represents the web service resides on a server—it's not part of the client application.

Making a web service available to receive client requests is known as **publishing a web service**; using a web service from a client application is known as **consuming a web service**. An application that consumes a web service consists of two parts—an object of a **proxy class** for interacting with the web service and a client application that consumes the web service by invoking methods on the object of the proxy class. The client code invokes methods on the proxy object, which handles the details of communicating with the web service (such as passing method arguments to the web service and receiving return values from the web service) on the client's behalf. This communication can occur over a local network, over the Internet or even with a web service on the same computer. The web service performs the corresponding task and returns the results to the proxy object, which then returns the results to the client code. Figure 28.1 depicts the interactions among the client code, the proxy class and the web service. As you'll soon see, Netbeans and Sun Java Studio Creator 2 create these proxy classes for you in your client applications.

Requests to and responses from web services created with **JAX-WS 2.0**—the most recent Java web services framework—are typically transmitted via SOAP. Any client capable of generating and processing SOAP messages can interact with a web service, regardless of the language in which the web service is written. We discuss SOAP in Section 28.5.

**Fig. 28.1** | Interaction between a web service client and a web service.

## 28.3 Creating, Publishing, Testing and Describing a Web Service

The following subsections demonstrate how to create, publish and test a `HugeInteger` web service that performs calculations with positive integers up to 100 digits long (maintained as arrays of digits). Such integers are much larger than Java's integral primitive types can

**1370**    [Chapter 28](#) **JAX-WS Web Services, Web 2.0 and Mash-Ups**

represent. The `HugeInteger` web service provides methods that take two “huge integers” (represented as `Strings`) and determine their sum, their difference, which is larger, which is smaller or whether the two numbers are equal. These methods will be services available to other applications via the web—hence the term web services.

### **28.3.1 Creating a Web Application Project and Adding a Web Service Class in Netbeans**

When you create a web service in Netbeans, you focus on the logic of the web service and let the IDE handle the web service’s infrastructure. To create a web service in Netbeans, you first create a project of type **Web Application**. Netbeans uses this project type for web applications that execute in browser-based clients and for web services that are invoked by other applications.

#### *Creating a Web Application Project in Netbeans 5.5*

To create a web application, perform the following steps:

1. Select **File > New Project** to open the **New Project** dialog.
2. Select **Web** from the dialog’s **Categories** list, then select **Web Application** from the **Projects** list. Click **Next >**.
3. Specify the name of your project (`HugeInteger`) in the **Project Name** field and specify where you’d like to store the project in the **Project Location** field. You can click the **Browse** button to select the location.
4. Select **Sun Java System Application Server** from the **Server** drop-down list.
5. Select **Java EE 5** from the **J2EE Version** drop-down list.
6. Click **Finish** to dismiss the **New Project** dialog.

This creates a web application that will run in a web browser. When you create a **Web Application** in Netbeans, the IDE generates additional files that support the web application. In this chapter, we discuss only the files that are specific to web services.

#### *Adding a Web Service Class to a Web Application Project*

To create a web service, perform the following steps to add a web service class to the project:

1. Under the **Projects** tab in Netbeans (just below the **File** menu), right click the `HugeInteger` project’s node and select **New > Web Service...** to open the **New Web Service** dialog.
2. Specify `HugeInteger` in the **Web Service Name** field.
3. Specify `com.deitel.jhttp7.ch28.hugeinteger` in the **Package** field.
4. Click **Finish** to dismiss the **New Web Service** dialog.

The IDE generates a sample web service class with the name you specified in *Step 2*. In this class, you’ll define the methods that your web service makes available to client applications. When you eventually build your application, the IDE will generate other supporting files (which we’ll discuss shortly) for your web service.

28.3 Creating, Publishing, Testing and Describing a Web Service **1371****28.3.2 Defining the HugeInteger Web Service in Netbeans**

Figure 28.2 contains the HugeInteger web service's code. You can implement this code yourself in the HugeInteger.java file created in Section 28.3.1, or you can simply replace the code in HugeInteger.java with a copy of our code from this example's folder. You can find this file in the project's src\java\com\deitel\jhttp7\ch28\hugeinteger folder. The book's examples can be downloaded from [www.deitel.com/books/jhttp7](http://www.deitel.com/books/jhttp7).

```

1 // Fig. 28.2: HugeInteger.java
2 // HugeInteger web service that performs operations on large integers.
3 package com.deitel.jhttp7.ch28.hugeinteger;
4
5 import javax.jws.WebService; // program uses the annotation @WebService
6 import javax.jws.WebMethod; // program uses the annotation @WebMethod
7 import javax.jws.WebParam; // program uses the annotation @WebParam
8
9 @WebService(// annotates the class as a web service
10 name = "HugeInteger", // sets class name
11 serviceName = "HugeIntegerService") // sets the service name
12 public class HugeInteger
13 {
14 private final static int MAXIMUM = 100; // maximum number of digits

**Fig. 28.2** | HugeInteger web service that performs operations on large integers. (Part 3 of 3.)

## 1374 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

Lines 5–7 import the annotations used in this example. By default, each new web service class created with the JAX-WS APIs is a **POJO (plain old Java object)**, meaning that—unlike prior Java web service APIs—you do not need to extend a class or implement an interface to create a Web service. When you compile a class that uses these JAX-WS 2.0 annotations, the compiler creates all the **server-side artifacts** that support the web service—that is, the compiled code framework that allows the web service to wait for client requests and respond to those requests once the service is deployed on an application server. Popular application servers that support Java web services include the Sun Java System Application Server ([www.sun.com/software/products/appsvr/index.xml](http://www.sun.com/software/products/appsvr/index.xml)), GlassFish ([glassfish.dev.java.net](http://glassfish.dev.java.net)), Apache Tomcat ([tomcat.apache.org](http://tomcat.apache.org)), BEA Weblogic Server ([www.bea.com](http://www.bea.com)) and JBoss Application Server ([www.jboss.org/products/jbossas](http://www.jboss.org/products/jbossas)). We use Sun Java System Application Server in this chapter.

Lines 9–11 contain a `@WebService` annotation (imported at line 5) with properties `name` and `serviceName`. The `@WebService annotation` indicates that class `HugeInteger` represents a web service. The annotation is followed by a set of parentheses containing optional elements. The annotation's `name element` (line 10) specifies the name of the proxy class that will be generated for the client. The annotation's `serviceName element` (line 11) specifies the name of the class that the client uses to obtain an object of the proxy class. [Note: If the `serviceName` element is not specified, the web service's name is assumed to be the class name followed by the word `Service`.] Netbeans places the `@WebService` annotation at the beginning of each new web service class you create. You can then add the `name` and `serviceName` properties in the parentheses following the annotation.

Line 14 declares the constant `MAXIMUM` that specifies the maximum number of digits for a `HugeInteger` (i.e., 100 in this example). Line 15 creates the array that stores the digits in a huge integer. Lines 18–40 declare method `toString`, which returns a `String` representation of a `HugeInteger` without any leading 0s. Lines 43–52 declare static method `parseHugeInteger`, which converts a `String` into a `HugeInteger`. The web service's methods `add`, `subtract`, `bigger`, `smaller` and `equals` use `parseHugeInteger` to convert their `String` arguments to `HugeIntegers` for processing.

`HugeInteger` methods `add`, `subtract`, `bigger`, `smaller` and `equals` are tagged with the `@WebMethod annotation` (lines 55, 81, 117, 133 and 141) to indicate that they can be called remotely. Any methods that are not tagged with `@WebMethod` are not accessible to clients that consume the web service. Such methods are typically utility methods within the web service class. Note that the `@WebMethod` annotations each use the `operationName` element to specify the method name that is exposed to the web service's client.

### Common Programming Error 28.1

*Failing to expose a method as a web method by declaring it with the `@WebMethod annotation` prevents clients of the web service from accessing the method.*

### Common Programming Error 28.2

*Methods with the `@WebMethod annotation` cannot be static. An object of the web service class must exist for a client to access the service's web methods.*

Each of the web methods in class `HugeInteger` specifies parameters that are annotated with the `@WebParam annotation` (e.g., lines 56–57 of method `add`). The optional `@WebParam` element `name` indicates the parameter name that is exposed to the web service's clients.

### 28.3 Creating, Publishing, Testing and Describing a Web Service **1375**

Lines 55–78 and 81–102 declare `HugeInteger` web methods `add` and `subtract`. We assume for simplicity that `add` does not result in overflow (i.e., the result will be 100 digits or fewer) and that the first argument to `subtract` will always be larger than the second. The `subtract` method calls method `borrow` (lines 105–114) when it is necessary to borrow 1 from the next digit to the left in the first argument—that is, when a particular digit in the left operand is smaller than the corresponding digit in the right operand. Method `borrow` adds 10 to the appropriate digit and subtracts 1 from the next digit to the left. This utility method is not intended to be called remotely, so it is not tagged with `@WebMethod`.

Lines 117–130 declare `HugeInteger` web method `bigger`. Line 123 invokes method `subtract` to calculate the difference between the numbers. If the first number is less than the second, this results in an exception. In this case, `bigger` returns `false`. If `subtract` does not throw an exception, then line 124 returns the result of the expression

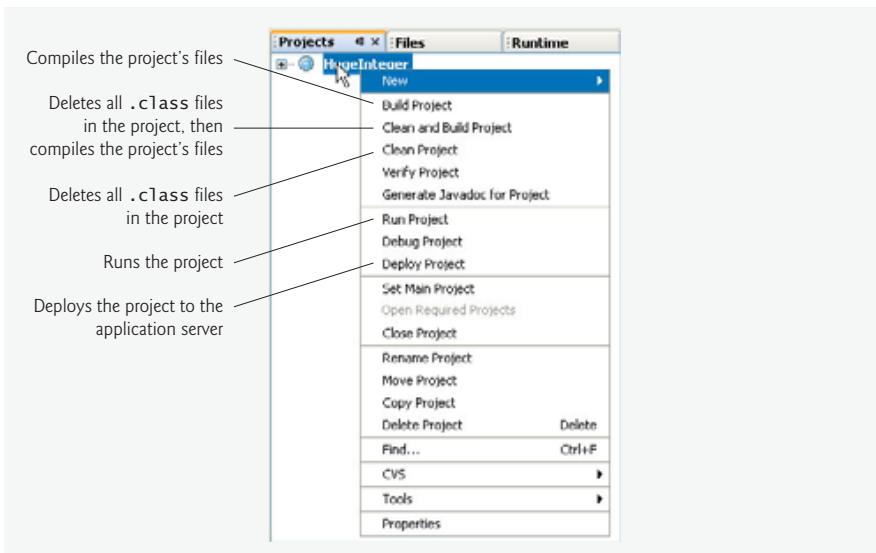

```
!difference.matches("^[0]+$")
```

This expression calls `String` method `matches` to determine whether the `String` `difference` matches the regular expression `"^[0]+$"`, which determines if the `String` consists only of one or more 0s. The symbols `^` and `$` indicate that `matches` should return `true` only if the entire `String` `difference` matches the regular expression. We then use the logical negation operator (`!`) to return the opposite `boolean` value. Thus, if the numbers are equal (i.e., their difference is 0), the preceding expression returns `false`—the first number is not greater than the second. Otherwise, the expression returns `true`. We discuss regular expressions in more detail in Section 30.7.

Lines 133–146 declare methods `smaller` and `equals`. Method `smaller` returns the result of invoking method `bigger` (line 137) with the arguments reversed—if `first` is less than `second`, then `second` is greater than `first`. Method `equals` invokes methods `bigger` and `smaller` (line 145). If either `bigger` or `smaller` returns `true`, line 145 returns `false` because the numbers are not equal. If both methods return `false`, the numbers are equal and line 145 returns `true`.

#### 28.3.3 Publishing the `HugeInteger` Web Service from Netbeans

Now that we've created the `HugeInteger` web service class, we'll use Netbeans to build and publish (i.e., deploy) the web service so that clients can consume its services. Netbeans handles all the details of building and deploying a web service for you. This includes creating the framework required to support the web service. Right click the project name (`HugeInteger`) in the Netbeans `Projects` tab to display the pop-up menu shown in Fig. 28.3. To determine if there are any compilation errors in your project, select the `Build Project` option. When the project compiles successfully, you can select `Deploy Project` to deploy the project to the server you selected when you set up the web application in Section 28.3.1. If the code in the project has changed since the last build, selecting `Deploy Project` also builds the project. Selecting `Run Project` executes the web application. If the web application was not previously built or deployed, this option performs these tasks first. Note that both the `Deploy Project` and `Run Project` options also start the application server (in our case Sun Java System Application Server) if it is not already running. To ensure that all source-code files in a project are recompiled during the next build operation, you can use the `Clean Project` or `Clean and Build Project` options. If you have not already done so, select `Deploy Project` now.

**1376**    Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

**Fig. 28.3** | Pop-up menu that appears when you right click a project name in the Netbeans **Projects** tab.

#### 28.3.4 Testing the HugeInteger Web Service with Sun Java System Application Server's Tester Web page

The next step is to test the HugeInteger web service. We previously selected the Sun Java System Application Server to execute this web application. This server can dynamically create a web page for testing a web service's methods from a web browser. To enable this capability:

1. Right click the project name (HugeInteger) in the Netbeans **Projects** tab and select **Properties** from the pop-up menu to display the **Project Properties** dialog.
2. Click **Run** under **Categories** to display the options for running the project.
3. In the **Relative URL** field, type /HugeIntegerService?Tester.
4. Click **OK** to dismiss the **Project Properties** dialog.

The **Relative URL** field specifies what should happen when the web application executes. If this field is empty, then the web application's default JSP displays when you run the project. When you specify /HugeIntegerService?Tester in this field, then run the project, Sun Java System Application Server builds the Tester web page and loads it into your web browser. Figure 28.4 shows the Tester web page for the HugeInteger web service. Once you've deployed the web service, you can also type the URL

`http://localhost:8080/HugeInteger/HugeIntegerService?Tester`

in your web browser to view the Tester web page. Note that HugeIntegerService is the name (specified in line 11 of Fig. 28.2) that clients, including the Tester web page, use to access the web service.

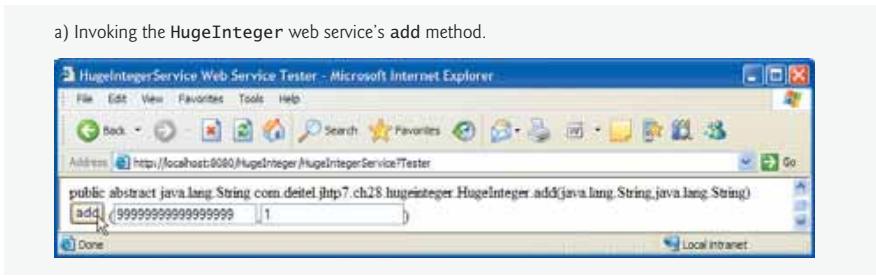

## 28.3 Creating, Publishing, Testing and Describing a Web Service

1377

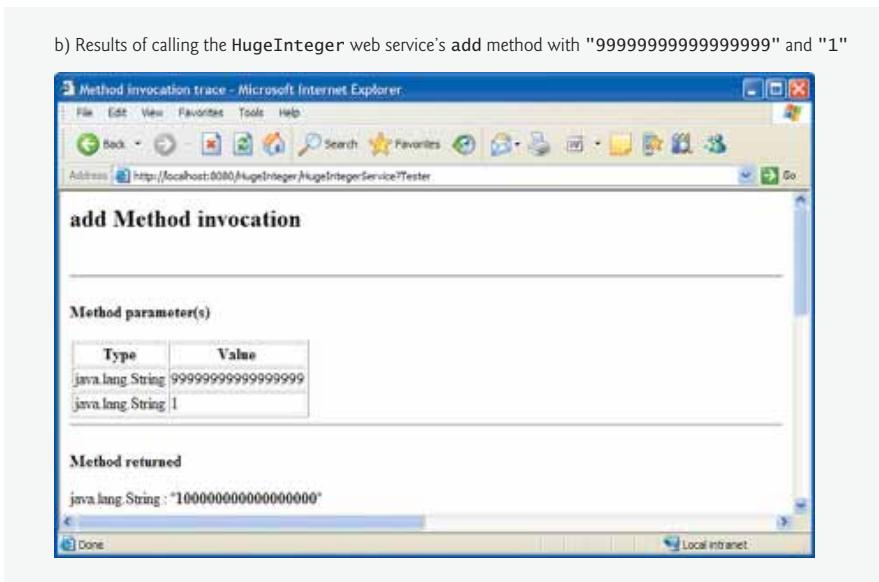

**Fig. 28.4** | Tester web page created by Sun Java System Application Server for the HugeInteger web service.

To test HugeInteger's web methods, type two positive integers into the textfields to the right of a particular method's button, then click the button to invoke the web method and see the result. Figure 28.5 shows the results of invoking HugeInteger's add method with the values 9999999999999999 and 1. Note that the number 9999999999999999 is larger than primitive type long can represent.

**Fig. 28.5** | Testing HugeInteger's add method. (Part 1 of 2.)

**1378 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups**

**Fig. 28.5** | Testing HugeInteger's add method. (Part 2 of 2.)

Note that you can access the web service only when the application server is running. If Netbeans launches the application server for you, it will automatically shut it down when you close Netbeans. To keep the application server up and running, you can launch it independently of Netbeans before you deploy or run web applications in Netbeans. For Sun Java System Application Server running on Windows, you can do this by selecting **Start > All Programs > Sun Microsystems > Application Server PE 9 > Start Default Server**. To shut down the application server, you can select the **Stop Default Server** option from the same location.

#### **Testing the HugeInteger Web Service from Another Computer**

If your computer is connected to a network and your computer allows HTTP requests, then you can test the web service from another computer on the network by typing the following URL into a browser on another computer:

`http://host:8080/HugeInteger/HugeIntegerService?Tester`

where *host* is the hostname or IP address of the computer on which the web service is deployed.

#### **Note to Windows XP Service Pack 2 Users**

For security reasons, computers running Windows XP Service Pack 2 do not allow HTTP requests from other computers by default. If you wish to allow other computers to connect to your computer using HTTP, perform the following steps:

1. Select **Start > Control Panel** to open your system's **Control Panel** window, then double click **Windows Firewall** to view the **Windows Firewall** settings dialog.

2. In the Windows Firewall settings dialog, click the Advanced tab, select Local Area Connection (or your network connection's name, if it is different) in the Network Connection Settings list box and click the Settings... button to display the Advanced Settings dialog.
3. In the Advanced Settings dialog, ensure that the checkbox for Web Server (HTTP) is checked to allow clients on other computers to submit requests to your computer's web server.
4. Click OK in the Advanced Settings dialog, then click OK in the Windows Firewall settings dialog.

### 28.3.5 Describing a Web Service with the Web Service Description Language (WSDL)

Once you implement a web service, compile it and deploy it on an application server, a client application can consume the web service. To do so, however, the client must know where to find the web service and must be provided with a description of how to interact with the web service—that is, what methods are available, what parameters they expect and what each method returns. For this purpose, JAX-WS uses the **Web Service Description Language (WSDL)**—a standard XML vocabulary for describing web services in a platform-independent manner.

You do not need to understand the details of WSDL to take advantage of it—the server generates a web service's WSDL dynamically for you, and client tools can parse the WSDL to help create the client-side proxy class that a client uses to access the web service. Since the WSDL is created dynamically, clients always receive a deployed web service's most up-to-date description. To view the WSDL for the HugeInteger web service (Fig. 28.6), enter the following URL in your browser:

```
http://localhost:8080/HugeInteger/HugeIntegerService?WSDL
```

or click the **WSDL File** link in the Tester web page (shown in Fig. 28.4).

#### *Accessing the HugeInteger Web Service's WSDL from Another Computer*

Eventually, you'll want clients on other computers to use your web service. Such clients need access to your web service's WSDL, which they would access with the following URL:

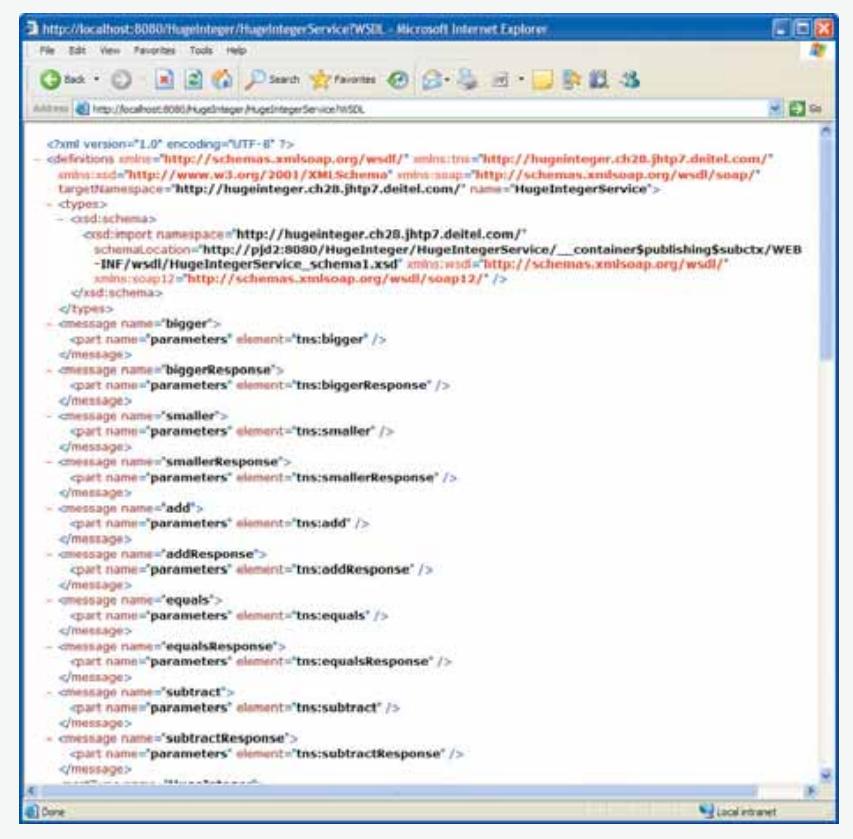

```
http://host:8080/HugeInteger/HugeIntegerService?WSDL
```

where *host* is the hostname or IP address of the computer on which the web service is deployed. As we discussed in Section 28.3.4, this will work only if your computer allows HTTP connections from other computers—as is the case for publicly accessible web and application servers.

## 28.4 Consuming a Web Service

Now that we have defined and deployed our web service, we can consume it from a client application. A web service client can be any type of application or even another web service. You enable a client application to consume a web service by [adding a web service](#)

**1380**    Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

The screenshot shows a Microsoft Internet Explorer window displaying the WSDL (Web Services Description Language) XML code for the HugeInteger web service. The URL in the address bar is `http://localhost:8080/HugeInteger/HugeIntegerService?wsdl`. The code itself is a large XML document defining various messages, parts, types, and schema imports related to arithmetic operations like add, subtract, multiply, and divide.

**Fig. 28.6** | A portion of the .wsdl file for the HugeInteger web service.

reference to the application. This process defines the proxy class that allows the client to access the web service.

#### 28.4.1 Creating a Client in Netbeans to Consume the HugeInteger Web Service

In this section, you'll use Netbeans to create a client Java desktop GUI application, then you'll add a web service reference to the project so the client can access the web service. When you add the web service reference, the IDE creates and compiles the **client-side artifacts**—the framework of Java code that supports the client-side proxy class. The client then calls methods on an object of the proxy class, which uses the rest of the artifacts to interact with the Web service.

##### *Creating a Desktop Application Project in Netbeans 5.5*

Before performing the steps in this section, ensure that the HugeInteger web service has been deployed and that the Sun Java System Application Server is running (see

28.4 Consuming a Web Service **I38I**

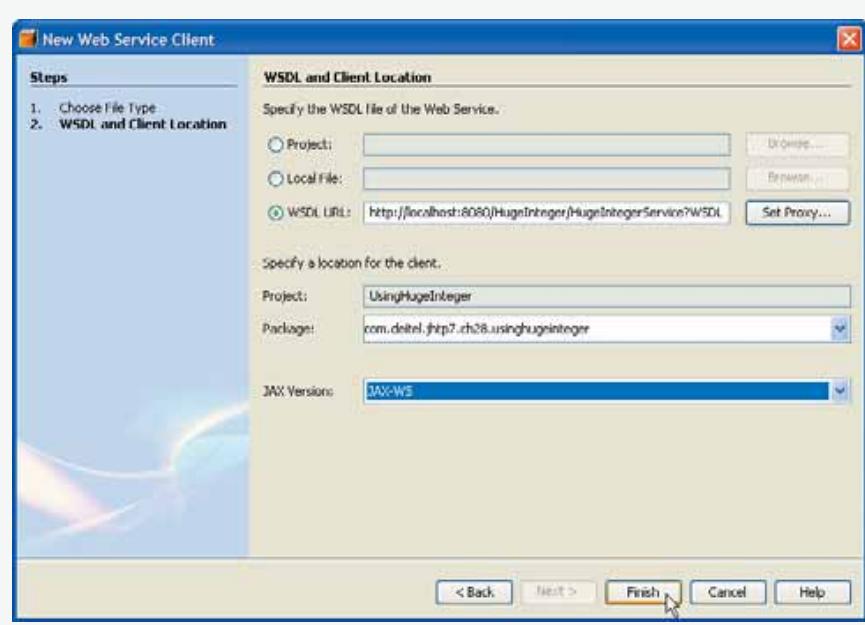

Section 28.3.3). Perform the following steps to create a client Java desktop application in Netbeans:

1. Select **File > New Project...** to open the **New Project** dialog.
2. Select **General** from the **Categories** list and **Java Application** from the **Projects** list.
3. Specify the name **UsingHugeInteger** in the **Project Name** field and uncheck the **Create Main Class** checkbox. In a moment, you'll add a subclass of **JFrame** that contains a **main** method.
4. Click **Finish** to create the project.

#### *Adding a Web Service Reference to an Application*

Next, you'll add a web service reference to your application so that it can interact with the **HugeInteger** web service. To add a web service reference, perform the following steps.

1. Right click the project name (**UsingHugeInteger**) in the Netbeans **Projects** tab.
2. Select **New > Web Service Client...** from the pop-up menu to display the **New Web Service Client** dialog (Fig. 28.7). This URL tells the IDE where to find the web service's WSDL description. [Note: If the Sun Java System Application Server is located on a different computer, replace **localhost** with the hostname or IP address of that computer.] The IDE uses this WSDL description to generate the

**Fig. 28.7** | New Web Service Client dialog.

**1382 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups**

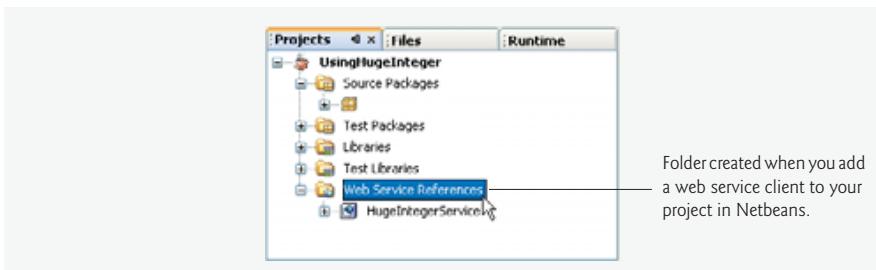

client-side artifacts that compose and support the proxy. Note that the **New Web Service Client** dialog enables you to search for web services in several locations. Many companies simply distribute the exact WSDL URLs for their web services, which you can place in the **WSDL URL** field.

4. In the **Package** field, specify `com.deitel.jhttp7.ch28.usinghugeinteger` as the package name.
5. Click **Finish** to dismiss the **New Web Service Client** dialog.

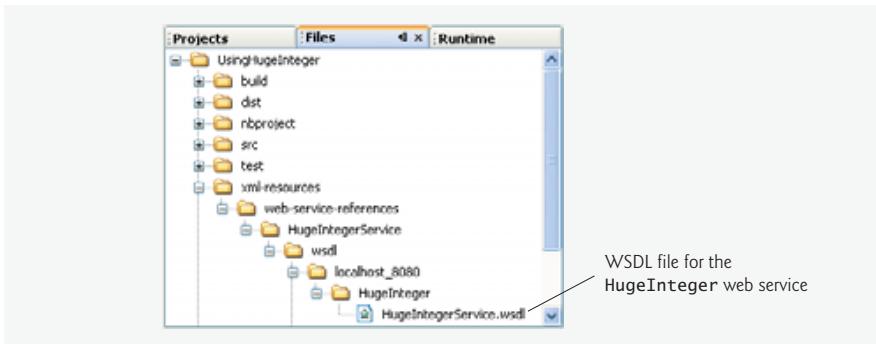

In the Netbeans **Projects** tab, the `UsingHugeInteger` project now contains a **Web Service References** folder with the proxy for the `HugeInteger` web service (Fig. 28.8). Note that the proxy's name is listed as `HugeIntegerService`, as we specified in line 11 of Fig. 28.2.

When you specify the web service you want to consume, Netbeans accesses the web service's WSDL information and copies it into a file in your project (named `HugeIntegerService.wsdl` in this example). You can view this file from the Netbeans **Files** tab by expanding the nodes in the `UsingHugeInteger` project's `xml-resources` folder as shown in Fig. 28.9. If the web service changes, the client-side artifacts and the client's copy of the WSDL file can be regenerated by right clicking the `HugeIntegerService` node shown in Fig. 28.8 and selecting **Refresh Client**.

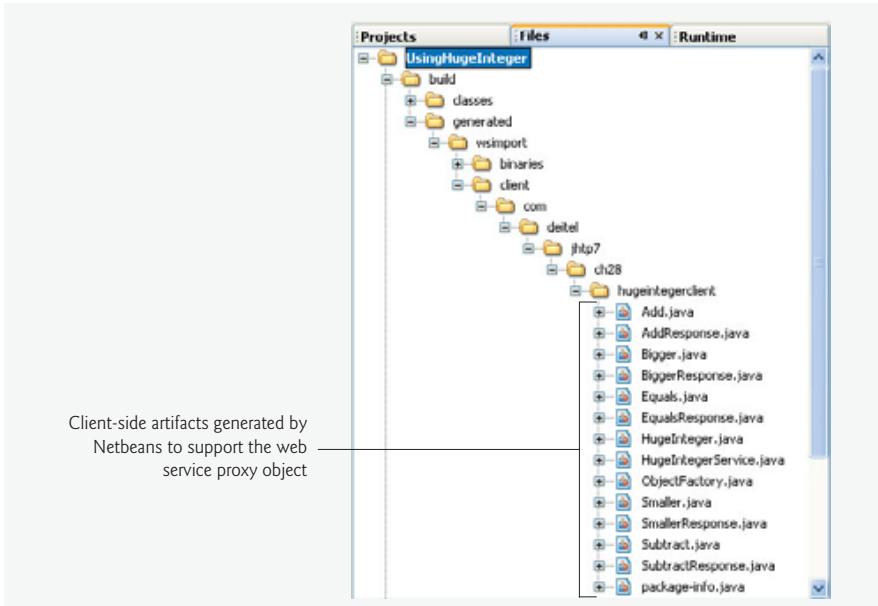

You can view the IDE-generated client-side artifacts by selecting the Netbeans **Files** tab and expanding the `UsingHugeInteger` project's `build` folder as shown in Fig. 28.10.

**Fig. 28.8** | Netbeans **Project** tab after adding a web service reference to the project.

**Fig. 28.9** | Locating the `HugeIntegerService.wsdl` file in the Netbeans **Files** tab.

28.4 Consuming a Web Service **1383**

**Fig. 28.10** | Viewing the HugeInteger web service's client-side artifacts generated by Netbeans.

#### 28.4.2 Consuming the HugeInteger Web Service

For this example, we use a GUI application to interact with the web service. To build the client application's GUI, you must first add a subclass of `JFrame` to the project. To do so, perform the following steps:

1. Right click the project name in the Netbeans Project tab.
2. Select New > JFrame Form... to display the New JFrame Form dialog.
3. Specify `UsingHugeIntegerJFrame` in the Class Name field.
4. Specify `com.deitel.jhttp7.ch28.hugeintegerclient` in the Package field.
5. Click Finish to close the New JFrame Form dialog.

Next, build the GUI shown in the sample screen captures at the end of Fig. 28.11. For more information on using Netbeans to build a GUI and create event handlers, see the GroupLayout Appendix.

The application in Fig. 28.11 uses the `HugeInteger` web service to perform computations with positive integers up to 100 digits long. To save space, we do not show the Netbeans auto-generated `initComponents` method, which contains the code that builds the GUI components, positions them and registers their event handlers. To view the complete source code, open the `UsingHugeIntegerJFrame.java` file in this example's folder under `src\java\com\deitel\jhttp7\ch28\hugeintegerclient`. Note that Netbeans places the GUI component instance variable declarations at the end of the class (lines 326–335). Java allows instance variables to be declared anywhere in a class's body as long as they are placed

**1384** Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

outside the class's methods. We continue to declare our own instance variables at the top of the class.

```

1 // Fig. 28.11: UsingHugeIntegerJFrame.java
2 // Client desktop application for the HugeInteger web service.
3 package com.deitel.jhttp7.ch28.hugeintegerclient;
4
5 // import classes for accessing HugeInteger web service's proxy

**Fig. 28.11** | Client desktop application for the HugeInteger web service. (Part 5 of 6.)

**Fig. 28.11** | Client desktop application for the HugeInteger web service. (Part 6 of 6.)

Lines 6–7 import the classes `HugeInteger` and `HugeIntegerService` that enable the client application to interact with the web service. We include these `import` declarations only for documentation purposes here. These classes are in the same package as `UsingHugeIntegerJFrame`, so these `import` declarations are not necessary. Notice that we do not have `import` declarations for most of the GUI components used in this example. When you create a GUI in Netbeans, it uses fully qualified class names (such as `javax.swing.JFrame` in line 11), so `import` declarations are unnecessary.

Lines 13–14 declare the variables of type `HugeIntegerService` and `HugeInteger`, respectively. Line 24 in the constructor creates a `HugeIntegerService` object. Line 25 uses this object's `getHugeIntegerPort` method to obtain the `HugeInteger` proxy object that the application uses to invoke the web service's method.

Lines 165–166, 189–190, 213–214, 240–241 and 267–268 in the various `JButton` event handlers invoke the `HugeInteger` web service's web methods. Note that each call is made on the local proxy object that is referenced by `hugeIntegerProxy`. The proxy object then communicates with the web service on the client's behalf.

The user enters two integers, each up to 100 digits long. Clicking any of the five `JButtons` causes the application to invoke a web method to perform the corresponding task and return the result. Our client application cannot process 100-digit numbers directly. Instead the client passes `String` representations of these numbers to the web service's web methods, which perform tasks for the client. The client application then uses the return value of each operation to display an appropriate message.

## 28.5 SOAP

SOAP (an acronym for Simple Object Access Protocol) is a platform-independent protocol that uses XML to facilitate remote procedure calls, typically over HTTP. SOAP is one

## 1390 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

common protocol for passing information between web service clients and web services. The protocol that transmits request-and-response messages is also known as the web service's **wire format** or **wire protocol**, because it defines how information is sent "along the wire."

Each request and response is packaged in a **SOAP message** (also known as a **SOAP envelope**)—an XML "wrapper" containing the information that a web service requires to process the message. SOAP messages are written in XML so that they are platform independent. With a few exceptions, most **firewalls**—security barriers that restrict communication among networks—allow HTTP traffic to pass through so that clients can browse websites on web servers behind firewalls. Thus, XML and HTTP enable computers on different platforms to send and receive SOAP messages with few limitations.

Web services also use SOAP for the extensive set of types it supports. The wire format used to transmit requests and responses must support all types passed between the applications. SOAP supports primitive types (e.g., `int`) and their wrapper types (e.g., `Integer`), as well as `Date`, `Time` and others. SOAP can also transmit arrays and objects of user-defined types (as you'll see in Section 28.8). For more information on SOAP, visit [www.w3.org/TR/soap/](http://www.w3.org/TR/soap/).

When a program invokes a web method, the request and all relevant information are packaged in a SOAP message and sent to the server on which the web service resides. The web service processes the SOAP message's contents (contained in a SOAP envelope), which specify the method that the client wishes to invoke and the method's arguments. This process of interpreting a SOAP message's contents is known as **parsing a SOAP message**. After the web service receives and parses a request, the proper method is called with any specified arguments, and the response is sent back to the client in another SOAP message. The client-side proxy parses the response, which contains the result of the method call, and returns the result to the client application.

Figure 28.5 used the `HugeInteger` web service's `Tester` web page to show the result of invoking `HugeInteger`'s `add` method with the values 9999999999999999 and 1. The `Tester` web page also shows the SOAP request and response messages (which were not previously shown). Figure 28.12 shows the same result with the SOAP messages that are displayed by the `Tester` application. In the request message from Fig. 28.12, the text

```
<ns1:add>
<first>9999999999999999</first>
<second>1</second>
</ns1:add>
```

specifies the method to call (`add`), the method's arguments (`first` and `second`) and the arguments' values (9999999999999999 and 1). Similarly, the text

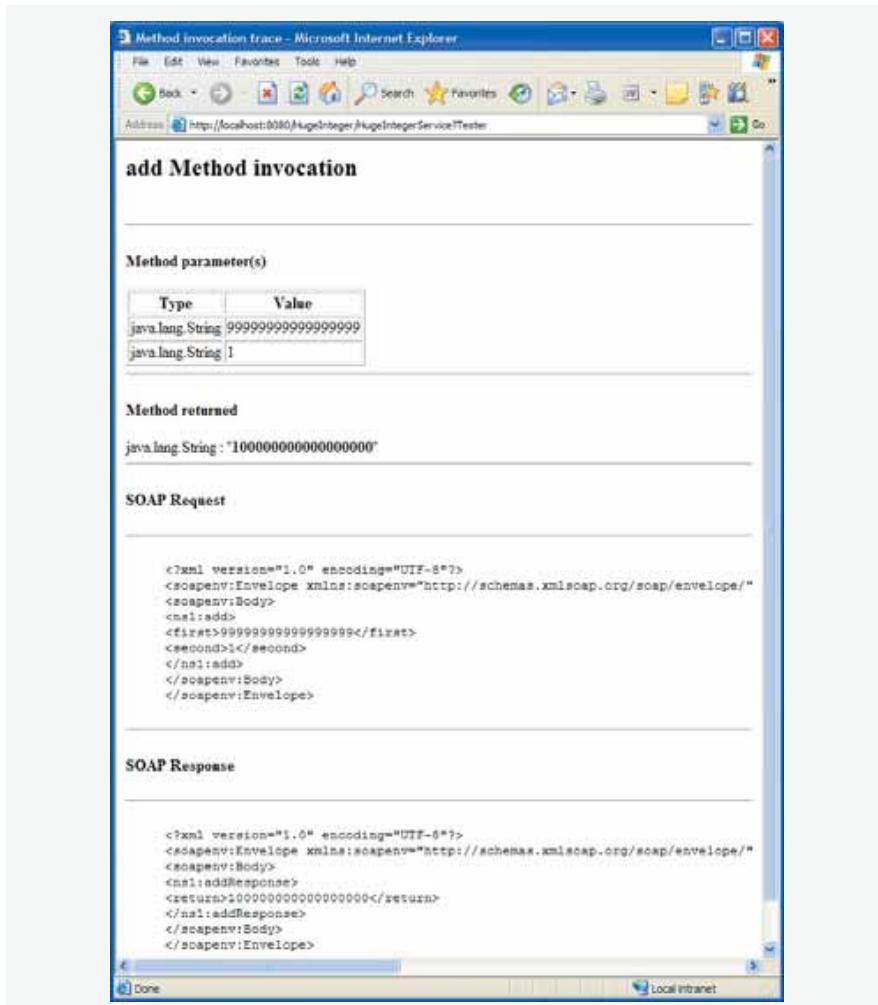

```
<ns1:addResponse>
<return>10000000000000000000</return>
</ns1:addResponse>
```

from the response message in Fig. 28.12 specifies the return value of method `add`.

As with the WSDL for a web service, the SOAP messages are generated for you automatically. So you don't need to understand the details of SOAP or XML to take advantage of it when publishing and consuming web services.

## 28.6 Session Tracking in Web Services

1391

**Fig. 28.12** | SOAP messages for the HugeInteger web service's add method as shown by the Sun Java System Application Server's Tester web page.

## 28.6 Session Tracking in Web Services

Section 26.7 described the advantages of using session tracking to maintain client state information so you can personalize the users' browsing experiences. Now we'll incorporate session tracking into a web service. Suppose a client application needs to call several methods from the same web service, possibly several times each. In such a case, it can be beneficial for the web service to maintain state information for the client, thus eliminating the need for client information to be passed between the client and the web service multiple times. For example, a web service that provides local restaurant reviews could store the cli-

**1392**    [Chapter 28](#) [JAX-WS Web Services, Web 2.0 and Mash-Ups](#)

ent user's street address during the initial request, then use it to return personalized, localized results in subsequent requests. Storing session information also enables a web service to distinguish between clients.

### **28.6.1 Creating a Blackjack Web Service**

Our next example is a web service that assists you in developing a blackjack card game. The `Blackjack` web service (Fig. 28.13) provides web methods to shuffle a deck of cards, deal a card from the deck and evaluate a hand of cards. After presenting the web service, we use it to serve as the dealer for a game of blackjack (Fig. 28.14). The `Blackjack` web service uses an `HttpSession` object to maintain a unique deck of cards for each client application. Several clients can use the service at the same time, but web method calls made by a specific client use only the deck of cards stored in that client's session. Our example uses the following blackjack rules:

*Two cards each are dealt to the dealer and the player. The player's cards are dealt face up. Only the first of the dealer's cards is dealt face up. Each card has a value. A card numbered 2 through 10 is worth its face value. Jacks, queens and kings each count as 10. Aces can count as 1 or 11—whichever value is more beneficial to the player (as we will soon see). If the sum of the player's two initial cards is 21 (i.e., the player was dealt a card valued at 10 and an ace, which counts as 11 in this situation), the player has "blackjack" and immediately wins the game—if the dealer does not also have blackjack (which would result in a "push"—i.e., a tie). Otherwise, the player can begin taking additional cards one at a time. These cards are dealt face up, and the player decides when to stop taking cards. If the player "busts" (i.e., the sum of the player's cards exceeds 21), the game is over, and the player loses. When the player is satisfied with the current set of cards, the player "stands" (i.e., stops taking cards), and the dealer's hidden card is revealed. If the dealer's total is 16 or less, the dealer must take another card; otherwise, the dealer must stand. The dealer must continue taking cards until the sum of the dealer's cards is greater than or equal to 17. If the dealer exceeds 21, the player wins. Otherwise, the hand with the higher point total wins. If the dealer and the player have the same point total, the game is a "push," and no one wins. Note that the value of an ace for a dealer depends on the dealer's other card(s) and the casino's house rules. A dealer typically must hit for totals of 16 or less and must stand for totals of 17 or more. However, for a "soft 17"—a hand with a total of 17 with one ace counted as 11—some casinos require the dealer to hit and some require the dealer to stand (we require the dealer to stand). Such a hand is known as a "soft 17" because taking another card cannot bust the hand.*

The web service (Fig. 28.13) stores each card as a `String` consisting of a number, 1–13, representing the card's face (ace through king, respectively), followed by a space and a digit, 0–3, representing the card's suit (hearts, diamonds, clubs or spades, respectively). For example, the jack of clubs is represented as "11 2", and the two of hearts is represented as "2 0". To create and deploy this web service, follow the steps presented in Sections 28.3.3–28.3.4 for the `HugeInteger` service.

```

**Fig. 28.13** | Blackjack web service that deals cards and evaluates hands. (Part 4 of 4.)

#### Session Tracking in Web Services

The Blackjack web service client first calls method `shuffle` (lines 40–71) to shuffle the deck of cards. This method also places the deck of cards into an `HttpSession` object that is specific to the client that called `shuffle`. To use session tracking in a Web service, you must include code for the resources that maintain the session state information. In the past, you had to write the sometimes tedious code to create these resources. JAX-WS, however, handles this for you via the `@Resource annotation`. This annotation enables tools like Netbeans to “inject” complex support code into your class, thus allowing you to focus on your business logic rather than the support code. The concept of using annotations to add code that supports your classes is known as `dependency injection`. Annotations like `@WebService`, `@WebMethod` and `@WebParam` also perform dependency injection.

Line 20 injects a `WebServiceContext` object into your class. A `WebServiceContext` object enables a web service to access and maintain information for a specific request, such as session state. As you look through the code in Fig. 28.13, you’ll notice that we never create the `WebServiceContext` object. All of the code necessary to create it is injected into the class by the `@Resource annotation`. Line 21 declares a variable of interface type `MessageContext` that the web service will use to obtain an `HttpSession` object for the current client. Line 22 declares the `HttpSession` variable that the web service will use to manipulate the session state information.

Line 44 in method `shuffle` uses the `WebServiceContext` object that was injected in line 20 to obtain a `MessageContext` object. Lines 45–46 then use the `MessageContext` object’s `get` method to obtain the `HttpSession` object for the current client. Method `get` receives a constant indicating what to get from the `MessageContext`. In this case, the constant `MessageContext.SERVLET_REQUEST` indicates that we’d like to get the `HttpServletRequest` object for the current client. We then call method `getSession` to get the `HttpSession` object from the `HttpServletRequest` object.

Lines 49–70 generate an `ArrayList` representing a deck of cards, shuffle the deck and store the deck in the client’s `session` object. Lines 51–53 use nested loops to generate `Strings` in the form `"face suit"` to represent each possible card in the deck. Lines 59–67 shuffle the deck by swapping each card with another card selected at random. Line 70 inserts the `ArrayList` in the `session` object to maintain the deck between method calls from a particular client.

Lines 25–37 define method `dealCard` as a web method. Lines 30–31 use the `session` object to obtain the `"deck"` session attribute that was stored in line 70 of method `shuffle`. Method `getAttribute` takes as a parameter a `String` that identifies the `Object` to obtain

28.6 Session Tracking in Web Services **1397**

In the JAX-WS 2.0 framework, the client must indicate whether it wants to allow the web service to maintain session information. Lines 50–51 in the constructor perform this task. We first cast the proxy object to interface type `BindingProvider`. A `BindingProvider` enables the client to manipulate the request information that will be sent to the server. This information is stored in an object that implements interface `RequestContext`. The `BindingProvider` and `RequestContext` are part of the framework that is created by the IDE when you add a web service client to the application. Next, lines 50–51 invoke the `BindingProvider`'s `get RequestContext` method to obtain the `RequestContext` object. Then the `RequestContext`'s `put` method is called to set the property `BindingProvider.SESSION_MAINTAIN_PROPERTY` to true, which enables session tracking from the client side so that the web service knows which client is invoking the service's web methods.

28.6 Session Tracking in Web Services **1405**

**Fig. 28.14** | Blackjack game that uses the Blackjack web service. (Part 9 of 10.)

## 1406 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

**Fig. 28.14** | Blackjack game that uses the Blackjack web service. (Part 10 of 10.)

Method `gameOver` (lines 178–215) displays all the dealer’s cards, shows the appropriate message in `statusJLabel` and displays the final point totals of both the dealer and the player. Method `gameOver` receives as an argument a member of the `GameStatus` enumeration (defined in lines 25–31). The enumeration represents whether the player tied, lost or won the game; its four members are `PUSH`, `LOSE`, `WIN` and `BLACKJACK`.

When the player clicks the `Deal` JButton, method `dealJButtonActionPerformed` (lines 567–618) clears all of the JLabels that display cards or game status information. Next, the deck is shuffled (line 581), and the player and dealer receive two cards each (lines 584–595). Lines 602–603 then total each hand. If the player and the dealer both obtain scores of 21, the program calls method `gameOver`, passing `GameStatus.PUSH` (line 607). If only the dealer has 21, the program passes `GameStatus.LOSE` to method `gameOver` (line 609). If only the player has 21 after the first two cards are dealt, the program passes `GameStatus.BLACKJACK` to method `gameOver` (line 611).

If `dealJButtonActionPerformed` does not call `gameOver`, the player can take more cards by clicking the `Hit` JButton, which calls `hitJButtonActionPerformed` in lines 543–564. Each time a player clicks `Hit`, the program deals the player one more card and displays it in the GUI. If the player exceeds 21, the game is over and the player loses. If the player has exactly 21, the player is not allowed to take any more cards, and method `dealerPlay` (lines 86–131) is called, causing the dealer to take cards until the dealer’s hand has a value of 17 or more (lines 98–106). If the dealer exceeds 21, the player wins (line 114); otherwise, the values of the hands are compared, and `gameOver` is called with the appropriate argument (lines 120–125).

Clicking the `Stand` JButton indicates that a player does not want to be dealt another card. Method `standJButtonActionPerformed` (lines 533–540) disables the `Hit` and `Stand` buttons, enables the `Deal` button then calls method `dealerPlay`.

## 1396 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

from the session state. The `HttpSession` can store many objects, provided that each has a unique identifier. Note that method `shuffle` must be called before method `dealCard` is called the first time for a client—otherwise, an exception occurs at lines 30–31 because `getAttribute` returns `null`. After obtaining the user's deck, `dealCard` gets the top card from the deck (line 33), removes it from the deck (line 34) and returns the card's value as a `String` (line 36). Without using session tracking, the deck of cards would need to be passed back and forth with each method call. Session tracking makes the `dealCard` method easy to call (it requires no arguments) and eliminates the overhead of sending the deck over the network multiple times.

Method `getHandValue` (lines 74–116) determines the total value of the cards in a hand by trying to attain the highest score possible without going over 21. Recall that an ace can be counted as either 1 or 11, and all face cards count as 10. This method does not use the `session` object because the deck of cards is not used in this method.

As you'll soon see, the client application maintains a hand of cards as a `String` in which each card is separated by a tab character. Line 78 tokenizes the hand of cards (represented by `dealt`) into individual cards by calling `String` method `split` and passing to it a `String` containing the delimiter characters (in this case, just a tab). Method `split` uses the delimiter characters to separate tokens in the `String`. Lines 83–103 count the value of each card. Lines 86–87 retrieve the first integer—the face—and use that value in the `switch` statement (lines 89–102). If the card is an ace, the method increments variable `aceCount`. We discuss how this variable is used shortly. If the card is an 11, 12 or 13 (jack, queen or king), the method adds 10 to the total value of the hand (line 97). If the card is anything else, the method increases the total by that value (line 100).

Because an ace can have either of two values, additional logic is required to process aces. Lines 106–113 of method `getHandValue` process the aces after all the other cards. If a hand contains several aces, only one ace can be counted as 11. The condition in line 109 determines whether counting one ace as 11 and the rest as 1 will result in a total that does not exceed 21. If this is possible, line 110 adjusts the total accordingly. Otherwise, line 112 adjusts the total, counting each ace as 1.

Method `getHandValue` maximizes the value of the current cards without exceeding 21. Imagine, for example, that the dealer has a 7 and receives an ace. The new total could be either 8 or 18. However, `getHandValue` always maximizes the value of the cards without going over 21, so the new total is 18.

### 28.6.2 Consuming the Blackjack Web Service

Now we use the Blackjack web service in a Java application (Fig. 28.14). The application keeps track of the player's and the dealer's cards, and the web service tracks the cards that have been dealt.

The constructor (lines 34–83) sets up the GUI (line 36), changes the background color of the window (line 40) and creates the Blackjack web service's proxy object (lines 46–47). In the GUI, each player has 11 `JLabels`—the maximum number of cards that can be dealt without automatically exceeding 21 (i.e., four aces, four twos and three threes). These `JLabels`s are placed in an `ArrayList` of `JLabels`, (lines 59–82), so we can index the `ArrayList` during the game to determine the `JLabel` that will display a particular card image.

## 28.7 Consuming a Database-Driven Web Service from a Web Application 1407

Method `displayCard` (lines 134–184) updates the GUI to display a newly dealt card. The method takes as arguments an integer index for the `JLabel` in the `ArrayList` that must have its image set and a `String` representing the card. An empty `String` indicates that we wish to display the card face down. If method `displayCard` receives a `String` that's not empty, the program extracts the face and suit from the `String` and uses this information to display the correct image. The `switch` statement (lines 159–173) converts the number representing the suit to an integer and assigns the appropriate character to `suit-Letter` (`h` for hearts, `d` for diamonds, `c` for clubs and `s` for spades). The character in `suit-Letter` is used to complete the image's file name (lines 176–178).

In this example, you learned how to set up a web service to support session handling so that you could keep track of each client's session state. You also learned how to indicate from a desktop client application that it wishes to take part in session tracking. You'll now learn how to access a database from a web service and how to consume a web service from a client web application.

## 28.7 Consuming a Database-Driven Web Service from a Web Application

Our prior examples accessed web services from desktop applications created in Netbeans. However, we can just as easily use them in web applications created with Netbeans or Sun Java Studio Creator 2. In fact, because web-based businesses are becoming increasingly prevalent, it is common for web applications to consume web services. In this section, we present an airline reservation web service that receives information regarding the type of seat a customer wishes to reserve and makes a reservation if such a seat is available. Later in the section, we present a web application that allows a customer to specify a reservation request, then uses the airline reservation web service to attempt to execute the request. We use Sun Java Studio Creator 2 to create the Web application.

### 28.7.1 Configuring Java DB in Netbeans and Creating the Reservation Database

In this example, our web service uses a `Reservation` database containing a single table named `Seats` to locate a seat matching a client's request. You'll build the `Reservation` database using the tools provided in Netbeans to create and manipulate Java DB databases.

#### *Adding a Java DB Database*

To add a Java DB database server in Netbeans, perform the following steps:

1. Select **Tools > Options...** to display the Netbeans **Options** dialog.
2. Click the **Advanced Options** button to display the **Advanced Options** dialog.
3. Under **IDE Configuration**, expand the **Server and External Tool Settings** node and select **Java DB Database**.
4. If the Java DB properties are not already configured, set the **Java DB Location** property to the location of Java DB on your system. JDK 6 comes with a bundled version of Java DB, which is located on Windows in the directory `C:\Program Files\Java\jdk1.6.0\db`. Sun Java System Application Server also comes bun-

**1408 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups**

ddled with Java DB at C:\Sun\AppServer\javadb. Also, set the **Database Location** property to the location where you'd like the Java DB databases to be stored.

*Creating a Java DB Database*

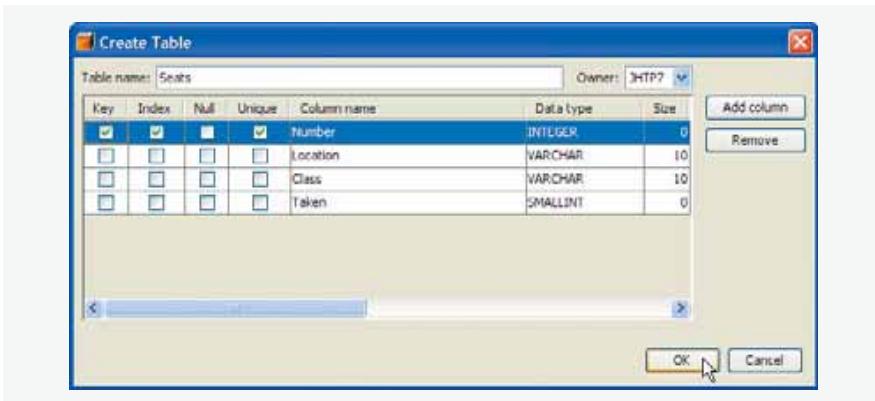

Now that database software is configured, create a new database as follows:

1. Select Tools > Java DB Database > Create Java DB Database....
2. Enter the name of the database to create (Reservation), a username (jhttp7) and a password (jhttp7), then click OK to create the database.

*Adding a Table and Data to the Seats Database*

You can use the Netbeans **Runtime** tab (to the right of the **Projects** and **Files** tabs) to create tables and to execute SQL statements that populate the database with data:

1. Click Netbeans **Runtime** tab and expand the **Databases** node.
2. Netbeans must be connected to the database to execute SQL statements. If Netbeans is already connected, proceed to *Step 3*. If Netbeans is not connected to the database, the icon appears next to the database's URL (jdbc:derby://localhost:1527/Reservation). In this case, right click the icon and click **Connect...**. Once connected, the icon changes to .
3. Expand the node for the Reservation database, right click the **Tables** node and select **Create Table...** to display the **Create Table** dialog. Add a table named Seats to the database, and set up the columns Number, Location, Class and Taken, as shown in Fig. 28.15. Use the **Add column** button to add a row in the dialog for each column in the database.
4. Next, use **INSERT INTO** commands to populate the database with the data shown in Fig. 28.16. To do this, right click the Seats table in the **Runtime** tab and select **Execute Command...** to display a **SQL Command** tab in Netbeans editor. The file **SQLStatementsForFig28\_16.txt** provided with this chapter's examples contains the 10 **INSERT INTO** commands that store the data shown in Fig. 28.16. Simply copy the text in that file and paste it into the **SQL Command** tab, then press the

**Fig. 28.15** | Seats table configuration.

28.7 Consuming a Database-Driven Web Service from a Web Application **1409**

Number	Location	Class	Taken
1	Aisle	Economy	0
2	Aisle	Economy	0
3	Aisle	First	0
4	Middle	Economy	0
5	Middle	Economy	0
6	Middle	First	0
7	Window	Economy	0
8	Window	Economy	0
9	Window	First	0
10	Window	First	0

**Fig. 28.16** | Seats table's data.

Run SQL button (SQL) to the right of the Connection drop-down list in the SQL Command tab to execute the commands. You can confirm that the data was inserted properly by right clicking the Seats table in the Runtime tab and selecting View Data....

*Creating the Reservation Web Service*

You can now create a web service that uses the Reservation database (Fig. 28.17). The airline reservation web service has a single web method—reserve (lines 25–73)—which searches a Reservation database containing a single table named Seats to locate a seat matching a user's request. The method takes two arguments—a String representing the desired seat type (i.e., "Window", "Middle" or "Aisle") and a String representing the desired class type (i.e., "Economy" or "First"). If it finds an appropriate seat, method reserve updates the database to make the reservation and returns true; otherwise, no reservation is made, and the method returns false. Note that the statements at lines 34–37 and lines 43–44 that query and update the database use objects of types ResultSet and Statement (introduced in Chapter 25).

Our database contains four columns—the seat number (i.e., 1–10), the seat type (i.e., Window, Middle or Aisle), the class type (i.e., Economy or First) and a column containing either 1 (true) or 0 (false) to indicate whether the seat is taken. Lines 34–37 retrieve the seat numbers of any available seats matching the requested seat and class type. This statement fills the resultSet with the results of the query

```
SELECT "Number"
FROM "Seats"
WHERE ("Taken" = 0) AND ("Type" = type) AND ("Class" = class)
```

The parameters *type* and *class* in the query are replaced with values of method reserve's *seatType* and *classType* parameters. When you use the Netbeans tools to create a data-

**1410** Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

base table and its columns, the Netbeans tools automatically place the table and column names in double quotes. For this reason, you must place the table and column names in double quotes in the SQL statements that interact with the `Reservation` database.

If `resultSet` is not empty (i.e., there at least one seat is available that matches the selected criteria), the condition in line 40 is `true` and the web service reserves the first matching seat number. Recall that `ResultSet` method `next` returns `true` if a nonempty row exists, and positions the cursor on that row. We obtain the seat number (line 42) by accessing `resultSet`'s first column (i.e., `resultSet.getInt(1)`—the first column in the row). Then lines 43–44 invoke `statement`'s `executeUpdate` method to execute the SQL:

```
UPDATE "Seats"
SET "Taken" = 1
WHERE ("Number" = number)
```

which marks the seat as taken in the database. The parameter `number` is replaced with the value of `seatNumber`. Method `reserve` returns `true` (line 45) to indicate that the reservation was successful. If there are no matching seats, or if an exception occurred, method `reserve` returns `false` (lines 48, 53, 58 and 70) to indicate that no seats matched the user's request.

```
1 // Fig. 28.17: Reservation.java

56 {
57 e.printStackTrace();
58 return false;
59 } // end catch
60 finally
61 {
62 try
63 {
64 statement.close();
65 connection.close();
66 } // end try
67 catch (Exception e)
68 {
69 e.printStackTrace();
70 return false;
71 } // end catch
72 } // end finally
73 } // end WebMethod reserve
74 } // end class Reservation

```

**Fig. 28.17** | Airline reservation web service. (Part 2 of 2.)**28.7.2 Creating a Web Application to Interact with the Reservation Web Service**

This section presents a `ReservationClient` web application that consumes the `Reservation` web service. The application allows users to select seats based on class ("Economy" or "First") and location ("Aisle", "Middle" or "Window"), then submit their requests to the airline reservation web service. If the database request is not successful, the application in-

## 1412 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

structs the user to modify the request and try again. The application presented here was built using Sun Java Studio Creator 2, JavaServer Faces (JSF) and the techniques presented in Chapters 26–27.

### *Adding a Web Service Reference to a Project Sun Java Studio Creator 2*

You can add a web service to a web application in Java Studio Creator 2 by performing the following steps:

1. Click the **Add Web Service...** button () to display the **Add Web Service** dialog.
2. Click the **Get Web Service Information** button.
3. Click **Add** to dismiss the dialog and add the web service's proxy to the web application. The web service now appears in Java Studio Creator 2's **Servers** tab under the **Web Services** node.
4. Right click the **ReservationService** node under the **Web Services** node and select **Add to Page** to create an instance of the web service's proxy class that you can use in the **Reserve** class that provides the logic of the JSP.

For the purpose of this example, we assume that you've already read Chapters 26–27, and thus know how to build a web application's GUI, create event handlers and add properties to a web application's session bean (introduced in Section 26.4.4).

### **Reserve.jsp**

**Reserve.jsp** (Fig. 28.18) defines two **DropDownList** objects and a **Button**. The **seatTypeDropDownList** (lines 26–31) displays all the seat types from which users can select. The **classDropDownList** (lines 32–37) provides choices for the class type. Users click the **Button** named **reserveButton** (lines 38–41) to submit requests after making selections from the **DropDownLists**. The page also defines three **Labels**—**instructionLabel** (lines 21–25) to display instructions, **successLabel** (lines 42–45) to indicate a successful reservation and **errorLabel** (lines 46–50) to display an appropriate message if no seat matching the user's selection is available. The page bean file (Fig. 28.19) attaches event handlers to **seatTypeDropDownList**, **classDropDownList** and **reserveButton**.

### **Reserve.java**

Figure 28.19 contains the page bean code that provides the logic for Reserve.jsp. (To save space, we do not show the autogenerated code in lines 28–283.) As discussed in Section 26.5.2, the class that represents the page's bean extends AbstractPageBean. When the user clicks Reserve in the JSP, the event handler reserveButton\_action (lines 285–319) executes. Line 289 creates a ReservationServiceClient proxy object. Lines 290–292 use this object to invoke the web service's reserve method, passing the selected seat type and class type as arguments. If reserve returns true, lines 296–301 hide the GUI components in the JSP and display the successLabel1 (line 300) to thank the user for making a reservation; otherwise, lines 305–310 ensure that the GUI components remain displayed and display the errorLabel1 (line 310) to notify the user that the requested seat type is not available and instructs the user to try again. When the user selects a value in one of

28.7 Consuming a Database-Driven Web Service from a Web Application **1415**

the DropDownList, the corresponding event handler—`seatTypeDropDownList_processValueChange` (lines 322–327) or `classDropDownList_processValueChange` (lines 330–335)—is called to set the session properties `seatType` and `classType`, which we added to the web application’s session bean. The values of these properties are used as the arguments in the call to the web service’s `reserve` method.

## 28.8 Passing an Object of a User-Defined Type to a Web Service

The web methods we've demonstrated so far each receive and return only primitive values or `String`s. Web services also can receive and return objects of user-defined types—known as **custom types**. This section presents an `EquationGenerator` web service that generates random arithmetic questions of type `Equation`. The client is a math-tutoring desktop application in which the user selects the type of mathematical question to attempt (addition, subtraction or multiplication) and the skill level of the user—level 1 uses one-digit numbers in each question, level 2 uses two-digit numbers and level 3 uses three-digit numbers. The client passes this information to the web service, which then generates an `Equation` consisting of random numbers with the proper number of digits. The client application receives the `Equation`, displays the sample question to the user in a Java application, allows the user to provide an answer and checks the answer to determine whether it is correct.

28.8 Passing an Object of a User-Defined Type to a Web Service **1417*****Serialization of User-Defined Types***

We mentioned earlier that all types passed to and from SOAP web services must be supported by SOAP. How, then, can SOAP support a type that is not even created yet? Custom types that are sent to or from a web service are serialized into XML format. This process is referred to as **XML serialization**. The process of serializing objects to XML and deserializing objects from XML is handled for you automatically.

***Requirements for User-Defined Types Used with Web Methods***

A class that is used to specify parameter or return types in web methods must meet several requirements:

1. It must provide a `public` default or no-argument constructor. When a web service or web service consumer receives an XML serialized object, the JAX-WS 2.0 Framework must be able to call this constructor when deserializing the object (i.e., converting it from XML back to a Java object).
2. Instance variables that should be serialized in XML format must have `public set` and `get` methods to access the `private` instance variables (recommended), or the instance variables must be declared `public` (not recommended).
3. Non-`public` instance variables that should be serialized must provide both `set` and `get` methods (even if they have empty bodies); otherwise, they are not serialized.

Any instance variable that is not serialized simply receives its default value (or the value provided by the no-argument constructor) when an object of the class is deserialized.

**Common Programming Error 28.3**

*A runtime error occurs if an attempt is made to deserialize an object of a class that does not have a default or no-argument constructor.*

***Defining Class Equation***

We define class `Equation` in Fig. 28.20. Lines 18–31 define a constructor that takes three arguments—two `ints` representing the left and right operands and a `String` that represents the arithmetic operation to perform. The constructor sets the `leftOperand`, `rightOperand` and `operationType` instance variables, then calculates the appropriate result. The no-argument constructor (lines 13–16) calls the three-argument constructor (lines 18–31) and passes default values. We do not use the no-argument constructor explicitly, but the XML serialization mechanism uses it when objects of this class are serialized. Because we provide a constructor with parameters, we must explicitly define the no-argument constructor in this class so that objects of the class can be passed to or returned from web methods.

```

111 } // end class Equation

```

**Fig. 28.20** | Class Equation that stores information about an equation. (Part 3 of 3.)

**1420** Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

Class `Equation` defines methods `getLeftHandSide` and `setLeftHandSide` (lines 41–44 and 77–80); `getRightHandSide` and `setRightHandSide` (lines 47–50 and 83–86); `getLeftOperand` and `setLeftOperand` (lines 53–56 and 89–92); `getRightOperand` and `setRightOperand` (lines 59–62 and 95–98); `getReturnValue` and `setReturnValue` (lines 65–68 and 101–104); and `getOperationType` and `setOperationType` (lines 71–74 and 107–110). The client of the web service does not need to modify the values of the instance variables. However, recall that a property can be serialized only if it has both a *get* and a *set* accessor, or if it is *public*. So we provided *set* methods with empty bodies for each of the class's instance variables. Method `getLeftHandSide` (lines 41–44) returns a `String` representing everything to the left of the equals (=) sign in the equation, and `getRightHandSide` (lines 47–50) returns a `String` representing everything to the right of the equals (=) sign. Method `getLeftOperand` (lines 53–56) returns the integer to the left of the operator, and `getRightOperand` (lines 59–62) returns the integer to the right of the operator. Method `getResultValue` (lines 65–68) returns the solution to the equation, and `getOperationType` (lines 71–74) returns the operator in the equation. The client in this example does not use the `rightHandSide` property, but we included it so future clients can use it.

***Creating the EquationGenerator Web Service***

Figure 28.21 presents the `EquationGenerator` web service, which creates random, customized Equations. This web service contains only method `generateEquation` (lines 18–31), which takes two parameters—the mathematical operation (one of "+", "-" or "\*") and an `int` representing the difficulty level (1–3).

```

1 // Fig. 22.20: Generator.java
2 // Web service that generates random equations
3 package com.deitel.jhttp7.ch28.equationgenerator;
4
5 import java.util.Random;
6 import javax.jws.WebService;
7 import javax.jws.WebMethod;
8 import javax.jws.WebParam;
9
10 @WebService(name = "EquationGenerator",
11 serviceName = "EquationGeneratorService")
12 public class EquationGenerator
13 {
14 private int minimum;
15 private int maximum;
16
17 // generates a math equation and returns it as an Equation object
18 @WebMethod(operationName = "generateEquation")
19 public Equation generateEquation(
20 @WebParam(name = "operation") String operation,
21 @WebParam(name = "difficulty") int difficulty)
22 {
23 minimum = (int) Math.pow(10, difficulty - 1);
24 maximum = (int) Math.pow(10, difficulty);
25 }

```

**Fig. 28.21** | Web service that generates random equations. (Part I of 2.)

## 28.8 Passing an Object of a User-Defined Type to a Web Service

1421

```

26 Random randomObject = new Random();
27
28 return new Equation(
29 randomObject.nextInt(maximum - minimum) + minimum,
30 randomObject.nextInt(maximum - minimum) + minimum, operation);
31 } // end method generateEquation
32 } // end class EquationGenerator

```

**Fig. 28.21** | Web service that generates random equations. (Part 2 of 2.)***Testing the EquationGenerator Web Service***

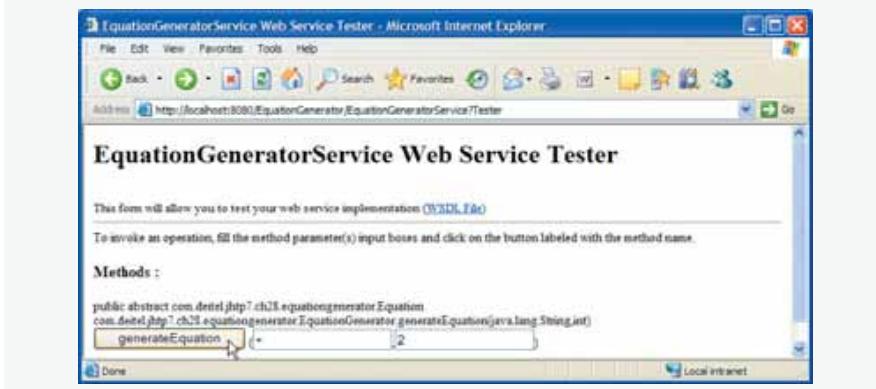

Figure 28.22 shows the result of testing the EquationGenerator web service with the Tester web page. In *part (b)* of the figure, note that the return value from our web method is XML encoded. However, this example differs from previous ones in that the XML specifies the values for all the data of the XML serialized object that is returned. The proxy class receives this return value and deserializes it into an object of class Equation, then passes it to the client.

Note that an Equation object is *not* being passed between the web service and the client. Rather, the information in the object is being sent as XML-encoded data. Clients created using Java will take the information and create a new Equation object. Clients created on other platforms, however, may use the information differently. Readers creating clients on other platforms should check the web services documentation for the specific platform they are using, to see how their clients may process custom types.

***Details of the EquationGenerator Web Service***

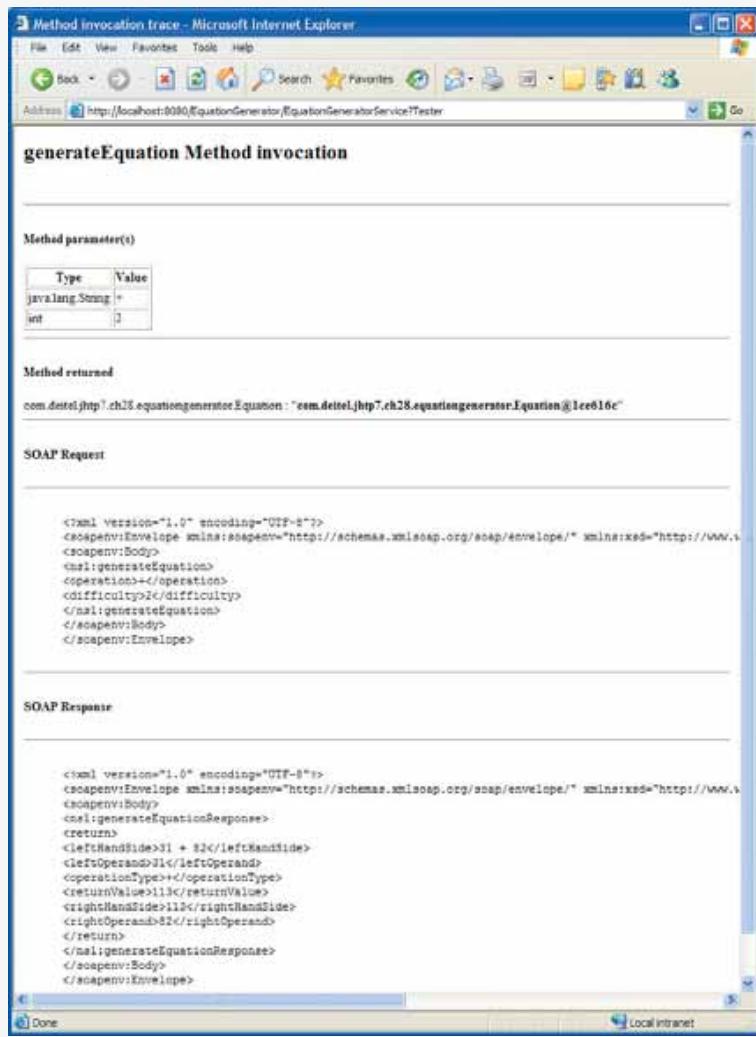

Let's examine web method generateEquation more closely. Lines 23–24 of Fig. 28.21 define the upper and lower bounds of the random numbers that the method uses to generate an Equation. To set these limits, the program first calls static method pow of class Math—this method raises its first argument to the power of its second argument. Variable

a) Using the EquationGenerator web service's Tester web page to generate an Equation.

**Fig. 28.22** | Testing a web method that returns an XML serialized Equation object. (Part 1 of 2.)

**1422 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups**

b) Result of generating an Equation.

**Fig. 28.22** | Testing a web method that returns an XML serialized Equation object. (Part 2 of 2.)

minimum's value is determined by raising 10 to a power one less than level (line 23). This calculates the smallest number with level digits. If level is 1, minimum is 1; if level is 2, minimum is 10; and if level is 3, minimum is 100. To calculate the value of maximum (the upper bound for any randomly generated numbers used to form an Equation), the program raises 10 to the power of the specified level argument (line 23). If level is 1, maximum is 10; if level is 2, maximum is 100; and if level is 3, maximum is 1000.

28.8 Passing an Object of a User-Defined Type to a Web Service **1423**

Lines 28–30 create and return a new `Equation` object consisting of two random numbers and the `String` operation received by `generateEquation`. The program calls `Random` method `nextInt`, which returns an `int` that is less than the specified upper bound. This method generates a left operand value that is greater than or equal to `minimum` but less than `maximum` (i.e., a number with `level` digits). The right operand is another random number with the same characteristics.

#### *Consuming the `EquationGenerator` Web Service*

The `Math Tutor` application (Fig. 28.23) uses the `EquationGenerator` web service. The application calls the web service's `generateEquation` method to create an `Equation` object. The tutor then displays the left-hand side of the `Equation` and waits for user input. Line 9 also declares a `GeneratorService` instance variable that we use to obtain an `EquationGenerator` proxy object. Lines 10–11 declare instance variables of types `EquationGenerator` and `Equation`.

After displaying an equation, the application waits for the user to enter an answer. The default setting for the difficulty level is **One-digit numbers**, but the user can change this by choosing a level from the **Choose level** `JComboBox`. Clicking any of the levels invokes `level1JComboBoxItemStateChanged` (lines 158–163), which sets the variable `difficulty` to the level selected by the user. Although the default setting for the question type is **Addition**, the user also can change this by selecting an operation from the **Choose operation** `JComboBox`. Doing so invokes `operationJComboBoxItemStateChanged` (lines 166–177), which sets the `String` operation to the appropriate mathematical symbol.

When the user clicks the **Generate Equation** `JButton`, method `generateButtonActionPerformed` (lines 207–221) invokes the `EquationGenerator` web service's `generateEquation` (line 212) method. After receiving an `Equation` object from the web service, the handler displays the left-hand side of the equation in `equationJLabel` (line 214) and enables the `checkAnswerJButton` so that the user can submit an answer. When the user clicks the **Check Answer** `JButton`, method `checkAnswerJButtonActionPerformed` (lines 180–204) determines whether the user provided the correct answer.

## 28.9 Wrap-Up

This chapter introduced JAX-WS 2.0 web services, which promote software portability and reusability in applications that operate over the Internet. You learned that a web service is a software component stored on one computer that can be accessed by an application (or other software component) on another computer over a network, communicating via such technologies as XML, SOAP and HTTP. We discussed several benefits of this kind of distributed computing—e.g., clients can access data on remote machines, clients lacking the processing power to perform specific computations can leverage remote machines' resources and entirely new types of innovative applications can be developed.

We explained how Netbeans, Sun Java Studio Creator 2 and the JAX-WS 2.0 APIs facilitate the creation and consumption of web services. We showed how to set up projects and files in these tools and how the tools manage the web service infrastructure necessary to support the web services you create. You learned how to define web services and web methods, as well as how to consume them both from Java desktop applications created in Netbeans and from web applications created in Sun Java Studio Creator 2. After explaining the mechanics of web services with our `HugeInteger` example, we demonstrated more sophisticated web services that use session tracking in both the server side and the client side, and web services that access databases using JDBC. We also explained XML serialization and showed how to pass objects of user-defined types to web services and return them from web services.

The next chapter discusses formatting output with method `System.out.printf` and with class `Formatter`.

## 28.10 Web Resources

In addition to the web resources shown here, you should also refer to the JSP-related web resources provided at the end of Chapter 26.

## Summary

### ***Section 28.1 Introduction***

- A web service is a software component stored on one computer that can be accessed via method calls by an application (or other software component) on another computer over a network.
- Web services communicate using such technologies as XML and HTTP.
- The Simple Object Access Protocol (SOAP) is an XML-based protocol that allows web services and clients to communicate in a platform-independent manner.
- Web services enable businesses to conduct transactions via standardized, widely available web services rather than relying on proprietary applications.
- Companies such as Amazon, Google, eBay, PayPal and many others are using web services to their advantage by making their server-side applications available to partners via web services.
- By purchasing web services and using extensive free web services, companies can spend less time developing new applications and can create innovative new applications.
- Netbeans 5.5 and Sun Java Studio Creator 2—both developed by Sun—are two of the many tools that enable programmers to "publish" and/or "consume" web services.

### **Section 28.2 Java Web Services Basics**

- The computer on which a web service resides is referred to as a remote machine or server. A client application that accesses a web service sends a method call over a network to the remote machine, which processes the call and returns a response over the network to the application.
- In Java, a web service is implemented as a class. The class that represents the web service resides on a server—it's not part of the client application.
- Making a web service available to receive client requests is known as publishing a web service; using a web service from a client application is known as consuming a web service.
- An application that consumes a web service consists of two parts—an object of a proxy class for interacting with the web service and a client application that consumes the web service by invoking methods on the proxy object. The proxy object handles the details of communicating with the web service on the client's behalf.
- Requests to and responses from web services created with JAX-WS 2.0 are typically transmitted via SOAP. Any client capable of generating and processing SOAP messages can interact with a web service, regardless of the language in which the web service is written.

### **Section 28.3.1 Creating a Web Application Project and Adding a Web Service Class in Netbeans**

- When you create a web service in Netbeans, you focus on the logic of the web service and let the IDE handle the web service's infrastructure.
- To create a web service in Netbeans, you first create a project of type **Web Application**. Netbeans uses this project type for web applications that execute in browser-based clients and for web services that are invoked by other applications.
- When you create a **Web Application** in Netbeans, the IDE generates additional files that support the web application.

### **Section 28.3.2 Defining the HugeInteger Web Service in Netbeans**

- By default, each new web service class created with the JAX-WS APIs is a POJO (plain old Java object)—you do not need to extend a class or implement an interface to create a Web service.
- When you compile a class that uses these JAX-WS 2.0 annotations, the compiler creates the compiled code framework that allows the web service to wait for and respond to client requests.
- The `@WebService` annotation indicates that a class represents a web service. Optional element `name` specifies the name of the proxy class that will be generated for the client. Optional element `serviceName` specifies the name of the class that the client uses to obtain a proxy object.
- Netbeans places the `@WebService` annotation at the beginning of each new web service class you create. You can add the optional `name` and `serviceName` elements in the annotation's parentheses.
- Methods that are tagged with the `@WebMethod` annotation can be called remotely.
- Methods that are not tagged with `@WebMethod` are not accessible to clients that consume the web service. Such methods are typically utility methods within the web service class.
- The `@WebMethod` annotation has an optional `operationName` element to specify the method name that is exposed to the web service's client.
- Parameters of web methods are annotated with the `@WebParam` annotation. The optional element `name` indicates the parameter name that is exposed to the web service's clients.

### **Section 28.3.3 Publishing the HugeInteger Web Service from Netbeans**

- Netbeans handles all the details of building and deploying a web service for you. This includes creating the framework required to support the web service.

## 1430 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

- To determine if there are any compilation errors in your project, right click the project name in the Netbeans **Projects** tab, then select the **Build Project** option.
- Select **Deploy Project** to deploy the project to the server you selected during application setup.
- Select **Run Project** to execute the web application.
- Both the **Deploy Project** and **Run Project** options also build the project if it has changed and start the application server if it is not already running.
- To ensure that all source-code files in a project are recompiled during the next build operation, you can use the **Clean Project** or **Clean and Build Project** options.

### *Section 28.3.4 Testing the HugeInteger Web Service with Sun Java System Application Server's Tester Web page*

- Sun Java System Application Server can dynamically create a **Tester** web page for testing a web service's methods from a web browser. You can enable this feature via the project's **Run** options.
- To display the **Tester** web page, run the web application from Netbeans or type the URL of the web service in the browser's address field followed by `?Tester`.
- A client can access a web service only when the application server is running. If Netbeans launches the application server for you, the server will shut down when you close Netbeans. To keep the application server up and running, you can launch it independently of Netbeans.

### *Section 28.3.5 Describing a Web Service with the Web Service Description Language (WSDL)*

- To consume a web service, a client must know where to find the web service and must be provided with the web service's description.
- JAX-WS uses the Web Service Description Language (WSDL)—a standard XML vocabulary for describing web services in a platform-independent manner.
- You do not need to understand WSDL to take advantage of it—the server generates a web service's WSDL dynamically for you and client tools can parse the WSDL to help create the client-side proxy class that a client uses to access the web service.
- Since the WSDL is created dynamically, clients always receive a deployed web service's most up-to-date description.
- To view the WSDL for a web service, type its URL in the browser's address field followed by `?WSDL` or click the **WSDL File** link in the Sun Java System Application Server's **Tester** web page.

### *Section 28.4 Consuming a Web Service*

- A web service client can be any type of application or even another web service.
- In Netbeans, you enable a client application to consume a web service by adding a web service reference to the application, which defines the client-side proxy class.

### *Section 28.4.1 Creating a Client in Netbeans to Consume the HugeInteger Web Service*

- When you add a web service reference, the IDE creates and compiles the client-side artifacts—the framework of Java code that supports the client-side proxy class.
- The client calls methods on a proxy object, which uses the client-side artifacts to interact with the web service.
- To add a web service reference, right click the client project name in the Netbeans **Projects** tab, then select **New > Web Service Client....** In the dialog's **WSDL URL** field, specify the URL of the web service's WSDL.

- Netbeans uses the WSDL description to generate the client-side proxy class and artifacts.
- When you specify the web service you want to consume, Netbeans copies the web service's WSDL into a file in your project. You can view this file from the Netbeans **Files** tab by expanding the nodes in the project's `xml-resources` folder.
- The client-side artifacts and the client's copy of the WSDL file can be regenerated by right clicking the web service's node in the Netbeans **Projects** tab and selecting **Refresh Client**.
- You can view the IDE-generated client-side artifacts by selecting the Netbeans **Files** tab and expanding the project's `build` folder.

### **Section 28.5 SOAP**

- SOAP is a commonly used, platform-independent, XML-based protocol that facilitates remote procedure calls, typically over HTTP.
- The protocol that transmits request-and-response messages is also known as the web service's wire format or wire protocol, because it defines how information is sent "along the wire."
- Each request and response is packaged in a SOAP message (also known as a SOAP envelope) containing the information that a web service requires to process the message.
- The wire format used to transmit requests and responses must support all types passed between the applications. SOAP supports primitive types and their wrapper types, as well as `Date`, `Time` and others. SOAP can also transmit arrays and objects of user-defined types.
- When a program invokes a web method, the request and all relevant information are packaged in a SOAP message and sent to the server on which the web service resides. The web service processes the SOAP message's contents, which specify the method to invoke and its arguments. After the web service receives and parses a request, the proper method is called, and the response is sent back to the client in another SOAP message. The client-side proxy parses the response, which contains the result of the method call, and returns the result to the client application.
- The SOAP messages are generated for you automatically. So you don't need to understand the details of SOAP or XML to take advantage of it when publishing and consuming web services.

### **Section 28.6 Session Tracking in Web Services**

- It can be beneficial for a web service to maintain client state information, thus eliminating the need to pass client information between the client and the web service multiple times. Storing session information also enables a web service to distinguish between clients.

#### **Section 28.6.1 Creating a Blackjack Web Service**

- To use session tracking in a Web service, you must include code for the resources that maintain the session state information. In the past, you had to write the sometimes tedious code to create these resources. JAX-WS, however, handles this for you via the `@Resource` annotation. This annotation enables tools like Netbeans to "inject" complex support code into your class, thus allowing you to focus on your business logic rather than the support code.
- Using annotations to add code that supports your classes is known as dependency injection. Annotations like `@WebService`, `@WebMethod` and `@WebParam` also perform dependency injection.
- A `WebServiceContext` object enables a web service to access and maintain information for a specific request, such as session state. The code that creates a `WebServiceContext` object is injected into the class by an `@Resource` annotation.
- The `WebServiceContext` object is used to obtain a `MessageContext` object. A web service uses a `MessageContext` to obtain an `HttpSession` object for the current client.
- The `MessageContext` object's `get` method is used to obtain the `HttpSession` object for the current client. Method `get` receives a constant indicating what to get from the `MessageContext`. The

## 1432 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups

constant `MessageContext.SERVLET_REQUEST` indicates that we'd like to get the `HttpServletRequest` object for the current client. We then call method `getSession` to get the `HttpSession` object from the `HttpServletRequest` object.

- `HttpSession` method `getAttribute` receives a `String` that identifies the `Object` to obtain from the session state.

### *Section 28.6.2 Consuming the Blackjack Web Service*

- In the JAX-WS 2.0 framework, the client must indicate whether it wants to allow the web service to maintain session information. To do this, first cast the proxy object to interface type `BindingProvider`. A `BindingProvider` enables the client to manipulate the request information that will be sent to the server. This information is stored in an object that implements interface `RequestContext`. The `BindingProvider` and `RequestContext` are part of the framework that is created by the IDE when you add a web service client to the application.
- Next, invoke the `BindingProvider`'s `getRequestContext` method to obtain the `RequestContext` object. Then call the `RequestContext`'s `put` method to set the property `BindingProvider.SESSION_MAINTAIN_PROPERTY` to `true`, which enables session tracking from the client side so that the web service knows which client is invoking the service's web methods.

### *Section 28.7.1 Configuring Java DB in Netbeans and Creating the Reservation Database*

- To add a Java DB database server in Netbeans, perform the following steps: Select `Tools > Options...` to display the Netbeans `Options` dialog. Click the `Advanced Options` button to display the `Advanced Options` dialog. Under `IDE Configuration`, expand the `Server and External Tool Settings` node and select `Java DB Database`. If the Java DB properties are not already configured, set the `Java DB Location` property to the location of Java DB on your system. Also, set the `Database Location` property to the location where you'd like the Java DB databases to be stored.
- To create a new database: Select `Tools > Java DB Database > Create Java DB Database....` Enter the name of the database to create, a username and a password, then click `OK` to create the database.
- You can use the Netbeans `Runtime` tab to create tables and to execute SQL statements that populate the database with data. Click the Netbeans `Runtime` tab and expand the `Databases` node.
- Netbeans must be connected to the database to execute SQL statements. If Netbeans is not connected to the database, the icon  appears next to the database's URL. In this case, right click the icon and click `Connect....` Once connected, the icon changes to .

### *Section 28.7.2 Creating a Web Application to Interact with the Reservation Web Service*

- You can add a web service to a web application in Java Studio Creator 2 by clicking the `Add Web Service...` button (). You can then specify the web service's WSDL in the dialog that appears.

### *Section 28.8 Passing an Object of a User-Defined Type to a Web Service*

- Web services can receive and return objects of user-defined types—known as custom types.
- Custom types that are sent to or from a web service using SOAP are serialized into XML format. This process is referred to as XML serialization and is handled for you automatically.
- A class that is used to specify parameter or return types in web methods must provide a `public` default or no-argument constructor. Also, any instance variables that should be serialized must have `public` `set` and `get` methods or the instance variables must be declared `public`.
- Any instance variable that is not serialized simply receives its default value (or the value provided by the no-argument constructor) when an object of the class is deserialized.

## Self-Review Exercises

- 28.1** State whether each of the following is *true* or *false*. If *false*, explain why.
- All methods of a web service class can be invoked by clients of that web service.
  - When consuming a web service in a client application created in Netbeans, you must create the proxy class that enables the client to communicate with the web service.
  - A proxy class communicating with a web service normally uses SOAP to send and receive messages.
  - Session tracking is automatically enabled in a client of a web service.
  - Web methods cannot be declared **static**.
  - A user-defined type used in a web service must define both *get* and *set* methods for any property that will be serialized.

**1434 Chapter 28 JAX-WS Web Services, Web 2.0 and Mash-Ups****28.2** Fill in the blanks for each of the following statements:

- When messages are sent between an application and a web service using SOAP, each message is placed in a(n) \_\_\_\_\_.
- A web service in Java is a(n) \_\_\_\_\_—it does not need to implement any interfaces or extend any classes.
- Web service requests are typically transported over the Internet via the \_\_\_\_\_ protocol.
- To set the exposed name of a web method, use the \_\_\_\_\_ element of the @WebMethod annotation.
- \_\_\_\_\_ transforms an object into a format that can be sent between a web service and a client.

**Answers to Self-Review Exercises**

**28.1** a) False. Only methods declared with the @WebMethod annotation can be invoked by a web service's clients. b) False. The proxy class is created by Netbeans when you add a web service client to the application. c) True. d) False. In the JAX-WS 2.0 framework, the client must indicate whether it wants to allow the web service to maintain session information. First, you must cast the proxy object to interface type BindingProvider, then use the BindingProvider's getRequestContext method to obtain the RequestContext object. Finally, you must use the RequestContext's put method to set the property BindingProvider.SESSION\_MAINTAIN\_PROPERTY to true. e) True. f) True.

**28.2** a) SOAP message or SOAP envelope. b) POJO (plain old Java object) c) HTTP. d) operationName. e) XML serialization.

**Exercises**

**28.3** (*Phone Book Web Service*) Create a web service that stores phone book entries in the database PhoneBookDB and a web client application that consumes this service. Use the steps in Section 28.7.1 to create the PhoneBook database. The database should contain one table—PhoneBook—with three columns—LastName, FirstName and PhoneNumber—each of type VARCHAR. The LastName and FirstName columns should store up to 30 characters. The PhoneNumber column should support phone numbers of the form (800) 555-1212 that contain 14 characters.

Give the client user the capability to enter a new contact (web method addEntry) and to find contacts by last name (web method getEntries). Pass only Strings as arguments to the web service. The getEntries web method should return an array of Strings that contains the matching phone book entries. Each String in the array should consist of the last name, first name and phone number for one phone book entry. These values should be separated by commas.

The SELECT query that will find a PhoneBook entry by last name should be:

```
SELECT LastName, FirstName, PhoneNumber
FROM PhoneBook
WHERE (LastName = LastName)
```

The INSERT statement that inserts a new entry into the PhoneBook database should be:

```
INSERT INTO PhoneBook (LastName, FirstName, PhoneNumber)
VALUES (LastName, FirstName, PhoneNumber)
```

**28.4** (*Phone Book Web Service Modification*) Modify Exercise 28.3 so that it uses a class named PhoneBookEntry to represent a row in the database. The client application should provide objects of type PhoneBookEntry to the web service when adding contacts and should receive objects of type PhoneBookEntry when searching for contacts.

Exercises **1435**

**28.5** (*Blackjack Web Service Modification*) Modify the blackjack web service example in Section 28.6 to include class Card. Modify web method dealCard so that it returns an object of type Card and modify web method getHandValue so that it receives an array of Card objects from the client. Also modify the client application to keep track of what cards have been dealt by using ArrayLists of Card objects. The proxy class created by Netbeans will treat a web method's array parameter as a List, so you can pass these ArrayLists of Card objects directly to the getHandValue method. Your Card class should include set and get methods for the face and suit of the card.

# Formatted Output

*All the news that's fit to print.*

—Adolph S. Ochs

*What mad pursuit? What struggle to escape?*

—John Keats

*Remove not the landmark on the boundary of the fields.*

—Amenehope

## OBJECTIVES

In this chapter you will learn:

- To understand input and output streams.
- To use `printf` formatting.
- To print with field widths and precisions.
- To use formatting flags in the `printf` format string.
- To print with an argument index.
- To output literals and escape sequences.
- To format output with class `Formatter`.

**Outline**

- 29.1 Introduction
- 29.2 Streams
- 29.3 Formatting Output with `printf`
- 29.4 Printing Integers
- 29.5 Printing Floating-Point Numbers
- 29.6 Printing Strings and Characters
- 29.7 Printing Dates and Times
- 29.8 Other Conversion Characters
- 29.9 Printing with Field Widths and Precisions
- 29.10 Using Flags in the `printf` Format String
- 29.11 Printing with Argument Indices
- 29.12 Printing Literals and Escape Sequences
- 29.13 Formatting Output with Class `Formatter`
- 29.14 Wrap-Up

[Summary](#) | [Terminology](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#)

## 29.1 Introduction

An important part of the solution to any problem is the presentation of the results. In this chapter, we discuss the formatting features of method `printf` and class `Formatter` (package `java.util`). Method `printf` formats and outputs data to the standard output stream—`System.out`. Class `Formatter` formats and outputs data to a specified destination, such as a string or a file output stream.

Many features of `printf` were discussed earlier in the text. This chapter summarizes those features and introduces others, such as displaying date and time data in various formats, reordering output based on the index of the argument and displaying numbers and strings with various flags.

## 29.2 Streams

Input and output are usually performed with streams, which are sequences of bytes. In input operations, the bytes flow from a device (e.g., a keyboard, a disk drive, a network connection) to main memory. In output operations, bytes flow from main memory to a device (e.g., a display screen, a printer, a disk drive, a network connection).

When program execution begins, three streams are connected to the program automatically. Normally, the standard input stream is connected to the keyboard, and the standard output stream is connected to the screen. A third stream, the **standard error stream** (`System.err`), is typically connected to the screen and is used to output error messages to the screen so they can be viewed immediately—even when the standard output stream is writing into a file. Operating systems typically allow these streams to be redirected to other devices. Streams are discussed in detail in Chapter 14, Files and Streams, and Chapter 24, Networking.

### 29.3 Formatting Output with printf

Precise output formatting is accomplished with `printf`. [Note: Java SE 5 borrowed this feature from the C programming language.] Method `printf` can perform the following formatting capabilities, each of which is discussed in this chapter:

1. Rounding floating-point values to an indicated number of decimal places.
2. Aligning a column of numbers with decimal points appearing one above the other.
3. Right justification and left justification of outputs.
4. Inserting literal characters at precise locations in a line of output.
5. Representing floating-point numbers in exponential format.
6. Representing integers in octal and hexadecimal format. (See Appendix E, Number Systems, for more information on octal and hexadecimal values.)
7. Displaying all types of data with fixed-size field widths and precisions.
8. Displaying dates and times in various formats.

Every call to `printf` supplies as the first argument a **format string** that describes the output format. The format string may consist of **fixed text** and **format specifiers**. Fixed text is output by `printf` just as it would be output by `System.out` methods `print` or `println`. Each format specifier is a placeholder for a value and specifies the type of data to output. Format specifiers also may include optional formatting information.

In the simplest form, each format specifier begins with a percent sign (%) and is followed by a **conversion character** that represents the data type of the value to output. For example, the format specifier %s is a placeholder for a string, and the format specifier %d is a placeholder for an `int` value. The optional formatting information is specified between the percent sign and the conversion character. The optional formatting information includes an argument index, flags, field width and precision. We define each of these and show examples of them throughout this chapter.

### 29.4 Printing Integers

An integer is a whole number, such as 776, 0 or -52, that contains no decimal point. Integer values are displayed in one of several formats. Figure 29.1 describes the **integral conversion characters**.

Figure 29.2 prints an integer using each of the integral conversions. In lines 9–10, note that the plus sign is not displayed by default, but the minus sign is. Later in this chapter (Fig. 29.14) we will see how to force plus signs to print.

The `printf` method has the form

```
printf(format-string, argument-list);
```

where *format-string* describes the output format, and *argument-list* contains the values that correspond to each format specifier in *format-string*. There can be many format specifiers in one format string.

Each format string in lines 8–10 specifies that `printf` should output a decimal integer (%d) followed by a newline character. At the format specifier's position, `printf` substitutes the value of the first argument after the format string. If the format string contained mul-

tiple format specifiers, at each subsequent format specifier's position, `printf` would substitute the value of the next argument in the argument list. The `%o` format specifier in line 11 outputs the integer in octal format. The `%x` format specifier in line 12 outputs the integer in hexadecimal format. The `%X` format specifier in line 13 outputs the integer in hexadecimal format with capital letters.

## 29.5 Printing Floating-Point Numbers

A floating-point value contains a decimal point, as in 33.5, 0.0 or -657.983. Floating-point values are displayed in one of several formats. Figure 29.3 describes the floating-point conversions. The **conversion characters e** and **E** display floating-point values in **computerized scientific notation** (also called **exponential notation**). Exponential notation

**1440** Chapter 29 Formatted Output

Conversion character	Description
e or E	Display a floating-point value in exponential notation. When conversion character E is used, the output is displayed in uppercase letters.
f	Display a floating-point value in decimal format.
g or G	Display a floating-point value in either the floating-point format f or the exponential format e based on the magnitude of the value. If the magnitude is less than $10^{-3}$ , or greater than or equal to $10^7$ , the floating-point value is printed with e (or E). Otherwise, the value is printed in format f. When conversion character G is used, the output is displayed in uppercase letters.
a or A	Display a floating-point number in hexadecimal format. When conversion character A is used, the output is displayed in uppercase letters.

**Fig. 29.3** | Floating-point conversion characters.

is the computer equivalent of the scientific notation used in mathematics. For example, the value 150.4582 is represented in scientific notation in mathematics as

$$1.504582 \times 10^2$$

and is represented in exponential notation as

$$1.504582e+02$$

in Java. This notation indicates that 1.504582 is multiplied by 10 raised to the second power (e+02). The e stands for “exponent.”

Values printed with the conversion characters e, E and f are output with six digits of precision to the right of the decimal point by default (e.g., 1.045921)—other precisions must be specified explicitly. For values printed with the conversion character g, the precision represents the total number of digits displayed, excluding the exponent. The default is six digits (e.g., 12345678.9 is displayed as 1.234567e+07). **Conversion character f** always prints at least one digit to the left of the decimal point. Conversion characters e and E print lowercase e and uppercase E preceding the exponent and always print exactly one digit to the left of the decimal point. Rounding occurs if the value being formatted has more significant digits than the precision.

**Conversion character g** (or **G**) prints in either e (E) or f format, depending on the floating-point value. For example, the values 0.0000875, 87500000.0, 8.75, 87.50 and 875.0 are printed as 8.750000e-05, 8.750000e+07, 8.750000, 87.50000 and 875.00000 with the conversion character g. The value 0.0000875 uses e notation because the magnitude is less than  $10^{-3}$ . The value 87500000.0 uses e notation because the magnitude is greater than  $10^7$ . Figure 29.4 demonstrates each of the floating-point conversion characters.

```

**Fig. 29.4** | Using floating-point conversion characters.

## 29.6 Printing Strings and Characters

The `c` and `s` conversion characters are used to print individual characters and strings, respectively. Conversion character `s` can also print objects with the results of implicit calls to method `toString`. **Conversion characters c** and **C** require a `char` argument. **Conversion characters s** and **S** can take a `String` or any `Object` (this includes all subclasses of `Object`) as an argument. When an object is passed to the conversion character `s`, the program implicitly uses the object's `toString` method to obtain the `String` representation of the object. When conversion characters `C` and `S` are used, the output is displayed in uppercase letters. The program shown in Fig. 29.5 displays characters, strings and objects with conversion characters `c` and `s`. Note that autoboxing occurs at line 10 when an `int` constant is assigned to an `Integer` object. Line 15 associates an `Integer` object argument to the conversion character `s`, which implicitly invokes the `toString` method to get the integer value. Note that you can also output an `Integer` object using the `%d` format specifier. In this case, the `int` value in the `Integer` object will be unboxed and output.

```

1 // Fig. 29.5: CharStringConversion.java
2 // Using character and string conversion characters.
3
4 public class CharStringConversion
5 {

```

**Fig. 29.5** | Using character and string conversion characters. (Part I of 2.)

## 1442 Chapter 29 Formatted Output

```

6 public static void main(String args[])
7 {
8 char character = 'A'; // initialize char
9 String string = "This is also a string"; // String object
10 Integer integer = 1234; // initialize integer (autoboxing)
11
12 System.out.printf("%c\n", character);
13 System.out.printf("%s\n", "This is a string");
14 System.out.printf("%s\n", string);
15 System.out.printf("%S\n", string);
16 System.out.printf("%s\n", integer); // implicit call to toString
17 } // end main
18 } // end class CharStringConversion

```

```

A
This is a string
This is also a string
THIS IS ALSO A STRING
1234

```

Fig. 29.5 | Using character and string conversion characters. (Part 2 of 2.)

**Common Programming Error 29.1**

Using %c to print a string causes an *IllegalFormatConversionException*—a string cannot be converted to a character.

**29.7 Printing Dates and Times**

With the **conversion character t** or **T**, we can print dates and times in various formats. Conversion character **t** or **T** is always followed by a **conversion suffix character** that specifies the date and/or time format. When conversion character **T** is used, the output is displayed in uppercase letters. Figure 29.6 lists the common conversion suffix characters for formatting **date and time compositions** that display both the date and the time. Figure 29.7 lists the common conversion suffix characters for formatting dates. Figure 29.8 lists the common conversion suffix characters for formatting times. To view the complete list of conversion suffix characters, visit the website [java.sun.com/javase/6/docs/api/java/util/Formatter.html](http://java.sun.com/javase/6/docs/api/java/util/Formatter.html).

Conversion suffix character	Description
c	Display date and time formatted as day month date hour:minute:second time-zone year with three characters for day and month, two digits for date, hour, minute and second and four digits for year—for example, Wed Mar 03 16:30:25 GMT-05:00 2004. The 24-hour clock is used. In this example, GMT-05:00 is the time zone.

Fig. 29.6 | Date and time composition conversion suffix characters. (Part 1 of 2.)

29.7 Printing Dates and Times **1443**

Conversion suffix character	Description
F	Display date formatted as year-month-date with four digits for the year and two digits each for the month and the date (e.g., 2004-05-04).
D	Display date formatted as month/day/year with two digits each for the month, day and year (e.g., 03/03/04).
r	Display time formatted as hour:minute:second AM PM with two digits each for the hour, minute and second (e.g., 04:30:25 PM). The 12-hour clock is used.
R	Display time formatted as hour:minute with two digits each for the hour and minute (e.g., 16:30). The 24-hour clock is used.
T	Display time formatted as hour:minute:second with two digits for the hour, minute and second (e.g., 16:30:25). The 24-hour clock is used.

**Fig. 29.6** | Date and time composition conversion suffix characters. (Part 2 of 2.)

Conversion suffix character	Description
A	Display full name of the day of the week (e.g., Wednesday).
a	Display the three-character short name of the day of the week (e.g., Wed).
B	Display full name of the month (e.g., March).
b	Display the three-character short name of the month (e.g., Mar).
d	Display the day of the month with two digits, padding with leading zeros as necessary (e.g., 03).
m	Display the month with two digits, padding with leading zeros as necessary (e.g., 07).
e	Display the day of month without leading zeros (e.g., 3).
Y	Display the year with four digits (e.g., 2004).
y	Display the last two digits of the year with leading zeros as necessary (e.g., 04).
j	Display the day of the year with three digits, padding with leading zeros as necessary (e.g., 016).

**Fig. 29.7** | Date formatting conversion suffix characters.

**1444** Chapter 29 Formatted Output

Conversion suffix character	Description
H	Display hour in 24-hour clock with a leading zero as necessary (e.g., 16).
I	Display hour in 12-hour clock with a leading zero as necessary (e.g., 04).
k	Display hour in 24-hour clock without leading zeros (e.g., 16).
l	Display hour in 12-hour clock without leading zeros (e.g., 4).
M	Display minute with a leading zero as necessary (e.g., 06).
S	Display second with a leading zero as necessary (e.g., 05).
Z	Display the abbreviation for the time zone (e.g., GMT-05:00, stands for Eastern Standard Time, which is 5 hours behind Greenwich Mean Time).
p	Display morning or afternoon marker in lowercase (e.g., pm).
P	Display morning or afternoon marker in uppercase (e.g., PM).

**Fig. 29.8** | Time formatting conversion suffix characters.

Figure 29.9 uses the conversion character `t` with the conversion suffix characters to display dates and times in various formats. Conversion character `t` requires the corresponding argument to be of type `long`, `Long`, `Calendar` or `Date` (both in package `java.util`)—objects of each of these classes can represent dates and times. Class `Calendar` is the preferred class for this purpose because some constructors and methods in class `Date` are replaced by those in class `Calendar`. Line 10 invokes static method `getInstance` of `Calendar` to obtain a calendar with the current date and time. Lines 13–17, 20–22 and 25–26 use this `Calendar` object in `printf` statements as the value to be formatted with conversion character `t`. Note that lines 20–22 and 25–26 use the optional `argument index` ("1\$") to indicate that all format specifiers in the format string use the first argument after the format string in the argument list. You will learn more about argument indices in Section 29.11. Using the argument index eliminates the need to repeatedly list the same argument.

```

1 // Fig. 29.9: DateTimeTest.java
2 // Formatting dates and times with conversion character t and T.
3 import java.util.Calendar;
4
5 public class DateTimeTest
6 {
7 public static void main(String args[])
8 {
9 // get current date and time
10 Calendar dateTime = Calendar.getInstance();
11
12 // printing with conversion characters for date/time compositions
13 System.out.printf("%tc\n", dateTime);

```

## 29.8 Other Conversion Characters

The remaining conversion characters are `b`, `B`, `h`, `H`, `%` and `n`. These are described in Fig. 29.10.

Conversion character	Description
<code>b</code> or <code>B</code>	Print "true" or "false" for the value of a boolean or Boolean. These conversion characters can also format the value of any reference. If the reference is non-null, "true" is output; otherwise, "false" is output. When conversion character <code>B</code> is used, the output is displayed in uppercase letters.
<code>h</code> or <code>H</code>	Print the string representation of an object's hash-code value in hexadecimal format. If the corresponding argument is <code>null</code> , " <code>null</code> " is printed. When conversion character <code>H</code> is used, the output is displayed in uppercase letters.
<code>%</code>	Print the percent character.
<code>n</code>	Print the platform-specific line separator (e.g., <code>\r\n</code> on Windows or <code>\n</code> on UNIX/LINUX).

**Fig. 29.10** | Other conversion specifiers.

**1446** Chapter 29 Formatted Output

Lines 9–10 of Fig. 29.11 use %b to print the value of boolean values false and true. Line 11 associates a String to %b, which returns true because it is not null. Line 12 associates a null object to %B, which displays FALSE because test is null. Lines 13–14 use %h to print the string representations of the hash-code values for strings "hello" and "Hello". These values could be used to store or locate the strings in a Hashtable or HashMap (both discussed in Chapter 19, Collections). Note that the hash-code values for these two strings differ because one string starts with a lowercase letter and the other with an uppercase letter. Line 15 uses %H to print null in uppercase letters. The last two printf statements (lines 16–17) use %% to print the % character in a string and %n to print a platform-specific line separator.

**Common Programming Error 29.2**

*Trying to print a literal percent character using % rather than %% in the format string might cause a difficult-to-detect logic error. When % appears in a format string, it must be followed by a conversion character in the string. The single percent could accidentally be followed by a legitimate conversion character, thus causing a logic error.*

```

1 // Fig. 29.11: OtherConversion.java
2 // Using the b, B, h, H, % and n conversion characters.
3
4 public class OtherConversion
5 {
6 public static void main(String args[])
7 {
8 Object test = null;
9 System.out.printf("%b\n", false);
10 System.out.printf("%b\n", true);
11 System.out.printf("%b\n", "Test");
12 System.out.printf("%B\n", test);
13 System.out.printf("Hashcode of \"hello\" is %h\n", "hello");
14 System.out.printf("Hashcode of \"Hello\" is %h\n", "Hello");
15 System.out.printf("Hashcode of null is %H\n", test);
16 System.out.printf("Printing a %% in a format string\n");
17 System.out.printf("Printing a new line %nnext line starts here");

## 29.9 Printing with Field Widths and Precisions

1447

## 29.9 Printing with Field Widths and Precisions

The exact size of a field in which data is printed is specified by a **field width**. If the field width is larger than the data being printed, the data will be right justified within that field by default. (We demonstrate left justification in Section 29.10.) The programmer inserts an integer representing the field width between the percent sign (%) and the conversion character (e.g., %4d) in the format specifier. Figure 29.12 prints two groups of five numbers each, right justifying those numbers that contain fewer digits than the field width. Note that the field width is increased to print values wider than the field and that the minus sign for a negative value uses one character position in the field. Also, if no field width is specified, the data prints in exactly as many positions as it needs. Field widths can be used with all format specifiers except the line separator (%n).

### Common Programming Error 29.3

*Not providing a sufficiently large field width to handle a value to be printed can offset other data being printed and produce confusing outputs. Know your data!*

```

1 // Fig. 29.12: FieldWidthTest.java
2 // Right justifying integers in fields.
3
4 public class FieldWidthTest
5 {
6 public static void main(String args[])
7 {
8 System.out.printf("%4d\n", 1);
9 System.out.printf("%4d\n", 12);
10 System.out.printf("%4d\n", 123);
11 System.out.printf("%4d\n", 1234);
12 System.out.printf("%4d\n\n", 12345); // data too large
13
14 System.out.printf("%4d\n", -1);
15 System.out.printf("%4d\n", -12);
16 System.out.printf("%4d\n", -123);
17 System.out.printf("%4d\n", -1234); // data too large
18 System.out.printf("%4d\n", -12345); // data too large
19 } // end main

-12345

```

**Fig. 29.12** | Right justifying integers in fields.

**1448** Chapter 29 Formatted Output

Method `printf` also provides the ability to specify the precision with which data is printed. Precision has different meanings for different types. When used with floating-point conversion characters `e` and `f`, the precision is the number of digits that appear after the decimal point. When used with conversion character `g`, the precision is the maximum number of significant digits to be printed. When used with conversion character `s`, the precision is the maximum number of characters to be written from the string. To use precision, place between the percent sign and the conversion specifier a decimal point (.) followed by an integer representing the precision. Figure 29.13 demonstrates the use of precision in format strings. Note that when a floating-point value is printed with a precision smaller than the original number of decimal places in the value, the value is rounded. Also note that the format specifier `%.3g` indicates that the total number of digits used to display the floating-point value is 3. Because the value has three digits to the left of the decimal point, the value is rounded to the ones position.

The field width and the precision can be combined by placing the field width, followed by a decimal point, followed by a precision between the percent sign and the conversion character, as in the statement

```
printf("%9.3f", 123.456789);
```

which displays 123.457 with three digits to the right of the decimal point right justified in a nine-digit field—this number will be preceded in its field by two blanks.

```

1 // Fig. 29.13: PrecisionTest.java
2 // Using precision for floating-point numbers and strings.
3 public class PrecisionTest
4 {
5 public static void main(String args[])

**Fig. 29.13** | Using precision for floating-point numbers and strings.

29.10 Using Flags in the `printf` Format String 1449**29.10 Using Flags in the `printf` Format String**

Various flags may be used with method `printf` to supplement its output formatting capabilities. Seven flags are available for use in format strings (Fig. 29.14).

To use a flag in a format string, place the flag immediately to the right of the percent sign. Several flags may be used in the same format specifier. Figure 29.15 demonstrates right justification and left justification of a string, an integer, a character and a floating-point number. Note that line 9 serves as a counting mechanism for the screen output.

Figure 29.16 prints a positive number and a negative number, each with and without the `+ flag`. Note that the minus sign is displayed in both cases, but the plus sign is displayed only when the `+ flag` is used.

Flag	Description
- (minus sign)	Left justify the output within the specified field.
+ (plus sign)	Display a plus sign preceding positive values and a minus sign preceding negative values.
space	Print a space before a positive value not printed with the + flag.
#	Prefix 0 to the output value when used with the octal conversion character o. Prefix 0x to the output value when used with the hexadecimal conversion character x.
0 (zero)	Pad a field with leading zeros.
,	Use the locale-specific thousands separator (i.e., ',' for U.S. locale) to display decimal and floating-point numbers.
(	Enclose negative numbers in parentheses.

**Fig. 29.14** | Format string flags.

```

1 // Fig. 29.15: MinusFlagTest.java
2 // Right justifying and left justifying values.
3
4 public class MinusFlagTest
5 {
6 public static void main(String args[])
7 {
8 System.out.println("Columns:");
9 System.out.println("012345678901234567890123456789\n");
10 System.out.printf("%10s%10d%10c%10f\n\n", "hello", 7, 'a', 1.23);
11 System.out.printf(
12 "%-10s%-10d%-10c%-10f\n", "hello", 7, 'a', 1.23);
13 } // end main
14 } // end class MinusFlagTest

```

**Fig. 29.15** | Right justifying and left justifying values. (Part 1 of 2.)

**1450** Chapter 29 Formatted Output

```
Columns:
0123456789012345678901234567890123456789

 hello 7 a 1.230000
hello 7 a 1.230000
```

7 {
8 System.out.printf("%d\t%d\n", 786, -786);
9 System.out.printf("%+d\t%+d\n", 786, -786);
10 } // end main
11 } // end class PlusFlagTest
```

```
786 -786
+786 -786
```

**Fig. 29.16** | Printing numbers with and without the + flag.

Figure 29.17 prefixes a space to the positive number with the **space flag**. This is useful for aligning positive and negative numbers with the same number of digits. Note that the value `-547` is not preceded by a space in the output because of its minus sign. Figure 29.18 uses the **# flag** to prefix `0` to the octal value and `0x` to the hexadecimal value.

Figure 29.19 combines the **+** flag, the **0** flag and the space flag to print `452` in a field of width `9` with a **+** sign and leading zeros, next prints `452` in a field of width `9` using only the **0** flag, then prints `452` in a field of width `9` using only the space flag.

```
1 // Fig. 29.17: SpaceFlagTest.java

**Fig. 29.21** | Using the ( flag to place parentheses around negative numbers.

### 29.11 Printing with Argument Indices

An **argument index** is an optional integer followed by a \$ sign that indicates the argument's position in the argument list. For example, lines 20–21 and 24–25 in Fig. 29.9 use argument index "1\$" to indicate that all format specifiers use the first argument in the argument list. Argument indices enable programmers to reorder the output so that the arguments in the argument list are not necessarily in the order of their corresponding format specifiers. Argument indices also help avoid duplicating arguments. Figure 29.22 demonstrates how to print arguments in the argument list in reverse order using the argument index.

```

1 // Fig. 29.22: ArgumentIndexTest
2 // Reordering output with argument indices.
3

```

**Fig. 29.22** | Reordering output with argument indices. (Part 1 of 2.)

29.12 Printing Literals and Escape Sequences **1453**

```

4 public class ArgumentIndexTest
5 {
6 public static void main(String args[])
7 {
8 System.out.printf(
9 "Parameter list without reordering: %s %s %s %s\n",
10 "first", "second", "third", "fourth");
11 System.out.printf(
12 "Parameter list after reordering: %4$s %3$s %2$s %1$s\n",
13 "first", "second", "third", "fourth");
14 } // end main
15 } // end class ArgumentIndexTest

```

Parameter list without reordering: first second third fourth  
 Parameter list after reordering: fourth third second first

**Fig. 29.22** | Reordering output with argument indices. (Part 2 of 2.)

## 29.12 Printing Literals and Escape Sequences

Most literal characters to be printed in a `printf` statement can simply be included in the format string. However, there are several “problem” characters, such as the quotation mark (") that delimits the format string itself. Various control characters, such as newline and tab, must be represented by escape sequences. An escape sequence is represented by a backslash (\), followed by an escape character. Figure 29.23 lists the escape sequences and the actions they cause.

### Common Programming Error 29.4

Attempting to print as literal data in a `printf` statement a double quote or backslash character without preceding that character with a backslash to form a proper escape sequence might result in a syntax error.

Escape sequence	Description
\' (single quote)	Output the single quote (') character.
\\" (double quote)	Output the double quote (") character.
\\\ (backslash)	Output the backslash (\) character.
\b (backspace)	Move the cursor back one position on the current line.
\f (new page or form feed)	Move the cursor to the start of the next logical page.
\n (newline)	Move the cursor to the beginning of the next line.
\r (carriage return)	Move the cursor to the beginning of the current line.
\t (horizontal tab)	Move the cursor to the next horizontal tab position.

**Fig. 29.23** | Escape sequences.

**1454** Chapter 29 Formatted Output

### 29.13 Formatting Output with Class Formatter

So far, we have discussed displaying formatted output to the standard output stream. What should we do if we want to send formatted outputs to other output streams or devices, such as a JTextArea or a file? The solution relies on class `Formatter` (in package `java.util`), which provides the same formatting capabilities as `printf`. `Formatter` is a utility class that enables programmers to output formatted data to a specified destination, such as a file on disk. By default, a `Formatter` creates a string in memory. Figure 29.24 demonstrates how to use a `Formatter` to build a formatted string, which is then displayed in a message dialog.

Line 11 creates a `Formatter` object using the default constructor, so this object will build a string in memory. Other constructors are provided to allow you to specify the destination to which the formatted data should be output. For details, see [java.sun.com/javase/6/docs/api/java/util/Formatter.html](http://java.sun.com/javase/6/docs/api/java/util/Formatter.html).

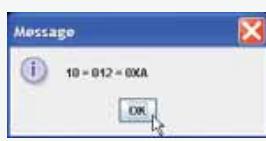

Line 12 invokes method `format` to format the output. Like `printf`, method `format` takes a format string and an argument list. The difference is that `printf` sends the formatted output directly to the standard output stream, while `format` sends the formatted output to the destination specified by its constructor (a string in memory in this program). Line 15 invokes the `Formatter`'s `toString` method to get the formatted data as a string, which is then displayed in a message dialog.

Note that class `String` also provides a static convenience method named `format` that enables you to create a string in memory without the need to first create a `Formatter` object. Lines 11–12 and line 15 in Fig. 29.24 could have been replaced by

```
String s = String.format("%d = %#o = %#X", 10, 10, 10);
JOptionPane.showMessageDialog(null, s);
```

```

1 // Fig. Fig. 29.24: FormatterTest.java
2 // Format string with class Formatter.
3 import java.util.Formatter;
4 import javax.swing.JOptionPane;
5
6 public class FormatterTest
7 {
8 public static void main(String args[])
9 {
10 // create Formatter and format output
11 Formatter formatter = new Formatter();
12 formatter.format("%d = %#o = %#X", 10, 10, 10);
13
14 // display output in JOptionPane
15 JOptionPane.showMessageDialog(null, formatter.toString());
16 } // end main
17 } // end class FormatterTest
```

**Fig. 29.24** | Formatting output with class `Formatter`.

## 29.14 Wrap-Up

This chapter summarized how to display formatted output with various format characters and flags. We displayed decimal numbers using format characters d, o, x and X. We displayed floating-point numbers using format characters e, E, f, g and G. We displayed date and time in various format using format characters t and T and their conversion suffix characters. You learned how to display output with field widths and precisions. We introduced the flags +, -, space, #, 0, comma and C that are used together with the format characters to produce output. We also demonstrated how to format output with class `Formatter`. In the next chapter, we discuss the `String` class's methods for manipulating strings. We also introduce regular expressions and demonstrate how to validate user input with regular expressions.

### Summary

#### *Section 29.2 Streams*

- Input and output are usually performed with streams, which are sequences of bytes. In input operations, the bytes flow from a device to main memory. In output operations, bytes flow from main memory to a device.
- Normally, the standard input stream is connected to the keyboard, and the standard output stream is connected to the computer screen.

#### *Section 29.3 Formatting Output with printf*

- The `printf` format string describes the formats in which the output values appear. The format specifier consists of argument index, flags, field widths, precisions and conversion characters.

#### *Section 29.4 Printing Integers*

- Integers are printed with the conversion characters d for decimal integers, o for integers in octal form and x (or X) for integers in hexadecimal form. When the conversion character X is used, the output is displayed in uppercase letters.

#### *Section 29.5 Printing Floating-Point Numbers*

- Floating-point values are printed with the conversion characters e (or E) for exponential notation, f for regular floating-point notation, and g (or G) for either e (or E) notation or f notation. When the g conversion specifier is indicated, the e conversion character is used if the value is less than  $10^{-3}$  or greater than or equal to  $10^7$ ; otherwise, the f conversion character is used. When the conversion characters E and G are used, the output is displayed in uppercase letters.

#### *Section 29.6 Printing Strings and Characters*

- The conversion character c prints a character.
- The conversion character s (or S) prints a string of characters. When the conversion character S is used, the output is displayed in uppercase letters.

#### *Section 29.7 Printing Dates and Times*

- The conversion character t (or T) followed by a conversion suffix character prints the date and time in various forms. When the conversion character T is used, the output is displayed in uppercase letters.
- Conversion character t (or T) requires the argument to be of type `long`, `Long`, `Calendar` or `Date`.

**1456**    [Chapter 29](#) Formatted Output***Section 29.8 Other Conversion Characters***

- Conversion character `b` (or `B`) outputs the string representation of a `boolean` or `Boolean`. These conversion characters also output "true" for non-`null` references and "false" for `null` references. When conversion character `B` is used, the output is displayed in uppercase letters.
- Conversion character `h` (or `H`) returns `null` for a `null` reference and a `String` representation of the hash-code value (in base 16) of the object. Hash codes are used to store and retrieve objects in `Hashtables` and `HashMaps`. When conversion character `H` is used, the output is displayed in uppercase letters.
- The conversion character `n` prints the platform-specific line separator.
- The conversion character `%` is used to display a literal `%`.

***Section 29.9 Printing with Field Widths and Precision***

- If the field width is larger than the object being printed, the object is right justified in the field.
- Field widths can be used with all conversion characters except the line-separator conversion.
- Precision used with floating-point conversion characters `e` and `f` indicates the number of digits that appear after the decimal point. Precision used with floating-point conversion character `g` indicates the number of significant digits to appear.
- Precision used with conversion character `s` indicates the number of characters to be printed.
- The field width and the precision can be combined by placing the field width, followed by a decimal point, followed by the precision between the percent sign and the conversion character.

***Section 29.10 Using Flags in the `printf` Format String***

- The `-` flag left justifies its argument in a field.
- The `+` flag prints a plus sign for positive values and a minus sign for negative values.
- The space flag prints a space preceding a positive value. The space flag and the `+` flag cannot be used together in an integral conversion character.
- The `#` flag prefixes `0` to octal values and `0x` to hexadecimal values.
- The `0` flag prints leading zeros for a value that does not occupy its entire field.
- The comma `,` flag uses the locale-specific thousands separator (i.e., `,` for U.S. locale) to display integer and floating-point numbers.
- The `(` flag encloses a negative number in parentheses.

***Section 29.11 Printing with Argument Indices***

- An argument index is an optional decimal integer followed by a `$` sign that indicates the position of the argument in the argument list.
- Argument indices enable programmers to reorder the output so that the arguments in the argument list are not necessarily in the order of their corresponding format specifiers. Argument indices also help avoid duplicating arguments.

***Section 29.13 Formatting Output with Class Formatter***

- Class `Formatter` (in package `java.util`) provides the same formatting capabilities as `printf`. `Formatter` is a utility class that enables programmers to print formatted output to various destinations, including GUI components, files and other output streams.
- Class `Formatter`'s method `format` outputs formatted data to the destination specified by the `Formatter` constructor.
- The static method `format` of class `String` formats data and returns the formatted data as a `String`.

## Terminology

# flag	H conversion character
% conversion character	H conversion suffix character
C flag	hexadecimal format
+ (plus) flag	I conversion suffix character
- (minus) flag	integer conversion
, (comma) flag	j conversion suffix character
0 (zero) flag	K conversion suffix character
A conversion suffix character	left justification
a conversion suffix character	m conversion suffix character
alignment	M conversion suffix character
argument index	n conversion character
b conversion character	o conversion character
B conversion character	octal format
B conversion suffix character	P conversion suffix character
b conversion suffix character	p conversion suffix character
c conversion character	precision
C conversion suffix character	printf method
conversion character	r conversion suffix character
d conversion character	redirect a stream
D conversion suffix character	right justification
e conversion character	rounding
E conversion character	s conversion character
e conversion suffix character	S conversion character
exponential floating-point format	S conversion suffix character
f conversion character	scientific notation
F conversion suffix character	space flag
field width	standard error stream
flag	standard input stream
floating-point	standard output stream
floating-point number conversion	stream
format method of Formatter	t conversion character
format method of String	T conversion character
format specifier	T conversion suffix character
format string	toString method of Formatter
Formatter class	x conversion character
g conversion character	Y conversion suffix character
G conversion character	y conversion suffix character
h conversion character	Z conversion suffix character

## Self-Review Exercises

- 29.1** Fill in the blanks in each of the following:
- All input and output is dealt with in the form of \_\_\_\_\_.
  - The \_\_\_\_\_ stream is normally connected to the keyboard.
  - The \_\_\_\_\_ stream is normally connected to the computer screen.
  - System.out's \_\_\_\_\_ method can be used to format text that is displayed on the standard output.
  - The conversion character \_\_\_\_\_ may be used to output a decimal integer.

**1458 Chapter 29 Formatted Output**

- f) The conversion characters \_\_\_\_\_ and \_\_\_\_\_ are used to display integers in octal and hexadecimal form, respectively.
- g) The conversion character \_\_\_\_\_ is used to display a floating-point value in exponential notation.
- h) The conversion characters e and f are displayed with \_\_\_\_\_ digits of precision to the right of the decimal point if no precision is specified.
- i) The conversion characters \_\_\_\_\_ and \_\_\_\_\_ are used to print strings and characters, respectively.
- j) The conversion character \_\_\_\_\_ and conversion suffix character \_\_\_\_\_ are used to print time for the 24-hour clock as hour:minute:second.
- k) The \_\_\_\_\_ flag causes output to be left justified in a field.
- l) The \_\_\_\_\_ flag causes values to be displayed with either a plus sign or a minus sign.
- m) The argument index \_\_\_\_\_ corresponds to the second argument in the argument list.
- n) Class \_\_\_\_\_ has the same capability as printf, but allows programmers to print formatted output to various destinations besides the standard output stream.
- 29.2** Find the error in each of the following and explain how it can be corrected.
- The following statement should print the character 'c'.  
`System.out.printf( "%c\n", "c" );`
  - The following statement should print 9.375%.  
`System.out.printf( ".3%", 9.375 );`
  - The following statement should print the third argument in the argument list.  
`System.out.printf( "%2$\n", "Mon", "Tue", "Wed", "Thu", "Fri" );`
  - `System.out.printf( ""A string in quotes"" );`
  - `System.out.printf( %d %d, 12, 20 );`
  - `System.out.printf( "%s\n", 'Richard' );`
- 29.3** Write a statement for each of the following:
- Print 1234 right justified in a 10-digit field.
  - Print 123.456789 in exponential notation with a sign (+ or -) and 3 digits of precision.
  - Print 100 in octal form preceded by 0.
  - Given a Calendar object calendar, print a date formatted as month/day/year (each with two digits).
  - Given a Calendar object calendar, print a time for the 24-hour clock as hour:minute:second (each with two digits) using argument index and conversion suffix characters for formatting time.
  - Print 3.33333 with a sign (+ or -) in a field of 20 characters with a precision of 3.

**Answers to Self-Review Exercises**

- 29.1** a) Streams. b) Standard input. c) Standard output. d) printf. e) d. f) o, x or X. g) e or E. h) 6. i) s or S, c or C. j) t, T. k) - (minus). l) + (plus). m) 2\$. n) Formatter.
- 29.2** a) Error: Conversion character c expects an argument of primitive type char.  
Correction: To print the character 'c', change "c" to 'c'.
- b) Error: Trying to print the literal character % without using the format specifier %.  
Correction: Use %% to print a literal % character.
- c) Error: Argument index does not start with 0; e.g., the first argument is 1\$.  
Correction: To print the third argument use 3\$.
- d) Error: Trying to print the literal character " without using the \" escape sequence.  
Correction: Replace each quote in the inner set of quotes with \".
- e) Error: The format string is not enclosed in double quotes.  
Correction: Enclose %d %d in double quotes.

Exercises **1459**

- f) Error: The string to be printed is enclosed in single quotes.  
 Correction: Use double quotes instead of single quotes to represent a string.
- 29.3** a) `System.out.printf( "%10d\n", 1234 );`  
 b) `System.out.printf( "%+.3e\n", 123.456789 );`  
 c) `System.out.printf( "%#o\n", 100 );`  
 d) `System.out.printf( "%tD\n", calendar );`  
 e) `System.out.printf( "%1$tH:%1$tM:%1$tS\n", calendar );`  
 f) `System.out.printf( "%+20.3f\n", 3.333333 );`

**Exercises**

- 29.4** Write statement(s) for each of the following:
- Print integer 40000 right justified in a 15-digit field.
  - Print 200 with and without a sign.
  - Print 100 in hexadecimal form preceded by 0x.
  - Print 1.234 with three digits of precision in a nine-digit field with preceding zeros.
- 29.5** Show what is printed by each of the following statements. If a statement is incorrect, indicate why.
- `System.out.printf( "%-10d\n", 10000 );`
  - `System.out.printf( "%c\n", "This is a string" );`
  - `System.out.printf( "%8.3f\n", 1024.987654 );`
  - `System.out.printf( "%#o\n%#X\n", 17, 17 );`
  - `System.out.printf( "% d\n%+d\n", 1000000, 1000000 );`
  - `System.out.printf( "%10.2e\n", 444.93738 );`
  - `System.out.printf( "%d\n", 10.987 );`
- 29.6** Find the error(s) in each of the following program segments. Show the corrected statement.
- `System.out.printf( "%s\n", 'Happy Birthday' );`
  - `System.out.printf( "%c\n", 'Hello' );`
  - `System.out.printf( "%c\n", "This is a string" );`
  - The following statement should print "Bon Voyage" with the double quotes:  
`System.out.printf( """%s""", "Bon Voyage" );`
  - The following statement should print "Today is Friday":  
`System.out.printf( "Today is %s\n", "Monday", "Friday" );`
  - `System.out.printf( 'Enter your name: ' );`
  - `System.out.printf( %f, 123.456 );`
  - The following statement should print the current time in the format "hh:mm:ss":  
`Calendar dateTime = Calendar.getInstance();  
 System.out.printf( "%1$tk:1$tl:%1$ts\n", dateTime );`
- 29.7** (*Printing Dates and Times*) Write a program that prints dates and times in the following forms:

```
GMT-05:00 04/30/04 09:55:09 AM
GMT-05:00 April 30 2004 09:55:09
2004-04-30 day-of-the-month:30
2004-04-30 day-of-the-year:121
Fri Apr 30 09:55:09 GMT-05:00 2004
```

[Note: Depending on your location, you may get a time zone other than GMT-05:00.]

- 29.8** Write a program to test the results of printing the integer value 12345 and the floating-point value 1.2345 in fields of various sizes.

**1460** Chapter 29 Formatted Output

**29.9** (*Rounding Numbers*) Write a program that prints the value 100.453627 rounded to the nearest digit, tenth, hundredth, thousandth and ten thousandth.

**29.10** Write a program that inputs a word from the keyboard and determines its length. Print the word using twice the length as the field width.

**29.11** (*Converting Fahrenheit Temperature to Celsius*) Write a program that converts integer Fahrenheit temperatures from 0 to 212 degrees to floating-point Celsius temperatures with three digits of precision. Use the formula

```
celsius = 5.0 / 9.0 * (fahrenheit - 32);
```

to perform the calculation. The output should be printed in two right-justified columns of 10 characters each, and the Celsius temperatures should be preceded by a sign for both positive and negative values.

**29.12** Write a program to test all the escape sequences in Fig. 29.23. For the escape sequences that move the cursor, print a character before and after the escape sequence so that it is clear where the cursor has moved.

**29.13** Write a program that uses the conversion character g to output the value 9876.12345. Print the value with precisions ranging from 1 to 9.

*The chief defect of Henry King  
Was chewing little bits of string.*

—Hilaire Belloc

*Vigorous writing is concise.  
A sentence should contain no unnecessary words, a paragraph no unnecessary sentences.*

—William Strunk, Jr.

*I have made this letter longer than usual, because I lack the time to make it short.*

—Blaise Pascal

# Strings, Characters and Regular Expressions

## OBJECTIVES

In this chapter you will learn:

- To create and manipulate immutable character string objects of class `String`.
- To create and manipulate mutable character string objects of class `StringBuilder`.
- To create and manipulate objects of class `Character`.
- To use a  `StringTokenizer` object to break a `String` object into tokens.
- To use regular expressions to validate `String` data entered into an application.

**1462    Chapter 30  Strings, Characters and Regular Expressions****Outline**

Special Section: Advanced String Manipulation

Special Section: Challenging String-Manipulation Projects

## 30.1 Introduction

This chapter introduces Java’s string- and character-processing capabilities. The techniques discussed here are appropriate for validating program input, displaying information to users and other text-based manipulations. They are also appropriate for developing text editors, word processors, page-layout software, computerized typesetting systems and other kinds of text-processing software. We have already presented several string-processing capabilities in earlier chapters. This chapter discusses in detail the capabilities of class `String`, class `StringBuilder` and class `Character` from the `java.lang` package and class `StringTokenizer` from the `java.util` package. These classes provide the foundation for string and character manipulation in Java.

The chapter also discusses regular expressions that provide applications with the capability to validate input. The functionality is located in the `String` class along with classes `Matcher` and `Pattern` located in the `java.util.regex` package.

## 30.2 Fundamentals of Characters and Strings

Characters are the fundamental building blocks of Java source programs. Every program is composed of a sequence of characters that—when grouped together meaningfully—are interpreted by the computer as a series of instructions used to accomplish a task. A program may contain **character literals**. A character literal is an integer value represented as a character in single quotes. For example, 'z' represents the integer value of z, and '\n' represents the integer value of newline. The value of a character literal is the integer value of the character in the **Unicode character set**. Appendix B presents the integer equivalents of the characters in the ASCII character set, which is a subset of Unicode (discussed in Appendix I). For detailed information on Unicode, visit [www.unicode.org](http://www.unicode.org).

Recall from Section 2.2 that a string is a sequence of characters treated as a single unit. A string may include letters, digits and various **special characters**, such as +, -, \*, / and \$. A string is an object of class `String`. **String literals** (stored in memory as `String` objects) are written as a sequence of characters in double quotation marks, as in:

<code>"John Q. Doe"</code>	(a name)
<code>"9999 Main Street"</code>	(a street address)
<code>"Waltham, Massachusetts"</code>	(a city and state)
<code>"(201) 555-1212"</code>	(a telephone number)

A string may be assigned to a `String` reference. The declaration

```
String color = "blue";
```

initializes `String` variable `color` to refer to a `String` object that contains the string "blue".

### Performance Tip 30.1

*Java treats all string literals with the same contents as a single String object that has many references to it. This conserves memory.*

## 30.3 Class String

Class `String` is used to represent strings in Java. The next several subsections cover many of class `String`'s capabilities.

### 30.3.1 String Constructors

Class `String` provides constructors for initializing `String` objects in a variety of ways. Four of the constructors are demonstrated in the `main` method of Fig. 30.1.

Line 12 instantiates a new `String` object using class `String`'s no-argument constructor and assigns its reference to `s1`. The new `String` object contains no characters (the **empty string**) and has a length of 0.

Line 13 instantiates a new `String` object using class `String`'s constructor that takes a `String` object as an argument and assigns its reference to `s2`. The new `String` object contains the same sequence of characters as the `String` object `s` that is passed as an argument to the constructor.

### Software Engineering Observation 30.1

*It is not necessary to copy an existing String object. String objects are **immutable**—their character contents cannot be changed after they are created, because class String does not provide any methods that allow the contents of a String object to be modified.*

**1464** Chapter 30 Strings, Characters and Regular Expressions

```

1 // Fig. 30.1: StringConstructors.java
2 // String class constructors.
3
4 public class StringConstructors
5 {
6 public static void main(String args[])
7 {
8 char charArray[] = { 'b', 'i', 'r', 't', 'h', ' ', 'd', 'a', 'y' };
9 String s = new String("hello");
10
11 // use String constructors
12 String s1 = new String();
13 String s2 = new String(s);
14 String s3 = new String(charArray);
15 String s4 = new String(charArray, 6, 3);
16
17 System.out.printf(
18 "s1 = %s\ns2 = %s\ns3 = %s\ns4 = %s\n",
19 s1, s2, s3, s4); // display strings
20 } // end main
21 } // end class StringConstructors

```

```

s1 =
s2 = hello
s3 = birth day
s4 = day

```

**Fig. 30.1** | String class constructors.

Line 14 instantiates a new `String` object and assigns its reference to `s3` using class `String`'s constructor that takes a char array as an argument. The new `String` object contains a copy of the characters in the array.

Line 15 instantiates a new `String` object and assigns its reference to `s4` using class `String`'s constructor that takes a char array and two integers as arguments. The second argument specifies the starting position (the offset) from which characters in the array are accessed. Remember that the first character is at position 0. The third argument specifies the number of characters (the count) to access in the array. The new `String` object contains a string formed from the accessed characters. If the offset or the count specified as an argument results in accessing an element outside the bounds of the character array, a `StringIndexOutOfBoundsException` is thrown.

**Common Programming Error 30.1**

Attempting to access a character that is outside the bounds of a string (i.e., an index less than 0 or an index greater than or equal to the string's length) results in a `StringIndexOutOfBoundsException`.

**30.3.2 String Methods `length`, `charAt` and `getChars`**

`String` methods `length`, `charAt` and `getChars` return the length of a string, obtain the character at a specific location in a string and retrieve a set of characters from a string as a char array, respectively. The application in Fig. 30.2 demonstrates each of these methods.

## 30.3 Class String 1465

```

1 // Fig. 30.2: StringMiscellaneous.java
2 // This application demonstrates the length, charAt and getChars
3 // methods of the String class.
4
5 public class StringMiscellaneous
6 {
7 public static void main(String args[])
8 {
9 String s1 = "hello there";
10 char charArray[] = new char[5];
11
12 System.out.printf("s1: %s", s1);
13
14 // test length method
15 System.out.printf("\nLength of s1: %d", s1.length());
16
17 // loop through characters in s1 with charAt and display reversed
18 System.out.print("\nThe string reversed is: ");
19
20 for (int count = s1.length() - 1; count >= 0; count--)
21 System.out.printf("%s ", s1.charAt(count));
22
23 // copy characters from string into charArray
24 s1.getChars(0, 5, charArray, 0);
25 System.out.print("\nThe character array is: ");
26
27 for (char character : charArray)
28 System.out.print(character);
29
30 System.out.println();
31 } // end main
32 } // end class StringMiscellaneous

```

```

s1: hello there
Length of s1: 11
The string reversed is: e r e h t o l l e h
The character array is: hello

```

**Fig. 30.2** | String class character-manipulation methods.

Line 15 uses `String` method `length` to determine the number of characters in string `s1`. Like arrays, strings know their own length. However, unlike arrays, you cannot access a `String`'s length via a `length` field—instead you must call the `String`'s `length` method.

Lines 20–21 print the characters of the string `s1` in reverse order (and separated by spaces). `String` method `charAt` (line 21) returns the character at a specific position in the string. Method `charAt` receives an integer argument that is used as the index and returns the character at that position. Like arrays, the first element of a string is at position 0.

Line 24 uses `String` method `getChars` to copy the characters of a string into a character array. The first argument is the starting index in the string from which characters are to be copied. The second argument is the index that is one past the last character to be copied from the string. The third argument is the character array into which the characters

## 1466 Chapter 30 Strings, Characters and Regular Expressions

are to be copied. The last argument is the starting index where the copied characters are placed in the target character array. Next, line 28 prints the `char` array contents one character at a time.

### 30.3.3 Comparing Strings

Chapter 7 discussed sorting and searching arrays. Frequently, the information being sorted or searched consists of strings that must be compared to place them into the proper order or to determine whether a string appears in an array (or other collection). Class `String` provides several methods for comparing strings—these are demonstrated in the next two examples.

To understand what it means for one string to be greater than or less than another, consider the process of alphabetizing a series of last names. You would, no doubt, place “Jones” before “Smith” because the first letter of “Jones” comes before the first letter of “Smith” in the alphabet. But the alphabet is more than just a list of 26 letters—it is an ordered set of characters. Each letter occurs in a specific position within the set. Z is more than just a letter of the alphabet—it is specifically the twenty-sixth letter of the alphabet.

How does the computer know that one letter comes before another? All characters are represented in the computer as numeric codes (see Appendix B). When the computer compares strings, it actually compares the numeric codes of the characters in the strings.

Figure 30.3 demonstrates `String` methods `equals`, `equalsIgnoreCase`, `compareTo` and `regionMatches` and using the equality operator `==` to compare `String` objects.

```

1 // Fig. 30.3: StringCompare.java
2 // String methods equals, equalsIgnoreCase, compareTo and regionMatches.
3
4 public class StringCompare
5 {
6 public static void main(String args[])
7 {
8 String s1 = new String("hello"); // s1 is a copy of "hello"
9 String s2 = "goodbye";
10 String s3 = "Happy Birthday";
11 String s4 = "happy birthday";
12
13 System.out.printf(
14 "s1 = %s\ns2 = %s\ns3 = %s\ns4 = %s\n", s1, s2, s3, s4);
15
16 // test for equality
17 if (s1.equals("hello")) // true
18 System.out.println("s1 equals \"hello\"");
19 else
20 System.out.println("s1 does not equal \"hello\"");
21
22 // test for equality with ==
23 if (s1 == "hello") // false; they are not the same object
24 System.out.println("s1 is the same object as \"hello\"");
25 else
26 System.out.println("s1 is not the same object as \"hello\"");

```

**Fig. 30.3 |** String comparisons. (Part I of 2.)

## 30.3 Class String 1467

```

27 // test for equality (ignore case)
28 if (s3.equalsIgnoreCase(s4)) // true
29 System.out.printf("%s equals %s with case ignored\n", s3, s4);
30 else
31 System.out.println("s3 does not equal s4");
32
33 // test compareTo
34 System.out.printf(
35 "\ns1.compareTo(s2) is %d", s1.compareTo(s2));
36 System.out.printf(
37 "\ns2.compareTo(s1) is %d", s2.compareTo(s1));
38 System.out.printf(
39 "\ns1.compareTo(s1) is %d", s1.compareTo(s1));
40 System.out.printf(
41 "\ns3.compareTo(s4) is %d", s3.compareTo(s4));
42 System.out.printf(
43 "\ns4.compareTo(s3) is %d\n\n", s4.compareTo(s3));
44
45 // test regionMatches (case sensitive)
46 if (s3.regionMatches(0, s4, 0, 5))
47 System.out.println("First 5 characters of s3 and s4 match");
48 else
49 System.out.println(
50 "First 5 characters of s3 and s4 do not match");
51
52 // test regionMatches (ignore case)
53 if (s3.regionMatches(true, 0, s4, 0, 5))
54 System.out.println("First 5 characters of s3 and s4 match");
55 else
56 System.out.println(
57 "First 5 characters of s3 and s4 do not match");
58
59 } // end main
60 } // end class StringCompare

```

```

s1 = hello
s2 = goodbye
s3 = Happy Birthday
s4 = happy birthday

s1 equals "hello"
s1 is not the same object as "hello"
Happy Birthday equals happy birthday with case ignored

s1.compareTo(s2) is 1
s2.compareTo(s1) is -1
s1.compareTo(s1) is 0
s3.compareTo(s4) is -32
s4.compareTo(s3) is 32

First 5 characters of s3 and s4 do not match
First 5 characters of s3 and s4 match

```

**Fig. 30.3** | String comparisons. (Part 2 of 2.)

**1468** Chapter 30 Strings, Characters and Regular Expressions

The condition at line 17 uses method `equals` to compare string `s1` and the string literal "hello" for equality. Method `equals` (a method of class `Object` overridden in `String`) tests any two objects for equality—the strings contained in the two objects are identical. The method returns `true` if the contents of the objects are equal, and `false` otherwise. The preceding condition is `true` because string `s1` was initialized with the string literal "hello". Method `equals` uses a **lexicographical comparison**—it compares the integer Unicode values (see Appendix I, Unicode®, for more information) that represent each character in each string. Thus, if the string "hello" is compared with the string "HELLO", the result is `false`, because the integer representation of a lowercase letter is different from that of the corresponding uppercase letter.

The condition at line 23 uses the equality operator `==` to compare string `s1` for equality with the string literal "hello". Operator `==` has different functionality when it is used to compare references than when it is used to compare values of primitive types. When primitive-type values are compared with `==`, the result is `true` if both values are identical. When references are compared with `==`, the result is `true` if both references refer to the same object in memory. To compare the actual contents (or state information) of objects for equality, a method must be invoked. In the case of `Strings`, that method is `equals`. The preceding condition evaluates to `false` at line 23 because the reference `s1` was initialized with the statement

```
s1 = new String("hello");
```

which creates a new `String` object with a copy of string literal "hello" and assigns the new object to variable `s1`. If `s1` had been initialized with the statement

```
s1 = "hello";
```

which directly assigns the string literal "hello" to variable `s1`, the condition would be `true`. Remember that Java treats all string literal objects with the same contents as one `String` object to which there can be many references. Thus, lines 8, 17 and 23 all refer to the same `String` object "hello" in memory.

**Common Programming Error 30.2**

*Comparing references with == can lead to logic errors, because == compares the references to determine whether they refer to the same object, not whether two objects have the same contents. When two identical (but separate) objects are compared with ==, the result will be false. When comparing objects to determine whether they have the same contents, use method equals.*

If you are sorting `Strings`, you may compare them for equality with method `equalsIgnoreCase`, which ignores whether the letters in each string are uppercase or lowercase when performing the comparison. Thus, the string "hello" and the string "HELLO" compare as equal. Line 29 uses `String` method `equalsIgnoreCase` to compare string `s3`—Happy Birthday—for equality with string `s4`—happy birthday. The result of this comparison is `true` because the comparison ignores case sensitivity.

Lines 35–44 use method `compareTo` to compare strings. Method `compareTo` is declared in the `Comparable` interface and implemented in the `String` class. Line 36 compares string `s1` to string `s2`. Method `compareTo` returns 0 if the strings are equal, a negative number if the string that invokes `compareTo` is less than the string that is passed as an argu-

## 30.3 Class String 1469

ment and a positive number if the string that invokes `compareTo` is greater than the string that is passed as an argument. Method `compareTo` uses a lexicographical comparison—it compares the numeric values of corresponding characters in each string. (For more information on the exact value returned by the `compareTo` method, see [java.sun.com/javase/6/docs/api/java/lang/String.html](http://java.sun.com/javase/6/docs/api/java/lang/String.html).)

The condition at line 47 uses `String` method `regionMatches` to compare portions of two strings for equality. The first argument is the starting index in the string that invokes the method. The second argument is a comparison string. The third argument is the starting index in the comparison string. The last argument is the number of characters to compare between the two strings. The method returns `true` only if the specified number of characters are lexicographically equal.

Finally, the condition at line 54 uses a five-argument version of `String` method `regionMatches` to compare portions of two strings for equality. When the first argument is `true`, the method ignores the case of the characters being compared. The remaining arguments are identical to those described for the four-argument `regionMatches` method.

The next example (Fig. 30.4) demonstrates `String` methods `startsWith` and `endsWith`. Method `main` creates array `strings` containing the strings "started", "starting", "ended" and "ending". The remainder of method `main` consists of three `for` statements that test the elements of the array to determine whether they start with or end with a particular set of characters.

```

1 // Fig. 30.4: StringStartEnd.java
2 // String methods startsWith and endsWith.
3
4 public class StringStartEnd
5 {
6 public static void main(String args[])
7 {
8 String strings[] = { "started", "starting", "ended", "ending" };
9
10 // test method startsWith
11 for (String string : strings)
12 {
13 if (string.startsWith("st"))
14 System.out.printf("\"%s\" starts with \"st\"\n", string);
15 } // end for
16
17 System.out.println();
18
19 // test method startsWith starting from position 2 of string
20 for (String string : strings)
21 {
22 if (string.startsWith("art", 2))
23 System.out.printf(
24 "\"%s\" starts with \"art\" at position 2\n", string);
25 } // end for
26
27 System.out.println();

```

**Fig. 30.4** | `String` class `startsWith` and `endsWith` methods. (Part I of 2.)

**1470** Chapter 30 Strings, Characters and Regular Expressions

```

28
29 // test method endsWith
30 for (String string : strings)
31 {
32 if (string.endsWith("ed"))
33 System.out.printf("\"%s\" ends with \"ed\"\n", string);
34 } // end for
35 } // end main
36 } // end class StringStartEnd

```

```

"started" starts with "st"
"starting" starts with "st"

"started" starts with "art" at position 2
"starting" starts with "art" at position 2

"started" ends with "ed"
"ended" ends with "ed"

```

**Fig. 30.4** | String class startsWith and endsWith methods. (Part 2 of 2.)

Lines 11–15 use the version of method `startsWith` that takes a `String` argument. The condition in the `if` statement (line 13) determines whether each `String` in the array starts with the characters "st". If so, the method returns `true` and the application prints that `String`. Otherwise, the method returns `false` and nothing happens.

Lines 20–25 use the `startsWith` method that takes a `String` and an integer as arguments. The integer specifies the index at which the comparison should begin in the string. The condition in the `if` statement (line 22) determines whether each `String` in the array has the characters "art" beginning with the third character in each string. If so, the method returns `true` and the application prints the `String`.

The third `for` statement (lines 30–34) uses method `endsWith`, which takes a `String` argument. The condition at line 32 determines whether each `String` in the array ends with the characters "ed". If so, the method returns `true` and the application prints the `String`.

### 30.3.4 Locating Characters and Substrings in Strings

Often it is useful to search for a character or set of characters in a string. For example, if you are creating your own word processor, you might want to provide a capability for searching through documents. Figure 30.5 demonstrates the many versions of `String` methods `indexOf` and `lastIndexOf` that search for a specified character or substring in a string. All the searches in this example are performed on the string `letters` (initialized with "abcdefghijklmabcdefghijklm") in method `main`. Lines 11–16 use method `indexOf` to locate the first occurrence of a character in a string. If method `indexOf` finds the character, it returns the character's index in the string—otherwise, `indexOf` returns `-1`. There are two versions of `indexOf` that search for characters in a string. The expression in line 12 uses the version of method `indexOf` that takes an integer representation of the character to find. The expression at line 14 uses another version of method `indexOf`, which takes two integer arguments—the character and the starting index at which the search of the string should begin.

## 30.3 Class String 1471

The statements at lines 19–24 use method `lastIndexOf` to locate the last occurrence of a character in a string. Method `lastIndexOf` performs the search from the end of the string toward the beginning. If method `lastIndexOf` finds the character, it returns the index of the character in the string—otherwise, `lastIndexOf` returns `-1`. There are two versions of `lastIndexOf` that search for characters in a string. The expression at line 20 uses the version that takes the integer representation of the character. The expression at line 22 uses the version that takes two integer arguments—the integer representation of the character and the index from which to begin searching backward.

```

1 // Fig. 30.5: StringIndexMethods.java
2 // String searching methods indexOf and lastIndexOf.
3
4 public class StringIndexMethods
5 {
6 public static void main(String args[])
7 {
8 String letters = "abcdefghijklmabcdefghijklm";
9
10 // test indexOf to locate a character in a string
11 System.out.printf(
12 "'c' is located at index %d\n", letters.indexOf('c'));
13 System.out.printf(
14 "'a' is located at index %d\n", letters.indexOf('a', 1));
15 System.out.printf(
16 "'$' is located at index %d\n\n", letters.indexOf('$'));
17
18 // test lastIndexOf to find a character in a string
19 System.out.printf("Last 'c' is located at index %d\n",
20 letters.lastIndexOf('c'));
21 System.out.printf("Last 'a' is located at index %d\n",
22 letters.lastIndexOf('a', 25));
23 System.out.printf("Last '$' is located at index %d\n\n",
24 letters.lastIndexOf('$'));
25
26 // test indexOf to locate a substring in a string
27 System.out.printf("\"def\" is located at index %d\n",
28 letters.indexOf("def"));
29 System.out.printf("\"def\" is located at index %d\n",
30 letters.indexOf("def", 7));
31 System.out.printf("\"hello\" is located at index %d\n\n",
32 letters.indexOf("hello"));
33
34 // test lastIndexOf to find a substring in a string
35 System.out.printf("Last \"def\" is located at index %d\n",
36 letters.lastIndexOf("def"));
37 System.out.printf("Last \"def\" is located at index %d\n",
38 letters.lastIndexOf("def", 25));
39 System.out.printf("Last \"hello\" is located at index %d\n",
40 letters.lastIndexOf("hello"));
41 } // end main
42 } // end class StringIndexMethods

```

**Fig. 30.5** | String class searching methods. (Part I of 2.)

**1472** Chapter 30 Strings, Characters and Regular Expressions

```
'c' is located at index 2
'a' is located at index 13
'$' is located at index -1

Last 'c' is located at index 15
Last 'a' is located at index 13
Last '$' is located at index -1

"def" is located at index 3
"def" is located at index 16
"hello" is located at index -1

Last "def" is located at index 16
Last "def" is located at index 16
Last "hello" is located at index -1
```

**Fig. 30.5** | String class searching methods. (Part 2 of 2.)

Lines 27–40 demonstrate versions of methods `indexOf` and `lastIndexOf` that each take a `String` as the first argument. These versions perform identically to those described earlier except that they search for sequences of characters (or substrings) that are specified by their `String` arguments. If the substring is found, these methods return the index in the string of the first character in the substring.

### 30.3.5 Extracting Substrings from Strings

Class `String` provides two `substring` methods to enable a new `String` object to be created by copying part of an existing `String` object. Each method returns a new `String` object. Both methods are demonstrated in Fig. 30.6.

```
1 // Fig. 30.6: SubString.java
2 // String class substring methods.
3
4 public class SubString
5 {
6 public static void main(String args[])
7 {
8 String letters = "abcdefghijklmabcdefghijklm";
9
10 // test substring methods
11 System.out.printf("Substring from index 20 to end is \"%s\"\n",
12 letters.substring(20));
13 System.out.printf("%s \"%s\"\n",
14 "Substring from index 3 up to, but not including 6 is",
15 letters.substring(3, 6));
16 } // end main
17 } // end class SubString
```

```
Substring from index 20 to end is "hijklm"
Substring from index 3 up to, but not including 6 is "def"
```

**Fig. 30.6** | String class substring methods.

## 30.3 Class String 1473

The expression `letters.substring( 20 )` at line 12 uses the `substring` method that takes one integer argument. The argument specifies the starting index in the original string `letters` from which characters are to be copied. The `substring` returned contains a copy of the characters from the starting index to the end of the string. Specifying an index outside the bounds of the string causes a `StringIndexOutOfBoundsException`.

The expression `letters.substring( 3, 6 )` at line 15 uses the `substring` method that takes two integer arguments. The first argument specifies the starting index from which characters are copied in the original string. The second argument specifies the index one beyond the last character to be copied (i.e., copy up to, but not including, that index in the string). The `substring` returned contains a copy of the specified characters from the original string. Specifying an index outside the bounds of the string causes a `StringIndexOutOfBoundsException`.

### 30.3.6 Concatenating Strings

`String` method `concat` (Fig. 30.7) concatenates two `String` objects and returns a new `String` object containing the characters from both original strings. The expression `s1.concat( s2 )` at line 13 forms a string by appending the characters in string `s2` to the characters in string `s1`. The original `Strings` to which `s1` and `s2` refer are not modified.

```

1 // Fig. 30.7: StringConcatenation.java
2 // String concat method.
3
4 public class StringConcatenation
5 {
6 public static void main(String args[])
7 {
8 String s1 = new String("Happy ");
9 String s2 = new String("Birthday");
10
11 System.out.printf("s1 = %s\ns2 = %s\n\n", s1, s2);
12 System.out.printf(
13 "Result of s1.concat(s2) = %s\n", s1.concat(s2));
14 System.out.printf("s1 after concatenation = %s\n", s1);
15 } // end main
16 } // end class StringConcatenation

```

```

s1 = Happy
s2 = Birthday

Result of s1.concat(s2) = Happy Birthday
s1 after concatenation = Happy

```

**Fig. 30.7** | `String` method `concat`.

### 30.3.7 Miscellaneous String Methods

Class `String` provides several methods that return modified copies of strings or that return character arrays. These methods are demonstrated in the application in Fig. 30.8.

**1474** Chapter 30 Strings, Characters and Regular Expressions

```

1 // Fig. 30.8: StringMiscellaneous2.java
2 // String methods replace, toLowerCase, toUpperCase, trim and toCharArray.
3
4 public class StringMiscellaneous2
5 {
6 public static void main(String args[])
7 {
8 String s1 = new String("hello");
9 String s2 = new String("GOODBYE");
10 String s3 = new String(" spaces ");
11
12 System.out.printf("s1 = %s\ns2 = %s\ns3 = %s\n\n", s1, s2, s3);
13
14 // test method replace
15 System.out.printf(
16 "Replace 'l' with 'L' in s1: %s\n\n", s1.replace('l', 'L'));
17
18 // test toLowerCase and toUpperCase
19 System.out.printf("s1.toUpperCase() = %s\n", s1.toUpperCase());
20 System.out.printf("s2.toLowerCase() = %s\n\n", s2.toLowerCase());
21
22 // test trim method
23 System.out.printf("s3 after trim = \"%s\"\n\n", s3.trim());
24
25 // test toCharArray method
26 char charArray[] = s1.toCharArray();
27 System.out.print("s1 as a character array = ");
28
29 for (char character : charArray)
30 System.out.print(character);
31
32 System.out.println();
33 } // end main
34 } // end class StringMiscellaneous2

```

```

s1 = hello
s2 = GOODBYE
s3 = spaces

Replace 'l' with 'L' in s1: helLo

s1.toUpperCase() = HELLO
s2.toLowerCase() = goodbye

s3 after trim = "spaces"

s1 as a character array = hello

```

**Fig. 30.8** | String methods replace, toLowerCase, toUpperCase, trim and toCharArray.

Line 16 uses `String` method `replace` to return a new `String` object in which every occurrence in string `s1` of character 'l' (lowercase el) is replaced with character 'L'. Method `replace` leaves the original string unchanged. If there are no occurrences of the first argument in the string, method `replace` returns the original string.

## 30.3 Class String 1475

Line 19 uses `String` method `toUpperCase` to generate a new `String` with uppercase letters where corresponding lowercase letters exist in `s1`. The method returns a new `String` object containing the converted string and leaves the original string unchanged. If there are no characters to convert, method `toUpperCase` returns the original string.

Line 20 uses `String` method `toLowerCase` to return a new `String` object with lowercase letters where corresponding uppercase letters exist in `s2`. The original string remains unchanged. If there are no characters in the original string to convert, `toLowerCase` returns the original string.

Line 23 uses `String` method `trim` to generate a new `String` object that removes all white-space characters that appear at the beginning or end of the string on which `trim` operates. The method returns a new `String` object containing the string without leading or trailing white space. The original string remains unchanged.

Line 26 uses `String` method `toCharArray` to create a new character array containing a copy of the characters in string `s1`. Lines 29–30 output each `char` in the array.

### 30.3.8 String Method `valueOf`

As we have seen, every object in Java has a `toString` method that enables a program to obtain the object's string representation. Unfortunately, this technique cannot be used with primitive types because they do not have methods. Class `String` provides static methods that take an argument of any type and convert the argument to a `String` object. Figure 30.9 demonstrates the `String` class `valueOf` methods.

```

1 // Fig. 30.9: StringValueOf.java
2 // String valueOf methods.
3
4 public class StringValueOf
5 {
6 public static void main(String args[])
7 {
8 char charArray[] = { 'a', 'b', 'c', 'd', 'e', 'f' };
9 boolean booleanValue = true;
10 char characterValue = 'Z';
11 int integerValue = 7;
12 long longValue = 1000000000L; // L suffix indicates long
13 float floatValue = 2.5f; // f indicates that 2.5 is a float
14 double doubleValue = 33.333; // no suffix, double is default
15 Object objectRef = "hello"; // assign string to an Object reference
16
17 System.out.printf(
18 "char array = %s\n", String.valueOf(charArray));
19 System.out.printf("part of char array = %s\n",
20 String.valueOf(charArray, 3, 3));
21 System.out.printf(
22 "boolean = %s\n", String.valueOf(booleanValue));
23 System.out.printf(
24 "char = %s\n", String.valueOf(characterValue));
25 System.out.printf("int = %s\n", String.valueOf(integerValue));
26 System.out.printf("long = %s\n", String.valueOf(longValue));

```

**Fig. 30.9** | String class `valueOf` methods. (Part I of 2.)

**1476** Chapter 30 Strings, Characters and Regular Expressions

```

27 System.out.printf("float = %s\n", String.valueOf(floatValue));
28 System.out.printf(
29 "double = %s\n", String.valueOf(doubleValue));
30 System.out.printf("Object = %s", String.valueOf(objectRef));
31 } // end main
32 } // end class StringValueOf

```

```

char array = abcdef
part of char array = def
boolean = true
char = Z
int = 7
long = 10000000000
float = 2.5
double = 33.333
Object = hello

```

**Fig. 30.9** | String class valueOf methods. (Part 2 of 2.)

The expression `String.valueOf( charArray )` at line 18 uses the character array `charArray` to create a new `String` object. The expression `String.valueOf( charArray, 3, 3 )` at line 20 uses a portion of the character array `charArray` to create a new `String` object. The second argument specifies the starting index from which the characters are used. The third argument specifies the number of characters to be used.

There are seven other versions of method `valueOf`, which take arguments of type `boolean`, `char`, `int`, `long`, `float`, `double` and `Object`, respectively. These are demonstrated in lines 21–30. Note that the version of `valueOf` that takes an `Object` as an argument can do so because all `Objects` can be converted to `Strings` with method `toString`.

[*Note:* Lines 12–13 use literal values `10000000000L` and `2.5f` as the initial values of `long` variable `longValue` and `float` variable `floatValue`, respectively. By default, Java treats integer literals as type `int` and floating-point literals as type `double`. Appending the letter `L` to the literal `10000000000` and appending letter `f` to the literal `2.5` indicates to the compiler that `10000000000` should be treated as a `long` and that `2.5` should be treated as a `float`. An uppercase `L` or lowercase `l` can be used to denote a variable of type `long` and an uppercase `F` or lowercase `f` can be used to denote a variable of type `float`.]

## 30.4 Class StringBuilder

Once a `String` object is created, its contents can never change. We now discuss the features of class `StringBuilder` for creating and manipulating dynamic string information—that is, modifiable strings. Every `StringBuilder` is capable of storing a number of characters specified by its capacity. If the capacity of a `StringBuilder` is exceeded, the capacity is automatically expanded to accommodate the additional characters. Class `StringBuilder` is also used to implement operators `+` and `+=` for `String` concatenation.

### Performance Tip 30.2

*Java can perform certain optimizations involving `String` objects (such as sharing one `String` object among multiple references) because it knows these objects will not change. `Strings` (not `StringBuilder`s) should be used if the data will not change.*

30.4 Class *StringBuilder* 1477**Performance Tip 30.3**

*In programs that frequently perform string concatenation, or other string modifications, it is often more efficient to implement the modifications with class *StringBuilder*.*

**Software Engineering Observation 30.2**

**StringBuilders* are not thread safe. If multiple threads require access to the same dynamic string information, use class *StringBuffer* in your code. Classes *StringBuilder* and *StringBuffer* are identical, but class *StringBuffer* is thread safe.*

**30.4.1 *StringBuilder* Constructors**

Class *StringBuilder* provides four constructors. We demonstrate three of these in Fig. 30.10. Line 8 uses the no-argument *StringBuilder* constructor to create a *StringBuilder* with no characters in it and an initial capacity of 16 characters (the default for a *StringBuilder*). Line 9 uses the *StringBuilder* constructor that takes an integer argument to create a *StringBuilder* with no characters in it and the initial capacity specified by the integer argument (i.e., 10). Line 10 uses the *StringBuilder* constructor that takes a *String* argument (in this case, a string literal) to create a *StringBuilder* containing the characters in the *String* argument. The initial capacity is the number of characters in the *String* argument plus 16.

The statements in lines 12–14 use the method *toString* of class *StringBuilder* to output the *StringBuilder*s with the *printf* method. In Section 30.4.4, we discuss how Java uses *StringBuilder* objects to implement the + and += operators for string concatenation.

```

1 // Fig. 30.10: StringBuilderConstructors.java
2 // StringBuilder constructors.
3
4 public class StringBuilderConstructors
5 {
6 public static void main(String args[])
7 {
8 StringBuilder buffer1 = new StringBuilder();
9 StringBuilder buffer2 = new StringBuilder(10);
10 StringBuilder buffer3 = new StringBuilder("hello");
11
12 System.out.printf("buffer1 = \"%s\"\n", buffer1.toString());
13 System.out.printf("buffer2 = \"%s\"\n", buffer2.toString());
14 System.out.printf("buffer3 = \"%s\"\n", buffer3.toString());
15 } // end main
16 } // end class StringBuilderConstructors

```

```

buffer1 = ""
buffer2 = ""
buffer3 = "hello"

```

**Fig. 30.10** | *StringBuilder* class constructors.

**1478** Chapter 30 Strings, Characters and Regular Expressions

### 30.4.2 StringBuilder Methods `length`, `capacity`, `setLength` and `ensureCapacity`

Class `StringBuilder` provides methods `length` and `capacity` to return the number of characters currently in a `StringBuilder` and the number of characters that can be stored in a `StringBuilder` without allocating more memory, respectively. Method `ensureCapacity` guarantees that a `StringBuilder` has at least the specified capacity. Method `setLength` increases or decreases the length of a `StringBuilder`. Figure 30.11 demonstrates these methods.

The application contains one `StringBuilder` called `buffer`. Line 8 uses the `StringBuilder` constructor that takes a `String` argument to initialize the `StringBuilder` with "Hello, how are you?". Lines 10–11 print the contents, length and capacity of the `StringBuilder`. Note in the output window that the capacity of the `StringBuilder` is initially 35. Recall that the `StringBuilder` constructor that takes a `String` argument initializes the capacity to the length of the string passed as an argument plus 16.

Line 13 uses method `ensureCapacity` to expand the capacity of the `StringBuilder` to a minimum of 75 characters. Actually, if the original capacity is less than the argument, the method ensures a capacity that is the greater of the number specified as an argument and twice the original capacity plus 2. The `StringBuilder`'s current capacity remains unchanged if it is more than the specified capacity.

```

1 // Fig. 30.11: StringBuilderCapLen.java
2 // StringBuilder length, setLength, capacity and ensureCapacity methods.
3
4 public class StringBuilderCapLen
5 {
6 public static void main(String args[])
7 {
8 StringBuilder buffer = new StringBuilder("Hello, how are you?");
9
10 System.out.printf("buffer = %s\nlength = %d\ncapacity = %d\n\n",
11 buffer.toString(), buffer.length(), buffer.capacity());
12
13 buffer.ensureCapacity(75);
14 System.out.printf("New capacity = %d\n\n", buffer.capacity());
15
16 buffer.setLength(10);
17 System.out.printf("New length = %d\nbuffer = %s\n",
18 buffer.length(), buffer.toString());
19 } // end main
20 } // end class StringBuilderCapLen

```

```

buffer = Hello, how are you?
length = 19
capacity = 35

New capacity = 75

New length = 10
buffer = Hello, how

```

**Fig. 30.11** | `StringBuilder` methods `length` and `capacity`.

30.4 Class `StringBuilder` 1479**Performance Tip 30.4**

*Dynamically increasing the capacity of a `StringBuilder` can take a relatively long time. Executing a large number of these operations can degrade the performance of an application. If a `StringBuilder` is going to increase greatly in size, possibly multiple times, setting its capacity high at the beginning will increase performance.*

Line 16 uses method `setLength` to set the length of the `StringBuilder` to 10. If the specified length is less than the current number of characters in the `StringBuilder`, the buffer is truncated to the specified length (i.e., the characters in the `StringBuilder` after the specified length are discarded). If the specified length is greater than the number of characters currently in the `StringBuilder`, null characters (characters with the numeric representation 0) are appended until the total number of characters in the `StringBuilder` is equal to the specified length.

### 30.4.3 `StringBuilder` Methods `charAt`, `setCharAt`, `getChars` and `reverse`

Class `StringBuilder` provides methods `charAt`, `setCharAt`, `getChars` and `reverse` to manipulate the characters in a `StringBuilder`. Each of these methods is demonstrated in Fig. 30.12.

```

1 // Fig. 30.12: StringBuilderChars.java
2 // StringBuilder methods charAt, setCharAt, getChars and reverse.
3
4 public class StringBuilderChars
5 {
6 public static void main(String args[])
7 {
8 StringBuilder buffer = new StringBuilder("hello there");
9
10 System.out.printf("buffer = %s\n", buffer.toString());
11 System.out.printf("Character at 0: %s\nCharacter at 4: %s\n\n",
12 buffer.charAt(0), buffer.charAt(4));
13
14 char charArray[] = new char[buffer.length()];
15 buffer.getChars(0, buffer.length(), charArray, 0);
16 System.out.print("The characters are: ");
17
18 for (char character : charArray)
19 System.out.print(character);
20
21 buffer.setCharAt(0, 'H');
22 buffer.setCharAt(6, 'T');
23 System.out.printf("\n\nbuffer = %s", buffer.toString());
24
25 buffer.reverse();
26 System.out.printf("\n\nbuffer = %s\n", buffer.toString());
27 } // end main
28 } // end class StringBuilderChars

```

**Fig. 30.12** | `StringBuilder` class character-manipulation methods. (Part I of 2.)

**1480** Chapter 30 Strings, Characters and Regular Expressions

```

buffer = hello there
Character at 0: h
Character at 4: o

The characters are: hello there

buffer = Hello There

buffer = erehT olleH

```

**Fig. 30.12** | StringBuilder class character-manipulation methods. (Part 2 of 2.)

Method `charAt` (line 12) takes an integer argument and returns the character in the `StringBuilder` at that index. Method `getChars` (line 15) copies characters from a `StringBuilder` into the character array passed as an argument. This method takes four arguments—the starting index from which characters should be copied in the `StringBuilder`, the index one past the last character to be copied from the `StringBuilder`, the character array into which the characters are to be copied and the starting location in the character array where the first character should be placed. Method `setCharAt` (lines 21 and 22) takes an integer and a character argument and sets the character at the specified position in the `StringBuilder` to the character argument. Method `reverse` (line 25) reverses the contents of the `StringBuilder`.

**Common Programming Error 30.3**

Attempting to access a character that is outside the bounds of a `StringBuilder` (i.e., with an index less than 0 or greater than or equal to the `StringBuilder`'s length) results in a `StringIndexOutOfBoundsException`.

**30.4.4 StringBuilder append Methods**

Class `StringBuilder` provides overloaded `append` methods (demonstrated in Fig. 30.13) to allow values of various types to be appended to the end of a `StringBuilder`. Versions are provided for each of the primitive types and for character arrays, `Strings`, `Objects`, `StringBuilders` and `CharSequences`. (Remember that method `toString` produces a string representation of any `Object`.) Each of the methods takes its argument, converts it to a string and appends it to the `StringBuilder`.

```

1 // Fig. 30.13: StringBuilderAppend.java
2 // StringBuilder append methods.
3
4 public class StringBuilderAppend
5 {
6 public static void main(String args[])
7 {
8 Object objectRef = "hello";
9 String string = "goodbye";
10 char charArray[] = { 'a', 'b', 'c', 'd', 'e', 'f' };
11 boolean booleanValue = true;
12 char characterValue = 'Z';

```

**Fig. 30.13** | StringBuilder class append methods. (Part 1 of 2.)

30.4 Class `StringBuilder` 1481

```

13 int integerValue = 7;
14 long longValue = 10000000000L;
15 float floatValue = 2.5f; // f suffix indicates 2.5 is a float
16 double doubleValue = 33.333;
17
18 StringBuilder lastBuffer = new StringBuilder("last buffer");
19 StringBuilder buffer = new StringBuilder();
20
21 buffer.append(objectRef);
22 buffer.append("\n"); // each of these contains new line
23 buffer.append(string);
24 buffer.append("\n");
25 buffer.append(charArray);
26 buffer.append("\n");
27 buffer.append(charArray, 0, 3);
28 buffer.append("\n");
29 buffer.append(booleanValue);
30 buffer.append("\n");
31 buffer.append(characterValue);
32 buffer.append("\n");
33 buffer.append(integerValue);
34 buffer.append("\n");
35 buffer.append(longValue);
36 buffer.append("\n");
37 buffer.append(floatValue);
38 buffer.append("\n");
39 buffer.append(doubleValue);
40 buffer.append("\n");
41 buffer.append(lastBuffer);
42
43 System.out.printf("buffer contains %s\n", buffer.toString());
44 } // end main
45 } // end StringBuilderAppend

```

```

buffer contains hello
goodbye
abcdef
abc
true
Z
7
10000000000
2.5
33.333
last buffer

```

**Fig. 30.13** | `StringBuilder` class append methods. (Part 2 of 2.)

Actually, the compiler uses `StringBuilder` and the `append` methods to implement the `+` and `+=` operators for `String` concatenation. For example, assuming the declarations

```

String string1 = "hello";
String string2 = "BC";
int value = 22;

```

## 1482 Chapter 30 Strings, Characters and Regular Expressions

the statement

```
String s = string1 + string2 + value;
```

concatenates "hello", "BC" and 22. The concatenation is performed as follows:

```
new StringBuilder().append("hello").append("BC").append(22).toString();
```

First, Java creates an empty `StringBuilder`, then appends to it the string "hello", the string "BC" and the integer 22. Next, `StringBuilder`'s method `toString` converts the `StringBuilder` to a `String` object to be assigned to `String s`. The statement

```
s += "!" ;
```

is performed as follows:

```
s = new StringBuilder().append(s).append("!").toString();
```

First, Java creates an empty `StringBuilder`, then it appends to the `StringBuilder` the current contents of `s` followed by "!". Next, `StringBuilder`'s method `toString` converts the `StringBuilder` to a string representation, and the result is assigned to `s`.

### 30.4.5 `StringBuilder` Insertion and Deletion Methods

Class `StringBuilder` provides overloaded `insert` methods to allow values of various types to be inserted at any position in a `StringBuilder`. Versions are provided for each of the primitive types and for character arrays, `Strings`, `Objects` and `CharSequences`. Each method takes its second argument, converts it to a string and inserts it immediately preceding the index specified by the first argument. The first argument must be greater than or equal to 0 and less than the length of the `StringBuilder`—otherwise, a `StringIndexOutOfBoundsException` occurs. Class `StringBuilder` also provides methods `delete` and `deleteCharAt` for deleting characters at any position in a `StringBuilder`. Method `delete` takes two arguments—the starting index and the index one past the end of the characters to delete. All characters beginning at the starting index up to but not including the ending index are deleted. Method `deleteCharAt` takes one argument—the index of the character to delete. Invalid indices cause both methods to throw a `StringIndexOutOfBoundsException`. Methods `insert`, `delete` and `deleteCharAt` are demonstrated in Fig. 30.14.

```

1 // Fig. 30.14: StringBuilderInsert.java
2 // StringBuilder methods insert, delete and deleteCharAt.
3
4 public class StringBuilderInsert
5 {
6 public static void main(String args[])
7 {
8 Object objectRef = "hello";
9 String string = "goodbye";
10 char charArray[] = { 'a', 'b', 'c', 'd', 'e', 'f' };
11 boolean booleanValue = true;
12 char characterValue = 'K';

```

**Fig. 30.14** | `StringBuilder` methods `insert` and `delete`. (Part I of 2.)

30.5 Class Character **1483**

```

13 int integerValue = 7;
14 long longValue = 10000000;
15 float floatValue = 2.5f; // f suffix indicates that 2.5 is a float
16 double doubleValue = 33.333;
17
18 StringBuilder buffer = new StringBuilder();
19
20 buffer.insert(0, objectRef);
21 buffer.insert(0, " "); // each of these contains two spaces
22 buffer.insert(0, string);
23 buffer.insert(0, " ");
24 buffer.insert(0, charArray);
25 buffer.insert(0, " ");
26 buffer.insert(0, charArray, 3, 3);
27 buffer.insert(0, " ");
28 buffer.insert(0, booleanValue);
29 buffer.insert(0, " ");
30 buffer.insert(0, characterValue);
31 buffer.insert(0, " ");
32 buffer.insert(0, integerValue);
33 buffer.insert(0, " ");
34 buffer.insert(0, longValue);
35 buffer.insert(0, " ");
36 buffer.insert(0, floatValue);
37 buffer.insert(0, " ");
38 buffer.insert(0, doubleValue);
39
40 System.out.printf(
41 "buffer after inserts:\n%s\n", buffer.toString());
42
43 buffer.deleteCharAt(10); // delete 5 in 2.5
44 buffer.delete(2, 6); // delete .333 in 33.333
45
46 System.out.printf(
47 "buffer after deletes:\n%s\n", buffer.toString());
48 } // end main
49 } // end class StringBuilderInsert

```

```

buffer after inserts:
33.333 2.5 10000000 7 K true def abcdef goodbye hello

buffer after deletes:
33 2. 10000000 7 K true def abcdef goodbye hello

```

**Fig. 30.14** | *StringBuilder* methods *insert* and *delete*. (Part 2 of 2.)

## 30.5 Class Character

Recall from Chapter 17 that Java provides eight type-wrapper classes—*Boolean*, *Character*, *Double*, *Float*, *Byte*, *Short*, *Integer* and *Long*—that enable primitive-type values to be treated as objects. In this section, we present class *Character*—the type-wrapper class for primitive type *char*.

**1484**    Chapter 30  Strings, Characters and Regular Expressions

Most Character methods are `static` methods designed for convenience in processing individual `char` values. These methods take at least a character argument and perform either a test or a manipulation of the character. Class `Character` also contains a constructor that receives a `char` argument to initialize a `Character` object. Most of the methods of class `Character` are presented in the next three examples. For more information on class `Character` (and all the type-wrapper classes), see the `java.lang` package in the Java API documentation.

Figure 30.15 demonstrates some `static` methods that test characters to determine whether they are a specific character type and the `static` methods that perform case conversions on characters. You can enter any character and apply the methods to the character.

Line 15 uses `Character` method `isDefined` to determine whether character `c` is defined in the Unicode character set. If so, the method returns `true`, and otherwise, it returns `false`. Line 16 uses `Character` method `isDigit` to determine whether character `c` is a defined Unicode digit. If so, the method returns `true`, and otherwise, it returns `false`.

```

1 // Fig. 30.15: StaticCharMethods.java
2 // Static Character testing methods and case conversion methods.
3 import java.util.Scanner;
4
5 public class StaticCharMethods
6 {
7 public static void main(String args[])
8 {
9 Scanner scanner = new Scanner(System.in); // create scanner
10 System.out.println("Enter a character and press Enter");
11 String input = scanner.next();
12 char c = input.charAt(0); // get input character
13
14 // display character info
15 System.out.printf("is defined: %b\n", Character.isDefined(c));
16 System.out.printf("is digit: %b\n", Character.isDigit(c));
17 System.out.printf("is first character in a Java identifier: %b\n",
18 Character.isJavaIdentifierStart(c));
19 System.out.printf("is part of a Java identifier: %b\n",
20 Character.isJavaIdentifierPart(c));
21 System.out.printf("is letter: %b\n", Character.isLetter(c));
22 System.out.printf(
23 "is letter or digit: %b\n", Character.isLetterOrDigit(c));
24 System.out.printf(
25 "is lower case: %b\n", Character.isLowerCase(c));
26 System.out.printf(
27 "is upper case: %b\n", Character.isUpperCase(c));
28 System.out.printf(
29 "to upper case: %s\n", Character.toUpperCase(c));
30 System.out.printf(
31 "to lower case: %s\n", Character.toLowerCase(c));
32 } // end main
33 } // end class StaticCharMethods

```

**Fig. 30.15** | Character class `static` methods for testing characters and converting character case. (Part I of 2.)

## 30.5 Class Character 1485

```
Enter a character and press Enter
A
is defined: true
is digit: false
is first character in a Java identifier: true
is part of a Java identifier: true
is letter: true
is letter or digit: true
is lower case: false
is upper case: true
to upper case: A
to lower case: a
```

```
Enter a character and press Enter
8
is defined: true
is digit: true
is first character in a Java identifier: false
is part of a Java identifier: true
is letter: false
is letter or digit: true
is lower case: false
is upper case: false
to upper case: 8
to lower case: 8
```

```
Enter a character and press Enter
$
is defined: true
is digit: false
is first character in a Java identifier: true
is part of a Java identifier: true
is letter: false
is letter or digit: false
is lower case: false
is upper case: false
to upper case: $
to lower case: $
```

**Fig. 30.15** | Character class static methods for testing characters and converting character case. (Part 2 of 2.)

Line 18 uses `Character` method `isJavaIdentifierStart` to determine whether `c` is a character that can be the first character of an identifier in Java—that is, a letter, an underscore (\_) or a dollar sign (\$). If so, the method returns `true`, and otherwise, it returns `false`. Line 20 uses `Character` method `isJavaIdentifierPart` to determine whether character `c` is a character that can be used in an identifier in Java—that is, a digit, a letter, an underscore (\_) or a dollar sign (\$). If so, the method returns `true`, and otherwise, `false`.

Line 21 uses `Character` method `isLetter` to determine whether character `c` is a letter. If so, the method returns `true`, and otherwise, `false`. Line 23 uses `Character` method

**1486** Chapter 30 Strings, Characters and Regular Expressions

`isLetterOrDigit` to determine whether character `c` is a letter or a digit. If so, the method returns `true`, and otherwise, `false`.

Line 25 uses `Character` method `isLowerCase` to determine whether character `c` is a lowercase letter. If so, the method returns `true`, and otherwise, `false`. Line 27 uses `Character` method `isUpperCase` to determine whether character `c` is an uppercase letter. If so, the method returns `true`, and otherwise, `false`.

Line 29 uses `Character` method `toUpperCase` to convert the character `c` to its uppercase equivalent. The method returns the converted character if the character has an uppercase equivalent, and otherwise, the method returns its original argument. Line 31 uses `Character` method `toLowerCase` to convert the character `c` to its lowercase equivalent. The method returns the converted character if the character has a lowercase equivalent, and otherwise, the method returns its original argument.

Figure 30.16 demonstrates static `Character` methods `digit` and `forDigit`, which convert characters to digits and digits to characters, respectively, in different number systems. Common number systems include decimal (base 10), octal (base 8), hexadecimal (base 16) and binary (base 2). The base of a number is also known as its `radix`. For more information on conversions between number systems, see Appendix E.

```

1 // Fig. 30.16: StaticCharMethods2.java
2 // Static Character conversion methods.
3 import java.util.Scanner;
4
5 public class StaticCharMethods2
6 {
7 // create StaticCharMethods2 object execute application
8 public static void main(String args[])
9 {
10 Scanner scanner = new Scanner(System.in);
11
12 // get radix
13 System.out.println("Please enter a radix:");
14 int radix = scanner.nextInt();
15
16 // get user choice
17 System.out.printf("Please choose one:\n1 -- %s\n2 -- %s\n",
18 "Convert digit to character", "Convert character to digit");
19 int choice = scanner.nextInt();
20
21 // process request
22 switch (choice)
23 {
24 case 1: // convert digit to character
25 System.out.println("Enter a digit:");
26 int digit = scanner.nextInt();
27 System.out.printf("Convert digit to character: %s\n",
28 Character.forDigit(digit, radix));
29 break;
30

```

**Fig. 30.16** | Character class static conversion methods. (Part I of 2.)

30.5 Class Character 1487

```

31 case 2: // convert character to digit
32 System.out.println("Enter a character: ");
33 char character = scanner.next().charAt(0);
34 System.out.printf("Convert character to digit: %s\n",
35 Character.digit(character, radix));
36 break;
37 } // end switch
38 } // end main
39 } // end class StaticCharMethods2

```

```

Please enter a radix:
16
Please choose one:
1 -- Convert digit to character
2 -- Convert character to digit
2
Enter a character:
A
Convert character to digit: 10

```

```

Please enter a radix:
16
Please choose one:
1 -- Convert digit to character
2 -- Convert character to digit
1
Enter a digit:
13
Convert digit to character: d

```

**Fig. 30.16** | Character class static conversion methods. (Part 2 of 2.)

Line 28 uses method `forDigit` to convert the integer `digit` into a character in the number system specified by the integer `radix` (the base of the number). For example, the decimal integer 13 in base 16 (the `radix`) has the character value 'd'. Lowercase and uppercase letters represent the same value in number systems. Line 35 uses method `digit` to convert the character `c` into an integer in the number system specified by the integer `radix` (the base of the number). For example, the character 'A' is the base 16 (the `radix`) representation of the base 10 value 10. The radix must be between 2 and 36, inclusive.

Figure 30.17 demonstrates the constructor and several non-static methods of class `Character`—`charValue`, `toString` and `equals`. Lines 8–9 instantiate two `Character` objects by autoboxing the character constants 'A' and 'a', respectively. Line 12 uses `Character` method `charValue` to return the char value stored in `Character` object `c1`. Line 12 returns a string representation of `Character` object `c2` using method `toString`. The condition in the `if...else` statement at lines 14–17 uses method `equals` to determine whether the object `c1` has the same contents as the object `c2` (i.e., the characters inside each object are equal).

**1488** Chapter 30 Strings, Characters and Regular Expressions

```

1 // Fig. 30.17: OtherCharMethods.java
2 // Non-static Character methods.
3
4 public class OtherCharMethods
5 {
6 public static void main(String args[])
7 {
8 Character c1 = 'A';
9 Character c2 = 'a';
10
11 System.out.printf(
12 "c1 = %s\n" + "c2 = %s\n\n", c1.charValue(), c2.toString());
13

```

c1 = A
c2 = a

c1 and c2 are not equal

```

**Fig. 30.17** | Character class non-static methods.

## 30.6 Class StringTokenizer

When you read a sentence, your mind breaks the sentence into **tokens**—individual words and punctuation marks, each of which conveys meaning to you. Compilers also perform tokenization. They break up statements into individual pieces like keywords, identifiers, operators and other programming-language elements. We now study Java's `StringTokenizer` class (from package `java.util`), which breaks a string into its component tokens. Tokens are separated from one another by **delimiters**, typically white-space characters such as space, tab, newline and carriage return. Other characters can also be used as delimiters to separate tokens. The application in Fig. 30.18 demonstrates class `StringTokenizer`.

When the user presses the *Enter* key, the input sentence is stored in variable `sentence`. Line 17 creates a `StringTokenizer` for `sentence`. This `StringTokenizer` constructor takes a string argument and creates a `StringTokenizer` for it, and will use the default delimiter string "`\t\n\r\f`" consisting of a space, a tab, a carriage return and a newline for tokenization. There are two other constructors for class `StringTokenizer`. In the version that takes two `String` arguments, the second `String` is the delimiter string. In the version that takes three arguments, the second `String` is the delimiter string and the third argument (a `boolean`) determines whether the delimiters are also returned as tokens (only if the argument is `true`). This is useful if you need to know what the delimiters are.

Line 19 uses `StringTokenizer` method `countTokens` to determine the number of tokens in the string to be tokenized. The condition at line 21 uses `StringTokenizer` method `hasMoreTokens` to determine whether there are more tokens in the string being tokenized. If so, line 22 prints the next token in the `String`. The next token is obtained

## 30.7 Regular Expressions, Class Pattern and Class Matcher

1489

```

1 // Fig. 30.18: TokenTest.java
2 // StringTokenizer class.
3 import java.util.Scanner;
4 import java.util.StringTokenizer;
5
6 public class TokenTest
7 {
8 // execute application
9 public static void main(String args[])
10 {
11 // get sentence
12 Scanner scanner = new Scanner(System.in);
13 System.out.println("Enter a sentence and press Enter");
14 String sentence = scanner.nextLine();
15
16 // process user sentence
17 StringTokenizer tokens = new StringTokenizer(sentence);
18 System.out.printf("Number of elements: %d\nThe tokens are:\n",
19 tokens.countTokens());
20
21 while (tokens.hasMoreTokens())
22 System.out.println(tokens.nextToken());
23 } // end main
24 } // end class TokenTest

```

```

Enter a sentence and press Enter
This is a sentence with seven tokens
Number of elements: 7
The tokens are:
This
is
a
sentence
with
seven
tokens

```

**Fig. 30.18** | StringTokenizer object used to tokenize strings.

with a call to StringTokenizer method `nextToken`, which returns a `String`. The token is output using `println`, so subsequent tokens appear on separate lines.

If you would like to change the delimiter string while tokenizing a string, you may do so by specifying a new delimiter string in a `nextToken` call as follows:

```
tokens.nextToken(newDelimiterString);
```

This feature is not demonstrated in Fig. 30.18.

## 30.7 Regular Expressions, Class Pattern and Class Matcher

Regular expressions are sequences of characters and symbols that define a set of strings. They are useful for validating input and ensuring that data is in a particular format. For

**1490** Chapter 30 Strings, Characters and Regular Expressions

example, a ZIP code must consist of five digits, and a last name must contain only letters, spaces, apostrophes and hyphens. One application of regular expressions is to facilitate the construction of a compiler. Often, a large and complex regular expression is used to validate the syntax of a program. If the program code does not match the regular expression, the compiler knows that there is a syntax error within the code.

Class `String` provides several methods for performing regular-expression operations, the simplest of which is the matching operation. `String` method `matches` receives a string that specifies the regular expression and matches the contents of the `String` object on which it is called to the regular expression. The method returns a `boolean` indicating whether the match succeeded.

A regular expression consists of literal characters and special symbols. Figure 30.19 specifies some **predefined character classes** that can be used with regular expressions. A character class is an escape sequence that represents a group of characters. A digit is any numeric character. A **word character** is any letter (uppercase or lowercase), any digit or the underscore character. A whitespace character is a space, a tab, a carriage return, a newline or a form feed. Each character class matches a single character in the string we are attempting to match with the regular expression.

Regular expressions are not limited to these predefined character classes. The expressions employ various operators and other forms of notation to match complex patterns. We examine several of these techniques in the application in Figs. 30.20 and 30.21 which validates user input via regular expressions. [Note: This application is not designed to match all possible valid user input.]

Figure 30.20 validates user input. Line 9 validates the first name. To match a set of characters that does not have a predefined character class, use square brackets, `[]`. For example, the pattern `"[aeiou]"` matches a single character that is a vowel. Character ranges are represented by placing a dash (`-`) between two characters. In the example, `"[A-Z]"` matches a single uppercase letter. If the first character in the brackets is `"^"`, the expression accepts any character other than those indicated. However, it is important to note that `"[^Z]"` is not the same as `"[A-Y]"`, which matches uppercase letters A–Y—`"[^Z]"` matches any character other than capital Z, including lowercase letters and non-letters such as the newline character. Ranges in character classes are determined by the letters' integer values. In this example, `"[A-Za-z]"` matches all uppercase and lowercase letters. The range `"[A-z]"` matches all letters and also matches those characters (such as % and 6) with an integer value between uppercase Z and lowercase a (for more information on integer values of characters see Appendix B, ASCII Character Set). Like predefined character classes, character classes delimited by square brackets match a single character in the search object.

Character	Matches	Character	Matches
<code>\d</code>	any digit	<code>\D</code>	any nondigit
<code>\w</code>	any word character	<code>\W</code>	any nonword character
<code>\s</code>	any white-space character	<code>\S</code>	any nonwhite-space

**Fig. 30.19** | Predefined character classes.

## 30.7 Regular Expressions, Class Pattern and Class Matcher

1491

```

1 // Fig. 30.20: ValidateInput.java
2 // Validate user information using regular expressions.
3
4 public class ValidateInput
5 {
6 // validate first name
7 public static boolean validateFirstName(String firstName)
8 {
9 return firstName.matches("[A-Z][a-zA-Z]*");
10 } // end method validateFirstName
11
12 // validate last name
13 public static boolean validateLastName(String lastName)
14 {
15 return lastName.matches("[a-zA-z]+([-][a-zA-Z]+)*");
16 } // end method validateLastName
17
18 // validate address
19 public static boolean validateAddress(String address)
20 {
21 return address.matches(
22 "\d+\s+([a-zA-Z]+[a-zA-Z]+\s[a-zA-Z]+)");
23 } // end method validateAddress
24
25 // validate city
26 public static boolean validateCity(String city)
27 {
28 return city.matches("([a-zA-Z]+[a-zA-Z]+\s[a-zA-Z]+)");
29 } // end method validateCity
30
31 // validate state
32 public static boolean validateState(String state)
33 {
34 return state.matches("([a-zA-Z]+[a-zA-Z]+\s[a-zA-Z]+)");
35 } // end method validateState
36
37 // validate zip
38 public static boolean validateZip(String zip)
39 {
40 return zip.matches("\d{5}");
41 } // end method validateZip
42
43 // validate phone
44 public static boolean validatePhone(String phone)
45 {
46 return phone.matches("[1-9]\d{2}-[1-9]\d{2}-\d{4}");
47 } // end method validatePhone
48 } // end class ValidateInput

```

**Fig. 30.20** | Validating user information using regular expressions.

In line 9, the asterisk after the second character class indicates that any number of letters can be matched. In general, when the regular-expression operator "\*" appears in a regular expression, the application attempts to match zero or more occurrences of the

**1492** Chapter 30 Strings, Characters and Regular Expressions

subexpression immediately preceding the "\*". Operator "+" attempts to match one or more occurrences of the subexpression immediately preceding "+". So both "A\*" and "A+" will match "AAA", but only "A\*" will match an empty string.

If method validateFirstName returns true (line 29), the application attempts to validate the last name (line 31) by calling validateLastName (lines 13–16 of Fig. 30.20). The

```

1 // Fig. 30.21: Validate.java
2 // Validate user information using regular expressions.
3 import java.util.Scanner;
4
5 public class Validate
6 {
7 public static void main(String[] args)
8 {
9 // get user input
10 Scanner scanner = new Scanner(System.in);
11 System.out.println("Please enter first name:");
12 String firstName = scanner.nextLine();
13 System.out.println("Please enter last name:");
14 String lastName = scanner.nextLine();
15 System.out.println("Please enter address:");
16 String address = scanner.nextLine();
17 System.out.println("Please enter city:");
18 String city = scanner.nextLine();
19 System.out.println("Please enter state:");
20 String state = scanner.nextLine();
21 System.out.println("Please enter zip:");
22 String zip = scanner.nextLine();
23 System.out.println("Please enter phone:");
24 String phone = scanner.nextLine();
25
26 // validate user input and display error message
27 System.out.println("\nValidate Result:");
28
29 if (!ValidateInput.validateFirstName(firstName))
30 System.out.println("Invalid first name");
31 else if (!ValidateInput.validateLastName(lastName))
32 System.out.println("Invalid last name");
33 else if (!ValidateInput.validateAddress(address))
34 System.out.println("Invalid address");
35 else if (!ValidateInput.validateCity(city))
36 System.out.println("Invalid city");
37 else if (!ValidateInput.validateState(state))
38 System.out.println("Invalid state");
39 else if (!ValidateInput.validateZip(zip))
40 System.out.println("Invalid zip code");
41 else if (!ValidateInput.validatePhone(phone))
42 System.out.println("Invalid phone number");
43 else
44 System.out.println("Valid input. Thank you.");
45 } // end main
46 } // end class Validate

```

Validate Result:  
 Valid input. Thank you.

**Fig. 30.21** | Inputs and validates data from user using the `ValidateInput` class. (Part 2 of 2.)

regular expression to validate the last name matches any number of letters split by spaces, apostrophes or hyphens.

Line 33 validates the address by calling method `validateAddress` (lines 19–23 of Fig. 30.20). The first character class matches any digit one or more times (`\d+`). Note that two \ characters are used, because \ normally starts an escape sequences in a string. So `\d` in a Java string represents the regular expression pattern `\d`. Then we match one or more white-space characters (`\s+`). The character "|" allows a match of the expression to its left or to its right. For example, "Hi (John|Jane)" matches both "Hi John" and "Hi Jane". The parentheses are used to group parts of the regular expression. In this example, the left side of | matches a single word, and the right side matches two words separated by any amount of white space. So the address must contain a number followed by one or two words. Therefore, "10 Broadway" and "10 Main Street" are both valid addresses in this example. The city (lines 26–29 of Fig. 30.20) and state (lines 32–35 of Fig. 30.20) methods

**1494** Chapter 30 Strings, Characters and Regular Expressions

also match any word of at least one character or, alternatively, any two words of at least one character if the words are separated by a single space. This means both `Wal``t``ham` and `West``Newton` would match.

**Quantifiers**

The asterisk (\*) and plus (+) are formally called **quantifiers**. Figure 30.22 lists all the quantifiers. We have already discussed how the asterisk (\*) and plus (+) quantifiers work. All quantifiers affect only the subexpression immediately preceding the quantifier. Quantifier question mark (?) matches zero or one occurrences of the expression that it quantifies. A set of braces containing one number ( $\{n\}$ ) matches exactly  $n$  occurrences of the expression it quantifies. We demonstrate this quantifier to validate the zip code in Fig. 30.20 at line 40. Including a comma after the number enclosed in braces matches at least  $n$  occurrences of the quantified expression. The set of braces containing two numbers ( $\{n, m\}$ ), matches between  $n$  and  $m$  occurrences of the expression that it qualifies. Quantifiers may be applied to patterns enclosed in parentheses to create more complex regular expressions.

All of the quantifiers are **greedy**. This means that they will match as many occurrences as they can as long as the match is still successful. However, if any of these quantifiers is followed by a question mark (?), the quantifier becomes **reluctant** (sometimes called **lazy**). It then will match as few occurrences as possible as long as the match is still successful.

The zip code (line 40 in Fig. 30.20) matches a digit five times. This regular expression uses the digit character class and a quantifier with the digit 5 between braces. The phone number (line 46 in Fig. 30.20) matches three digits (the first one cannot be zero) followed by a dash followed by three more digits (again the first one cannot be zero) followed by four more digits.

`String` Method `matches` checks whether an entire string conforms to a regular expression. For example, we want to accept "Smith" as a last name, but not "9@Smith#". If only a substring matches the regular expression, method `matches` returns `false`.

**Replacing Substrings and Splitting Strings**

Sometimes it is useful to replace parts of a string or to split a string into pieces. For this purpose, class `String` provides methods `replaceAll`, `replaceFirst` and `split`. These methods are demonstrated in Fig. 30.23.

Quantifier	Matches
*	Matches zero or more occurrences of the pattern.
+	Matches one or more occurrences of the pattern.
?	Matches zero or one occurrences of the pattern.
{ $n$ }	Matches exactly $n$ occurrences.
{ $n, m$ }	Matches at least $n$ occurrences.
{ $n, m$ }	Matches between $n$ and $m$ (inclusive) occurrences.

**Fig. 30.22** | Quantifiers used in regular expressions.

30.7 Regular Expressions, Class Pattern and Class Matcher 1495

Method `replaceAll` replaces text in a string with new text (the second argument) wherever the original string matches a regular expression (the first argument). Line 14 replaces every instance of "\*" in `firstString` with "^". Note that the regular expression ("\\\*") precedes character \* with two backslashes. Normally, \* is a quantifier indicating

```

1 // Fig. 30.23: RegexSubstitution.java
2 // Using methods replaceFirst, replaceAll and split.
3
4 public class RegexSubstitution
5 {
6 public static void main(String args[])
7 {
8 String firstString = "This sentence ends in 5 stars *****";
9 String secondString = "1, 2, 3, 4, 5, 6, 7, 8";
10
11 System.out.printf("Original String 1: %s\n", firstString);
12
13 // replace '*' with '^'
14 firstString = firstString.replaceAll("*", "^");
15
16 System.out.printf("^ substituted for *: %s\n", firstString);
17
18 // replace 'stars' with 'carets'
19 firstString = firstString.replaceAll("stars", "carets");
20
21 System.out.printf(
22 "\\"carets\\" substituted for \\\"stars\\\": %s\n", firstString);
23
24 // replace words with 'word'
25 System.out.printf("Every word replaced by \\\"word\\\": %s\n\n",
26 firstString.replaceAll("\\w+", "word"));
27
28 System.out.printf("Original String 2: %s\n", secondString);
29
30 // replace first three digits with 'digit'
31 for (int i = 0; i < 3; i++)
32 secondString = secondString.replaceFirst("\\d", "digit");
33
34 System.out.printf(
35 "First 3 digits replaced by \\\"digit\\\" : %s\n", secondString);
36 String output = "String split at commas: [";
37
38 String[] results = secondString.split(",\\s*"); // split on commas
39
40 for (String string : results)
41 output += "\\" + string + "\", "; // output results
42
43 // remove the extra comma and add a bracket
44 output = output.substring(0, output.length() - 2) + "]";
45 System.out.println(output);
46 } // end main
47 } // end class RegexSubstitution

```

**Fig. 30.23** | Methods `replaceFirst`, `replaceAll` and `split`. (Part I of 2.)

**1496** Chapter 30 Strings, Characters and Regular Expressions

```

Original String 1: This sentence ends in 5 stars *****
^ substituted for *: This sentence ends in 5 stars ^^^^^
"carets" substituted for "stars": This sentence ends in 5 carets ^^^^^
Every word replaced by "word": word word word word word word ^^^^^

Original String 2: 1, 2, 3, 4, 5, 6, 7, 8
First 3 digits replaced by "digit" : digit, digit, digit, 4, 5, 6, 7, 8
String split at commas: ["digit", "digit", "digit", "4", "5", "6", "7", "8"]

```

**Fig. 30.23** | Methods replaceFirst, replaceAll and split. (Part 2 of 2.)

that a regular expression should match any number of occurrences of a preceding pattern. However, in line 14, we want to find all occurrences of the literal character \*—to do this, we must escape character \* with character \. Escaping a special regular-expression character with \ instructs the matching engine to find the actual character. Since the expression is stored in a Java string and \ is a special character in Java strings, we must include an additional \. So the Java string "\\\*" represents the regular-expression pattern \\* which matches a single \* character in the search string. In line 19, every match for the regular expression "stars" in firstString is replaced with "carets".

Method `replaceFirst` (line 32) replaces the first occurrence of a pattern match. Java `Strings` are immutable, therefore method `replaceFirst` returns a new string in which the appropriate characters have been replaced. This line takes the original string and replaces it with the string returned by `replaceFirst`. By iterating three times we replace the first three instances of a digit (\d) in secondString with the text "digit".

Method `split` divides a string into several substrings. The original string is broken in any location that matches a specified regular expression. Method `split` returns an array of strings containing the substrings between matches for the regular expression. In line 38, we use method `split` to tokenize a string of comma-separated integers. The argument is the regular expression that locates the delimiter. In this case, we use the regular expression ",\\s\*" to separate the substrings wherever a comma occurs. By matching any white-space characters, we eliminate extra spaces from the resulting substrings. Note that the commas and white-space characters are not returned as part of the substrings. Again, note that the Java string ",\\s\*" represents the regular expression ,\s\*.

**Classes Pattern and Matcher**

In addition to the regular-expression capabilities of class `String`, Java provides other classes in package `java.util.regex` that help developers manipulate regular expressions. Class `Pattern` represents a regular expression. Class `Matcher` contains both a regular-expression pattern and a `CharSequence` in which to search for the pattern.

`CharSequence` is an interface that allows read access to a sequence of characters. The interface requires that the methods `charAt`, `length`, `subSequence` and `toString` be declared. Both `String` and `StringBuilder` implement interface `CharSequence`, so an instance of either of these classes can be used with class `Matcher`.

**Common Programming Error 30.4**

A regular expression can be tested against an object of any class that implements interface `CharSequence`, but the regular expression must be a `String`. Attempting to create a regular expression as a `StringBuilder` is an error.

30.7 Regular Expressions, Class Pattern and Class Matcher 1497

If a regular expression will be used only once, static `Pattern` method `matches` can be used. This method takes a string that specifies the regular expression and a `CharSequence` on which to perform the match. This method returns a boolean indicating whether the search object (the second argument) matches the regular expression.

If a regular expression will be used more than once, it is more efficient to use static `Pattern` method `compile` to create a specific `Pattern` object for that regular expression. This method receives a string representing the pattern and returns a new `Pattern` object, which can then be used to call method `matcher`. This method receives a `CharSequence` to search and returns a `Matcher` object.

`Matcher` provides method `matches`, which performs the same task as `Pattern` method `matches`, but receives no arguments—the search pattern and search object are encapsulated in the `Matcher` object. Class `Matcher` provides other methods, including `find`, `lookingAt`, `replaceFirst` and `replaceAll`.

Figure 30.24 presents a simple example that employs regular expressions. This program matches birthdays against a regular expression. The expression matches only birthdays that do not occur in April and that belong to people whose names begin with "J".

Lines 11–12 create a `Pattern` by invoking static `Pattern` method `compile`. The dot character `.` in the regular expression (line 12) matches any single character except a newline character.

```

1 // Fig. 30.24: RegexMatches.java
2 // Demonstrating Classes Pattern and Matcher.
3 import java.util.regex.Matcher;
4 import java.util.regex.Pattern;
5
6 public class RegexMatches
7 {
8 public static void main(String args[])
9 {
10 // create regular expression
11 Pattern expression =
12 Pattern.compile("J.*\\d[0-35-9]-\\d\\d-\\d\\d");
13
14 String string1 = "Jane's Birthday is 05-12-75\n" +
15 "Dave's Birthday is 11-04-68\n" +
16 "John's Birthday is 04-28-73\n" +
17 "Joe's Birthday is 12-17-77";
18
19 // match regular expression to string and print matches
20 Matcher matcher = expression.matcher(string1);
21
22 while (matcher.find())
23 System.out.println(matcher.group());
24 } // end main
25 } // end class RegexMatches

```

```

Jane's Birthday is 05-12-75
Joe's Birthday is 12-17-77

```

**Fig. 30.24** | Regular expressions checking birthdays.

**1498** Chapter 30 Strings, Characters and Regular Expressions

Line 20 creates the `Matcher` object for the compiled regular expression and the matching sequence (`string1`). Lines 22–23 use a `while` loop to iterate through the string. Line 22 uses `Matcher` method `find` to attempt to match a piece of the search object to the search pattern. Each call to this method starts at the point where the last call ended, so multiple matches can be found. `Matcher` method `lookingAt` performs the same way, except that it always starts from the beginning of the search object and will always find the first match if there is one.

**Common Programming Error 30.5**

*Method `matches` (from class `String`, `Pattern` or `Matcher`) will return true only if the entire search object matches the regular expression. Methods `find` and `lookingAt` (from class `Matcher`) will return true if a portion of the search object matches the regular expression.*

Line 23 uses `Matcher` method `group`, which returns the string from the search object that matches the search pattern. The string that is returned is the one that was last matched by a call to `find` or `lookingAt`. The output in Fig. 30.24 shows the two matches that were found in `string1`.

**Regular Expression Web Resources**

The following websites provide more information on regular expressions.

[java.sun.com/docs/books/tutorial/extra/regex/index.html](http://java.sun.com/docs/books/tutorial/extra/regex/index.html)

This tutorial explains how to use Java's regular-expression API.

[java.sun.com/javase/6/docs/api/java/util/regex/package-summary.html](http://java.sun.com/javase/6/docs/api/java/util/regex/package-summary.html)

This page is the javadoc overview of package `java.util.regex`.

[developer.java.sun.com/developer/technicalArticles/releases/1.4regex](http://developer.java.sun.com/developer/technicalArticles/releases/1.4regex)

Thoroughly describes Java's regular-expression capabilities.

## 30.8 Wrap-Up

In this chapter, you learned about more `String` methods for selecting portions of `Strings` and manipulating `Strings`. You also learned about the `Character` class and some of the methods it declares to handle `chars`. The chapter also discussed the capabilities of the `StringBuilder` class for creating `Strings`. The end of the chapter discussed regular expressions, which provide a powerful capability to search and match portions of `Strings` that fit a particular pattern.

## Summary

### Section 30.2 Fundamentals of Characters and Strings

- A character literal's value is its integer value in the Unicode character set. `Strings` can include letters, digits and special characters such as `+`, `-`, `*`, `/` and `$`. A `String` in Java is an object of class `String`. `String` literals are often referred to as `String` objects and are written in double quotes in a program.

### Section 30.3 Class `String`

- `String` objects are immutable—their character contents cannot be changed after they are created.

**Summary 1499**

- `String` method `length` returns the number of characters in a `String`.
- `String` method `charAt` returns the character at a specific position.
- `String` method `equals` tests any two objects for equality. The method returns `true` if the contents of the `Strings` are equal, `false` otherwise. Method `equals` uses a lexicographical comparison for `Strings`.
- When primitive-type values are compared with `==`, the result is `true` if both values are identical. When references are compared with `==`, the result is `true` if both references refer to the same object in memory.
- Java treats all string literals with the same contents as a single `String` object.
- `String` method `equalsIgnoreCase` performs a case-insensitive string comparison.
- `String` method `compareTo` uses a lexicographical comparison and returns 0 if the strings it is comparing are equal, a negative number if the string that `compareTo` is invoked on is less than the `String` that is passed as an argument and a positive number if the string that `compareTo` is invoked on is greater than the string that is passed as an argument.
- `String` method `regionMatches` compares portions of two strings for equality.
- `String` method `startsWith` determines whether a string starts with the characters specified as an argument. `String` method `endsWith` determines whether a string ends with the characters specified as an argument.
- `String` method `indexOf` locates the first occurrence of a character or a substring in a string. `String` method `lastIndexOf` locates the last occurrence of a character or a substring in a string.
- `String` method `substring` copies and returns part of an existing string object.
- `String` method `concat` concatenates two string objects and returns a new string object containing the characters from both original strings.
- `String` method `replace` returns a new string object that replaces every occurrence in a `String` of its first character argument with its second character argument.
- `String` method `toUpperCase` returns a new string with uppercase letters in the positions where the original string had lowercase letters. `String` method `toLowerCase` returns a new string with lowercase letters in the positions where the original string had uppercase letters.
- `String` method `trim` returns a new string object in which all white-space characters (e.g., spaces, newlines and tabs) have been removed from the beginning and end of a string.
- `String` method `toCharArray` returns a char array containing a copy of the string's characters.
- `String` class static method `valueOf` returns its argument converted to a string.

**Section 30.4 Class `StringBuilder`**

- Class `StringBuilder` provides constructors that enable `StringBuilder`s to be initialized with no characters and an initial capacity of 16 characters, with no characters and an initial capacity specified in the integer argument, or with a copy of the characters of the `String` argument and an initial capacity that is the number of characters in the `String` argument plus 16.
- `StringBuilder` method `length` returns the number of characters currently stored in a `StringBuilder`. `StringBuilder` method `capacity` returns the number of characters that can be stored in a `StringBuilder` without allocating more memory.
- `StringBuilder` method `ensureCapacity` ensures that a `StringBuilder` has at least the specified capacity. `StringBuilder` method `setLength` increases or decreases the length of a `StringBuilder`.
- `StringBuilder` method `charAt` returns the character at the specified index. `StringBuilder` method `setCharAt` sets the character at the specified position. `StringBuilder` method `getChars` copies characters in the `StringBuilder` into the character array passed as an argument.

## 1500 Chapter 30 Strings, Characters and Regular Expressions

- Class `StringBuilder` provides overloaded `append` methods to add primitive-type, character array, `String`, `Object` and `CharSequence` values to the end of a `StringBuilder`. `StringBuilder`s and the `append` methods are used by the Java compiler to implement the `+` and `+=` concatenation operators.
- Class `StringBuilder` provides overloaded `insert` methods to insert primitive-type, character array, `String`, `Object` and `CharSequence` values at any position in a `StringBuilder`.

### *Section 30.5 Class Character*

- Class `Character` provides a constructor that takes a `char` argument.
- `Character` method `isDefined` determines whether a character is defined in the Unicode character set. If so, the method returns `true`—otherwise, it returns `false`.
- `Character` method `isDigit` determines whether a character is a defined Unicode digit. If so, the method returns `true`—otherwise, it returns `false`.
- `Character` method `isJavaIdentifierStart` determines whether a character can be used as the first character of an identifier in Java [i.e., a letter, an underscore (`_`) or a dollar sign (`$`)]. If so, the method returns `true`—otherwise, it returns `false`.
- `Character` method `isJavaIdentifierPart` determines whether a character can be used in an identifier in Java [i.e., a digit, a letter, an underscore (`_`) or a dollar sign (`$`)]. `Character` method `isLetter` determines whether a character is a letter. `Character` method `isLetterOrDigit` determines whether a character is a letter or a digit. In each case, if so, the method returns `true`—otherwise, it returns `false`.
- `Character` method `isLowerCase` determines whether a character is a lowercase letter. `Character` method `isUpperCase` determines whether a character is an uppercase letter. In both cases, if so, the method returns `true`—otherwise, `false`.
- `Character` method `toUpperCase` converts a character to its uppercase equivalent. `Character` method `toLowerCase` converts a character to its lowercase equivalent.
- `Character` method `digit` converts its character argument into an integer in the number system specified by its integer argument `radix`. `Character` method `forDigit` converts its integer argument `digit` into a character in the number system specified by its integer argument `radix`.
- `Character` method `charValue` returns the `char` stored in a `Character` object. `Character` method `toString` returns a `String` representation of a `Character`.

### *Section 30.6 Class StringTokenizer*

- `StringTokenizer`'s default constructor creates a `StringTokenizer` for its string argument that will use the default delimiter string "`\t\n\r\f`", consisting of a space, a tab, a newline and a carriage return for tokenization.
- `StringTokenizer` method `countTokens` returns the number of tokens in a string to be tokenized.
- `StringTokenizer` method `hasMoreTokens` determines whether there are more tokens in the string being tokenized.
- `StringTokenizer` method `nextToken` returns a `String` with the next token.

### *Section 30.7 Regular Expressions, Class Pattern and Class Matcher*

- Regular expressions are sequences of characters and symbols that define a set of strings. They are useful for validating input and ensuring that data is in a particular format.
- `String` method `matches` receives a string that specifies the regular expression and matches the contents of the `String` object on which it is called to the regular expression. The method returns a `boolean` indicating whether the match succeeded.

[Summary](#)**1501**

- A character class is an escape sequence that represents a group of characters. Each character class matches a single character in the string we are attempting to match with the regular expression.
- A word character (`\w`) is any letter (uppercase or lowercase), any digit or the underscore character.
- A whitespace character (`\s`) is a space, a tab, a carriage return, a newline or a form feed.
- A digit (`\d`) is any numeric character.
- To match a set of characters that does not have a predefined character class, use square brackets, `[]`. Ranges can be represented by placing a dash (-) between two characters. If the first character in the brackets is "`^`", the expression accepts any character other than those indicated.
- When the regular expression operator `"*"` appears in a regular expression, the program attempts to match zero or more occurrences of the subexpression immediately preceding the `"*"`.
- Operator `"+"` attempts to match one or more occurrences of the subexpression preceding it.
- The character `"|"` allows a match of the expression to its left or to its right.
- The parentheses `( )` are used to group parts of the regular expression.
- The asterisk `(*)` and plus `(+)` are formally called quantifiers.
- All quantifiers affect only the subexpression immediately preceding the quantifier.
- Quantifier question mark `(?)` matches zero or one occurrences of the expression that it quantifies.
- A set of braces containing one number `{n}` matches exactly  $n$  occurrences of the expression it quantifies. Including a comma after the number enclosed in braces matches at least  $n$  occurrences of the quantified expression.
- A set of braces containing two numbers `{n,m}` matches between  $n$  and  $m$  occurrences of the expression that it qualifies.
- All of the quantifiers are greedy, which means that they will match as many occurrences as they can as long as the match is successful.
- If any of these quantifiers is followed by a question mark `(?)`, the quantifier becomes reluctant, matching as few occurrences as possible as long as the match is successful.
- `String` method `replaceAll` replaces text in a string with new text (the second argument) wherever the original string matches a regular expression (the first argument).
- Escaping a special regular-expression character with a `\` instructs the regular-expression matching engine to find the actual character, as opposed to what it represents in a regular expression.
- `String` method `replaceFirst` replaces the first occurrence of a pattern match. Java `Strings` are immutable, therefore method `replaceFirst` returns a new string in which the appropriate characters have been replaced.
- `String` method `split` divides a string into several substrings. The original string is broken in any location that matches a specified regular expression. Method `split` returns an array of strings containing the substrings between matches for the regular expression.
- Class `Pattern` represents a regular expression.
- Class `Matcher` contains both a regular-expression pattern and a `CharSequence` in which to search for the pattern.
- `CharSequence` is an interface that allows read access to a sequence of characters. Both `String` and `StringBuilder` implement interface `CharSequence`, so an instance of either of these classes can be used with class `Matcher`.
- If a regular expression will be used only once, static `Pattern` method `matches` takes a string that specifies the regular expression and a `CharSequence` on which to perform the match. This method returns a `boolean` indicating whether the search object matches the regular expression.

## 1502 Chapter 30 Strings, Characters and Regular Expressions

- If a regular expression will be used more than once, it is more efficient to use static `Pattern` method `compile` to create a specific `Pattern` object for that regular expression. This method receives a string representing the pattern and returns a new `Pattern` object.
- `Pattern` method `matcher` receives a `CharSequence` to search and returns a `Matcher` object.
- `Matcher` method `matches` performs the same task as `Pattern` method `matches`, but receives no arguments.
- `Matcher` method `find` attempts to match a piece of the search object to the search pattern. Each call to this method starts at the point where the last call ended, so multiple matches can be found.
- `Matcher` method `lookingAt` performs the same as `find`, except that it always starts from the beginning of the search object and will always find the first match if there is one.
- `Matcher` method `group` returns the string from the search object that matches the search pattern. The string that is returned is the one that was last matched by a call to `find` or `lookingAt`.

<code>lastIndexOf</code> method of class <code>String</code>	word character

Self-Review Exercises **1503****Self-Review Exercises**

- 30.1** State whether each of the following is *true* or *false*. If *false*, explain why.
- When `String` objects are compared using `==`, the result is *true* if the `Strings` contain the same values.
  - A `String` can be modified after it is created.
- 30.2** For each of the following, write a single statement that performs the indicated task:
- Compare the string in `s1` to the string in `s2` for equality of contents.
  - Append the string `s2` to the string `s1`, using `+=`.
  - Determine the length of the string in `s1`.

**Answers to Self-Review Exercises**

- 30.1** a) False. `String` objects are compared using operator `==` to determine whether they are the same object in memory.  
 b) False. `String` objects are immutable and cannot be modified after they are created. `StringBuilder` objects can be modified after they are created.
- 30.2** a) `s1.equals( s2 )`  
 b) `s1 += s2;`  
 c) `s1.length()`

**Exercises**

**30.3** Write an application that uses `String` method `compareTo` to compare two strings input by the user. Output whether the first string is less than, equal to or greater than the second.

**30.4** Write an application that uses `String` method `regionMatches` to compare two strings input by the user. The application should input the number of characters to be compared and the starting index of the comparison. The application should state whether the strings are equal. Ignore the case of the characters when performing the comparison.

**30.5** Write an application that uses random-number generation to create sentences. Use four arrays of strings called `article`, `noun`, `verb` and `preposition`. Create a sentence by selecting a word at random from each array in the following order: `article`, `noun`, `verb`, `preposition`, `article` and `noun`. As each word is picked, concatenate it to the previous words in the sentence. The words should be separated by spaces. When the final sentence is output, it should start with a capital letter and end with a period. The application should generate 20 sentences and output them to a text area.

**30.6** The `article` array should contain the articles "the", "a", "one", "some" and "any"; the `noun` array should contain the nouns "boy", "girl", "dog", "town" and "car"; the `verb` array should contain the verbs "drove", "jumped", "ran", "walked" and "skipped"; the `preposition` array should contain the prepositions "to", "from", "over", "under" and "on".

**30.7** After the preceding application is written, modify it to produce a short story consisting of several of these sentences. (How about the possibility of a random term-paper writer?)

**30.8** (*Limericks*) A limerick is a humorous five-line verse in which the first and second lines rhyme with the fifth, and the third line rhymes with the fourth. Using techniques similar to those developed in Exercise 30.5, write a Java application that produces random limericks. Polishing this application to produce good limericks is a challenging problem, but the result will be worth the effort!

**30.9** (*Pig Latin*) Write an application that encodes English-language phrases into pig Latin. Pig Latin is a form of coded language. There are many different ways to form pig Latin phrases. For simplicity, use the following algorithm:

**1504 Chapter 30 Strings, Characters and Regular Expressions**

To form a pig Latin phrase from an English-language phrase, tokenize the phrase into words with an object of class  `StringTokenizer`. To translate each English word into a pig Latin word, place the first letter of the English word at the end of the word and add the letters "ay." Thus, the word "jump" becomes "umpjay," the word "the" becomes "hetay," and the word "computer" becomes "omputercay." Blanks between words remain as blanks. Assume the following: The English phrase consists of words separated by blanks, there are no punctuation marks and all words have two or more letters. Method `printLatinWord` should display each word. Each token returned from `nextToken` is passed to method `printLatinWord` to print the pig Latin word. Enable the user to input the sentence. Keep a running display of all the converted sentences in a textarea.

**30.10** Write an application that inputs a telephone number as a string in the form (555) 555-5555. The application should use an object of class  `StringTokenizer` to extract the area code as a token, the first three digits of the phone number as a token and the last four digits of the phone number as a token. The seven digits of the phone number should be concatenated into one string. Both the area code and the phone number should be printed. Remember that you will have to change delimiter characters during the tokenization process.

**30.11** Write an application that inputs a line of text, tokenizes the line with an object of class  `StringTokenizer` and outputs the tokens in reverse order. Use space characters as delimiters.

**30.12** Use the string-comparison methods discussed in this chapter and the techniques for sorting arrays developed in Chapter 16 to write an application that alphabetizes a list of strings. Allow the user to enter the strings in a text field. Display the results in a textarea.

**30.13** Write an application that inputs a line of text and outputs the text twice—once in all uppercase letters and once in all lowercase letters.

**30.14** Write an application that inputs a line of text and a search character and uses `String` method `indexOf` to determine the number of occurrences of the character in the text.

**30.15** Write an application based on the application in Exercise 30.14 that inputs a line of text and uses `String` method `indexOf` to determine the total number of occurrences of each letter of the alphabet in the text. Uppercase and lowercase letters should be counted together. Store the totals for each letter in an array, and print the values in tabular format after the totals have been determined.

**30.16** Write an application that reads a line of text, tokenizes the line using space characters as delimiters and outputs only those words beginning with the letter "b".

**30.17** Write an application that reads a line of text, tokenizes it using space characters as delimiters and outputs only those words ending with the letters "ED".

**30.18** Write an application that inputs an integer code for a character and displays the corresponding character. Modify this application so that it generates all possible three-digit codes in the range from 000 to 255 and attempts to print the corresponding characters.

**30.19** Write your own versions of `String` search methods `indexOf` and `lastIndexOf`.

**30.20** Write an application that reads a five-letter word from the user and produces every possible three-letter string that can be derived from the letters of that word. For example, the three-letter words produced from the word "bathe" include "ate," "bat," "bet," "tab," "hat," "the" and "tea."

### Special Section: Advanced String-Manipulation Exercises

The preceding exercises are keyed to the text and designed to test your understanding of fundamental string-manipulation concepts. This section includes a collection of intermediate and advanced string-manipulation exercises. You should find these problems challenging, yet entertaining. The problems vary considerably in difficulty. Some require an hour or two of application writ-

## Special Section: Advanced String-Manipulation Exercises

1505

ing and implementation. Others are useful for lab assignments that might require two or three weeks of study and implementation. Some are challenging term projects.

**30.21** (*Text Analysis*) The availability of computers with string-manipulation capabilities has resulted in some rather interesting approaches to analyzing the writings of great authors. Much attention has been focused on whether William Shakespeare ever lived. Some scholars believe there is substantial evidence indicating that Christopher Marlowe actually penned the masterpieces attributed to Shakespeare. Researchers have used computers to find similarities in the writings of these two authors. This exercise examines three methods for analyzing texts with a computer.

- Write an application that reads a line of text from the keyboard and prints a table indicating the number of occurrences of each letter of the alphabet in the text. For example,

To be, or not to be: that is the question:

contains one “a,” two “b’s,” no “c’s,” and so on.

- Write an application that reads a line of text and prints a table indicating the number of one-letter words, two-letter words, three-letter words, and so on, appearing in the text. For example, Fig. 30.25 shows the counts for the phrase

Whether 'tis nobler in the mind to suffer

- Write an application that reads a line of text and prints a table indicating the number of occurrences of each different word in the text. The first version of your application should include the words in the table in the same order in which they appear in the text. For example, the lines

To be, or not to be: that is the question:

Whether 'tis nobler in the mind to suffer

contain the word “to” three times, the word “be” two times, the word “or” once, and so on. A more interesting (and useful) printout should then be attempted in which the words are sorted alphabetically.

**30.22** (*Printing Dates in Various Formats*) Dates are printed in several common formats. Two of the more common formats are

04/25/1955 and April 25, 1955

Write an application that reads a date in the first format and prints it in the second format.

Word length	Occurrences
1	0
2	2
3	1
4	2 (including 'tis)
5	0
6	2
7	1

**Fig. 30.25** | Word-length counts for the string  
"Whether 'tis nobler in the mind to suffer".

**1506**    [Chapter 30 Strings, Characters and Regular Expressions](#)

**30.23** (*Check Protection*) Computers are frequently employed in check-writing systems, such as payroll and accounts payable applications. There are many strange stories about weekly paychecks being printed (by mistake) for amounts in excess of \$1 million. Incorrect amounts are printed by computerized check-writing systems because of human error or machine failure. Systems designers build controls into their systems to prevent such erroneous checks from being issued.

Another serious problem is the intentional alteration of a check amount by someone who plans to cash a check fraudulently. To prevent a dollar amount from being altered, some computerized check-writing systems employ a technique called check protection. Checks designed for imprinting by computer contain a fixed number of spaces in which the computer may print an amount. Suppose a paycheck contains eight blank spaces in which the computer is supposed to print the amount of a weekly paycheck. If the amount is large, then all eight of the spaces will be filled. For example,

```
1,230.60 (check amount)

12345678 (position numbers)
```

On the other hand, if the amount is less than \$1000, then several of the spaces would ordinarily be left blank. For example,

```
99.87

12345678
```

contains three blank spaces. If a check is printed with blank spaces, it is easier for someone to alter the amount of the check. To prevent a check from being altered, many check-writing systems insert *leading asterisks* to protect the amount as follows:

```
***99.87

12345678
```

Write an application that inputs a dollar amount to be printed on a check, then prints the amount in check-protected format with leading asterisks if necessary. Assume that nine spaces are available for printing the amount.

**30.24** (*Writing the Word Equivalent of a Check Amount*) Continuing the discussion in Exercise 30.23, we reiterate the importance of designing check-writing systems to prevent alteration of check amounts. One common security method requires that the check amount be written in numbers and spelled out in words as well. Even if someone is able to alter the numerical amount of the check, it is extremely difficult to change the amount in words. Write an application that inputs a numeric check amount and writes the word equivalent of the amount. For example, the amount 112.43 should be written as

ONE hundred TWELVE and 43/100

**30.25** (*Morse Code*) Perhaps the most famous of all coding schemes is the Morse code, developed by Samuel Morse in 1832 for use with the telegraph system. The Morse code assigns a series of dots and dashes to each letter of the alphabet, each digit, and a few special characters (e.g., period, comma, colon, semicolon). In sound-oriented systems, the dot represents a short sound and the dash represents a long sound. Other representations of dots and dashes are used with light-oriented systems and signal-flag systems. Separation between words is indicated by a space or, simply, the absence of a dot or dash. In a sound-oriented system, a space is indicated by a short time during which no sound is transmitted. The international version of the Morse code appears in Fig. 30.26.

N	-.	5	.....
O	---	6	-.....
P	.---.	7	----..
Q	---.	8	----..-
R	.-.	9	----.
S	...	0	-----

**Fig. 30.26** | The letters of the alphabet as expressed in international Morse code.

Write an application that reads an English-language phrase and encodes it into Morse code. Also write an application that reads a phrase in Morse code and converts it into the English-language equivalent. Use one blank between each Morse-coded letter and three blanks between each Morse-coded word.

**30.26 (Metric Conversion Application)** Write an application that will assist the user with metric conversions. Your application should allow the user to specify the names of the units as strings (i.e., centimeters, liters, grams, and so on, for the metric system and inches, quarts, pounds, and so on, for the English system) and should respond to simple questions, such as

```
"How many inches are in 2 meters?"
"How many liters are in 10 quarts?"
```

Your application should recognize invalid conversions. For example, the question

```
"How many feet are in 5 kilograms?"
```

is not meaningful because "feet" is a unit of length, whereas "kilograms" is a unit of mass.

**1508** Chapter 30 Strings, Characters and Regular Expressions

### Special Section: Challenging String-Manipulation Projects

**30.27** (*Project: A Spelling Checker*) Many popular word-processing software packages have built-in spell checkers. In this project, you are asked to develop your own spell-checker utility. We make suggestions to help get you started. You should then consider adding more capabilities. Use a computerized dictionary (if you have access to one) as a source of words.

Why do we type so many words with incorrect spellings? In some cases, it is because we simply do not know the correct spelling, so we make a best guess. In some cases, it is because we transpose two letters (e.g., “default” instead of “default”). Sometimes we double-type a letter accidentally (e.g., “hanndy” instead of “handy”). Sometimes we type a nearby key instead of the one we intended (e.g., “biryhday” instead of “birthday”), and so on.

Design and implement a spell-checker application in Java. Your application should maintain an array `wordList` of strings. Enable the user to enter these strings. [*Note:* In Chapter 14, we have introduced file processing. With this capability, you can obtain the words for the spell checker from a computerized dictionary stored in a file.]

Your application should ask a user to enter a word. The application should then look up that word in the `wordList` array. If the word is in the array, your application should print “Word is spelled correctly.” If the word is not in the array, your application should print “Word is not spelled correctly.” Then your application should try to locate other words in `wordList` that might be the word the user intended to type. For example, you can try all possible single transpositions of adjacent letters to discover that the word “default” is a direct match to a word in `wordList`. Of course, this implies that your application will check all other single transpositions, such as “edfault,” “dfeault,” “deafult,” “defalut” and “defautl.” When you find a new word that matches one in `wordList`, print it in a message, such as

Did you mean “default”?

Implement other tests, such as replacing each double letter with a single letter, and any other tests you can develop to improve the value of your spell checker.

**30.28** (*Project: A Crossword Puzzle Generator*) Most people have worked a crossword puzzle, but few have ever attempted to generate one. Generating a crossword puzzle is suggested here as a string-manipulation project requiring substantial sophistication and effort.

There are many issues the programmer must resolve to get even the simplest crossword-puzzle-generator application working. For example, how do you represent the grid of a crossword puzzle inside the computer? Should you use a series of strings or two-dimensional arrays?

The programmer needs a source of words (i.e., a computerized dictionary) that can be directly referenced by the application. In what form should these words be stored to facilitate the complex manipulations required by the application?

If you are really ambitious, you will want to generate the clues portion of the puzzle, in which the brief hints for each across word and each down word are printed. Merely printing a version of the blank puzzle itself is not a simple problem.

# Operator Precedence Chart

## A.1 Operator Precedence

Operators are shown in decreasing order of precedence from top to bottom (Fig. A.1).

Operator	Description	Associativity
<code>++</code>	unary postfix increment	right to left
<code>--</code>	unary postfix decrement	
<code>++</code>	unary prefix increment	right to left
<code>--</code>	unary prefix decrement	
<code>+</code>	unary plus	
<code>-</code>	unary minus	
<code>!</code>	unary logical negation	
<code>~</code>	unary bitwise complement	
<code>( type )</code>	unary cast	
<code>*</code>	multiplication	left to right
<code>/</code>	division	
<code>%</code>	remainder	
<code>+</code>	addition or string concatenation	left to right
<code>-</code>	subtraction	
<code>&lt;&lt;</code>	left shift	left to right
<code>&gt;&gt;</code>	signed right shift	
<code>&gt;&gt;&gt;</code>	unsigned right shift	

**Fig. A.1** | Operator precedence chart. (Part I of 2.)

**1510** Chapter A Operator Precedence Chart

Operator	Description	Associativity
<	less than	left to right
<=	less than or equal to	
>	greater than	
>=	greater than or equal to	
<code>instanceof</code>	type comparison	
<code>==</code>	is equal to	left to right
<code>!=</code>	is not equal to	
<code>&amp;</code>	bitwise AND boolean logical AND	left to right
<code>^</code>	bitwise exclusive OR boolean logical exclusive OR	left to right
<code> </code>	bitwise inclusive OR boolean logical inclusive OR	left to right
<code>&amp;&amp;</code>	conditional AND	left to right
<code>  </code>	conditional OR	left to right
<code>?:</code>	conditional	right to left
<code>=</code>	assignment	right to left
<code>+=</code>	addition assignment	
<code>-=</code>	subtraction assignment	
<code>*=</code>	multiplication assignment	
<code>/=</code>	division assignment	
<code>%=</code>	remainder assignment	
<code>&amp;=</code>	bitwise AND assignment	
<code>^=</code>	bitwise exclusive OR assignment	
<code> =</code>	bitwise inclusive OR assignment	
<code>&lt;&lt;=</code>	bitwise left shift assignment	
<code>&gt;&gt;=</code>	bitwise signed-right-shift assignment	
<code>&gt;&gt;&gt;=</code>	bitwise unsigned-right-shift assignment

## ASCII Character Set

	0	1	2	3	4	5	6	7	8	9
0	nul	soh	stx	etx	eot	enq	ack	bel	bs	ht
1	n1	vt	ff	cr	so	si	dle	dc1	dc2	dc3
2	dc4	nak	syn	etb	can	em	sub	esc	fs	gs
3	rs	us	sp	!	"	#	\$	%	&	'
4	(	)	*	+	,	-	.	/	0	1
5	2	3	4	5	6	7	8	9	:	;
6	<	=	>	?	@	A	B	C	D	E
7	F	G	H	I	J	K	L	M	N	O
8	P	Q	R	S	T	U	V	W	X	Y
9	Z	[	\	]	^	_	,	a	b	c
10	d	e	f	g	h	i	j	k	l	m
11	n	o	p	q	r	s	t	u	v	w
12	x	y	z	{		}	~	del		

**Fig. B.1** | ASCII character set.

The digits at the left of the table are the left digits of the decimal equivalent (0–127) of the character code, and the digits at the top of the table are the right digits of the character code. For example, the character code for “F” is 70, and the character code for “&” is 38.

Most users of this book are interested in the ASCII character set used to represent English characters on many computers. The ASCII character set is a subset of the Unicode character set used by Java to represent characters from most of the world’s languages. For more information on the Unicode character set, see the web bonus Appendix I, Unicode®.

## Keywords and Reserved Words

Java Keywords				
abstract	assert	boolean	break	byte
case	catch	char	class	continue
default	do	double	else	enum
extends	final	finally	float	for
if	implements	import	instanceof	int
interface	long	native	new	package
private	protected	public	return	short
static	strictfp	super	switch	synchronized
this	throw	throws	transient	try
void	volatile	while		
<i>Keywords that are not currently used</i>				
const	goto			

**Fig. C.1** | Java keywords.

Java also contains the reserved words `true` and `false`, which are `boolean` literals, and `null`, which is the literal that represents a reference to nothing. Like keywords, these reserved words cannot be used as identifiers.

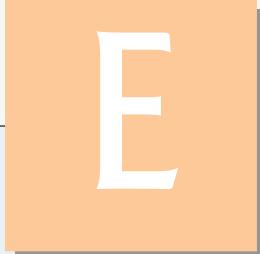

# Primitive Types

Type	Size in bits	Values	Standard
<code>boolean</code>		<code>true</code> or <code>false</code>	
<i>[Note: A <code>boolean</code>'s representation is specific to the Java Virtual Machine on each platform.]</i>			
<code>char</code>	16	<code>'\u0000'</code> to <code>'\uFFFF'</code> (0 to 65535)	(ISO Unicode character set)
<code>byte</code>	8	-128 to +127 (-2 <sup>7</sup> to 2 <sup>7</sup> - 1)	
<code>short</code>	16	-32,768 to +32,767 (-2 <sup>15</sup> to 2 <sup>15</sup> - 1)	
<code>int</code>	32	-2,147,483,648 to +2,147,483,647 (-2 <sup>31</sup> to 2 <sup>31</sup> - 1)	
<code>long</code>	64	-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807 (-2 <sup>63</sup> to 2 <sup>63</sup> - 1)	
<code>float</code>	32	<i>Negative range:</i> -3.4028234663852886E+38 to -1.40129846432481707e-45 <i>Positive range:</i> 1.40129846432481707e-45 to 3.4028234663852886E+38	(IEEE 754 floating point)
<code>double</code>	64	<i>Negative range:</i> -1.7976931348623157E+308 to -4.94065645841246544e-324 <i>Positive range:</i> 4.94065645841246544e-324 to 1.7976931348623157E+308	(IEEE 754 floating point)

**Fig. D.1** | Java primitive types.

# Number Systems

## OBJECTIVES

In this appendix you will learn:

- To understand basic number systems concepts, such as base, positional value and symbol value.
- To understand how to work with numbers represented in the binary, octal and hexadecimal number systems.
- To abbreviate binary numbers as octal numbers or hexadecimal numbers.
- To convert octal numbers and hexadecimal numbers to binary numbers.
- To convert back and forth between decimal numbers and their binary, octal and hexadecimal equivalents.
- To understand binary arithmetic and how negative binary numbers are represented using two's complement notation.

*Here are only numbers ratified.*

—William Shakespeare

*Nature has some sort of arithmetic-geometrical coordinate system, because nature has all kinds of models. What we experience of nature is in models, and all of nature's models are so beautiful.*

*It struck me that nature's system must be a real beauty, because in chemistry we find that the associations are always in beautiful whole numbers—there are no fractions.*

—Richard Buckminster Fuller

**E.1 Introduction 1515**

## E.1 Introduction

In this appendix, we introduce the key number systems that Java programmers use, especially when they are working on software projects that require close interaction with machine-level hardware. Projects like this include operating systems, computer networking software, compilers, database systems and applications requiring high performance.

When we write an integer such as 227 or -63 in a Java program, the number is assumed to be in the decimal (base 10) number system. The digits in the decimal number system are 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9. The lowest digit is 0 and the highest digit is 9—one less than the base of 10. Internally, computers use the binary (base 2) number system. The binary number system has only two digits, namely 0 and 1. Its lowest digit is 0 and its highest digit is 1—one less than the base of 2.

As we will see, binary numbers tend to be much longer than their decimal equivalents. Programmers who work in assembly languages and in high-level languages like Java that enable programmers to reach down to the machine level, find it cumbersome to work with binary numbers. So two other number systems—the octal number system (base 8) and the hexadecimal number system (base 16)—are popular primarily because they make it convenient to abbreviate binary numbers.

In the octal number system, the digits range from 0 to 7. Because both the binary number system and the octal number system have fewer digits than the decimal number system, their digits are the same as the corresponding digits in decimal.

The hexadecimal number system poses a problem because it requires 16 digits—a lowest digit of 0 and a highest digit with a value equivalent to decimal 15 (one less than the base of 16). By convention, we use the letters A through F to represent the hexadecimal digits corresponding to decimal values 10 through 15. Thus in hexadecimal we can have numbers like 876 consisting solely of decimal-like digits, numbers like 8A55F consisting of digits and letters and numbers like FFE consisting solely of letters. Occasionally, a hexadecimal number spells a common word such as FACE or FEED—this can appear strange to programmers accustomed to working with numbers. The digits of the binary, octal, decimal and hexadecimal number systems are summarized in Fig. E.1–Fig. E.2.

Each of these number systems uses positional notation—each position in which a digit is written has a different positional value. For example, in the decimal number 937 (the 9, the 3 and the 7 are referred to as symbol values), we say that the 7 is written in the ones position, the 3 is written in the tens position and the 9 is written in the hundreds position. Note that each of these positions is a power of the base (base 10) and that these powers begin at 0 and increase by 1 as we move left in the number (Fig. E.3).

**1516** Appendix E Number Systems

Binary digit	Octal digit	Decimal digit	Hexadecimal digit
0	0	0	0
1	1	1	1
	2	2	2
	3	3	3
	4	4	4
	5	5	5
	6	6	6
	7	7	7
		8	8
		9	9
			A (decimal value of 10)
			B (decimal value of 11)
			C (decimal value of 12)
			D (decimal value of 13)
			E (decimal value of 14)
			F (decimal value of 15)

**Fig. E.1** | Digits of the binary, octal, decimal and hexadecimal number systems.

Attribute	Binary	Octal	Decimal	Hexadecimal
Base	2	8	10	16
Lowest digit	0	0	0	0
Highest digit	1	7	9	F

**Fig. E.2** | Comparing the binary, octal, decimal and hexadecimal number systems.

Positional values in the decimal number system			
Decimal digit	9	3	7
Position name	Hundreds	Tens	Ones
Positional value	100	10	1
Positional value as a power of the base (10)	$10^2$	$10^1$	$10^0$

**Fig. E.3** | Positional values in the decimal number system.

For longer decimal numbers, the next positions to the left would be the thousands position (10 to the 3rd power), the ten-thousands position (10 to the 4th power), the hun-

E.1 Introduction **1517**

dred-thousands position (10 to the 5th power), the millions position (10 to the 6th power), the ten-millions position (10 to the 7th power) and so on.

In the binary number 101, the rightmost 1 is written in the ones position, the 0 is written in the twos position and the leftmost 1 is written in the fours position. Note that each position is a power of the base (base 2) and that these powers begin at 0 and increase by 1 as we move left in the number (Fig. E.4). So,  $101 = 2^2 + 2^0 = 4 + 1 = 5$ .

For longer binary numbers, the next positions to the left would be the eights position (2 to the 3rd power), the sixteens position (2 to the 4th power), the thirty-twos position (2 to the 5th power), the sixty-four position (2 to the 6th power) and so on.

In the octal number 425, we say that the 5 is written in the ones position, the 2 is written in the eights position and the 4 is written in the sixty-four position. Note that each of these positions is a power of the base (base 8) and that these powers begin at 0 and increase by 1 as we move left in the number (Fig. E.5).

For longer octal numbers, the next positions to the left would be the five-hundred-and-twelves position (8 to the 3rd power), the four-thousand-and-ninety-sixes position (8 to the 4th power), the thirty-two-thousand-seven-hundred-and-sixty-eights position (8 to the 5th power) and so on.

In the hexadecimal number 3DA, we say that the A is written in the ones position, the D is written in the sixteens position and the 3 is written in the two-hundred-and-fifty-sixes position. Note that each of these positions is a power of the base (base 16) and that these powers begin at 0 and increase by 1 as we move left in the number (Fig. E.6).

For longer hexadecimal numbers, the next positions to the left would be the four-thousand-and-ninety-sixes position (16 to the 3rd power), the sixty-five-thousand-five-hundred-and-thirty-sixes position (16 to the 4th power) and so on.

Positional values in the binary number system			
Binary digit	1	0	1
Position name	Fours	Twos	Ones
Positional value	4	2	1
Positional value as a power of the base (2)	$2^2$	$2^1$	$2^0$

**Fig. E.4** | Positional values in the binary number system.

Positional values in the octal number system			
Decimal digit	4	2	5
Position name	Sixty-four	Eights	Ones
Positional value	64	8	1
Positional value as a power of the base (8)	$8^2$	$8^1$	$8^0$

**Fig. E.5** | Positional values in the octal number system.

**1518** Appendix E Number Systems

Positional values in the hexadecimal number system			
Decimal digit	3	D	A
Position name	Two-hundred-and-fifty-sixes	Sixteens	Ones
Positional value	256	16	1
Positional value as a power of the base (16)	$16^2$	$16^1$	$16^0$

**Fig. E.6** | Positional values in the hexadecimal number system.

## E.2 Abbreviating Binary Numbers as Octal and Hexadecimal Numbers

The main use for octal and hexadecimal numbers in computing is for abbreviating lengthy binary representations. Figure E.7 highlights the fact that lengthy binary numbers can be expressed concisely in number systems with higher bases than the binary number system.

Decimal number	Binary representation	Octal representation	Hexadecimal representation
0	0	0	0
1	1	1	1
2	10	2	2
3	11	3	3
4	100	4	4
5	101	5	5
6	110	6	6
7	111	7	7
8	1000	10	8
9	1001	11	9
10	1010	12	A
11	1011	13	B
12	1100	14	C
13	1101	15	D
14	1110	16	E
15	1111	17	F
16	10000	20	10

**Fig. E.7** | Decimal, binary, octal and hexadecimal equivalents.

### E.3 Converting Octal and Hexadecimal Numbers to Binary Numbers 1519

A particularly important relationship that both the octal number system and the hexadecimal number system have to the binary system is that the bases of octal and hexadecimal (8 and 16 respectively) are powers of the base of the binary number system (base 2). Consider the following 12-digit binary number and its octal and hexadecimal equivalents. See if you can determine how this relationship makes it convenient to abbreviate binary numbers in octal or hexadecimal. The answer follows the numbers.

Binary number	Octal equivalent	Hexadecimal equivalent
100011010001	4321	8D1

To see how the binary number converts easily to octal, simply break the 12-digit binary number into groups of three consecutive bits each and write those groups over the corresponding digits of the octal number as follows:

100	011	010	001
4	3	2	1

Note that the octal digit you have written under each group of three bits corresponds precisely to the octal equivalent of that 3-digit binary number, as shown in Fig. E.7.

The same kind of relationship can be observed in converting from binary to hexadecimal. Break the 12-digit binary number into groups of four consecutive bits each and write those groups over the corresponding digits of the hexadecimal number as follows:

1000	1101	0001
8	D	1

Notice that the hexadecimal digit you wrote under each group of four bits corresponds precisely to the hexadecimal equivalent of that 4-digit binary number as shown in Fig. E.7.

### E.3 Converting Octal and Hexadecimal Numbers to Binary Numbers

In the previous section, we saw how to convert binary numbers to their octal and hexadecimal equivalents by forming groups of binary digits and simply rewriting them as their equivalent octal digit values or hexadecimal digit values. This process may be used in reverse to produce the binary equivalent of a given octal or hexadecimal number.

For example, the octal number 653 is converted to binary simply by writing the 6 as its 3-digit binary equivalent 110, the 5 as its 3-digit binary equivalent 101 and the 3 as its 3-digit binary equivalent 011 to form the 9-digit binary number 110101011.

The hexadecimal number FAD5 is converted to binary simply by writing the F as its 4-digit binary equivalent 1111, the A as its 4-digit binary equivalent 1010, the D as its 4-digit binary equivalent 1101 and the 5 as its 4-digit binary equivalent 0101 to form the 16-digit 1111101011010101.

### E.4 Converting from Binary, Octal or Hexadecimal to Decimal

We are accustomed to working in decimal, and therefore it is often convenient to convert a binary, octal, or hexadecimal number to decimal to get a sense of what the number is “really” worth. Our diagrams in Section E.1 express the positional values in decimal. To

**1520** Appendix E Number Systems

convert a number to decimal from another base, multiply the decimal equivalent of each digit by its positional value and sum these products. For example, the binary number 110101 is converted to decimal 53, as shown in Fig. E.8.

To convert octal 7614 to decimal 3980, we use the same technique, this time using appropriate octal positional values, as shown in Fig. E.9.

To convert hexadecimal AD3B to decimal 44347, we use the same technique, this time using appropriate hexadecimal positional values, as shown in Fig. E.10.

Converting a binary number to decimal					
Positional values:	32	16	8	4	2
Symbol values:	1	1	0	1	0
Products:	1*32=32	1*16=16	0*8=0	1*4=4	0*2=0
Sum:	= 32 + 16 + 0 + 4 + 0s + 1 =	53			

**Fig. E.8** | Converting a binary number to decimal.

Converting an octal number to decimal				
Positional values:	512	64	8	1
Symbol values:	7	6	1	4
Products	7*512=3584	6*64=384	1*8=8	4*1=4
Sum:	= 3584 + 384 + 8 + 4 =	3980		

**Fig. E.9** | Converting an octal number to decimal.

Converting a hexadecimal number to decimal				
Positional values:	4096	256	16	1
Symbol values:	A	D	3	B
Products	A*4096=40960	D*256=3328	3*16=48	B*1=11
Sum:	= 40960 + 3328 + 48 + 11 =	44347		

**Fig. E.10** | Converting a hexadecimal number to decimal.

## E.5 Converting from Decimal to Binary, Octal or Hexadecimal

The conversions in Section E.4 follow naturally from the positional notation conventions. Converting from decimal to binary, octal, or hexadecimal also follows these conventions.

## E.5 Converting from Decimal to Binary, Octal or Hexadecimal 1521

Suppose we wish to convert decimal 57 to binary. We begin by writing the positional values of the columns right to left until we reach a column whose positional value is greater than the decimal number. We do not need that column, so we discard it. Thus, we first write:

Positional values:	64	32	16	8	4	2	1
--------------------	----	----	----	---	---	---	---

Then we discard the column with positional value 64, leaving:

Positional values:	32	16	8	4	2	1
--------------------	----	----	---	---	---	---

Next we work from the leftmost column to the right. We divide 32 into 57 and observe that there is one 32 in 57 with a remainder of 25, so we write 1 in the 32 column. We divide 16 into 25 and observe that there is one 16 in 25 with a remainder of 9 and write 1 in the 16 column. We divide 8 into 9 and observe that there is one 8 in 9 with a remainder of 1. The next two columns each produce quotients of 0 when their positional values are divided into 1, so we write 0s in the 4 and 2 columns. Finally, 1 into 1 is 1, so we write 1 in the 1 column. This yields:

Positional values:	32	16	8	4	2	1
Symbol values:	1	1	1	0	0	1

and thus decimal 57 is equivalent to binary 111001.

To convert decimal 103 to octal, we begin by writing the positional values of the columns until we reach a column whose positional value is greater than the decimal number. We do not need that column, so we discard it. Thus, we first write:

Positional values:	512	64	8	1
--------------------	-----	----	---	---

Then we discard the column with positional value 512, yielding:

Positional values:	64	8	1
--------------------	----	---	---

Next we work from the leftmost column to the right. We divide 64 into 103 and observe that there is one 64 in 103 with a remainder of 39, so we write 1 in the 64 column. We divide 8 into 39 and observe that there are four 8s in 39 with a remainder of 7 and write 4 in the 8 column. Finally, we divide 1 into 7 and observe that there are seven 1s in 7 with no remainder, so we write 7 in the 1 column. This yields:

Positional values:	64	8	1
Symbol values:	1	4	7

and thus decimal 103 is equivalent to octal 147.

To convert decimal 375 to hexadecimal, we begin by writing the positional values of the columns until we reach a column whose positional value is greater than the decimal number. We do not need that column, so we discard it. Thus, we first write:

Positional values:	4096	256	16	1
--------------------	------	-----	----	---

Then we discard the column with positional value 4096, yielding:

Positional values:	256	16	1
--------------------	-----	----	---

Next we work from the leftmost column to the right. We divide 256 into 375 and observe that there is one 256 in 375 with a remainder of 119, so we write 1 in the 256 column. We divide 16 into 119 and observe that there are seven 16s in 119 with a

**I522** Appendix E Number Systems

remainder of 7 and write 7 in the 16 column. Finally, we divide 1 into 7 and observe that there are seven 1s in 7 with no remainder, so we write 7 in the 1 column. This yields:

Positional values:	256	16	1
Symbol values:	1	7	7

and thus decimal 375 is equivalent to hexadecimal 177.

## E.6 Negative Binary Numbers: Two's Complement Notation

The discussion so far in this appendix has focused on positive numbers. In this section, we explain how computers represent negative numbers using *two's complement notation*. First we explain how the two's complement of a binary number is formed, then we show why it represents the negative value of the given binary number.

Consider a machine with 32-bit integers. Suppose

```
int value = 13;
```

The 32-bit representation of `value` is

```
00000000 00000000 00000000 00001101
```

To form the negative of `value` we first form its *one's complement* by applying Java's bitwise complement operator (`~`):

```
onesComplementOfValue = ~value;
```

Internally, `~value` is now `value` with each of its bits reversed—ones become zeros and zeros become ones, as follows:

```
value:
00000000 00000000 00000000 00001101

~value (i.e., value's ones complement):
11111111 11111111 11111111 11110010
```

To form the two's complement of `value`, we simply add 1 to `value`'s one's complement. Thus

```
Two's complement of value:
11111111 11111111 11111111 11110011
```

Now if this is in fact equal to  $-13$ , we should be able to add it to binary 13 and obtain a result of 0. Let us try this:

```
00000000 00000000 00000000 00001101
+11111111 11111111 11111111 11110011

00000000 00000000 00000000 00000000
```

The carry bit coming out of the leftmost column is discarded and we indeed get 0 as a result. If we add the one's complement of a number to the number, the result would be all 1s. The key to getting a result of all zeros is that the two's complement is one more than the one's complement. The addition of 1 causes each column to add to 0 with a carry of 1. The carry keeps moving leftward until it is discarded from the leftmost bit, and thus the resulting number is all zeros.

## E.6 Negative Binary Numbers: Two's Complement Notation

1523

Computers actually perform a subtraction, such as

```
x = a - value;
```

by adding the two's complement of `value` to `a`, as follows:

```
x = a + (~value + 1);
```

Suppose `a` is 27 and `value` is 13 as before. If the two's complement of `value` is actually the negative of `value`, then adding the two's complement of `value` to `a` should produce the result 14. Let us try this:

a (i.e., 27)	00000000 00000000 00000000 00011011
+(~value + 1)	+11111111 11111111 11111111 11110011
-----	
	00000000 00000000 00000000 00001110

which is indeed equal to 14.

## Summary

- An integer such as 19 or 227 or -63 in a Java program is assumed to be in the decimal (base 10) number system. The digits in the decimal number system are 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9. The lowest digit is 0 and the highest digit is 9—one less than the base of 10.
- Internally, computers use the binary (base 2) number system. The binary number system has only two digits, namely 0 and 1. Its lowest digit is 0 and its highest digit is 1—one less than the base of 2.
- The octal number system (base 8) and the hexadecimal number system (base 16) are popular primarily because they make it convenient to abbreviate binary numbers.
- The digits of the octal number system range from 0 to 7.
- The hexadecimal number system poses a problem because it requires 16 digits—a lowest digit of 0 and a highest digit with a value equivalent to decimal 15 (one less than the base of 16). By convention, we use the letters A through F to represent the hexadecimal digits corresponding to decimal values 10 through 15.
- Each number system uses positional notation—each position in which a digit is written has a different positional value.
- A particularly important relationship of both the octal number system and the hexadecimal number system to the binary system is that the bases of octal and hexadecimal (8 and 16 respectively) are powers of the base of the binary number system (base 2).
- To convert an octal to a binary number, replace each octal digit with its three-digit binary equivalent.
- To convert a hexadecimal number to a binary number, simply replace each hexadecimal digit with its four-digit binary equivalent.
- Because we are accustomed to working in decimal, it is convenient to convert a binary, octal or hexadecimal number to decimal to get a sense of the number's "real" worth.
- To convert a number to decimal from another base, multiply the decimal equivalent of each digit by its positional value and sum the products.
- Computers represent negative numbers using two's complement notation.

**1524** Appendix E Number Systems

- To form the negative of a value in binary, first form its one's complement by applying Java's bitwise complement operator (`~`). This reverses the bits of the value. To form the two's complement of a value, simply add one to the value's one's complement.

**Terminology**

base	digit
base 2 number system	hexadecimal number system
base 8 number system	negative value
base 10 number system	octal number system
base 16 number system	one's complement notation
binary number system	positional notation
bitwise complement operator ( <code>~</code> )	positional value
conversions	symbol value
decimal number system	two's complement notation

**Self-Review Exercises**

- E.1** The bases of the decimal, binary, octal and hexadecimal number systems are \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_ respectively.
- E.2** In general, the decimal, octal and hexadecimal representations of a given binary number contain (more/fewer) digits than the binary number contains.
- E.3** (True/False) A popular reason for using the decimal number system is that it forms a convenient notation for abbreviating binary numbers simply by substituting one decimal digit per group of four binary bits.
- E.4** The (octal / hexadecimal / decimal) representation of a large binary value is the most concise (of the given alternatives).
- E.5** (True/False) The highest digit in any base is one more than the base.
- E.6** (True/False) The lowest digit in any base is one less than the base.
- E.7** The positional value of the rightmost digit of any number in either binary, octal, decimal or hexadecimal is always \_\_\_\_\_.
- E.8** The positional value of the digit to the left of the rightmost digit of any number in binary, octal, decimal or hexadecimal is always equal to \_\_\_\_\_.
- E.9** Fill in the missing values in this chart of positional values for the rightmost four positions in each of the indicated number systems:

decimal	1000	100	10	1
hexadecimal	...	256	...	...
binary	...	...	...	...
octal	512	...	8	...

- E.10** Convert binary 110101011000 to octal and to hexadecimal.
- E.11** Convert hexadecimal FACE to binary.
- E.12** Convert octal 7316 to binary.
- E.13** Convert hexadecimal 4FEC to octal. (*Hint:* First convert 4FEC to binary, then convert that binary number to octal.)
- E.14** Convert binary 1101110 to decimal.

Answers to Self-Review Exercises **1525**

- E.15** Convert octal 317 to decimal.
- E.16** Convert hexadecimal EFD4 to decimal.
- E.17** Convert decimal 177 to binary, to octal and to hexadecimal.
- E.18** Show the binary representation of decimal 417. Then show the one's complement of 417 and the two's complement of 417.
- E.19** What is the result when a number and its two's complement are added to each other?

**Answers to Self-Review Exercises**

- E.1** 10, 2, 8, 16.
- E.2** Fewer.
- E.3** False. Hexadecimal does this.
- E.4** Hexadecimal.
- E.5** False. The highest digit in any base is one less than the base.
- E.6** False. The lowest digit in any base is zero.
- E.7** 1 (the base raised to the zero power).
- E.8** The base of the number system.
- E.9** Fill in the missing values in this chart of positional values for the rightmost four positions in each of the indicated number systems:

decimal	1000	100	10	1
hexadecimal	4096	256	16	1
binary	8	4	2	1
octal	512	64	8	1

- E.10** Octal 6530; Hexadecimal D58.
- E.11** Binary 1111 1010 1100 1110.
- E.12** Binary 111 011 001 110.
- E.13** Binary 0 100 111 111 101 100; Octal 47754.
- E.14** Decimal  $2+4+8+32+64=110$ .
- E.15** Decimal  $7+1*8+3*64=7+8+192=207$ .
- E.16** Decimal  $4+13*16+15*256+14*4096=61396$ .
- E.17** Decimal 177  
to binary:

```
256 128 64 32 16 8 4 2 1
128 64 32 16 8 4 2 1
(1*128)+(0*64)+(1*32)+(1*16)+(0*8)+(0*4)+(0*2)+(1*1)
10110001
```

to octal:

```
512 64 8 1
64 8 1
(2*64)+(6*8)+(1*1)
261
```

**1526** Appendix E Number Systems

to hexadecimal:

```
256 16 1
16 1
(11*16)+(1*1)
(B*16)+(1*1)
B1
```

**E.18** Binary:

```
512 256 128 64 32 16 8 4 2 1
256 128 64 32 16 8 4 2 1
(1*512)+(0*256)+(0*128)+(0*64)+(1*32)+(0*16)+(0*8)+(0*4)+(0*2)+(1*1)
110100001
```

One's complement: 001011110

Two's complement: 001011111

Check: Original binary number + its two's complement

```
110100001
001011111

000000000
```

**E.19** Zero.**Exercises**

**E.20** Some people argue that many of our calculations would be easier in the base 12 number system because 12 is divisible by so many more numbers than 10 (for base 10). What is the lowest digit in base 12? What would be the highest symbol for the digit in base 12? What are the positional values of the rightmost four positions of any number in the base 12 number system?

**E.21** Complete the following chart of positional values for the rightmost four positions in each of the indicated number systems:

decimal	1000	100	10	1
base 6	...	...	6	...
base 13	...	169	...	...
base 3	27	...	...	...

**E.22** Convert binary 10010111010 to octal and to hexadecimal.

**E.23** Convert hexadecimal 3A7D to binary.

**E.24** Convert hexadecimal 765F to octal. (*Hint:* First convert 765F to binary, then convert that binary number to octal.)

**E.25** Convert binary 1011110 to decimal.

**E.26** Convert octal 426 to decimal.

**E.27** Convert hexadecimal FFFF to decimal.

**E.28** Convert decimal 299 to binary, to octal and to hexadecimal.

**E.29** Show the binary representation of decimal 779. Then show the one's complement of 779 and the two's complement of 779.

**E.30** Show the two's complement of integer value -1 on a machine with 32-bit integers.

# GroupLayout

## F.1 Introduction

Java SE 6 includes a powerful new layout manager called [GroupLayout](#), which is the default layout manager in the Netbeans 5.5 IDE ([www.netbeans.org](http://www.netbeans.org)). In this appendix, we overview GroupLayout, then demonstrate how to use the Netbeans 5.5 IDE's [Matisse GUI designer](#) to create a GUI using GroupLayout to position the components. Netbeans generates the GroupLayout code for you automatically. Though you can write GroupLayout code by hand, in most cases you'll use a GUI design tool like the one provided by Netbeans to take advantage of GroupLayout's power. For more details on GroupLayout, see the list of web resources at the end of this appendix.

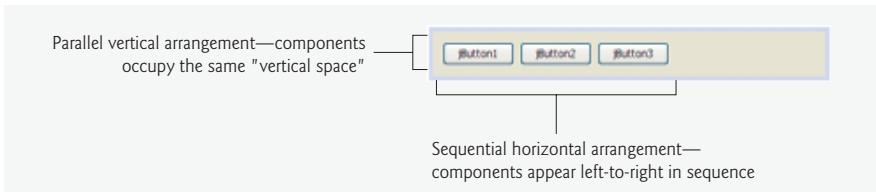

## F.2 GroupLayout Basics

Chapters 11 and 22 presented several layout managers that provide basic GUI layout capabilities. We also discussed how to combine layout managers and multiple containers to create more complex layouts. Most layout managers do not give you precise control over the positioning of components. In Chapter 22, we discussed the [GridBagLayout](#), which provides more precise control over the position and size of your GUI components. It allows you to specify the horizontal and vertical position of each component, the number of rows and columns each component occupies in the grid, and how components grow and shrink as the size of the container changes. This is all specified at once with a [GridBagConstraints](#) object. Class [GroupLayout](#) is the next step in layout management. GroupLayout is more flexible, because you can specify the horizontal and vertical layouts of your components independently.

### *Sequential and Parallel Arrangements*

Components are arranged either sequentially or in parallel. The three [JButtons](#) in Fig. F.1 are arranged with [sequential horizontal orientation](#)—they appear left to right in sequence. Vertically, the components are arranged in parallel, so, in a sense, they “occupy the same vertical space.” Components can also be arranged sequentially in the vertical

## 1528 Appendix F GroupLayout

**Fig. F.1** | JButtons arranged sequentially for their horizontal orientation and in parallel for their vertical orientation.

direction and in parallel in the horizontal direction, as you'll see in Section F.3. To prevent overlapping components, components with parallel vertical orientation are normally arranged with sequential horizontal orientation (and vice versa).

### Groups and Alignment

To create more complex user interfaces, GroupLayout allows you to create **groups** that contain sequential or parallel elements. Within a group you can have GUI components, other groups and gaps. Placing a group within another group is similar to building a GUI using nested containers, such as a JPanel that contains other JPanel's, which in turn contain GUI components.

When you create a group, you can specify the **alignment** of the group's elements. Class GroupLayout contains four constants for this purpose—LEADING,.TRAILING, CENTER and BASELINE. The constant BASELINE applies only to vertical orientations. In horizontal orientation, the constants LEADING,.TRAILING and CENTER represent left justified, right justified and centered, respectively. In vertical orientation, LEADING,.TRAILING and CENTER align the components at their tops, bottoms or vertical centers, respectively. Aligning components with BASELINE indicates they should be aligned using the baseline of the font for the components' text. For more information about font baselines, see Section 12.4.

### Spacing

GroupLayout by default uses the recommended GUI design guidelines of the underlying platform for spacing between components. The **addGap** method of GroupLayout nested classes **GroupLayout.Group**, **GroupLayout.SequentialGroup** and **GroupLayout.ParallelGroup** allows you to control the spacing between components.

### Sizing Components

By default, GroupLayout uses each component's **getMinimumSize**, **getMaximumSize** and **getPreferredSize** methods to help determine the component's size. You can override the default settings.

## F.3 Building a Color Chooser

We now present a Color Chooser application to demonstrate the GroupLayout layout manager. The application consists of three JSlider objects, each representing the values from 0 to 255 for specifying the red, green and blue values of a color. The selected values for each JSlider will be used to display a filled rectangle of the specified color. We build the application using Netbeans 5.5. For an more detailed introduction to developing GUI applications in the NetBeans IDE, see [www.netbeans.org/kb/trails/matisse.html](http://www.netbeans.org/kb/trails/matisse.html).

### F.3 Building a ColorChooser 1529

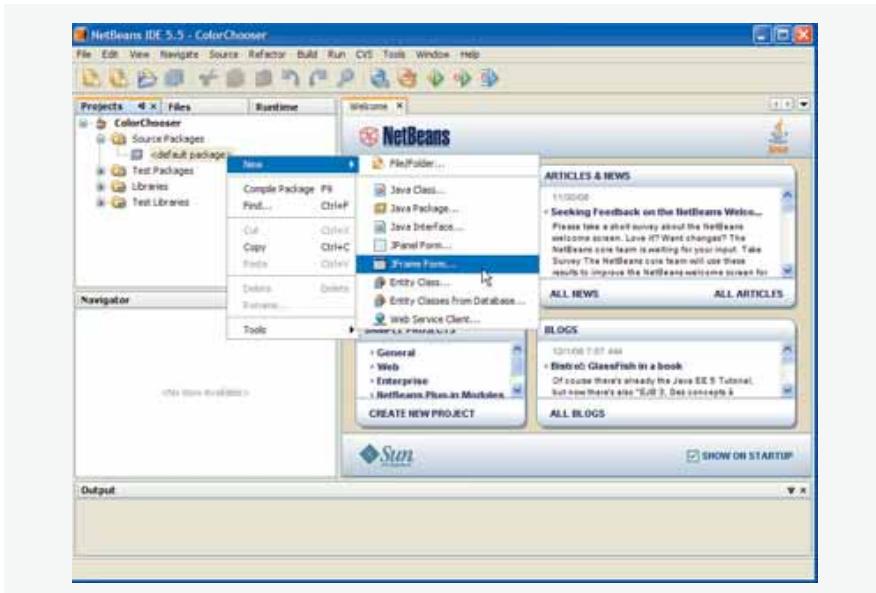

#### *Create a New Project*

Begin by opening a new NetBeans project. Select **File > New Project....** In the **New Project** dialog, choose **General** from the **Categories** list and **Java Application** from the **Projects** list then click **Next >**. Specify **ColorChooser** as the project name and uncheck the **Create Main Class** checkbox. You can also specify the location of your project in the **Project Location** field. Click **Finish** to create the project.

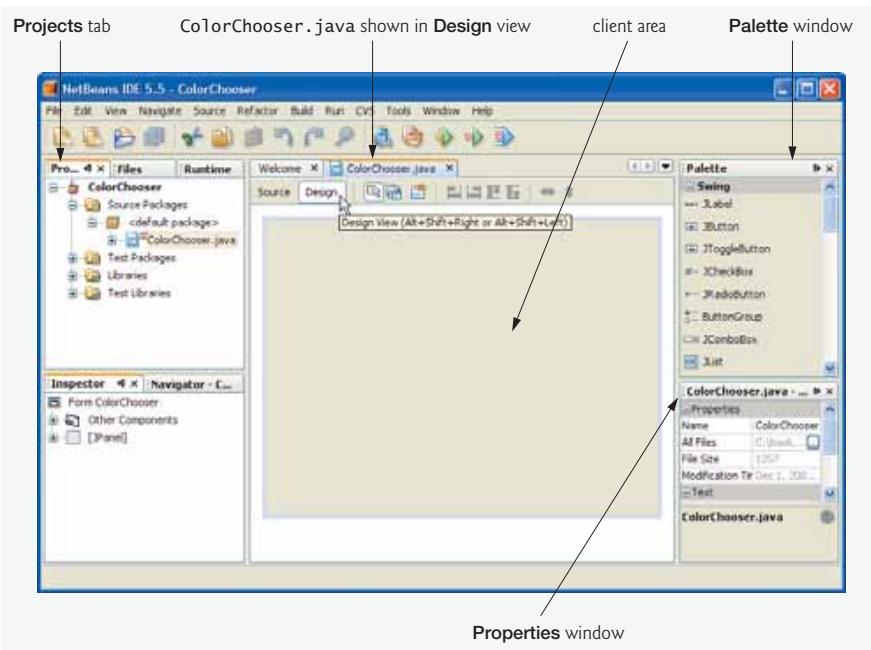

#### *Add a New Subclass of JFrame to the Project*

In the IDE's **Projects** tab just below the **File** menu and toolbar (Fig. F.2), expand the **Source Packages** node. Right-click the **<default package>** node that appears and select **New > JPanel Form**. In the **New JPanel Form** dialog, specify **ColorChooser** as the class name and click **Finish**. This subclass of **JFrame** will display the application's GUI components. The Netbeans window should now appear similar to Fig. F.3 with the **ColorChooser** class shown in **Design** view. The **Source** and **Design** buttons at the top of the **ColorChooser.java** window allow you to switch between editing the source code and designing the GUI.

**Design** view shows only the **ColorChooser**'s client area (i.e., the area that will appear inside the window's borders). To build a GUI visually, you can drag GUI components from the **Palette** window onto the client area. You can configure the properties of each component by selecting it, then modifying the property values that appear in the **Properties** window (Fig. F.3). When you select a component, the **Properties** window displays three buttons—**Properties**, **Events** and **Code** (see Fig. F.4)—that enable you to configure various aspects of the component.

**Fig. F.2** | Adding a new **JFrame Form** to the **ColorChooser** project.

**1530 Appendix F GroupLayout**

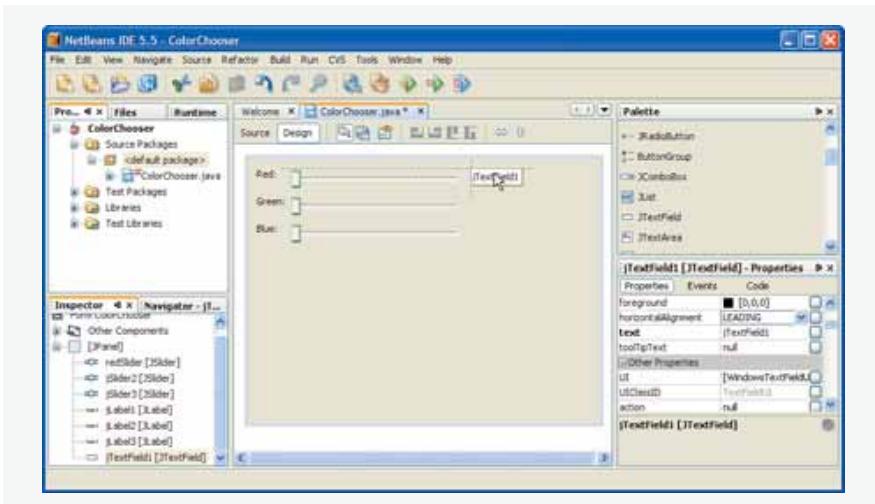

**Fig. F.3** | Class `ColorChooser` shown in the Netbeans **Design** view.

#### *Build the GUI*

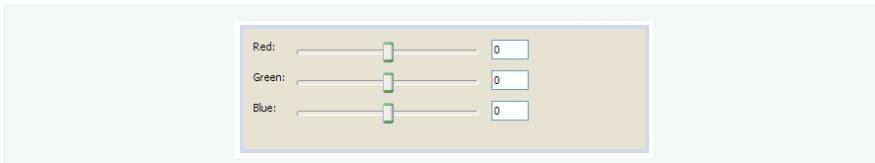

Drag three `JSliders` from the **Palette** onto the `JFrame` (you may need to scroll through the **Palette**). As you drag components near the edges of the client area or near other components, Netbeans displays **guide lines** (Fig. F.4) that show you the recommended distances and alignments between the component you are dragging, the edges of the client area and other components. As you follow the steps to build the GUI, use the guide lines to arrange the components into three rows and three columns as in Fig. F.5. Use the **Properties** window to rename the `JSliders` to `redJSlider`, `greenJSlider` and `blueJSlider`. Select the first `JSlider`, then click the **Code** button in the **Properties** window and change the **Variable Name** property to `redSlider`. Repeat this process to rename the other two `JSliders`. Then, select each `JSlider` and change its `maximum` property to 255 so that it will produce values in the range 0–255, and change its `value` property to 0 so the `JSlider`'s thumb will initially be at the left of the `JSlider`.

Drag three `JLabels` from the **Palette** to the `JFrame` to label each `JSlider` with the color it represents. Name the `JLabels` `redJLabel`, `greenJLabel` and `blueJLabel`, respectively. Each `JLabel` should be placed to the left of the corresponding `JSlider` (Fig. F.5). Change each `JLabel`'s `text` property either by double clicking the `JLabel` and typing the new text, or by selecting the `JLabel` and changing the `text` property in the **Properties** window.

Add a `JTextField` next to each of the `JSliders` to display the value of the slider. Name the `JTextFields` `redJTextField`, `greenJTextField` and `blueJTextField`, respectively. Change each `JTextField`'s `text` property to 0 using the same techniques as you did for the `JLabels`. Change each `JTextField`'s `columns` property to 4.

F.3 Building a Color Chooser **1531**

**Fig. F.4** | Positioning the first JTextField.

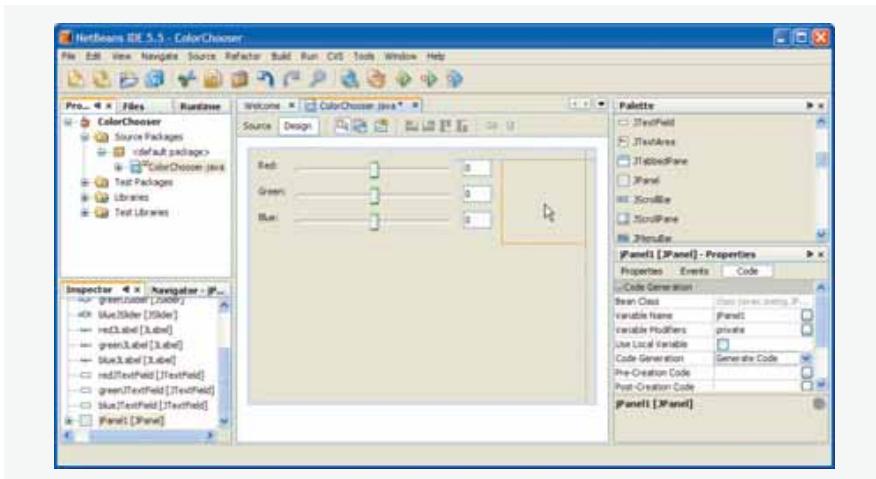

**Fig. F.5** | Layout of the JLabels, JSLiders and JTextFields.

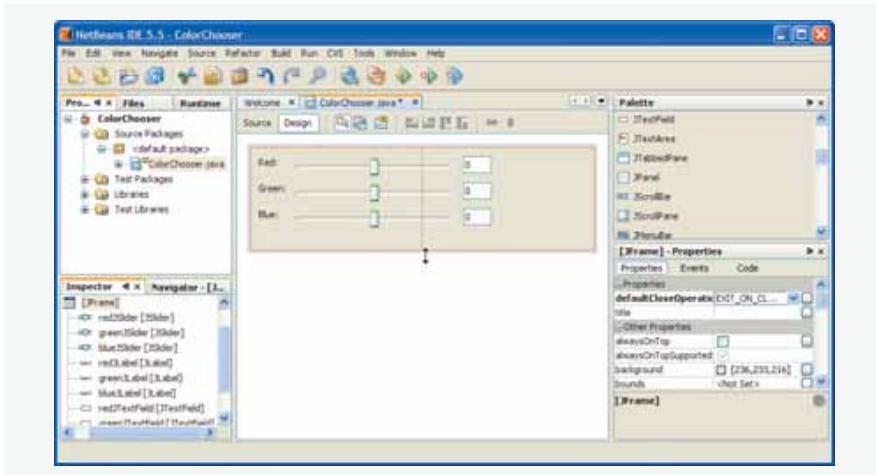

Double click the border of the client area to display the **Set Form Designer Size** dialog and change the first number (which represents the width) to 410, then click **OK**. This makes the client area wide enough to accommodate the JPanel you'll add next. Finally, add a JPanel named colorJPanel to the right of this group of components. Use the guide lines as shown in Fig. F.6 to place the JPanel. Change this JPanel's background color to display the selected color. Finally, drag the bottom border of the client area toward the top of the **Design** area until you see the snap-to line that shows the recommended height of the client area (based on the components in the client area) as shown in Fig. F.7.

#### *Editing the Source Code and Adding Event Handlers*

The IDE automatically generated the GUI code, including methods for initializing components and aligning them using the GroupLayout layout manager. We must add the desired functionality to the components' event handlers. To add an event handler for a component, right click it and position the mouse over the **Events** option in the pop-up menu. You can then select the category of event you wish to handle and the specific event within that category. For example, to add the JSlider event handlers for this example, right click each JSlider and select **Events > Change > stateChanged**. When you do this, Netbeans adds a ChangeListener to the JSlider and switches from **Design** view to **Source** view where you can place code in the event handler. Use the **Design** button to return to **Design**

**1532**    [Appendix F](#) [GroupLayout](#)

**Fig. F.6** | Positioning the JPanel.

**Fig. F.7** | Setting the height of the client area.

view and repeat the preceding steps to add the event handlers for the other two JSliders. To complete the event handlers, first add the method in Fig. F.8. In each JSlider event handler set the corresponding JTextField to the new value of the JSlider, then call method changeColor. Finally, in the constructor after the call to initComponents, add the line

```
colorJPanel.setBackground(java.awt.Color.BLACK);
```

Figure F.9 shows the completed `ColorChooser` class exactly as it is generated in Netbeans “in the raw.” More and more software development is done with tools that generate complex code like this, saving you the time and effort of doing it yourself..

## F.3 Building a ColorChooser 1533

```

1 // changes the colorJPanel's background color based on the current
2 // values of the JSliders
3 public void changeColor()
4 {
5 colorJPanel.setBackground(new java.awt.Color(
6 redJSlider.getValue(), greenJSlider.getValue(),
7 blueJSlider.getValue()));
8 } // end method changeColor

```

**Fig. F.8** | Method that changes the colorJPanel's background color based on the values of the three JSliders.

```

**Fig. F.9** | ColorChooser class that uses GroupLayout for its GUI layout. (Part 6 of 6.)

Method `initComponents` (lines 36–161) was entirely generated by Netbeans based on your interactions with the GUI designer. This method contains the code that creates and formats the GUI. Lines 38–93 construct and initialize the GUI components. Lines 95–161 specify the layout of those components using `GroupLayout`. Lines 108–133 specify the horizontal group and lines 134–159 specify the vertical group.

We manually added the statement that changes the `color JPanel`'s background color in line 18 and the `changeColor` method in lines 23–28. When the user moves the thumb on one of the `JSliders`, the `JSlider`'s event handler sets the text in its corresponding `JTextField` to the `JSlider`'s new value (lines 165, 171 and 177), then calls method `changeColor` (lines 166, 172 and 178) to update the `color JPanel`'s background color. Method `changeColor` gets the current value of each `JSlider` (lines 26–27) and uses these values as the arguments to the `Color` constructor to create a new `Color`.

# Java Desktop Integration Components (JDIC)

## G.1 Introduction

The **Java Desktop Integration Components (JDIC)** are part of an open-source project aimed at allowing better integration between Java applications and the platforms on which they execute. Some JDIC features include:

- interacting with the underlying platform to launch native applications (such as web browsers and email clients)
- displaying a splash screen when an application begins execution to indicate to the user that the application is loading
- creating icons in the system tray (also called the taskbar status area or notification area) to provide access to Java applications running in the background
- registering file-type associations, so that files of specified types will automatically open in corresponding Java applications
- creating installer packages, and more.

The JDIC homepage ([jdic.dev.java.net/](http://jdic.dev.java.net/)) includes an introduction to JDIC, downloads, documentation, FAQs, demos, articles, blogs, announcements, incubator projects, a developer's page, forums, mailing lists, and more. Java SE 6 now includes some of the features mentioned above. We discuss several of these features here.

## G.2 Splash Screens

Java application users often perceive a performance problem, because nothing appears on the screen when you first launch an application. One way to show a user that your program is loading is to display a **splash screen**—a borderless window that appears temporarily while an application loads. Java SE 6 provides the new command-line option **-splash** for

G.2 Splash Screens **1541**

the `java` command to accomplish this task. This option enables you to specify a PNG, GIF or JPG image that should display when your application begins loading. To demonstrate this new option, we created a program (Fig. G.1) that sleeps for 5 seconds (so you can view the splash screen) then displays a message at the command line. The directory for this example includes a PNG format image to use as the splash screen. To display the splash screen when this application loads, use the command

```
java -splash:DeitelBug.png SplashDemo
```

```

1 // Fig. G.1: SplashDemo.java
2 // Splash screen demonstration.
3 public class SplashDemo
4 {
5 public static void main(String[] args)
6 {
7 try
8 {
9 Thread.sleep(5000);
10 } // end try
11 catch (InterruptedException e)
12 {
13 e.printStackTrace();
14 } // end catch
15
16 System.out.println(
17 "This was the splash screen demo.");
18 } // end method main
19 } // end class SplashDemo

```

**Fig. G.1** | Splash screen displayed with the `-splash` option to the `java` command.

## 1542 Appendix G Java Desktop Integration Components (JDIC)

Once you've initiated the splash screen display, you can interact with it programmatically via the `SplashScreen` class of the `java.awt` package. You might do this to add some dynamic content to the splash screen. For more information on working with splash screens, see the following sites:

```
java.sun.com/developer/technicalArticles/J2SE/Desktop/javase6/
 SplashScreen/
java.sun.com/javase/6/docs/api/java.awt/SplashScreen.html
```

### G.3 Desktop Class

Java SE 6's new `Desktop` class enables you to specify a file or URI that you'd like to open using the underlying platform's appropriate application. For example, if Firefox is your computer's default browser, you can use the `Desktop` class's `browse` method to open a web site in Firefox. In addition, you can open an email composition window in your system's default email client, open a file in its associated application and print a file using the associated application's print command. Figure G.2 demonstrates the first three of these capabilities.

The event handler at lines 22–52 obtains the index number of the task the user selects in the `tasksJComboBox` (line 25) and the `String` that represents the file or URI to process (line 26). Line 28 uses `Desktop` static method `isDesktopSupported` to determine whether class `Desktop`'s features are supported on the platform on which this application runs. If they are, line 32 uses `Desktop` static method `getDesktop`, to obtain a `Desktop` object. If the user selected the option to open the default browser, line 37 creates a new `URI` object using the `String` input as the site to display in the browser, then passes the `URI` object to `Desktop` method `browse` which invokes the system's default browser and passes the `URI` to the browser for display. If the user selects the option to open a file in its associated program, line 40 creates a new `File` object using the `String` input as the file to open, then passes the `File` object to `Desktop` method `open` which passes the file to the appropriate application to open the file. Finally, if the user selects the option to compose an email, line 43 creates a new `URI` object using the `String` input as the email address to which the email will be sent, then passes the `URI` object to `Desktop` method `mail` which invokes the system's default email client and passes the `URI` to the email client as the email recipient. You can learn more about class `Desktop` at

```
java.sun.com/javase/6/docs/api/java.awt/Desktop.html
```

```
1 // Fig. G.2: DesktopDemo.java
2 // Use Desktop to launch default browser, open a file in its associated
3 // application and compose an email in the default email client.
4 import java.awt.Desktop;
5 import java.io.File;
6 import java.io.IOException;
7 import java.net.URI;
8
```

**Fig. G.2** | Use `Desktop` to launch the default browser, open a file in its associated application and compose an email in the default email client. (Part I of 3.)

G.3 Desktop Class **I543**

```

9 public class DesktopDemo extends javax.swing.JFrame
10 {
11 // constructor
12 public DesktopDemo()
13 {
14 initComponents();
15 } // end DesktopDemo constructor
16
17 // To save space, lines 20-84 of the Netbeans autogenerated GUI code
18 // are not shown here. The complete code for this example is located in
19 // the file DesktopDemo.java in this example's directory.
20
21 // determine selected task and perform the task
22 private void doTaskJButtonActionPerformed(
23 java.awt.event.ActionEvent evt)
24 {
25 int index = tasksJComboBox.getSelectedIndex();
26 String input = inputJTextField.getText();
27
28 if (Desktop.isDesktopSupported())
29 {
30 try
31 {
32 Desktop desktop = Desktop.getDesktop();
33
34 switch (index)
35 {
36 case 0: // open browser
37 desktopbrowse(new URI(input));
38 break;
39 case 1: // open file
40 desktop.open(new File(input));
41 break;
42 case 2: // open email composition window
43 desktop.mail(new URI(input));
44 break;
45 } // end switch
46 } // end try
47 catch (Exception e)
48 {
49 e.printStackTrace();
50 } // end catch
51 } // end if
52 } // end method doTaskJButtonActionPerformed
53
54 public static void main(String args[])
55 {
56 java.awt.EventQueue.invokeLater(
57 new Runnable()
58 {

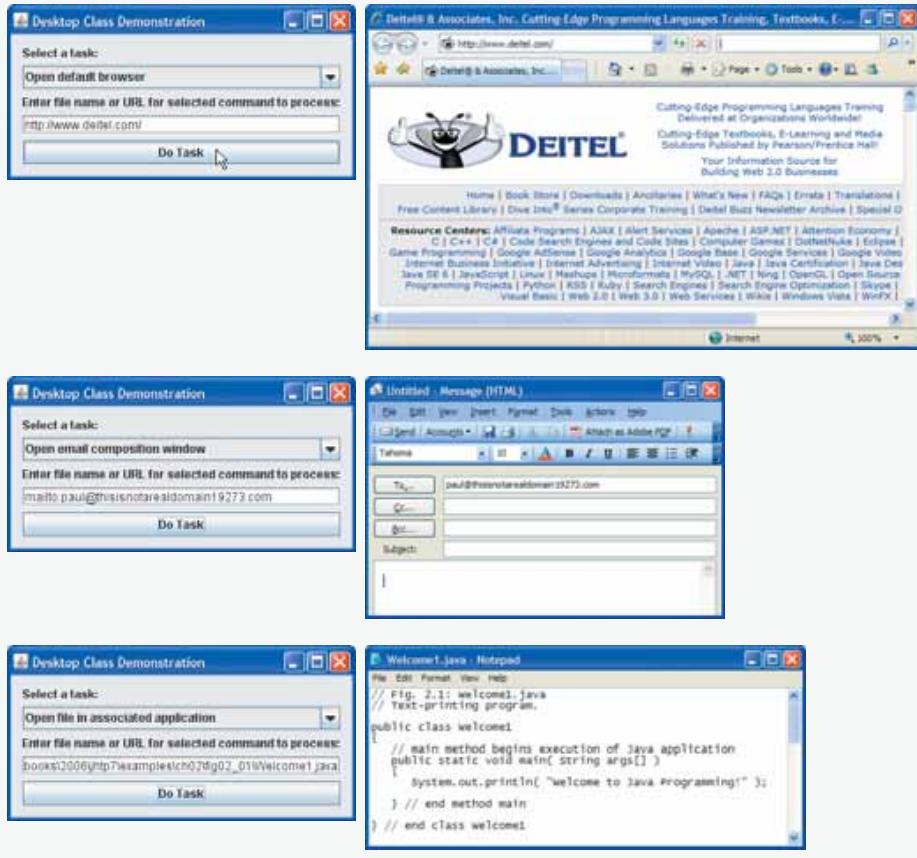

```

**Fig. G.2** | Use Desktop to launch the default browser, open a file in its associated application and compose an email in the default email client. (Part 2 of 3.)

**1544 Appendix G Java Desktop Integration Components (JDIC)**

```

59 public void run()
60 {
61 new DesktopDemo().setVisible(true);
62 }
63 }
64 }
65 } // end method main
66
67 // Variables declaration - do not modify
68 private javax.swing.JButton doTaskJButton;
69 private javax.swing.JLabel inputJLabel;
70 private javax.swing.JTextField inputJTextField;
71 private javax.swing.JLabel instructionLabel;
72 private javax.swing.JComboBox tasksJComboBox;
73 // End of variables declaration
74 }
```

**Fig. G.2** | Use Desktop to launch the default browser, open a file in its associated application and compose an email in the default email client. (Part 3 of 3.)

## G.4 Tray Icons

Tray icons generally appear in your system's system tray, taskbar status area or notification area. They typically provide quick access to applications that are executing in the background on your system. When you position the mouse over one of these icons, a tooltip appears indicating what application the icon represents. If you click the icon, a popup menu appears with options for that application.

Classes `SystemTray` and `TrayIcon` (both from package `java.awt`) enable you to create and manage your own tray icons in a platform independent manner. Class `SystemTray` provides access to the underlying platform's system tray—the class consists of three methods:

- static method `getDefaultSystemTray` returns the system tray
- method `addTrayIcon` adds a new `TrayIcon` to the system tray
- method `removeTrayIcon` removes an icon from the system tray

Class `TrayIcon` consists of several methods allowing users to specify an icon, a tooltip and a pop-up menu for the icon. In addition, tray icons support `ActionListeners`, `MouseListeners` and `MouseMotionListeners`. You can learn more about classes `SystemTray` and `TrayIcon` at

[java.sun.com/javase/6/docs/api/java.awt/SystemTray.html](http://java.sun.com/javase/6/docs/api/java.awt/SystemTray.html)  
[java.sun.com/javase/6/docs/api/java.awt/TrayIcon.html](http://java.sun.com/javase/6/docs/api/java.awt/TrayIcon.html)

## G.5 JDIC Incubator Projects

The JDIC Incubator Projects are developed, maintained and owned by members of the Java community. These projects are associated with, but not distributed with, JDIC. The Incubator Projects may eventually become part of the JDIC project once they have been fully developed and meet certain criteria. For more information about the Incubator Projects and to learn how you can setup an Incubator Project, visit

[jdic.dev.java.net/#incubator](http://jdic.dev.java.net/#incubator)

Current Incubator Projects include:

- FileUtil—A file utility API that extends the `java.io.File` class.
- Floating Dock Top-level Window—A Java API for developing a floating dock toplevel window.
- Icon Service—Returns a Java icon object from a native icon specification.
- Misc API —Hosts simple (one method, one class type of) APIs.
- Music Player Control API—Java API that controls native music players.
- SaverBeans Screensaver SDK—Java screensaver development kit.
- SystemInfo—Checks the system information.

## G.6 JDIC Demos

The JDIC site includes demos for `FileExplorer`, the browser package, the `TrayIcon` package, the Floating Dock class and the Wallpaper API ([jdic.dev.java.net/#demos](http://jdic.dev.java.net/#demos)). The source code for these demos is included in the JDIC download ([jdic.dev.java.net/servlets/ProjectDocumentList](http://jdic.dev.java.net/servlets/ProjectDocumentList)). For more demos, check out some of the incubator projects.

# Mashups

## *Introduction*

Building web application mashups is one of the signature topics of Web 2.0. The term mashup originated in the music world—a music mashup is a remix of two or more songs to create a new song. You can listen to some music mashups at [www.ccmixter.org/](http://www.ccmixter.org/). A web application mashup combines complementary functionality, usually accessed via web services (Chapter 28) and RSS feeds ([www.deitel.com/rss](http://www.deitel.com/rss) and [www.rssbus.com](http://www.rssbus.com)) from multiple web sites. You can create innovative and powerful Web 2.0 mashup applications much faster than if you have to write your applications from scratch. For example, [www.housingmaps.com](http://www.housingmaps.com) combines Craigslist apartment listings with Google Maps to display on a map all of the apartments for rent in a neighborhood.

## *Popular Mashups*

Figure H.1 shows some popular mashups.

URL	APIs	Description
<i>Popular Google Maps Mashups:</i>		
<a href="http://www.mappr.com/">www.mappr.com/</a>	Google Maps, Flickr	Find photos of sites across the US.
<a href="http://www.housingmaps.com/">www.housingmaps.com/</a>	Google Maps, Craigslist	Find available apartments and homes by neighborhood. Includes prices, pictures, the address and rental-agent contact information.
<a href="http://www.broadwayzone.com/">www.broadwayzone.com/</a>	Google Maps	Find the locations of theaters in New York City and the shows playing at each theater. Links to details about the show, ticket information and subway directions.

**Fig. H.1** | Popular mashups. (Part I of 2.)

## APIs Commonly Used in Mashups

1547

URL	APIs	Description
<a href="http://www.cribseek.com">www.cribseek.com</a>	Google Maps	Maps with properties for sale.
<a href="http://www.shackprices.com/">www.shackprices.com/</a>	Google Maps	Find the approximate value of your home based on recent home sales in your area.
<a href="http://www.mashmap.com/">www.mashmap.com/</a>	Google Maps	Click on a theater on the map to find movies and show times.
<a href="http://paul.kedrosky.com/publicloos/">paul.kedrosky.com/publicloos/</a>	Google Maps	Find public restrooms in San Francisco. Includes the address, a rating and comments about each restroom.
<i>Other Popular Mashups:</i>		
<a href="http://www.doubletrust.net">www.doubletrust.net</a>	Yahoo! Search, Google Search	Combines Yahoo! and Google search results into one page.
<a href="http://api.local.yahoo.com/eb/">api.local.yahoo.com/eb/</a>	Yahoo! Maps	Find the location of events (by date) in a geographical area.
<a href="http://www.csthota.com/geotagr">www.csthota.com/geotagr</a>	Microsoft Virtual Earth	Store and browse photos by geographic location.
<a href="http://www.kokogiak.com/amazon4/default.asp">www.kokogiak.com/amazon4/default.asp</a>	Amazon Web Services	Add Amazon items to your wish list, put the link to a book into your blog on Blogger, add a link to your del.icio.us bookmarks or look for the book in your local library.

**Fig. H.1** | Popular mashups. (Part 2 of 2.)

Now that you've read most of *Java How to Program, 7/e*, you're probably familiar with API categories including graphics, GUI, collections, multimedia, databases and many more. Nearly all of these provide enhanced *computing functionality*. Many web services APIs provide *business functionality*—eBay provides auction capabilities, Amazon provides book sales (and sales of other types of products, such as CDs, DVDs, electronic devices, and more), Google provides search capabilities, PayPal provides payment services, etc. These web services are typically free for non-commercial use; some impose (generally reasonable) fees for commercial use. This creates exciting possibilities for people building Internet-based applications and businesses.

#### APIs Commonly Used in Mashups

We have emphasized the importance of software reuse. Mashups are yet another form of software reuse that saves you time, money and effort—you can rapidly prototype starter versions of your applications, integrate business functionality, integrate search functionality and more. Figure H.2 shows some APIs commonly used in mashups.

**1548 Appendix H Mashups**

API source	URL	Functionality
Google Maps	<a href="http://www.google.com/apis/maps/">www.google.com/apis/maps/</a>	Maps
Yahoo! Maps	<a href="http://developer.yahoo.net/maps/">developer.yahoo.net/maps/</a>	Maps
Microsoft Virtual Earth	<a href="http://virtualearth.msn.com/">virtualearth.msn.com/</a>	Local search, maps
Amazon	<a href="http://aws.amazon.com/">aws.amazon.com/</a>	E-commerce
TypePad ATOM	<a href="http://www.sixapart.com/pronet/docs/typepad_atom_api">www.sixapart.com/pronet/docs/typepad_atom_api</a>	Blogging
Blogger ATOM feed	<a href="http://code.blogspot.com/">code.blogspot.com/</a>	Blogging
Flickr	<a href="http://developer.yahoo.net/flickr/index.html">developer.yahoo.net/flickr/index.html</a>	Photo sharing
YouTube	<a href="http://www.youtube.com/dev">www.youtube.com/dev</a>	Video sharing
PayPal	<a href="http://developer.paypal.com/">developer.paypal.com/</a>	Payments
del.icio.us	<a href="http://del.icio.us/help/api/">del.icio.us/help/api/</a>	Social bookmarking
Backpack	<a href="http://backpackit.com/">backpackit.com/</a>	Event scheduling
Dropcash	<a href="http://www.dropcash.com/">www.dropcash.com/</a>	Fundraising organizer
Upcoming.org	<a href="http://upcoming.org/services/api/">upcoming.org/services/api/</a>	Syndicate event listings
Google AdWords	<a href="http://www.google.com/apis/adwords/">www.google.com/apis/adwords/</a>	Manage Google AdWords advertising programs
eBay	<a href="http://developer.ebay.com/common/api">developer.ebay.com/common/api</a>	Auctions
SalesForce	<a href="http://www.salesforce.com/developer/">www.salesforce.com/developer/</a>	Customer Relationship Management (CRM)
Technorati	<a href="http://developers.technorati.com/wiki/TechnoratiApi">developers.technorati.com/wiki/TechnoratiApi</a>	Blog search

**Fig. H.2** | APIs commonly used to make mashups.***Deitel Mashups Research Center***

Our Mashups Resource Center, which is located at

[www.deitel.com/mashups/MashUpsResourceCenter.html](http://www.deitel.com/mashups/MashUpsResourceCenter.html)

focuses on the enormous amount of free mashup content available online. You'll find tutorials, articles, documentation, the latest books, articles, blogs, directories, tools, forums, etc., that will help you quickly develop mashup applications.

- Check out the newest and most popular mashups, including scores of Google Maps-based mashups showing you the locations of theaters, real estate for sale or rent, properties that have sold in your area, and even the locations of the public restrooms in San Francisco!
- Search ProgrammableWeb for mashups by category.
- Check out the Flickr APIs for adding photos to your applications, updating photos, replacing photos, example requests, and asynchronous uploading.

- Check out the article: “Building Mashups for Non-Programmers.”
- Check out the Smashforce tool that enables Salesforce.com users to mashup applications such as Google Maps with their Multiforce and Sforce enterprise applications.
- Find mashup sites such as ProgrammableWeb, Givezilla, Podbop, and Strmz.
- Check out IBM’s Enterprise Mashup Tool.
- Check out the search and mapping APIs from Microsoft, Yahoo! and Google that you can use in your mashup applications.
- Use Technorati APIs to find all of the blogs that link to a specific web site, search blogs for mentions of keywords, see which blogs are linked to a given blog and find blogs associated with a specific web site.
- Use the Backpack API to help organize tasks and events, plan your schedule, collaborate with others, monitor your competitors online and more.

#### *Deitel RSS Resource Center*

RSS feeds are also popular information sources for mashups. To learn more about RSS feeds, visit our RSS Resource Center at [www.deitel.com/RSS/](http://www.deitel.com/RSS/). Each week, we announce the latest Resource Center(s) in our free e-mail newsletter, the *Deitel Buzz Online*:

[www.deitel.com/newsletter/subscribe.html](http://www.deitel.com/newsletter/subscribe.html)

Please send suggestions for additional Resource Centers and improvements to existing Resource Centers to [deitel@deitel.com](mailto:deitel@deitel.com). Thanks!

#### *Mashup Performance and Reliability Issues*

There are several challenges when creating mashup applications. Your applications become susceptible to traffic and reliability problems on the Internet—circumstances generally beyond your control. Companies might suddenly change APIs that your applications use. Your application is dependent on hardware and software capabilities of other companies. Also, companies could impose fee structures on previously free web services or could increase existing fees.

#### *Mashup Tutorials*

This and the next several sections list extensive mashups resources from our Mashups Resource Center. Once you’ve mastered web services in Chapter 28, you should find building mashups straightforward. For each API you’d like to use, just visit the corresponding site, register and get your access key (if one is required), check out their sample implementations, and be sure to honor their “terms of service” agreements.

[www.programmableweb.com/howto](http://www.programmableweb.com/howto)

Tutorial: “How to Make Your Own Web Mashup,” from Programmableweb.com, is a 5-step tutorial for making a mashup. Topics include selecting a subject, finding your data, weighing your coding skills, signing up for an API, and starting to code. Includes a list of available APIs.

[blogs.msdn.com/jhawk/archive/2006/03/26/561658.aspx](http://blogs.msdn.com/jhawk/archive/2006/03/26/561658.aspx)

Tutorial: “Building a Mashup of National Parks Using the Atlas Virtual Earth Map Control,” by Jonathan Hawkins, shows you how to display pushpins on a Microsoft Virtual Earth map. Includes a brief tour of the application and a step-by-step guide to build this application (includes C# code).

## 1550 Appendix H Mashups

[www-128.ibm.com/developerworks/edu/x-dw-x-ultimashup1.html?  
ca=dgrlnxw07webMashupsPart1&s\\_cmp=gr&s\\_tact=105agx59](http://www-128.ibm.com/developerworks/edu/x-dw-x-ultimashup1.html?ca=dgrlnxw07webMashupsPart1&s_cmp=gr&s_tact=105agx59)

Tutorial: “The Ultimate Mashup—Web Services and the Semantic Web.” This six-part tutorial from IBM covers the concept of mashups, building an XML cache, RDF, Web Ontology Language (OWL), user control and more. The tutorial is primarily for IBM employees; others must register. [conferences.oreillynet.com/cs/et2005/view/e\\_sess/6241](http://conferences.oreillynet.com/cs/et2005/view/e_sess/6241)

Download the Mashup presentation from the O’Reilly Emerging Technology Conference.

[www.theurer.cc/blog/2005/11/03/how-to-build-a-maps-mash-up/](http://www.theurer.cc/blog/2005/11/03/how-to-build-a-maps-mash-up/)

Tutorial: “How to Build a Maps Mashup,” by Dan Theurer. Includes the JavaScript code and a sample mashup application.

### Mashup Directories

[www.programmableweb.com/mashups](http://www.programmableweb.com/mashups)

ProgrammableWeb ([www.programmableweb.com/mashups](http://www.programmableweb.com/mashups)) lists the latest mashups, APIs, and web platforms news and developments. It includes a directory of new mashups, the most popular mashups, and more. Search for mashups by common tags including mapping, photo, search, shopping, sports, travel, messaging, news, transit and real estate. Check out the Web 2.0 Mashup matrix with links to numerous mashups. For each site, you’ll find the mashups that have been created with the other sites in the matrix.

[www.programmableweb.com/matrix](http://www.programmableweb.com/matrix)

ProgrammableWeb includes a Web 2.0 Mashup matrix with links to numerous mashups. For each of the sites listed, find the mashups that have been created with the other sites in the matrix.

[googlemansia.blogspot.com/](http://googlemapsmania.blogspot.com/)

Lists numerous mashups that use Google Maps. Examples include Google Maps mashups with US hotels, public transit information, UK news and more.

[www.webmashup.com](http://www.webmashup.com)

An open directory for mashups and Web 2.0 APIs.

### Mashup Resources

[code.google.com/](http://code.google.com/)

Google APIs include Google Maps, Google AJAX Search API, Google Toolbar API, AdWords API, Google Data APIs, Google Checkout API and WikiWalki (Google APIs used in Google Maps).

[www.flickr.com/services/api/](http://www.flickr.com/services/api/)

APIs available from Flickr include updating photos, replacing photos, example requests and asynchronous uploading. API kits include Java, ActionScript, Cold Fusion, Common Lisp, cUrl, Delphi, .NET, Perl, PHP, PHP5, Python, REALbasic and Ruby.

[developers.technorati.com/wiki/TechnoratiApi](http://developers.technorati.com/wiki/TechnoratiApi)

APIs available at Technorati include CosmosQuery, SearchQuery, GetInfoQuery, OutboundQuery and BlogInfoQuery. New and experimental APIs include TagQuery, AttentionQuery and KeyInfo.

[mashworks.net/wiki/Building\\_Mash-ups\\_for\\_Non-Programmers](http://mashworks.net/wiki/Building_Mash-ups_for_Non-Programmers)

Article: “Building Mashups for Non-Programmers,” from MashWorks. Gives non-programmers sources for creating mashups, such as links to mapping services and examples of mashups created by non-programmers using both Google Maps and Flickr.

### Mashup Tools and Downloads

[mashup-tools.pbwiki.com/](http://mashup-tools.pbwiki.com)

Mashup Tools Wiki is a developer’s source for tools and tips for building technology mashups.

[programmableweb.com/faq](http://programmableweb.com/faq)

Mashups FAQ on ProgrammableWeb provides an introduction to mashups and APIs and discusses how to create your own mashups and more.

# Unicode®

## I.1 Introduction

The use of inconsistent [character encodings](#) (i.e., numeric values associated with characters) when developing global software products causes serious problems because computers process information using numbers. For example, the character “a” is converted to a numeric value so that a computer can manipulate that piece of data. Many countries and corporations have developed encoding systems that are incompatible with the encoding systems of other countries and corporations. For example, the Microsoft Windows operating system assigns the value 0xC0 to the character “A with a grave accent,” while the Apple Macintosh operating system assigns the same value to an upside-down question mark. This results in the misrepresentation and possible corruption of data.

In the absence of a universal character encoding standard, global software developers had to localize their products extensively before distribution. [Localization](#) includes the language translation and cultural adaptation of content. The process of localization usually includes significant modifications to the source code (e.g., the conversion of numeric values and the underlying assumptions made by programmers), which results in increased costs and delays in releasing the software. For example, an English-speaking programmer might design a global software product assuming that a single character can be represented by one byte. However, when those products are localized in Asian markets, the programmer’s assumptions are no longer valid because there are many more Asian characters, and therefore most, if not all, of the code needs to be rewritten. Localization is necessary with each release of a version. By the time a software product is localized for a particular market, a newer version, which needs to be localized as well, can be ready for distribution. As a result, it is cumbersome and costly to produce and distribute global software products in a market where there is no universal character encoding standard.

In response to this situation, the [Unicode Standard](#), an encoding standard that facilitates the production and distribution of software, was created. The Unicode Standard outlines a specification to produce consistent encoding of the world’s characters and symbols. Software products which handle text encoded in the Unicode Standard need to be

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## II Appendix I Unicode®

localized, but the localization process is simpler and more efficient because the numeric values need not be converted and the assumptions made by programmers about the character encoding are universal. The Unicode Standard is maintained by a non-profit organization called the [Unicode Consortium](#), whose members include Apple, IBM, Microsoft, Oracle, Sun Microsystems, Sybase and many others.

When the Consortium envisioned and developed the Unicode Standard, it wanted an encoding system that was [universal](#), [efficient](#), [uniform](#) and [unambiguous](#). A universal encoding system encompasses all commonly used characters. An efficient encoding system allows text files to be parsed quickly. A uniform encoding system assigns fixed values to all characters. An unambiguous encoding system represents a given character in a consistent manner. These four terms are referred to as the Unicode Standard design basis.

### I.2 Unicode Transformation Formats

Although Unicode incorporates the limited ASCII character set (i.e., a collection of characters), it encompasses a more comprehensive character set. In ASCII each character is represented by a byte containing 0s and 1s. One byte is capable of storing the binary numbers from 0 to 255. Each character is assigned a number between 0 and 255, thus ASCII-based systems can support only 256 characters, a tiny fraction of the world's characters. Unicode extends the ASCII character set by encoding the vast majority of the world's characters. The Unicode Standard encodes characters in a uniform numerical space from 0 to 10FFFF hexadecimal. An implementation will express these numbers in one of several transformation formats, choosing the one that best fits the particular application at hand.

Three such formats are in use, called [UTF-8](#), [UTF-16](#) and [UTF-32](#). UTF-8, a variable-width encoding form, requires one to four bytes to express each Unicode character. UTF-8 data consists of 8-bit bytes (sequences of one, two, three or four bytes depending on the character being encoded) and is well suited for ASCII-based systems when there is a predominance of one-byte characters (ASCII represents characters as one-byte). Currently, UTF-8 is widely implemented in UNIX systems and in databases.

The variable-width UTF-16 encoding form expresses Unicode characters in units of 16-bits (i.e., as two adjacent bytes, or a short integer in many machines). Most characters of Unicode are expressed in a single 16-bit unit. However, characters with values above FFFF hexadecimal are expressed with an ordered pair of 16-bit units called [surrogates](#). Surrogates are 16-bit integers in the range D800 through DFFF, which are used solely for the purpose of “escaping” into higher numbered characters. Approximately one million characters can be expressed in this manner. Although a surrogate pair requires 32 bits to represent characters, it is space-efficient to use these 16-bit units. Surrogates are rare characters in current implementations. Many string-handling implementations are written in terms of UTF-16. [Note: Details and sample-code for UTF-16 handling are available on the Unicode Consortium Web site at [www.unicode.org](http://www.unicode.org).]

Implementations that require significant use of rare characters or entire scripts encoded above FFFF hexadecimal, should use UTF-32, a 32-bit fixed-width encoding form that usually requires twice as much memory as UTF-16 encoded characters. The major advantage of the fixed-width UTF-32 encoding form is that it expresses all characters uniformly, so it is easy to handle in arrays.

There are few guidelines that state when to use a particular encoding form. The best encoding form to use depends on the computer system and business protocol, not on the

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

### I.3 Characters and Glyphs III

data itself. Typically, the UTF-8 encoding form should be used where computer systems and business protocols require data to be handled in 8-bit units, particularly in legacy systems being upgraded, because it often simplifies changes to existing programs. For this reason, UTF-8 has become the encoding form of choice on the Internet. Likewise, UTF-16 is the encoding form of choice on Microsoft Windows applications. UTF-32 is likely to become more widely used in the future as more characters are encoded with values above FFFF hexadecimal. UTF-32 requires less sophisticated handling than UTF-16 in the presence of surrogate pairs. Figure I.1 shows the different ways in which the three encoding forms handle character encoding.

Character	UTF-8	UTF-16	UTF-32
LATIN CAPITAL LETTER A	0x41	0x0041	0x00000041
GREEK CAPITAL LETTER ALPHA	0xCD 0x91	0x0391	0x00000391
CJK UNIFIED IDEOGRAPH-4E95	0xE4 0xBA 0x95	0x4E95	0x00004E95
OLD ITALIC LETTER A	0xF0 0x80 0x83 0x80	0xDC00 0xDF00	0x00010300

**Fig. I.1** | Correlation between the three encoding forms.

### I.3 Characters and Glyphs

The Unicode Standard consists of characters—written components (i.e., alphabets, numbers, punctuation marks, accent marks, etc.) that can be represented by numeric values. An example of such a character is U+0041 LATIN CAPITAL LETTER A. In the first character representation, **U+yyyy** is a **code value**, in which U+ refers to Unicode code values, as opposed to other hexadecimal values. The **yyyy** represents a four-digit hexadecimal number of an encoded character. Code values are bit combinations that represent encoded characters. Characters are represented using **glyphs**—various shapes, fonts and sizes for displaying characters. There are no code values for glyphs in the Unicode Standard. Examples of glyphs are shown in Fig. I.2.

The Unicode Standard encompasses the alphabets, ideographs, syllabaries, punctuation marks, **diacritics**, mathematical operators and other features, that comprise the written languages and scripts of the world. A diacritic is a special mark added to a character to distinguish it from another letter or to indicate an accent (e.g., in Spanish, the tilde “~” above the character “n”). Currently, Unicode provides code values for 96,382 character representations, with more than 878,000 code values reserved for future expansion.

**Fig. I.2** | Various glyphs of the character A.

**IV Appendix I Unicode®**

## I.4 Advantages/Disadvantages of Unicode

The Unicode Standard has several significant advantages that promote its use. One is the impact it has on the performance of the international economy. Unicode standardizes the characters for the world's writing systems to a uniform model that promotes transferring and sharing data. Programs developed using such a schema maintain their accuracy because each character has a single definition (i.e., *a* is always U+0061, % is always U+0025). This enables corporations to manage the high demands of international markets by processing different writing systems at the same time. All characters can be managed in an identical manner, thus avoiding any confusion caused by different character-code architectures. Moreover, managing data in a consistent manner eliminates data corruption, because data can be sorted, searched and manipulated using a consistent process.

Another advantage of the Unicode Standard is portability (i.e., software that can execute on disparate computers or with disparate operating systems). Most operating systems, databases, programming languages (including Java and Microsoft's .NET languages) and Web browsers currently support, or are planning to support, Unicode.

A disadvantage of the Unicode Standard is the amount of memory required by UTF-16 and UTF-32. ASCII character sets are 8-bits in length, so they require less storage than the default 16-bit Unicode character set. The **double-byte character set (DBCS)** encodes Asian characters with one or two bytes per character. The **multibyte character set (MBCS)** encodes characters with a variable number of bytes per character. In such instances, the UTF-16 or UTF-32 encoding forms may be used with little hindrance on memory and performance.

Another disadvantage of Unicode is that although it includes more characters than any other character set in common use, it does not yet encode all of the world's written characters. Also, UTF-8 and UTF-16 are variable-width encoding forms, so characters occupy different amounts of memory.

## I.5 Unicode Consortium's Web Site

If you would like to learn more about the Unicode Standard, visit [www.unicode.org](http://www.unicode.org). This site provides a wealth of information about the Unicode Standard. Currently, the home page is organized into various sections: New to Unicode, General Information, The Consortium, The Unicode Standard, Work in Progress and For Members, Key Specifications and Technical Publications.

The **New to Unicode** section consists of four subsections: **What is Unicode?**, **How to Use this Site**, **FAQ** and **Glossary of Unicode Terms**. The first subsection provides a technical introduction to Unicode by describing design principles, character interpretations and assignments, text processing and Unicode conformance. This subsection is recommended reading for anyone new to Unicode. Also, this subsection provides a list of related links that provide the reader with additional information about Unicode. The **How to Use this Site** subsection contains information about using and navigating the site as well hyperlinks to additional resources.

The **General Information** section contains five subsections: **Where is my Character?**, **Display Problems?**, **Useful Resources**, **Unicode Enabled Products** and **Mail Lists**. The main areas covered in this section include a link to the Unicode code charts (a complete listing of code values) assembled by the Unicode Consortium as well as a detailed outline on how to locate an encoded character in the code chart. Also, the section contains advice on how

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## I.6 Using Unicode ▼

to configure different operating systems and Web browsers so that the Unicode characters can be viewed properly. Moreover, from this section, the user can navigate to other sites that provide information on various topics, such as fonts, linguistics and such other standards as the [Armenian Standards Page](#) and the [Chinese GB 18030 Encoding Standard](#).

The [Consortium](#) section consists of eight subsections: [Who We Are](#), [Our Members](#), [How to Join](#), [Conferences](#), [Job Postings](#), [Press Info](#), [Policies & Positions](#) and [Contact Us](#). This section provides a list of the current Unicode Consortium members as well as information on how to become a member. Privileges for each member type—[full](#), [associate](#), [specialist](#) and [individual](#)—and the fees assessed to each member are listed here.

The [For Members](#) section consists of two subsections that are available only to consortium members: [Member Resources](#) and [Working Documents](#).

The [Unicode Standard](#) section consists of five subsections: [Start Here](#), [Latest Version](#), [Code Charts](#), [Unicode Character Database](#) and [Unihan Database](#). This section describes the updates applied to the latest version of the Unicode Standard and categorizes all defined encoding. The user can learn how the latest version has been modified to encompass more features and capabilities. For instance, one enhancement of Version 3.1 is that it contains additional encoded characters.

The [Key Specifications](#) and [Technical Publications](#) sections provide all the Unicode technical documentation.

The [Work in Progress](#) section consists of seven subsections: [Calendar of Meetings](#), [Proposals for Public Review](#), [Unicode Technical Committee](#), [UTC Meeting Minutes](#), [Proposed Characters](#), [Submitting Proposals](#) and [CLDR Technical Committee](#). This section presents the user with a catalog of the recent characters included into the Unicode Standard scheme as well as those characters being considered for inclusion. If users determine that a character has been overlooked, then they can submit a written proposal for the inclusion of that character. The [Submitting Proposals](#) subsection contains strict guidelines that must be adhered to when submitting written proposals. In addition, this section provides information about upcoming and past technical committee meetings.

## I.6 Using Unicode

Numerous programming languages (e.g., C, Java, JavaScript, Perl, Visual Basic) provide some level of support for the Unicode Standard. The application shown in Fig. I.3–Fig. I.4 prints the text “Welcome to Unicode!” in eight different languages: English, Russian, French, German, Japanese, Portuguese, Spanish and Traditional Chinese.

Class `UnicodeJFrame` (Fig. I.3) uses escape sequences to represent characters. An escape sequence is in the form `\uyyyy`, where `yyyy` represents the four-digit hexadecimal

```

## I.7 Character Ranges VII

```

1 // Fig. F.4: Unicode.java
2 // Display Unicode.
3 import javax.swing.JFrame;
4
5 public class Unicode
6 {
7 public static void main(String args[])
8 {
9 UnicodeJFrame unicodeJFrame = new UnicodeJFrame();
10 unicodeJFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 unicodeJFrame.setSize(350, 250);
12 unicodeJFrame.setVisible(true);
13 } // end method main
14 } // end class Unicode

```

**Fig. I.4** | Displaying Unicode.

code value. Lines 17–18 contain the series of escape sequences necessary to display “Welcome to Unicode!” in English. The first escape sequence (\u0057) equates to the character “W,” the second escape sequence (\u0065) equates to the character “e,” and so on. The \u0020 escape sequence (line 18) is the encoding for the space character. The \u0074 and \u006F escape sequences equate to the word “to.” Note that “Unicode” is not encoded because it is a registered trademark and has no equivalent translation in most languages. Line 18 also contains the \u0021 escape sequence for the exclamation point (!).

Lines 22–56 contain the escape sequences for the other seven languages. The Unicode Consortium’s Web site contains a link to code charts that lists the 16-bit Unicode code values. The English, French, German, Portuguese and Spanish characters are located in the **Basic Latin** block, the Japanese characters are located in the **Hiragana** block, the Russian characters are located in the **Cyrillic** block and the Traditional Chinese characters are located in the **CJK Unified Ideographs** block. The next section discusses these blocks.

## I.7 Character Ranges

The Unicode Standard assigns code values, which range from 0000 (**Basic Latin**) to E007F (**Tags**), to the written characters of the world. Currently, there are code values for 96,382 characters. To simplify the search for a character and its associated code value, the Unicode Standard generally groups code values by **script** and function (i.e., Latin characters are grouped in a block, mathematical operators are grouped in another block, etc.). As a rule, a script is a single writing system that is used for multiple languages (e.g., the Latin script

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## VIII Appendix I Unicode®

is used for English, French, Spanish, etc.). The **Code Charts** page on the Unicode Consortium Web site lists all the defined blocks and their respective code values. Figure I.5 lists some blocks (scripts) from the Web site and their range of code values.

Script	Range of code values
Arabic	U+0600–U+06FF
Basic Latin	U+0000–U+007F
Bengali (India)	U+0980–U+09FF
Cherokee (Native America)	U+13A0–U+13FF
CJK Unified Ideographs (East Asia)	U+4E00–U+9FFF
Cyrillic (Russia and Eastern Europe)	U+0400–U+04FF
Ethiopic	U+1200–U+137F
Greek	U+0370–U+03FF
Hangul Jamo (Korea)	U+1100–U+11FF
Hebrew	U+0590–U+05FF
Hiragana (Japan)	U+3040–U+309F
Khmer (Cambodia)	U+1780–U+17FF
Lao (Laos)	U+0E80–U+0EFF
Mongolian	U+1800–U+18AF
Myanmar	U+1000–U+109F
Ogham (Ireland)	U+1680–U+169F
Runic (Germany and Scandinavia)	U+16A0–U+16FF
Sinhala (Sri Lanka)	U+0D80–U+0DFF
Telugu (India)	U+0C00–U+0C7F
Thai	U+0E00–U+0E7F

**Fig. I.5** | Some character ranges.

### Self-Review Exercises

**I.1** Fill in the blanks in each of the following.

- Global software developers had to \_\_\_\_\_ their products to a specific market before distribution.
- The Unicode Standard is a(n) \_\_\_\_\_ standard that facilitates the uniform production and distribution of software products.
- The four design basis that comprises the Unicode Standard are: \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.
- Characters are represented using \_\_\_\_\_.
- Software that can execute on different operating systems is said to be \_\_\_\_\_.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

Answers to Self-Review Exercises **IX**

- I.2** State whether each of the following is *true* or *false*. If *false*, explain why.
- The Unicode Standard encompasses all the world's characters.
  - A Unicode code value is represented as U+*yyyy*, where *yyyy* represents a number in binary notation.
  - A diacritic is a character with a special mark that emphasizes an accent.
  - Unicode is portable.
  - When designing Java programs, a Unicode escape sequence is denoted by /*uyyyy*.

**Answers to Self-Review Exercises**

**I.1** a) localize. b) encoding. c) universal, efficient, uniform, unambiguous. d) glyphs. e) portable.

**I.2** a) False. It encompasses the majority of the world's characters. b) False. The *yyyy* represents a hexadecimal number. c) False. A diacritic is a special mark added to a character to distinguish it from another letter or to indicate an accent. d) True. e) False. A Unicode escape sequence is denoted by \*uyyyy*.

**Exercises**

**I.3** Navigate to the Unicode Consortium Web site ([www.unicode.org](http://www.unicode.org)) and write the hexadecimal code values for the following characters. In which block were they located?

- Latin letter "Z."
- Latin letter "n" with the "tilde (~)."
- Greek letter "delta."
- Mathematical operator "less than or equal to."
- Punctuation symbol "open quote (".)".

**I.4** Describe the Unicode Standard design basis.

**I.5** Define the following terms:

- code value.
- surrogates.
- Unicode Standard.

**I.6** Define the following terms:

- UTF-8.
- UTF-16.
- UTF-32.

**I.7** Describe a scenario where it is optimal to store your data in UTF-16 format.

**I.8** Using the Unicode Standard code values, write a Java program that prints your first and last name. The program should print your name in all uppercase letters and in all lowercase letters. If you know other languages, print your first and last name in those languages as well.

# Using the Java API Documentation

## J.1 Introduction

The Java class library contains thousands of predefined classes and interfaces that programmers can use to write their own applications. These classes are grouped into packages based on their functionality. For example, the classes and interfaces used for file processing are grouped into the `java.io` package, and the classes and interfaces for networking applications are grouped into the `java.net` package. The [Java API documentation](#) lists the `public` and `protected` members of each class and the `public` members of each interface in the Java class library. The documentation overviews all the classes and interfaces, summarizes their members (i.e., the fields, constructors and methods of classes, and the fields and methods of interfaces) and provides detailed descriptions of each member. Most Java programmers rely on this documentation when writing programs. Normally, programmers would search the API to find the following:

1. The package that contains a particular class or interface.
2. Relationships between a particular class or interface and other classes and interfaces.
3. Class or interface constants—normally declared as `public static final` fields.
4. Constructors to determine how an object of the class can be initialized.
5. The methods of a class to determine whether they are `static` or `non-static`, the number and types of the arguments you need to pass, the return types and any exceptions that might be thrown from the method.

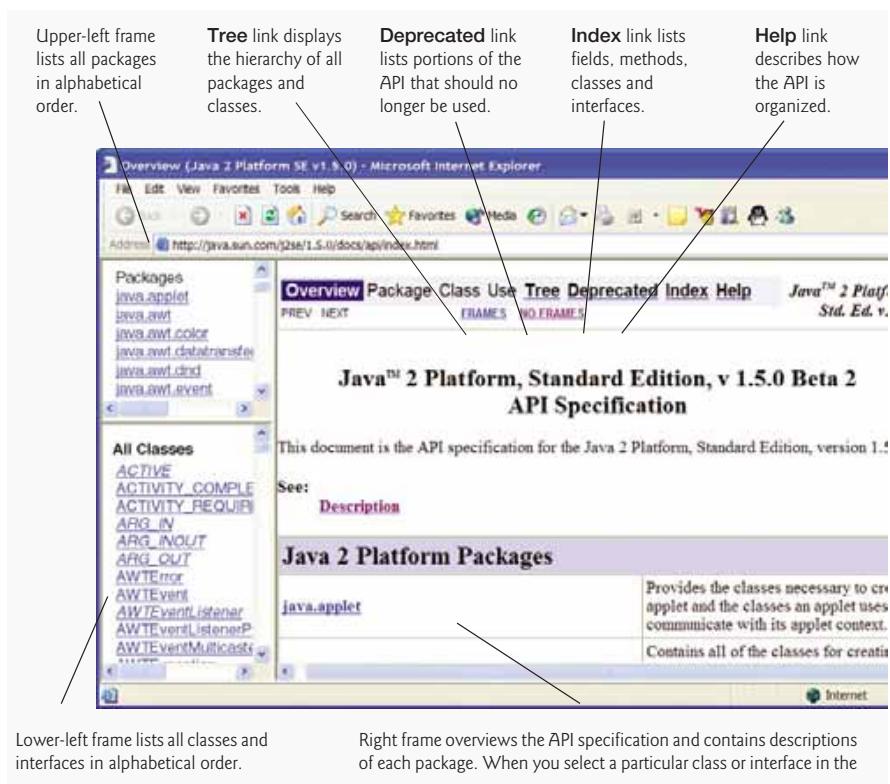

In addition, programmers often rely on the documentation to discover classes and interfaces that they have not used before. For this reason, we demonstrate the documentation with classes you know and classes you may not have studied yet. We show how to use the documentation to locate the information you need to use a class or interface effectively.

## XI Appendix J Using the Java API Documentation

### J.2 Navigating the Java API

The Java API documentation can be downloaded to your local hard disk or viewed online. To download the Java API documentation, go to [java.sun.com/javase/6/download.jsp](http://java.sun.com/javase/6/download.jsp) and locate the **DOWNLOAD** link in the **Java SE 6 Documentation** section. You'll be asked to accept a license agreement. To do this, click **Accept**, then click **Continue**. Click the **Java(TM) SE Development Kit Documentation 6** link to begin the download. After downloading the file, you can use a ZIP file-extraction program, such as WinZip ([www.winzip.com](http://www.winzip.com)), to extract the files. If you are using Windows, extract the contents to your JDK's installation directory. (See the *Before You Begin* section of this book for information on installing Java.) To view the API documentation on your local hard disk in Microsoft Windows, open `C:\Program Files\Java\jdk1.6.0\docs\api\index.html` page in your browser. To view the API documentation on line, go to [java.sun.com/javase/6/docs/api/index.html](http://java.sun.com/javase/6/docs/api/index.html) (Fig. J.1). [Note: We released this book to publication several days before the final Java SE 6 API documentation became available, so all the screen captures presented here are based on the release candidate documentation.]

**Fig. J.1** | Java API overview. (Courtesy of Sun Microsystems, Inc.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## J.2 Navigating the Java API XII

### *Frames in the API Documentation's index.html Page*

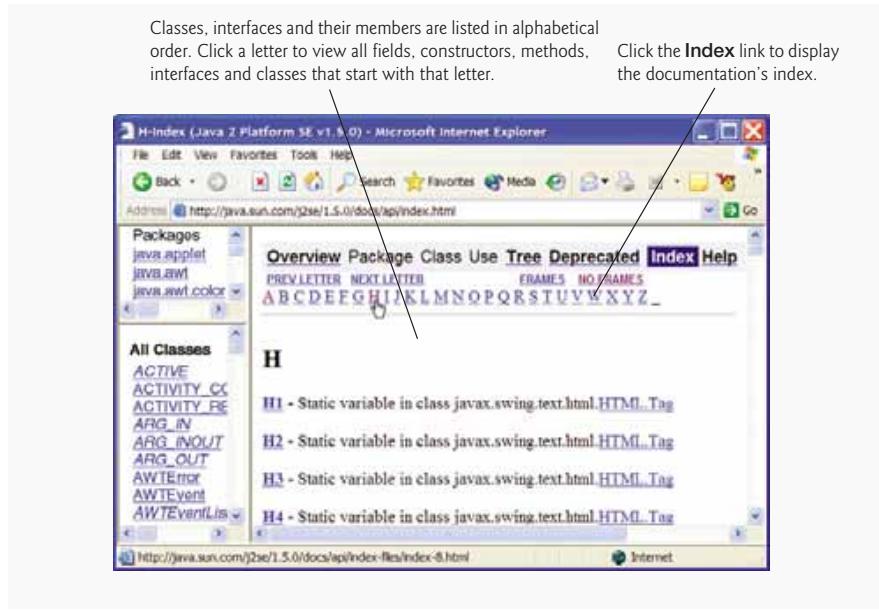

The API documentation is divided into three frames (see Fig. J.1). The upper-left frame lists all of the Java API's packages in alphabetical order. The lower-left frame initially lists the Java API's classes and interfaces in alphabetical order. Interface names are displayed in italic. When you click a specific package in the upper-left frame, the lower-left frame lists the classes and interfaces of the selected package. The right frame initially provides a brief description of each package of the Java API specification—read this overview to become familiar with the general capabilities of the Java APIs. If you select a class or interface in the lower-left frame, the right frame displays information about that class or interface.

### *Important Links in the index.html Page*

At the top of the right frame (Fig. J.1), there are four links—**Tree**, **Deprecated**, **Index** and **Help**. The **Tree** link displays the hierarchy of all packages, classes and interfaces in a tree structure. The **Deprecated** link displays interfaces, classes, exceptions, fields, constructors and methods that should no longer be used. The **Index** link displays classes, interfaces, fields, constructors and methods in alphabetical order. The **Help** link describes how the API documentation is organized. You should probably begin by reading the **Help** page.

### *Viewing the Index Page*

If you do not know the name of the class you are looking for, but you do know the name of a method or field, you can use the documentation's index to locate the class. The **Index** link is located near the upper-right corner of the right frame. The index page (Fig. J.2) displays fields, constructors, methods, interfaces and classes in alphabetical order. For example, if you are looking for Scanner method `hasNextInt`, but do not know the class name,

**Fig. J.2** | Viewing the **Index** page. (Courtesy of Sun Microsystems, Inc.)

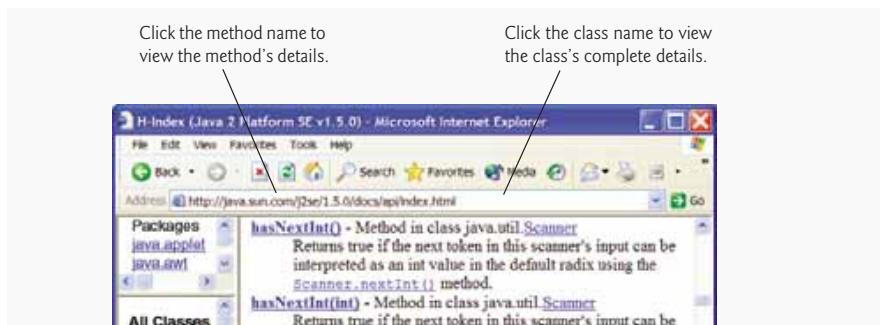

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

### XIII Appendix J Using the Java API Documentation

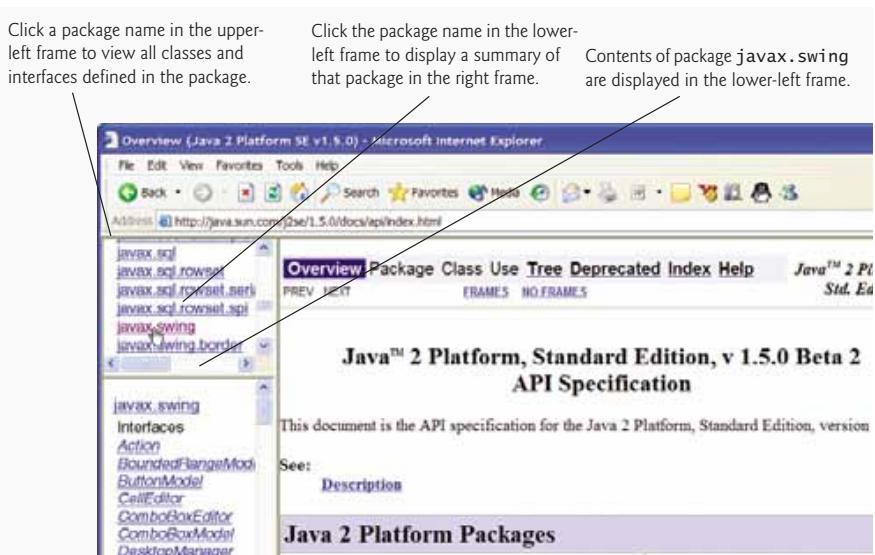

you can click the **H** link to go to the alphabetical listing of all items in the Java API that begin with "h". Scroll to method `hasNextInt` (Fig. J.3). Once there, each method named `hasNextInt` is listed with the package name and class to which the method belongs. From there, you can click the class name to view the class's complete details, or you can click the method name to view the method's details.

#### *Viewing a Specific Package*

When you click the package name in the upper-left frame, all classes and interfaces from that package are displayed in the lower-left frame and are divided into five subsections—**Interfaces**, **Classes**, **Enums**, **Exceptions** and **Errors**—each listed alphabetically. For example, the contents of package `javax.swing` are displayed in the lower-left frame (Fig. J.4)

**Fig. J.3** | Scroll to method `hasNextInt`. (Courtesy of Sun Microsystems, Inc.)

**Fig. J.4** | Clicking a package name in the upper-left frame to view all classes and interfaces declared in this package. (Courtesy of Sun Microsystems, Inc.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## J.2 Navigating the Java API XIV

when you click `javax.swing` in the upper-left frame. You can click the package name in the lower-left frame to get an overview of the package. If you think that a package contains several classes that could be useful in your application, the package overview can be especially helpful.

### *Viewing the Details of a Class*

When you click a class name or interface name in the lower-left frame, the right frame displays the details of that class or interface. First you will see the class's package name followed by a hierarchy that shows the class's relationship to other classes. You will also see a list of the interfaces implemented by the class and the class's known subclasses. Figure J.5 shows the beginning of the documentation page for class `JButton` from the `javax.swing` package. The page first shows the package name in which the class appears. This is followed by the

**Fig. J.5** | Clicking a class name to view detailed information about the class. (Courtesy of Sun Microsystems, Inc.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## XV Appendix J Using the Java API Documentation

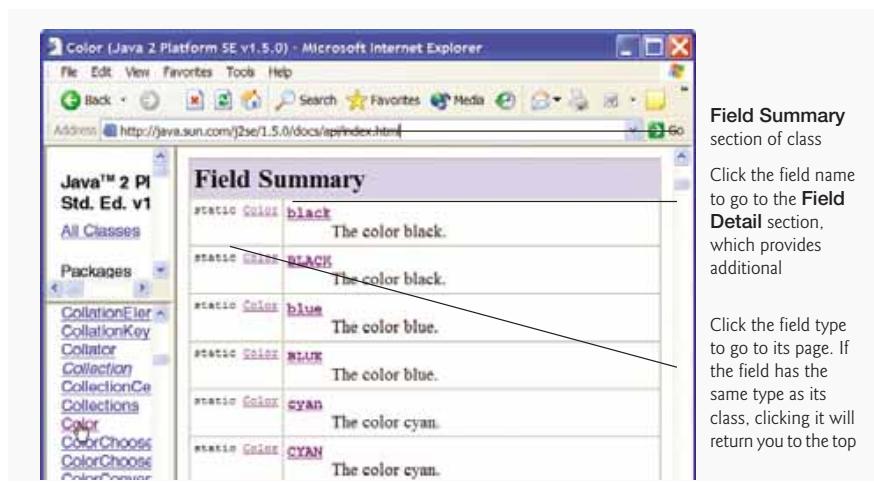

class hierarchy that leads to class `JButton`, the interfaces class `JButton` implements and the subclasses of class `JButton`. The bottom of the right frame shows the beginning of class `JButton`'s description. Note that when you look at the documentation for an interface, the right frame does not display a hierarchy for that interface. Instead, the right frame lists the interface's superinterfaces, known subinterfaces and known implementing classes.

### *Summary Sections in a Class's Documentation Page*

Other parts of each API page are listed below. Each part is presented only if the class contains or inherits the items specified. Class members shown in the summary sections are `public` unless they are explicitly marked as `protected`. A class's `private` members are not shown in the documentation, because they cannot be used directly in your programs.

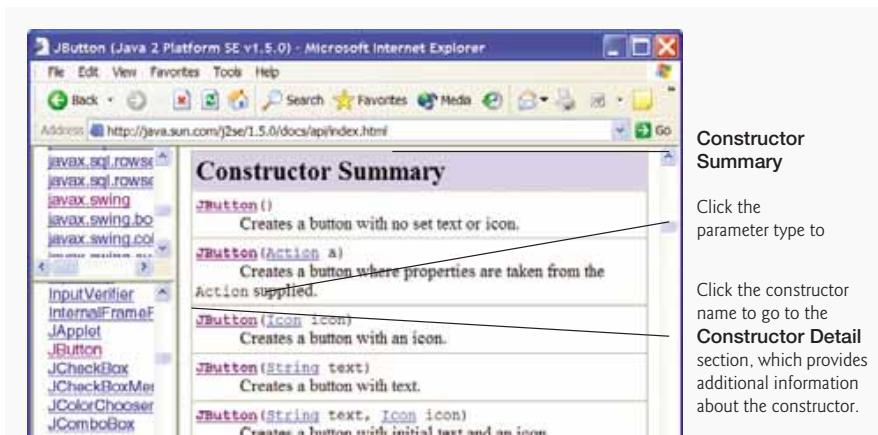

1. The **Nested Class Summary** section summarizes the class's `public` and `protected` nested classes—i.e., classes that are defined inside the class. Unless explicitly specified, these classes are `public` and `non-static`.
2. The **Field Summary** section summarizes the class's `public` and `protected` fields. Unless explicitly specified, these fields are `public` and `non-static`. Figure J.6 shows the **Field Summary** section of class `Color`.
3. The **Constructor Summary** section summarizes the class's constructors. Constructors are not inherited, so this section appears in the documentation for a class only if the class declares one or more constructors. Figure J.7 shows the **Constructor Summary** section of class `JButton`.
4. The **Method Summary** section summarizes the class's `public` and `protected` methods. Unless explicitly specified, these methods are `public` and `non-static`. Figure J.8 shows the **Method Summary** section of class `BufferedInputStream`.

Note that the summary sections typically provide only a one-sentence description of a class member. Additional details are presented in the detail sections discussed next.

**Fig. J.6 |** Field Summary section of class `Color`. (Courtesy of Sun Microsystems, Inc.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

J.2 Navigating the Java API **XVI**

**Fig. J.7** | Constructor Summary section of class JButton. (Courtesy of Sun Microsystems, Inc.)

**Fig. J.8** | Method Summary section of class BufferedInputStream. (Courtesy of Sun Microsystems, Inc.)

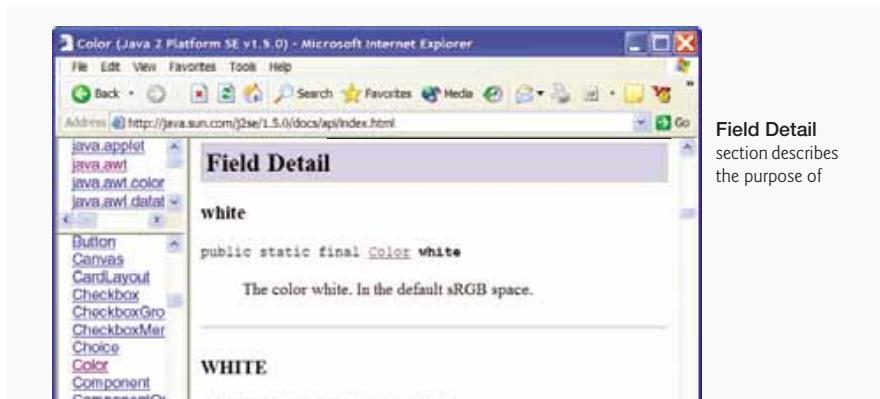

#### *Detail Sections in a Class's Documentation Page*

After the summary sections are detail sections that normally provide more discussion of particular class members. There is not a detail section for nested classes. When you click the link in the **Nested Class Summary** for a particular nested class, a documentation page describing that nested class is displayed. The detail sections are described below.

1. The **Field Detail** section provides the declaration of each field. It also discusses each field, including the field's modifiers and meaning. Figure J.9 shows the **Field Detail** section of class Color.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## XVII Appendix J Using the Java API Documentation

**Fig. J.9** | Field Detail section of class Color. (Courtesy of Sun Microsystems, Inc.)

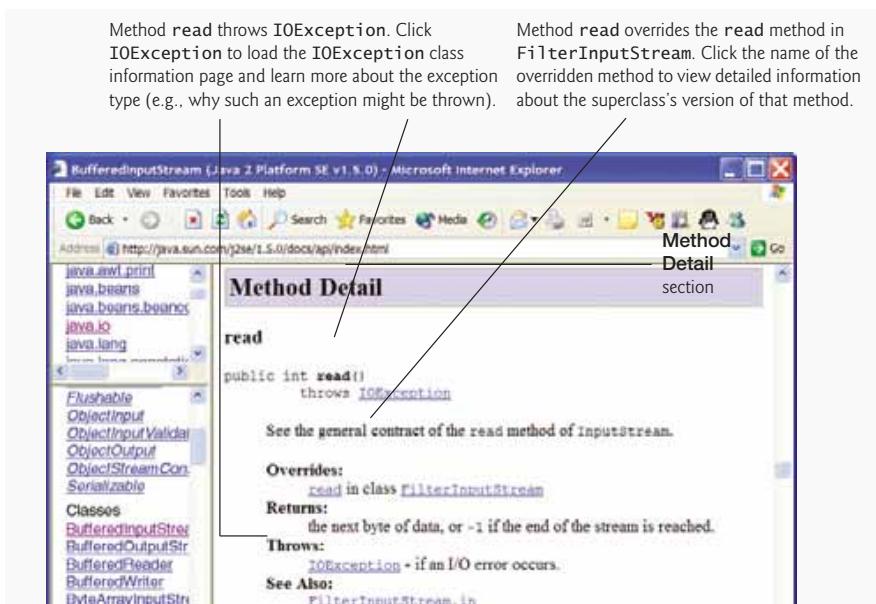

2. The **Constructor Detail** section provides the first line of each constructor's declaration and discusses the constructors. The discussion includes the modifiers of each constructor, a description of each constructor, each constructor's parameters and any exceptions thrown by each constructor. Figure J.10 shows the **Constructor Detail** section of class JButton.
3. The **Method Detail** section provides the first line of each method. The discussion of each method includes its modifiers, a more complete method description, the method's parameters, the method's return type and any exceptions thrown by the method. Figure J.11 shows the **Method Detail** section of class BufferedInputStream. The method details show you other methods that might be of interest (labeled as **See Also**). If the method overrides a method of the superclass, the name of the superclass method and the name of the superclass are provided so you can link to the method or superclass for more information.

**Fig. J.10** | Constructor Detail section of class JButton. (Courtesy of Sun Microsystems, Inc.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## J.2 Navigating the Java API XVIII

**Fig. J.11** | Method Detail section of class `BufferedInputStream`. (Courtesy of Sun Microsystems, Inc.)

As you look through the documentation, you will notice that there are often links to other fields, methods, nested-classes and top-level classes. These links enable you to jump from the class you are looking at to another relevant portion of the documentation.

# Creating Documentation with javadoc

## K.1 Introduction

In this appendix, we provide an introduction to **javadoc**—a tool used to create HTML files that document Java code. This tool is used by Sun to create the Java API documentation (Fig. K.1). We discuss the special Java comments and tags required by javadoc to create documentation based on your source code and how to execute the javadoc tool. For detailed information on javadoc, visit the javadoc home page at

[java.sun.com/javase/6/docs/technotes/guides/javadoc/index.html](http://java.sun.com/javase/6/docs/technotes/guides/javadoc/index.html)

## K.2 Documentation Comments

Before HTML files can be generated with the javadoc tool, programmers must insert special comments—called **documentation comments**—into their source files. Documentation comments are the only comments recognized by javadoc. Documentation comments begin with `/**` and end with `*/`. Like the traditional comments, documentation comments can span multiple lines. An example of a simple documentation comment is

```
/** Sorts integer array using MySort algorithm */
```

Like other comments, documentation comments are not translated into bytecodes. Because javadoc is used to create HTML files, documentation comments can contain HTML tags. For example, the documentation comment

```
/** Sorts integer array using MySort algorithm */
```

contains the HTML bold tags `<B>` and `</B>`. In the generated HTML files, `MySort` will appear in bold. As we will see, **javadoc tags** can also be inserted into the documentation comments to help javadoc document your source code. These tags—which begin with an `@` symbol—are not HTML tags.

146 * Gets the second.
147 * @return an <code>integer</code> specifying the second.
148 */
149 public int getSecond()
150 {
151 return second;
152 } // end method getSecond
153
154 /**
155 * Convert to String in universal-time format
156 * @return a <code>String</code> representation
157 * of the time in universal-time format
158 */
159 public String toUniversalString()
160 {
161 return String.format(
162 "%02d:%02d:%02d", getHour(), getMinute(), getSecond());
163 } // end method toUniversalString
164
165 /**
166 * Convert to String in standard-time format
167 * @return a <code>String</code> representation
168 * of the time in standard-time format
169 */
170 public String toStandardString()
171 {
172 return String.format("%d:%02d:%02d %s",
173 ((getHour() == 0 || getHour() == 12) ? 12 : getHour() % 12),
174 getMinute(), getSecond(), (getHour() < 12 ? "AM" : "PM"));
175 } // end method toStandardString
176 } // end class Time

```

**Fig. K.1** | Java source code file containing documentation comments. (Part 4 of 4.)

specifies the author of the class. More than one @author tag can be used to document multiple authors. [Note: The asterisks (\*) on each line between /\*\* and \*/ are not required. However, this is the recommended convention for aligning descriptions and javadoc tags. When parsing a documentation comment, javadoc discards all white-space characters up to the first non-white-space character in each line. If the first non-white-space character encountered is an asterisk, it is also discarded.]

Note that this documentation comment immediately precedes the class declaration—any code placed between the documentation comment and the class declaration causes javadoc to ignore the documentation comment. This is also true of other code structures (e.g., constructors, methods, instance variables.).

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

K.3 Documenting Java Source Code **XX**

### K.3 Documenting Java Source Code

In this section, we document a modified version of the `Time2` class from Fig. 8.5 using documentation comments. In the text that follows the example, we thoroughly discuss each of the javadoc tags used in the documentation comments. In the next section, we discuss how to use the `javadoc` tool to generate HTML documentation from this file.

Documentation comments are placed on the line before a class declaration, an interface declaration, a constructor, a method and a field (i.e., an instance variable or a reference). The first documentation comment (lines 5–9) introduces class `Time`. Line 6 is a description of class `Time` provided by the programmer. The description can contain as many lines as necessary to provide a description of the class to any programmer who may use it. Tags `@see` and `@author` are used to specify a `See Also:` note and an `Author:` note, respectively in the HTML documentation (Fig. K.2). The `See Also:` note specifies other related classes that may be of interest to a programmer using this class. The `@author` tag

```

1 // Fig. H.1: Time.java
2 // Time class declaration with set and get methods.
3 package com.deitel.jhttp6.appendH; // place Time in a package
4
5 /**
6 * This class maintains the time in 24-hour format.
7 * @see java.lang.Object
8 * @author Deitel & Associates, Inc.
9 */
10 public class Time
11 {
12 private int hour; // 0 - 23
13 private int minute; // 0 - 59
14 private int second; // 0 - 59
15
16 /**
17 * Time no-argument constructor initializes each instance variable
18 * to zero. This ensures that Time objects start in a consistent
19 * state. @throws Exception In the case of an invalid time
20 */
21 public Time() throws Exception
22 {
23 this(0, 0, 0); // invoke Time constructor with three arguments
24 } // end no-argument Time constructor
25
26 /**
27 * Time constructor
28 * @param h the hour
29 * @throws Exception In the case of an invalid time
30 */
31 public Time(int h) throws Exception
32 {
33 this(h, 0, 0); // invoke Time constructor with three arguments
34 } // end one-argument Time constructor
35

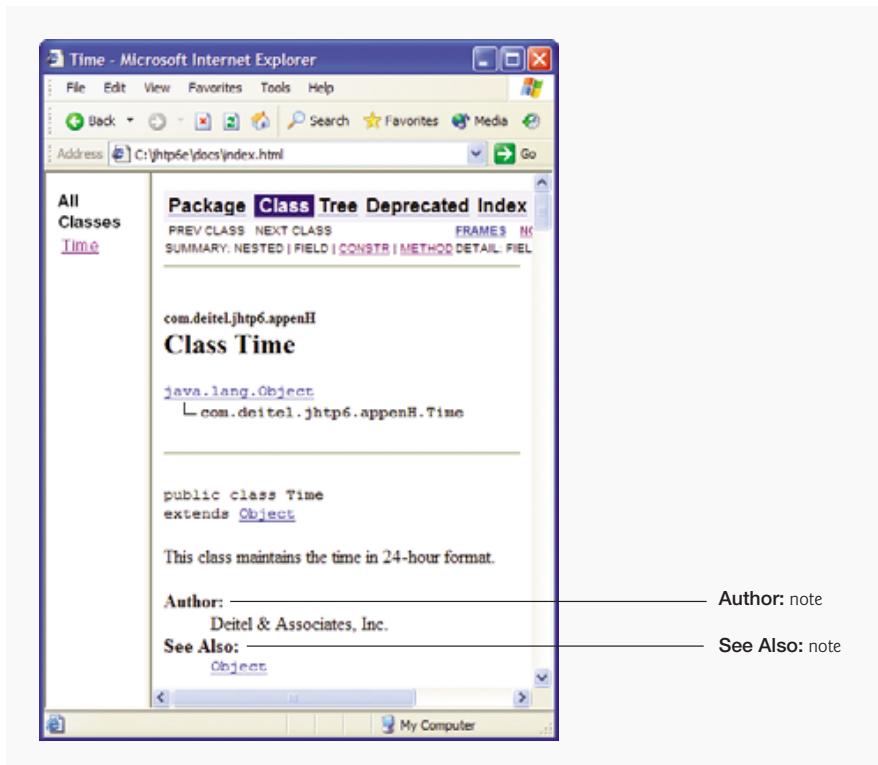

```

**Fig. K.1** | Java source code file containing documentation comments. (Part I of 4.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## K.3 Documenting Java Source Code

XXIV

**Fig. K.2** | Author: and See Also: notes generated by javadoc.

### Common Programming Error K.1

Placing an import statement between the class comment and the class declaration is a logic error. This causes the class comment to be ignored by javadoc.

### Software Engineering Observation K.1

Defining several fields in one comma-separated statement with a single comment above that statement will result in javadoc using that comment for all of the fields.

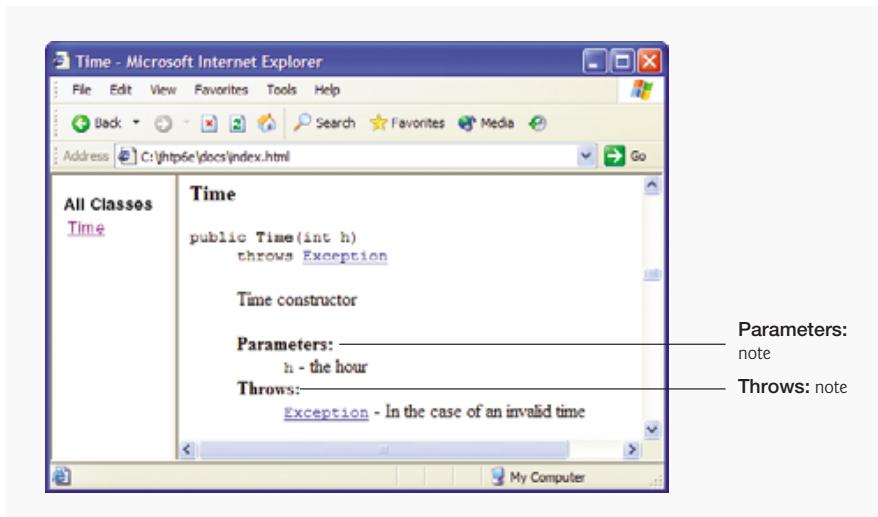

### Software Engineering Observation K.2

To produce proper javadoc documentation, you must declare every instance variable on a separate line.

The documentation comment on lines 26–30 describes the Time constructor. Tag `@param` describes a parameter to the constructor. Parameters appear in the HTML document in a **Parameters:** note (Fig. K.3) that is followed by a list of all parameters specified with the `@param` tag. For this constructor, the parameter's name is `h` and its description is "the hour". Tag `@param` can be used only with methods and constructors.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**XXV** Appendix K Creating Documentation with javadoc

**Fig. K.3** | **Parameters:** and **Throws:** note generated by javadoc.

The `@throws` tag specifies the exceptions thrown by this constructor. Like `@param` tags, `@throws` tags are only used with methods and constructors. One `@throws` should be supplied for each type of exception thrown by the method.

Documentation comments can contain multiple `@param` and `@see` tags. The documentation comment on lines 70–80 describes method `setTime`. The HTML generated for this method is shown in Fig. K.4. Three `@param` tags describe the method's parameters. This results in one **Parameters:** note which lists the three parameters. Methods `setHour`, `setMinute` and `setSecond` are tagged with `@see` to create hyperlinks to their descriptions in the HTML document. A `#` character is used instead of a dot when tagging a method or a field. This creates a link to the field or method name that follows the `#` character. We demonstrate three different ways (i.e., the fully qualified name, the class name qualification and no qualification) to tag methods using `@see` on lines 76–78. Line 76 uses the fully qualified name to tag the `setHour` method. If the fully qualified name is not given (lines 77 and 78), javadoc looks for the specified method or field in the following order: current class, superclasses, package and imported files.

The only other tag used in this file is `@return`, which specifies a **Returns:** note in the HTML documentation (Fig. K.5). The comment on lines 127–130 documents method `getHour`. Tag `@return` describes a method's return type to help the programmer understand how to use the return value of the method. By javadoc convention, programmers typeset source code (i.e., keywords, identifiers and expressions) with the HTML tags `<code>` and `</code>`. Several other javadoc tags are briefly summarized in Fig. K.6.

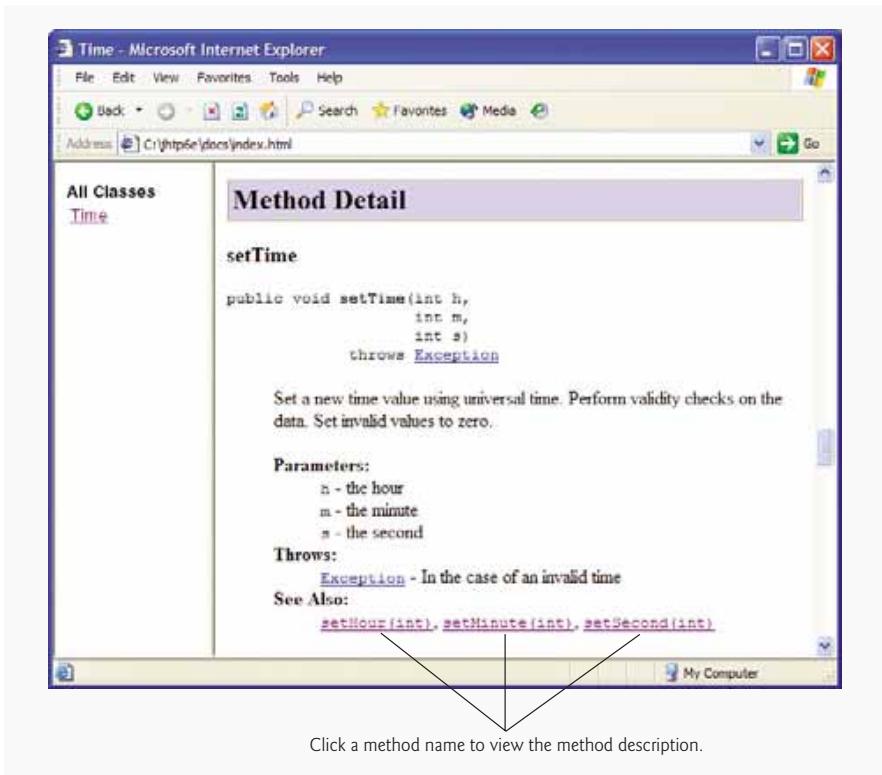

### Good Programming Practice K.1

Changing source code fonts in javadoc tags helps code names stand out from the rest of the description.

## XXVII Appendix K Creating Documentation with javadoc

javadoc tag	Description
<code>@deprecated</code>	Adds a <b>Deprecated</b> note. These are notes to programmers indicating that they should not use the specified features of the class. <b>Deprecated</b> notes normally appear when a class has been enhanced with new and improved features, but older features are maintained for backwards compatibility.
<code>{@link}</code>	This allows the programmer to insert an explicit hyperlink to another HTML document.
<code>@since</code>	Adds a <b>Since:</b> note. These notes are used for new versions of a class to indicate when a feature was first introduced. For example, the Java API documentation uses this to indicate features that were introduced in Java 1.5.
<code>@version</code>	Adds a <b>Version</b> note. These notes help maintain version number of the software containing the class or method.

**Fig. K.6** | Other javadoc tags.

## K.4 javadoc

In this section, we discuss how to execute the `javadoc` tool on a Java source file to create HTML documentation for the class in the file. Like other tools, `javadoc` is executed from the command line. The general form of the `javadoc` command is

```
javadoc options packages sources @files
```

where *options* is a list of command-line options, *packages* is a list of packages the user would like to document, *sources* is a list of java source files to document and *@files* is a list of text files containing the `javadoc` options, the names of packages and/or source files to send to the `javadoc` utility. [Note: All items are separated by spaces and *@files* is one word.] Figure K.7 shows a **Command Prompt** window containing the `javadoc` command we typed to generate the HTML documentation. For detailed information on the `javadoc`

```
C:\jhttp6e\appH_UsingJavadoc>javadoc -d C:\jhttp6e\docs -link "C:\Program Files\Java\jdk1.5.0\doc\api" -author Time.java
Creating destination directory: "C:\jhttp6e\docs\
Loading source file Time.java...
Constructing Javadoc information...

## K.5 Files Produced by javadoc XXVIII

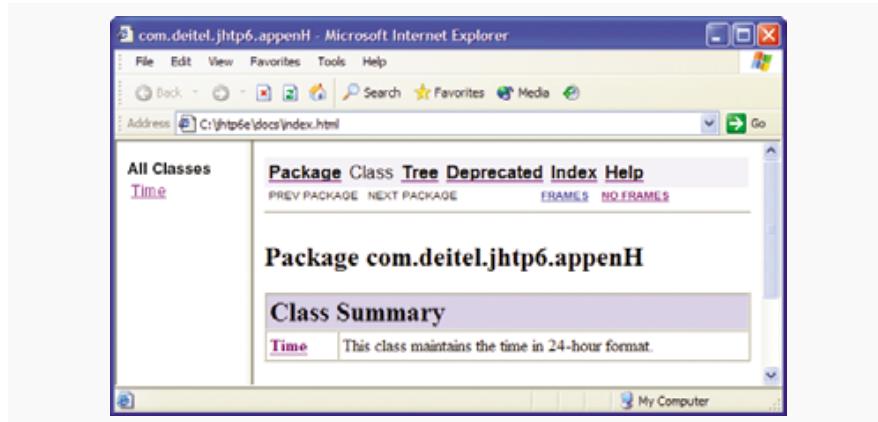

command, visit the javadoc reference guide and examples at [java.sun.com/j2se/5.0/docs/tooldocs/windows/javadoc.html](http://java.sun.com/j2se/5.0/docs/tooldocs/windows/javadoc.html).

In Fig. K.7, the **-d** option specifies the directory (e.g., C:\jhtp6\docs) where the HTML files will be stored on disk. We use the **-link** option so that our documentation links to Sun’s documentation (installed in the C:\Program Files\java\jdk1.5.0\docs directory). If the Sun documentation located in a different directory, specify that directory here; otherwise, you will receive an error from the javadoc tool. This creates a hyperlink between our documentation and Sun’s documentation (see Fig. K.4, where Java class `Exception` from package `java.lang` is hyperlinked). Without the **-link** argument, `Exception` appears as text in the HTML document—not a hyperlink to the Java API documentation for class `Exception`. The **-author** option instructs javadoc to process the `@author` tag (it ignores this tag by default).

### K.5 Files Produced by javadoc

In the last section, we executed the javadoc tool on the `Time.java` file. When javadoc executes, it displays the name of each HTML file it creates (see Fig. K.7). From the source file, javadoc created an HTML document for the class named `Time.html`. If the source file contains multiple classes or interfaces, a separate HTML document is created for each class. Because class `Time` belongs to a package, so the page will be created in the directory C:\jhtp6\docs\com\deitel\jhtp3\appenH (on Windows platforms). The C:\jhtp6\docs directory was specified with the **-d** command line option of javadoc, and the remaining directories were created based on the package statement.

Another file that javadoc creates is `index.html`. This is the starting HTML page in the documentation. To view the documentation you generate with javadoc, load `index.html` into your Web browser. In Fig. K.8, the right frame contains the page `index.html` and the left frame contains the page `allclasses-frame.html` which contains links to the source code’s classes. [Note: Our example does not contain multiple packages, so there is no frame listing the packages. Normally this frame would appear above the left frame (containing “All Classes”), as in Fig. K.1]

**Fig. K.8** | Index page.

## XXIX Appendix K Creating Documentation with javadoc

Figure K.9 shows class Time's index.html. Click **Time** in the left frame to load the Time class description. The navigation bar (at the top of the right frame) indicates which HTML page is currently loaded by highlighting the page's link (e.g., the **Class** link).

Clicking the **Tree** link (Fig. K.10) displays a class hierarchy for all the classes displayed in the left frame. In our example, we documented only class Time—which extends Object. Clicking the **Deprecated** link loads [deprecated-list.html](#) into the right frame. This page contains a list of all deprecated names. Because we did not use the @deprecated tag in this example, this page does not contain any information.

**Fig. K.9** | Class page.

**Fig. K.10** | Tree page.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

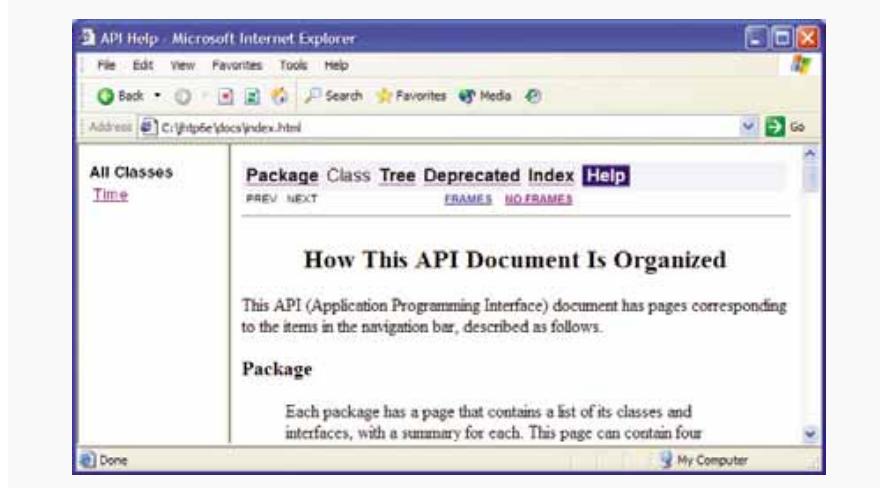

## K.5 Files Produced by javadoc XXX

Clicking the **Index** link loads the [index-all.html](#) page (Fig. K.11), which contains an alphabetical list of all classes, interfaces, methods and fields. Clicking the **Help** link loads [helpdoc.html](#) (Fig. K.12). This is a help file for navigating the documentation. A default help file is provided, but the programmer can specify other help files.

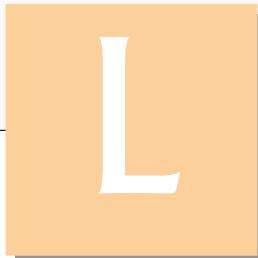

Among the other files generated by javadoc are [serialized-form.html](#) which documents Serializable and Externalizable classes and [package-list](#), a text file rather than an HTML file, which lists package names and is not actually part of the documentation. The [package-list](#) file is used by the `-link` command-line argument to resolve the external cross references, i.e., allows other documentations to link to this documentation.

# Bit Manipulation

## L.1 Introduction

This appendix presents an extensive discussion of bit-manipulation operators, followed by a discussion of class `BitSet`, which enables the creation of bit-array-like objects for setting and getting individual bit values. Java provides extensive bit-manipulation capabilities for programmers who need to get down to the “bits-and-bytes” level. Operating systems, test equipment software, networking software and many other kinds of software require that the programmer communicate “directly with the hardware.” We now discuss Java’s bit-manipulation capabilities and bitwise operators.

## L.2 Bit Manipulation and the Bitwise Operators

Computers represent all data internally as sequences of bits. Each bit can assume the value 0 or the value 1. On most systems, a sequence of eight bits forms a byte—the standard storage unit for a variable of type `byte`. Other types are stored in larger numbers of bytes. The bitwise operators can manipulate the bits of integral operands (i.e., operations of type `byte`, `char`, `short`, `int` and `long`), but not floating-point operands.

Note that the discussions of bitwise operators in this section show the binary representations of the integer operands. For a detailed explanation of the binary (also called base 2) number system, see Appendix E, Number Systems.

The bitwise operators are **bitwise AND (&)**, **bitwise inclusive OR (|)**, **bitwise exclusive OR (^)**, **left shift (<<)**, **signed right shift (>>)**, **unsigned right shift (>>>)** and **bitwise complement (~)**. The bitwise AND, bitwise inclusive OR and bitwise exclusive OR operators compare their two operands bit by bit. The bitwise AND operator sets each bit in the result to 1 if and only if the corresponding bit in both operands is 1. The bitwise inclusive OR operator sets each bit in the result to 1 if the corresponding bit in either (or both) operand(s) is 1. The bitwise exclusive OR operator sets each bit in the result to 1 if the corresponding bit in exactly one operand is 1. The left-shift operator shifts the bits of its left operand to the left by the number of bits specified in its right operand. The signed right shift operator shifts the bits in its left operand to the right by the number of bits spec-

## L.2 Bit Manipulation and the Bitwise Operators XXXII

ified in its right operand—if the left operand is negative, 1s are shifted in from the left; otherwise, 0s are shifted in from the left. The unsigned right shift operator shifts the bits in its left operand to the right by the number of bits specified in its right operand—0s are shifted in from the left. The bitwise complement operator sets all 0 bits in its operand to 1 in the result and sets all 1 bits in its operand to 0 in the result. The bitwise operators are summarized in Fig. L.1.

When using the bitwise operators, it is useful to display values in their binary representation to illustrate the effects of these operators. The application of Fig. L.2 allows the user to enter an integer from the standard input. Lines 10–12 read the integer from the standard input. The integer is displayed in its binary representation in groups of eight bits each. Often, the bitwise AND operator is used with an operand called a **mask**—an integer value with specific bits set to 1. Masks are used to hide some bits in a value while selecting other bits. In line 18, mask variable `displayMask` is assigned the value `1 << 31`, or

```
10000000 00000000 00000000 00000000
```

Lines 21–30 obtains a string representation of the integer, in bits. Line 24 uses the bitwise AND operator to combine variable `input` with variable `displayMask`. The left-shift operator shifts the value 1 from the low-order (rightmost) bit to the high-order (leftmost) bit in `displayMask` and fills in 0 from the right.

Line 24 determines whether the current leftmost bit of variable `value` is a 1 or 0 and displays '1' or '0', respectively, to the standard output. Assume that `input` contains `2000000000 (01110111 00110101 10010100 00000000)`. When `input` and `displayMask` are combined using `&`, all the bits except the high-order (leftmost) bit in variable `input` are “masked off” (hidden), because any bit “ANDed” with 0 yields 0. If the leftmost bit is 1, the

Operator	Name	Description
<code>&amp;</code>	bitwise AND	The bits in the result are set to 1 if the corresponding bits in the two operands are both 1.
<code> </code>	bitwise inclusive OR	The bits in the result are set to 1 if at least one of the corresponding bits in the two operands is 1.
<code>^</code>	bitwise exclusive OR	The bits in the result are set to 1 if exactly one of the corresponding bits in the two operands is 1.
<code>&lt;&lt;</code>	left shift	Shifts the bits of the first operand left by the number of bits specified by the second operand; fill from the right with 0.
<code>&gt;&gt;</code>	signed right shift	Shifts the bits of the first operand right by the number of bits specified by the second operand. If the first operand is negative, 1s are filled in from the left; otherwise, 0s are filled in from the left.
<code>&gt;&gt;&gt;</code>	unsigned right shift	Shifts the bits of the first operand right by the number of bits specified by the second operand; 0s are filled in from the left.
<code>~</code>	bitwise complement	All 0 bits are set to 1, and all 1 bits are set to 0.

## L.2 Bit Manipulation and the Bitwise Operators

**XXXIV**

expression `input & displayMask` evaluates to 1 and line 24 displays '1'; otherwise, line 24 displays '0'. Then line 26 left shifts variable `input` to the left by one bit with the expression `input <<= 1`. (This expression is equivalent to `input = input << 1`.) These steps are repeated for each bit in variable `input`. [Note: Class `Integer` provides method `toBinaryString`, which returns a string containing the binary representation of an integer.] Figure L.3 summarizes the results of combining two bits with the bitwise AND (`&`) operator.

**Common Programming Error L.1**

*Using the conditional AND operator (`&&`) instead of the bitwise AND operator (`&`) is a compilation error*

Figure L.4 demonstrates the bitwise AND operator, the bitwise inclusive OR operator, the bitwise exclusive OR operator and the bitwise complement operator. The program uses the `display` method (lines 7–25) of the utility class `BitRepresentation`.

Bit 1	Bit 2	Bit 1 & Bit 2
0	0	0
1	0	0
0	1	0
1	1	1

**Fig. L.3** | Bitwise AND operator (`&`) combining two bits.

## L.2 Bit Manipulation and the Bitwise Operators XXXVIII

The first output window in Fig. L.4 shows the results of combining the value 65535 and the value 1 with the bitwise AND operator (`&`; line 33). All the bits except the low-order bit in the value 65535 are “masked off” (hidden) by “ANDing” with the value 1.

The bitwise inclusive OR operator (`|`) sets each bit in the result to 1 if the corresponding bit in either (or both) operand(s) is 1. The second output window in Fig. L.4 shows the results of combining the value 15 and the value 241 by using the bitwise OR operator (line 44)—the result is 255. Figure L.6 summarizes the results of combining two bits with the bitwise inclusive OR operator.

The bitwise exclusive OR operator (`^`) sets each bit in the result to 1 if *exactly* one of the corresponding bits in its two operands is 1. The third output window in Fig. L.4 shows the results of combining the value 139 and the value 199 by using the exclusive OR operator (line 55)—the result is 76. Figure L.7 summarizes the results of combining two bits with the bitwise exclusive OR operator.

The bitwise complement operator (`~`) sets all 1 bits in its operand to 0 in the result and sets all 0 bits in its operand to 1 in the result—otherwise referred to as “taking the one’s complement of the value.” The fourth output window in Fig. L.4 shows the results of taking the one’s complement of the value 21845 (line 64). The result is -21846.

The application of Fig. L.8 demonstrates the left-shift operator (`<<`), the signed right-shift operator (`>>`) and the unsigned right-shift operator (`>>>`). The application asks the user to enter an integer and choose the operation, then performs a one-bit shift and displays the results of the shift in both integer and bitwise representation. We use the utility class `BitRepresentation` (Fig. L.5) to display the bit representation of an integer.

The left-shift operator (`<<`) shifts the bits of its left operand to the left by the number of bits specified in its right operand (performed at line 31 in Fig. L.8). Bits vacated to the right are replaced with 0s; 1s shifted off the left are lost. The first output window in Fig. L.8

Bit 1	Bit 2	Bit 1   Bit 2
0	0	0
1	0	1
0	1	1
1	1	1

**Fig. L.6** | Bitwise inclusive OR operator (`|`) combining two bits.

Bit 1	Bit 2	Bit 1 ^ Bit 2
0	0	0
1	0	1
0	1	1
1	1	0

Bit representation of 1073741824 is:
01000000 00000000 00000000 00000000

```

**Fig. L.8** | Bitwise shift operations. (Part 2 of 2.)

demonstrates the left-shift operator. Starting with the value 1, the left shift operation was chosen, resulting in the value 2.

The signed right-shift operator (>>) shifts the bits of its left operand to the right by the number of bits specified in its right operand (performed at line 37 in Fig. L.8). Performing a right shift causes the vacated bits at the left to be replaced by 0s if the number is positive or by 1s if the number is negative. Any 1s shifted off the right are lost. Next, the

## XLI Appendix L Bit Manipulation

output window the results of signed right shifting the value -2147483648, which is the value 1 being left shifted 31 times. Notice that the left-most bit is replaced by 1 because the number is negative.

The unsigned right-shift operator (`>>`) shifts the bits of its left operand to the right by the number of bits specified in its right operand (performed at line 43 Fig. L.8). Performing an unsigned right shift causes the vacated bits at the left to be replaced by 0s. Any 1s shifted off the right are lost. The third output window of Fig. L.8 shows the results of unsigned right shifting the value -2147483648. Notice that the left-most bit is replaced by 0. Each bitwise operator (except the bitwise complement operator) has a corresponding assignment operator. These [bitwise assignment operators](#) are shown in Fig. L.9.

### L.3 BitSet Class

Class `BitSet` makes it easy to create and manipulate [bit sets](#), which are useful for representing sets of boolean flags. `BitSets` are dynamically resizable—more bits can be added as needed, and a `BitSet` will grow to accommodate the additional bits. Class `BitSet` provides two constructors—a no-argument constructor that creates an empty `BitSet` and a constructor that receives an integer representing the number of bits in the `BitSet`. By default, each bit in a `BitSet` has a `false` value—the underlying bit has the value 0. A bit is set to `true` (also called “on”) with a call to `BitSet` method `set`, which receives the index of the bit to set as an argument. This makes the underlying value of that bit 1. Note that bit indices are zero based, like arrays. A bit is set to `false` (also called “off”) by calling `BitSet` method `clear`. This makes the underlying value of that bit 0. To obtain the value of a bit, use `BitSet` method `get`, which receives the index of the bit to get and returns a boolean value representing whether the bit at that index is on (`true`) or off (`false`).

Class `BitSet` also provides methods for combining the bits in two `BitSets`, using bitwise logical AND (`and`), bitwise logical inclusive OR (`or`), and bitwise logical exclusive OR (`xor`). Assuming that `b1` and `b2` are `BitSets`, the statement

```
b1.and(b2);
```

performs a bit-by-bit logical AND operation between `BitSets` `b1` and `b2`. The result is stored in `b1`. When `b2` has more bits than `b1`, the extra bits of `b2` are ignored. Hence, the size of `b1` remain unchanged. Bitwise logical inclusive OR and bitwise logical exclusive OR are performed by the statements

Bitwise assignment operators	
<code>&amp;=</code>	Bitwise AND assignment operator.
<code> =</code>	Bitwise inclusive OR assignment operator.
<code>^=</code>	Bitwise exclusive OR assignment operator.
<code>&lt;&lt;=</code>	Left-shift assignment operator.
<code>&gt;&gt;=</code>	Signed right-shift assignment operator.
<code>&gt;&gt;&gt;=</code>	Unsigned right-shift assignment operator.

**Fig. L.9** | Bitwise assignment operators.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**L.3 BitSet Class XLII**

```
b1.or(b2);
b1.xor(b2);
```

When `b2` has more bits than `b1`, the extra bits of `b2` are ignored. Hence the size of `b1` remains unchanged.

`BitSet` method `size` returns the number of bits in a `BitSet`. `BitSet` method `equals` compares two `BitSets` for equality. Two `BitSets` are equal if and only if each `BitSet` has identical values in corresponding bits. `BitSet` method `toString` creates a string representation of a `BitSet`'s contents.

Figure L.10 revisits the Sieve of Eratosthenes (for finding prime numbers), which we discussed in Exercise 7.27. This example uses a `BitSet` rather than an array to implement the algorithm. The application asks the user to enter an integer between 2 and 1023, displays all the prime numbers from 2 to 1023 and determines whether that number is prime.

```

1 // Fig. I.10: BitSetTest.java
2 // Using a BitSet to demonstrate the Sieve of Eratosthenes.
3 import java.util.BitSet;
4 import java.util.Scanner;
5
6 public class BitSetTest
7 {
8 public static void main(String args[])
9 {
10 // get input integer
11 Scanner scanner = new Scanner(System.in);
12 System.out.println("Please enter an integer from 2 to 1023");
13 int input = scanner.nextInt();
14
15 // perform Sieve of Eratosthenes
16 BitSet sieve = new BitSet(1024);
17 int size = sieve.size();
18
19 // set all bits from 2 to 1023
20 for (int i = 2; i < size; i++)
21 sieve.set(i);
22
23 // perform Sieve of Eratosthenes
24 int finalBit = (int) Math.sqrt(size);
25
26 for (int i = 2; i < finalBit; i++)
27 {
28 if (sieve.get(i))
29 {
30 for (int j = 2 * i; j < size; j += i)
31 sieve.clear(j);
32 } // end if
33 } // end for
34
35 int counter = 0;
36

```

**Fig. L.10** | Sieve of Eratosthenes, using a BitSet. (Part 2 of 2.)

Line 16 creates a BitSet of 1024 bits. We ignore the bits at indices zero and one in this application. Lines 20–21 set all the bits in the BitSet to “on” with BitSet method `set`. Lines 24–33 determine all the prime numbers from 2 to 1023. The integer `finalBit` specifies when the algorithm is complete. The basic algorithm is that a number is prime if it has no divisors other than 1 and itself. Starting with the number 2, once we know that a

L.3 BitSet Class **XLIV**

number is prime, we can eliminate all multiples of that number. The number 2 is divisible only by 1 and itself, so it is prime. Therefore, we can eliminate 4, 6, 8 and so on. Elimination of a value consists of setting its bit to “off” with `BitSet` method `clear` (line 31). The number 3 is divisible by 1 and itself. Therefore, we can eliminate all multiples of 3. (Keep in mind that all even numbers have already been eliminated.) After the list of primes is displayed, lines 48–51 uses `BitSet` method `get` (line 48) to determine whether the bit for the number the user entered is set. If so, line 49 displays a message indicating that the number is prime. Otherwise, line 51 displays a message indicating that the number is not prime.

### Self-Review Exercises

**L.1** Fill in the blanks in each of the following statements:

- Bits in the result of an expression using operator \_\_\_\_\_ are set to 1 if at least one of the corresponding bits in either operand is set to 1. Otherwise, the bits are set to 0.
- Bits in the result of an expression using operator \_\_\_\_\_ are set to 1 if the corresponding bits in each operand are set to 1. Otherwise, the bits are set to zero.
- Bits in the result of an expression using operator \_\_\_\_\_ are set to 1 if exactly one of the corresponding bits in either operand is set to 1. Otherwise, the bits are set to 0.
- The \_\_\_\_\_ operator shifts the bits of a value to the right with sign extension, and the \_\_\_\_\_ operator shifts the bits of a value to the right with zero extension.
- The \_\_\_\_\_ operator is used to shift the bits of a value to the left.
- The bitwise AND operator (`&`) is often used to \_\_\_\_\_ bits, that is, to select certain bits from a bit string while setting others to 0.

### Answers to Self-Review Exercises

**L.1** a) |. b) &. c) ^. d) >>, >>>. e) <<. f) mask.

### Exercises

**L.2** Explain the operation of each of the following methods of class `BitSet`:

- |                          |                        |
|--------------------------|------------------------|
| a) <code>set</code>      | b) <code>clear</code>  |
| c) <code>get</code>      | d) <code>and</code>    |
| e) <code>or</code>       | f) <code>xor</code>    |
| g) <code>size</code>     | h) <code>equals</code> |
| i) <code>toString</code> |                        |

**L.3** (*Shift Right*) Write an application that right shifts an integer variable four bits to the right with signed right shift, then shifts the same integer variable four bits to the right with unsigned right shift. The program should print the integer in bits before and after each shift operation. Run your program once with a positive integer and once with a negative integer.

**L.4** Show how shifting an integer left by one can be used to perform multiplication by two and how shifting an integer right by one can be used to perform division by two. Be careful to consider issues related to the sign of an integer.

**L.5** Write a program that reverses the order of the bits in an integer value. The program should input the value from the user and call method `reverseBits` to print the bits in reverse order. Print the value in bits both before and after the bits are reversed to confirm that the bits are reversed properly. You might want to implement both a recursive and an iterative solution.

# ATM Case Study Code

## M.1 ATM Case Study Implementation

This appendix contains the complete working implementation of the ATM system that we designed in the Software Engineering Case Study sections found at the ends of Chapters 3–8 and 10. The implementation comprises 670 lines of Java code. We consider the classes in the order in which we identified them in Section 3.10:

- ATM
- Screen
- Keypad
- CashDispenser
- DepositSlot
- Account
- BankDatabase
- Transaction
- BalanceInquiry
- Withdrawal
- Deposit

We apply the guidelines discussed in Section 8.19 and Section 10.9 to code these classes based on how we modeled them in the UML class diagrams of Figs. 10.21 and 10.22. To develop the bodies of class methods, we refer to the activity diagrams presented in Section 5.11 and the communication and sequence diagrams presented in Section 7.14. Note that our ATM design does not specify all the program logic and may not specify all the attributes and operations required to complete the ATM implementation. This is a normal part of the object-oriented design process. As we implement the system, we com-

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

M.2 Class ATM **XLVI**

plete the program logic and add attributes and behaviors as necessary to construct the ATM system specified by the requirements document in Section 2.9.

We conclude the discussion by presenting a Java application (`ATMCaseStudy`) that starts the ATM and puts the other classes in the system in use. Recall that we are developing a first version of the ATM system that runs on a personal computer and uses the computer's keyboard and monitor to approximate the ATM's keypad and screen. We also only simulate the actions of the ATM's cash dispenser and deposit slot. We attempt to implement the system, however, so that real hardware versions of these devices could be integrated without significant changes in the code.

## M.2 Class ATM

Class `ATM` (Fig. M.1) represents the ATM as a whole. Lines 6–12 implement the class's attributes. We determine all but one of these attributes from the UML class diagrams of Figs. 10.21 and 10.22. Note that we implement the UML Boolean attribute `userAuthenticated` in Fig. 10.22 as a `boolean` attribute in Java (line 6). Line 7 declares an attribute not found in our UML design—an `int` attribute `currentAccountNumber` that keeps track of the account number of the current authenticated user. We will soon see how the class uses this attribute. Lines 8–12 declare reference-type attributes corresponding to the `ATM` class's associations modeled in the class diagram of Fig. 10.21. These attributes allow the `ATM` to access its parts (i.e., its `Screen`, `Keypad`, `CashDispenser` and `DepositSlot`) and interact with the bank's account information database (i.e., a `BankDatabase` object).

```

1 // ATM.java
2 // Represents an automated teller machine
3
4 public class ATM
5 {
6 private boolean userAuthenticated; // whether user is authenticated
7 private int currentAccountNumber; // current user's account number
8 private Screen screen; // ATM's screen
9 private Keypad keypad; // ATM's keypad
10 private CashDispenser cashDispenser; // ATM's cash dispenser
11 private DepositSlot depositSlot; // ATM's deposit slot
12 private BankDatabase bankDatabase; // account information database
13
14 // constants corresponding to main menu options
15 private static final int BALANCE_INQUIRY = 1;
16 private static final int WITHDRAWAL = 2;
17 private static final int DEPOSIT = 3;
18 private static final int EXIT = 4;
19
20 // no-argument ATM constructor initializes instance variables

139 temp = new Withdrawal(currentAccountNumber, screen,
140 bankDatabase, keypad, cashDispenser);
141 break;
142 case DEPOSIT: // create new Deposit transaction
143 temp = new Deposit(currentAccountNumber, screen,
144 bankDatabase, keypad, depositSlot);
145 break;
146 } // end switch
147
148 return temp; // return the newly created object
149 } // end method createTransaction
150 } // end class ATM

```

**Fig. M.1** | Class ATM represents the ATM. (Part 4 of 4.)

Lines 15–18 declare integer constants that correspond to the four options in the ATM's main menu (i.e., balance inquiry, withdrawal, deposit and exit). Lines 21–30 declare class ATM's constructor, which initializes the class's attributes. When an ATM object is first created, no user is authenticated, so line 23 initializes userAuthenticated to `false`. Likewise, line 24 initializes `currentAccountNumber` to 0 because there is no current user yet. Lines 25–28 instantiate new objects to represent the parts of the ATM. Recall that class ATM has composition relationships with classes Screen, Keypad, CashDispenser and DepositSlot, so class ATM is responsible for their creation. Line 29 creates a new BankDatabase. [Note: If this were a real ATM system, the ATM class would receive a reference to an existing database object created by the bank. However, in this implementation we are only simulating the bank's database, so class ATM creates the BankDatabase object with which it interacts.]

The class diagram of Fig. 10.22 does not list any operations for class ATM. We now implement one operation (i.e., public method) in class ATM that allows an external client of the class (i.e., class ATMCaseStudy) to tell the ATM to run. ATM method `run` (lines 33–50) uses an infinite loop (lines 36–49) to repeatedly welcome a user, attempt to authenticate the user and, if authentication succeeds, allow the user to perform transactions. After an authenticated user performs the desired transactions and chooses to exit, the ATM resets itself, displays a goodbye message to the user and restarts the process. We use an infinite loop here to simulate the fact that an ATM appears to run continuously until the bank turns it off (an action beyond the user's control). An ATM user has the option to exit the system, but does not have the ability to turn off the ATM completely.

Inside method `run`'s infinite loop, lines 39–43 cause the ATM to repeatedly welcome and attempt to authenticate the user as long as the user has not been authenticated (i.e., `!userAuthenticated` is `true`). Line 41 invokes method `displayMessageLine` of the ATM's `screen` to display a welcome message. Like `Screen` method `displayMessage` designed in

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## M.2 Class ATM L

the case study, method `displayMessageLine` (declared in lines 13–16 of Fig. M.2) displays a message to the user, but this method also outputs a newline after displaying the message. We have added this method during implementation to give class `Screen`'s clients more control over the placement of displayed messages. Line 42 invokes class `ATM`'s private utility method `authenticateUser` (declared in lines 53–72) to attempt to authenticate the user.

We refer to the requirements document to determine the steps necessary to authenticate the user before allowing transactions to occur. Line 55 of method `authenticateUser` invokes method `displayMessage` of the `ATM`'s `screen` to prompt the user to enter an account number. Line 56 invokes method `getInput` of the `ATM`'s `keypad` to obtain the user's input, then stores the integer value entered by the user in a local variable `accountNumber`. Method `authenticateUser` next prompts the user to enter a PIN (line 57), and stores the PIN input by the user in a local variable `pin` (line 58). Next, lines 61–62 attempt to authenticate the user by passing the `accountNumber` and `pin` entered by the user to the `bankDatabase`'s `authenticateUser` method. Class `ATM` sets its `userAuthenticated` attribute to the `boolean` value returned by this method—`userAuthenticated` becomes `true` if authentication succeeds (i.e., `accountNumber` and `pin` match those of an existing `Account` in `bankDatabase`) and remains `false` otherwise. If `userAuthenticated` is `true`, line 67 saves the account number entered by the user (i.e., `accountNumber`) in the `ATM` attribute `currentAccountNumber`. The other methods of class `ATM` use this variable whenever an `ATM` session requires access to the user's account number. If `userAuthenticated` is `false`, lines 70–71 use the `screen`'s `displayMessageLine` method to indicate that an invalid account number and/or PIN was entered and the user must try again. Note that we set `currentAccountNumber` only after authenticating the user's account number and the associated PIN—if the database could not authenticate the user, `currentAccountNumber` remains 0.

After method `run` attempts to authenticate the user (line 42), if `userAuthenticated` is still `false`, the `while` loop in lines 39–43 executes again. If `userAuthenticated` is now `true`, the loop terminates and control continues with line 45, which calls class `ATM`'s utility method `performTransactions`.

Method `performTransactions` (lines 75–112) carries out an `ATM` session for an authenticated user. Line 78 declares a local `Transaction` variable to which we assign a `BalanceInquiry`, `Withdrawal` or `Deposit` object representing the `ATM` transaction currently being processed. Note that we use a `Transaction` variable here to allow us to take advantage of polymorphism. Also note that we name this variable after the role name included in the class diagram of Fig. 3.21—`currentTransaction`. Line 80 declares another local variable—a `boolean` called `userExited` that keeps track of whether the user has chosen to exit. This variable controls a `while` loop (lines 83–111) that allows the user to execute an unlimited number of transactions before choosing to exit. Within this loop, line 86 displays the main menu and obtains the user's menu selection by calling an `ATM` utility method `displayMainMenu` (declared in lines 115–124). This method displays the main menu by invoking methods of the `ATM`'s `screen` and returns a menu selection obtained from the user through the `ATM`'s `keypad`. Line 86 stores the user's selection returned by `displayMainMenu` in local variable `mainMenuSelection`.

After obtaining a main menu selection, method `performTransactions` uses a `switch` statement (lines 89–110) to respond to the selection appropriately. If `mainMenuSelection` is equal to any of the three integer constants representing transaction types (i.e., if the user chose to perform a transaction), lines 97–98 call utility method `createTransaction`

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## Appendix M ATM Case Study Code

(declared in lines 127–149) to return a newly instantiated object of the type that corresponds to the selected transaction. Variable `currentTransaction` is assigned the reference returned by `createTransaction`, then line 100 invokes method `execute` of this transaction to execute it. We will discuss `Transaction` method `execute` and the three `Transaction` subclasses shortly. Note that we assign the `Transaction` variable `currentTransaction` an object of one of the three `Transaction` subclasses so that we can execute transactions polymorphically. For example, if the user chooses to perform a balance inquiry, `mainMenuSelection` equals `BALANCE_INQUIRY`, leading `createTransaction` to return a `BalanceInquiry` object. Thus, `currentTransaction` refers to a `BalanceInquiry` and invoking `currentTransaction.execute()` results in `BalanceInquiry`'s version of `execute` being called.

Method `createTransaction` (lines 127–149) uses a `switch` statement (lines 132–146) to instantiate a new `Transaction` subclass object of the type indicated by the parameter `type`. Recall that method `performTransactions` passes `mainMenuSelection` to this method only when `mainMenuSelection` contains a value corresponding to one of the three transaction types. Therefore `type` equals either `BALANCE_INQUIRY`, `WITHDRAWAL` or `DEPOSIT`. Each case in the `switch` statement instantiates a new object by calling the appropriate `Transaction` subclass constructor. Note that each constructor has a unique parameter list, based on the specific data required to initialize the subclass object. A `BalanceInquiry` requires only the account number of the current user and references to the ATM's `screen` and the `bankDatabase`. In addition to these parameters, a `Withdrawal` requires references to the ATM's `keypad` and `cashDispenser`, and a `Deposit` requires references to the ATM's `keypad` and `depositSlot`. We discuss the transaction classes in more detail in Section M.9–Section M.12.

After executing a transaction (line 100 in `performTransactions`), `userExited` remains `false` and the `while` loop in lines 83–111 repeats, returning the user to the main menu. However, if a user does not perform a transaction and instead selects the main menu option to exit, line 104 sets `userExited` to `true` causing the condition of the `while` loop (`!userExited`) to become `false`. This `while` is the final statement of method `performTransactions`, so control returns to the calling method `run`. If the user enters an invalid main menu selection (i.e., not an integer from 1–4), lines 107–108 display an appropriate error message, `userExited` remains `false` and the user returns to the main menu to try again.

When `performTransactions` returns control to method `run`, the user has chosen to exit the system, so lines 46–47 reset the ATM's attributes `userAuthenticated` and `currentAccountNumber` to prepare for the next ATM user. Line 48 displays a goodbye message before the ATM starts over and welcomes the next user.

### M.3 Class Screen

Class `Screen` (Fig. M.2) represents the screen of the ATM and encapsulates all aspects of displaying output to the user. Class `Screen` approximates a real ATM's screen with a computer monitor and outputs text messages using standard console output methods `System.out.print`, `System.out.println` and `System.out.printf`. In this case study, we designed class `Screen` to have one operation—`displayMessage`. For greater flexibility in displaying messages to the `Screen`, we now declare three `Screen` methods—`displayMessage`, `displayMessageLine` and `displayDollarAmount`.

## M.4 Class Keypad LII

```

1 // Screen.java
2 // Represents the screen of the ATM
3
4 public class Screen
5 {
6 // display a message without a carriage return
7 public void displayMessage(String message)
8 {
9 System.out.print(message);
10 } // end method displayMessage
11
12 // display a message with a carriage return
13 public void displayMessageLine(String message)
14 {
15 System.out.println(message);
16 } // end method displayMessageLine
17
18 // displays a dollar amount
19 public void displayDollarAmount(double amount)
20 {
21 System.out.printf("$%,.2f", amount);
22 } // end method displayDollarAmount
23 } // end class Screen

```

**Fig. M.2** | Class Screen represents the screen of the ATM.

Method `displayMessage` (lines 7–10) takes a `String` as an argument and prints it to the console using `System.out.print`. The cursor stays on the same line, making this method appropriate for displaying prompts to the user. Method `displayMessageLine` (lines 13–16) does the same using `System.out.println`, which outputs a newline to move the cursor to the next line. Finally, method `displayDollarAmount` (lines 19–22) outputs a properly formatted dollar amount (e.g., \$1,234.56). Line 21 uses method `System.out.printf` to output a `double` value formatted with commas to increase readability and two decimal places. See Chapter 29, Formatted Output, for more information about formatting output with `printf`.

## M.4 Class Keypad

Class Keypad (Fig. M.3) represents the keypad of the ATM and is responsible for receiving all user input. Recall that we are simulating this hardware, so we use the computer's keyboard to approximate the keypad. We use class `Scanner` to obtain console input from the user. A computer keyboard contains many keys not found on the ATM's keypad. However, we assume that the user presses only the keys on the computer keyboard that also appear on the keypad—the keys numbered 0–9 and the *Enter* key.

Line 3 of class `Keypad` imports class `Scanner` for use in class `Keypad`. Line 7 declares `Scanner` variable `input` as an instance variable. Line 12 in the constructor creates a new `Scanner` object that reads input from the standard input stream (`System.in`) and assigns the object's reference to variable `input`. Method `getInput` (declared in lines 16–19) invokes `Scanner` method `nextInt` (line 18) to return the next integer input by the user. [Note: Method `nextInt` can throw an `InputMismatchException` if the user enters non-integer

### LIII Appendix M ATM Case Study Code

```

1 // Keypad.java
2 // Represents the keypad of the ATM
3 import java.util.Scanner; // program uses Scanner to obtain user input
4
5 public class Keypad
6 {
7 private Scanner input; // reads data from the command line
8
9 // no-argument constructor initializes the Scanner
10 public Keypad()
11 {
12 input = new Scanner(System.in);
13 } // end no-argument Keypad constructor
14
15 // return an integer value entered by user
16 public int getInput()
17 {
18 return input.nextInt(); // we assume that user enters an integer
19 } // end method getInput
20 } // end class Keypad

```

**Fig. M.3** | Class Keypad represents the ATM's keypad.

input. Because the real ATM's keypad permits only integer input, we assume that no exception will occur and do not attempt to fix this problem. See Chapter 13, Exception Handling, for information on catching exceptions.] Recall that `nextInt` obtains all the input used by the ATM. Keypad's `getInput` method simply returns the integer input by the user. If a client of class Keypad requires input that satisfies some particular criteria (i.e., a number corresponding to a valid menu option), the client must perform the appropriate error checking.

## M.5 Class CashDispenser

Class CashDispenser (Fig. M.4) represents the cash dispenser of the ATM. Line 7 declares constant `INITIAL_COUNT`, which indicates the initial count of bills in the cash dispenser when the ATM starts (i.e., 500). Line 8 implements attribute `count` (modeled in Fig. 10.22), which keeps track of the number of bills remaining in the CashDispenser at any time. The constructor (lines 11–14) sets `count` to the initial count. Class CashDispenser has two `public` methods—`dispenseCash` (lines 17–21) and `isSufficientCashAvailable` (lines 24–32). The class trusts that a client (i.e., `Withdrawal`) calls `dispenseCash` only after establishing that sufficient cash is available by calling `isSufficientCashAvailable`. Thus, `dispenseCash` simply simulates dispensing the requested amount without checking whether sufficient cash is available.

Method `isSufficientCashAvailable` (lines 24–32) has a parameter `amount` that specifies the amount of cash in question. Line 26 calculates the number of \$20 bills required to dispense the specified amount. The ATM allows the user to choose only withdrawal amounts that are multiples of \$20, so we divide `amount` by 20 to obtain the number of `billsRequired`. Lines 28–31 return `true` if the CashDispenser's `count` is greater than or equal to `billsRequired` (i.e., enough bills are available) and `false` otherwise (i.e., not

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

M.6 Class DepositSlot LIV

```

1 // CashDispenser.java
2 // Represents the cash dispenser of the ATM
3
4 public class CashDispenser
5 {
6 // the default initial number of bills in the cash dispenser
7 private final static int INITIAL_COUNT = 500;
8 private int count; // number of $20 bills remaining
9
10 // no-argument CashDispenser constructor initializes count to default
11 public CashDispenser()
12 {
13 count = INITIAL_COUNT; // set count attribute to default
14 } // end CashDispenser constructor
15
16 // simulates dispensing of specified amount of cash
17 public void dispenseCash(int amount)
18 {
19 int billsRequired = amount / 20; // number of $20 bills required
20 count -= billsRequired; // update the count of bills
21 } // end method dispenseCash
22
23 // indicates whether cash dispenser can dispense desired amount
24 public boolean isSufficientCashAvailable(int amount)
25 {
26 int billsRequired = amount / 20; // number of $20 bills required
27
28 if (count >= billsRequired)
29 return true; // enough bills available
30 else
31 return false; // not enough bills available
32 } // end method isSufficientCashAvailable
33 } // end class CashDispenser

```

**Fig. M.4** | Class CashDispenser represents the ATM's cash dispenser.

enough bills). For example, if a user wishes to withdraw \$80 (i.e., `billsRequired` is 4), but only three bills remain (i.e., `count` is 3), the method returns `false`.

Method `dispenseCash` (lines 17–21) simulates cash dispensing. If our system were hooked up to a real hardware cash dispenser, this method would interact with the device to physically dispense cash. Our simulated version of the method simply decreases the count of bills remaining by the number required to dispense the specified amount (line 20). Note that it is the responsibility of the client of the class (i.e., `Withdrawal`) to inform the user that cash has been dispensed—`CashDispenser` cannot interact directly with `Screen`.

## M.6 Class DepositSlot

Class `DepositSlot` (Fig. M.5) represents the deposit slot of the ATM. Like the version of class `CashDispenser` presented here, this version of class `DepositSlot` merely simulates the functionality of a real hardware deposit slot. `DepositSlot` has no attributes and only one method—`isEnvelopeReceived` (lines 8–11)—that indicates whether a deposit envelope was received.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## LV Appendix M ATM Case Study Code

```

1 // DepositSlot.java
2 // Represents the deposit slot of the ATM
3
4 public class DepositSlot
5 {
6 // indicates whether envelope was received (always returns true,
7 // because this is only a software simulation of a real deposit slot)
8 public boolean isEnvelopeReceived()
9 {
10 return true; // deposit envelope was received
11 } // end method isEnvelopeReceived
12 } // end class DepositSlot

```

**Fig. M.5** | Class DepositSlot represents the ATM's deposit slot.

Recall from the requirements document that the ATM allows the user up to two minutes to insert an envelope. The current version of method `isEnvelopeReceived` simply returns `true` immediately (line 10), because this is only a software simulation, and we assume that the user has inserted an envelope within the required time frame. If an actual hardware deposit slot were connected to our system, method `isEnvelopeReceived` might be implemented to wait for a maximum of two minutes to receive a signal from the hardware deposit slot indicating that the user has indeed inserted a deposit envelope. If `isEnvelopeReceived` were to receive such a signal within two minutes, the method would return `true`. If two minutes elapsed and the method still had not received a signal, then the method would return `false`.

## M.7 Class Account

Class `Account` (Fig. M.6) represents a bank account. Each `Account` has four attributes (modeled in Fig. 10.22)—`accountNumber`, `pin`, `availableBalance` and `totalBalance`. Lines 6–9 implement these attributes as private fields. Variable `availableBalance` represents the amount of funds available for withdrawal. Variable `totalBalance` represents the amount of funds available, plus the amount of deposited funds still pending confirmation or clearance.

`Class Account` has a constructor (lines 12–19) that takes an account number, the PIN established for the account, the initial available balance and the initial total balance as arguments. Lines 15–18 assign these values to the class's attributes (i.e., fields).

Method `validatePIN` (lines 22–28) determines whether a user-specified PIN (i.e., parameter `userPIN`) matches the PIN associated with the account (i.e., attribute `pin`). Recall that we modeled this method's parameter `userPIN` in the UML class diagram of Fig. 6.23. If the two PINs match, the method returns `true` (line 25); otherwise, it returns `false` (line 27).

Methods `getAvailableBalance` (lines 31–34) and `getTotalBalance` (lines 37–40) are *get* methods that return the values of `double` attributes `availableBalance` and `totalBalance`, respectively.

Method `credit` (lines 43–46) adds an amount of money (i.e., parameter `amount`) to an `Account` as part of a deposit transaction. Note that this method adds the `amount` only to attribute `totalBalance` (line 45). The money credited to an account during a deposit

M.7 Class Account **LVI**

```

1 // Account.java
2 // Represents a bank account
3
4 public class Account
5 {
6 private int accountNumber; // account number
7 private int pin; // PIN for authentication
8 private double availableBalance; // funds available for withdrawal
9 private double totalBalance; // funds available + pending deposits
10
11 // Account constructor initializes attributes
12 public Account(int theAccountNumber, int thePIN,
13 double theAvailableBalance, double theTotalBalance)
14 {
15 accountNumber = theAccountNumber;
16 pin = thePIN;
17 availableBalance = theAvailableBalance;
18 totalBalance = theTotalBalance;
19 } // end Account constructor
20
21 // determines whether a user-specified PIN matches PIN in Account
22 public boolean validatePIN(int userPIN)
23 {
24 if (userPIN == pin)
25 return true;
26 else
27 return false;
28 } // end method validatePIN
29
30 // returns available balance
31 public double getAvailableBalance()
32 {
33 return availableBalance;
34 } // end getAvailableBalance
35
36 // returns the total balance
37 public double getTotalBalance()
38 {
39 return totalBalance;
40 } // end method getTotalBalance
41
42 // credits an amount to the account
43 public void credit(double amount)
44 {
45 totalBalance += amount; // add to total balance
46 } // end method credit
47
48 // debits an amount from the account
49 public void debit(double amount)
50 {
51 availableBalance -= amount; // subtract from available balance
52 totalBalance -= amount; // subtract from total balance
53 } // end method debit

```

## LVII Appendix M ATM Case Study Code

```

54 // returns account number
55 public int getAccountNumber()
56 {
57 return accountNumber;
58 } // end method getAccountNumber
59 } // end class Account
60 }
```

**Fig. M.6** | Class Account represents a bank account. (Part 2 of 2.)

does not become available immediately, so we modify only the total balance. We assume that the bank updates the available balance appropriately at a later time. Our implementation of class Account includes only methods required for carrying out ATM transactions. Therefore, we omit the methods that some other bank system would invoke to add to attribute availableBalance (to confirm a deposit) or subtract from attribute totalBalance (to reject a deposit).

Method debit (lines 49–53) subtracts an amount of money (i.e., parameter amount) from an Account as part of a withdrawal transaction. This method subtracts the amount from both attribute availableBalance (line 51) and attribute totalBalance (line 52), because a withdrawal affects both measures of an account balance.

Method getAccountNumber (lines 56–59) provides access to an Account's accountNumber. We include this method in our implementation so that a client of the class (i.e., BankDatabase) can identify a particular Account. For example, BankDatabase contains many Account objects, and it can invoke this method on each of its Account objects to locate the one with a specific account number.

## M.8 Class BankDatabase

Class BankDatabase (Fig. M.7) models the bank's database with which the ATM interacts to access and modify a user's account information. We determine one reference-type attribute for class BankDatabase based on its composition relationship with class Account. Recall from Fig. 10.21 that a BankDatabase is composed of zero or more objects of class Account. Line 6 implements attribute accounts—an array of Account objects—to implement this composition relationship. Class BankDatabase has a no-argument constructor (lines 9–14) that initializes accounts to contain a set of new Account objects. For the sake of testing the system, we declare accounts to hold just two array elements (line 11), which we instantiate as new Account objects with test data (lines 12–13). Note that the Account constructor has four parameters—the account number, the PIN assigned to the account, the initial available balance and the initial total balance.

Recall that class BankDatabase serves as an intermediary between class ATM and the actual Account objects that contain a user's account information. Thus, the methods of class BankDatabase do nothing more than invoke the corresponding methods of the Account object belonging to the current ATM user.

We include private utility method getAccount (lines 17–28) to allow the BankDatabase to obtain a reference to a particular Account within array accounts. To locate the user's Account, the BankDatabase compares the value returned by method getAccountNumber for each element of accounts to a specified account number until it finds

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

M.8 Class BankDatabase LVIII

a match. Lines 20–25 traverse the accounts array. If the account number of currentAccount equals the value of parameter accountNumber, the method immediately returns the currentAccount. If no account has the given account number, then line 27 returns null.

```

1 // BankDatabase.java
2 // Represents the bank account information database
3
4 public class BankDatabase
5 {
6 private Account accounts[]; // array of Accounts
7
8 // no-argument BankDatabase constructor initializes accounts
9 public BankDatabase()
10 {
11 accounts = new Account[2]; // just 2 accounts for testing
12 accounts[0] = new Account(12345, 54321, 1000.0, 1200.0);
13 accounts[1] = new Account(98765, 56789, 200.0, 200.0);
14 } // end no-argument BankDatabase constructor
15
16 // retrieve Account object containing specified account number
17 private Account getAccount(int accountNumber)
18 {
19 // loop through accounts searching for matching account number
20 for (Account currentAccount : accounts)
21 {
22 // return current account if match found
23 if (currentAccount.getAccountNumber() == accountNumber)
24 return currentAccount;
25 } // end for
26
27 return null; // if no matching account was found, return null
28 } // end method getAccount
29
30 // determine whether user-specified account number and PIN match
31 // those of an account in the database
32 public boolean authenticateUser(int userAccountNumber, int userPIN)
33 {
34 // attempt to retrieve the account with the account number
35 Account userAccount = getAccount(userAccountNumber);
36
37 // if account exists, return result of Account method validatePIN
38 if (userAccount != null)
39 return userAccount.validatePIN(userPIN);
40 else
41 return false; // account number not found, so return false
42 } // end method authenticateUser
43
44 // return available balance of Account with specified account number
45 public double getAvailableBalance(int userAccountNumber)
46 {
47 return getAccount(userAccountNumber).getAvailableBalance();
48 } // end method getAvailableBalance

```

**Fig. M.7** | Class BankDatabase represents the bank's account information database. (Part I of 2.)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**LIX** Appendix M ATM Case Study Code

```

49 // return total balance of Account with specified account number
50 public double getTotalBalance(int userAccountNumber)
51 {
52 return getAccount(userAccountNumber).getTotalBalance();
53 } // end method getTotalBalance
54
55 // credit an amount to Account with specified account number
56 public void credit(int userAccountNumber, double amount)
57 {
58 getAccount(userAccountNumber).credit(amount);
59 } // end method credit
60
61 // debit an amount from of Account with specified account number
62 public void debit(int userAccountNumber, double amount)
63 {
64 getAccount(userAccountNumber).debit(amount);
65 } // end method debit
66 } // end class BankDatabase

```

**Fig. M.7** | Class BankDatabase represents the bank's account information database. (Part 2 of 2.)

Method `authenticateUser` (lines 32–42) proves or disproves the identity of an ATM user. This method takes a user-specified account number and user-specified PIN as arguments and indicates whether they match the account number and PIN of an `Account` in the database. Line 35 calls method `getAccount`, which returns either an `Account` with `userAccountNumber` as its account number or `null` to indicate that `userAccountNumber` is invalid. If `getAccount` returns an `Account` object, line 39 returns the boolean value returned by that object's `validatePIN` method. Note that `BankDatabase`'s `authenticateUser` method does not perform the PIN comparison itself—rather, it forwards `userPIN` to the `Account` object's `validatePIN` method to do so. The value returned by `Account` method `validatePIN` indicates whether the user-specified PIN matches the PIN of the user's `Account`, so method `authenticateUser` simply returns this value to the client of the class (i.e., ATM).

`BankDatabase` trusts the ATM to invoke method `authenticateUser` and receive a return value of `true` before allowing the user to perform transactions. `BankDatabase` also trusts that each `Transaction` object created by the ATM contains the valid account number of the current authenticated user and that this is the account number passed to the remaining `BankDatabase` methods as argument `userAccountNumber`. Methods `getAvailableBalance` (lines 45–48), `getTotalBalance` (lines 51–54), `credit` (lines 57–60) and `debit` (lines 63–66) therefore simply retrieve the user's `Account` object with utility method `getAccount`, then invoke the appropriate `Account` method on that object. We know that the calls to `getAccount` within these methods will never return `null`, because `userAccountNumber` must refer to an existing `Account`. Note that `getAvailableBalance` and `getTotalBalance` return the values returned by the corresponding `Account` methods. Also note that `credit` and `debit` simply redirect parameter `amount` to the `Account` methods they invoke.

M.9 Class Transaction lx

```

1 // Transaction.java
2 // Abstract superclass Transaction represents an ATM transaction
3
4 public abstract class Transaction
5 {
6 private int accountNumber; // indicates account involved
7 private Screen screen; // ATM's screen
8 private BankDatabase bankDatabase; // account info database
9
10 // Transaction constructor invoked by subclasses using super()
11 public Transaction(int userAccountNumber, Screen atmScreen,
12 BankDatabase atmBankDatabase)
13 {
14 accountNumber = userAccountNumber;
15 screen = atmScreen;
16 bankDatabase = atmBankDatabase;
17 } // end Transaction constructor
18
19 // return account number
20 public int getAccountNumber()
21 {
22 return accountNumber;
23 } // end method getAccountNumber
24
25 // return reference to screen
26 public Screen getScreen()
27 {
28 return screen;
29 } // end method getScreen
30
31 // return reference to bank database
32 public BankDatabase getBankDatabase()
33 {
34 return bankDatabase;
35 } // end method getBankDatabase
36
37 // perform the transaction (overridden by each subclass)
38 abstract public void execute();
39 } // end class Transaction

```

**Fig. M.8** | Abstract superclass Transaction represents an ATM transaction.

## M.9 Class Transaction

Class `Transaction` (Fig. M.8) is an abstract superclass that represents the notion of an ATM transaction. It contains the common features of subclasses `BalanceInquiry`, `Withdrawal` and `Deposit`. This class expands upon the “skeleton” code first developed in Section 10.9. Line 4 declares this class to be `abstract`. Lines 6–8 declare the class’s private attributes. Recall from the class diagram of Fig. 10.22 that class `Transaction` contains an attribute `accountNumber` (line 6) that indicates the account involved in the `Transaction`. We derive attributes `screen` (line 7) and `bankDatabase` (line 8) from class `Transaction`’s associations modeled in Fig. 10.21—all transactions require access to the ATM’s screen and the bank’s database.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## LXI Appendix M ATM Case Study Code

Class `Transaction` has a constructor (lines 11–17) that takes the current user's account number and references to the ATM's screen and the bank's database as arguments. Because `Transaction` is an abstract class, this constructor will never be called directly to instantiate `Transaction` objects. Instead, the constructors of the `Transaction` subclasses will use `super` to invoke this constructor.

Class `Transaction` has three public `get` methods—`getAccountNumber` (lines 20–23), `getScreen` (lines 26–29) and `getBankDatabase` (lines 32–35). `Transaction` subclasses inherit these methods from `Transaction` and use them to gain access to class `Transaction`'s private attributes.

Class `Transaction` also declares an abstract method `execute` (line 38). It does not make sense to provide an implementation for this method, because a generic transaction cannot be executed. Thus, we declare this method to be abstract and force each `Transaction` subclass to provide its own concrete implementation that executes that particular type of transaction.

### M.10 Class BalanceInquiry

Class `BalanceInquiry` (Fig. M.9) extends `Transaction` and represents a balance inquiry ATM transaction. `BalanceInquiry` does not have any attributes of its own, but it inherits `Transaction` attributes `accountNumber`, `screen` and `bankDatabase`, which are accessible through `Transaction`'s public `get` methods. The `BalanceInquiry` constructor takes arguments corresponding to these attributes and simply forwards them to `Transaction`'s constructor using `super` (line 10).

Class `BalanceInquiry` overrides `Transaction`'s abstract method `execute` to provide a concrete implementation (lines 14–35) that performs the steps involved in a balance inquiry. Lines 17–18 get references to the bank database and the ATM's screen by invoking methods inherited from superclass `Transaction`. Lines 21–22 retrieve the available balance of the account involved by invoking method `getAvailableBalance` of `bankDatabase`. Note that line 22 uses inherited method `getAccountNumber` to get the account number of the current user, which it then passes to `getAvailableBalance`. Lines 25–26 retrieve the total balance of the current user's account. Lines 29–34 display the balance information on the ATM's screen. Recall that `displayDollarAmount` takes a `double` argument and outputs it to the screen formatted as a dollar amount. For example, if a user's `availableBalance` is `1000.5`, line 31 outputs `$1,000.50`. Note that line 34 inserts a blank line of output to separate the balance information from subsequent output (i.e., the main menu repeated by class `ATM` after executing the `BalanceInquiry`).

### M.11 Class Withdrawal

Class `Withdrawal` (Fig. M.10) extends `Transaction` and represents a withdrawal ATM transaction. This class expands upon the “skeleton” code for this class developed in Fig. 10.24. Recall from the class diagram of Fig. 10.21 that class `Withdrawal` has one attribute, `amount`, which line 6 implements as an `int` field. Figure 10.21 models associations between class `Withdrawal` and classes `Keypad` and `CashDispenser`, for which lines 7–8 implement reference-type attributes `keypad` and `cashDispenser`, respectively. Line 11 declares a constant corresponding to the cancel menu option. We will soon discuss how the class uses this constant.

M.11 Class Withdrawal **LXII**

```

1 // BalanceInquiry.java
2 // Represents a balance inquiry ATM transaction
3
4 public class BalanceInquiry extends Transaction
5 {
6 // BalanceInquiry constructor
7 public BalanceInquiry(int userAccountNumber, Screen atmScreen,
8 BankDatabase atmBankDatabase)
9 {
10 super(userAccountNumber, atmScreen, atmBankDatabase);
11 } // end BalanceInquiry constructor
12
13 // performs the transaction
14 public void execute()
15 {
16 // get references to bank database and screen
17 BankDatabase bankDatabase = getBankDatabase();
18 Screen screen = getScreen();
19
20 // get the available balance for the account involved
21 double availableBalance =
22 bankDatabase.getAvailableBalance(getAccountNumber());
23
24 // get the total balance for the account involved
25 double totalBalance =
26 bankDatabase.getTotalBalance(getAccountNumber());
27
28 // display the balance information on the screen
29 screen.displayMessageLine("\nBalance Information:");
30 screen.displayMessage(" - Available balance: ");
31 screen.displayDollarAmount(availableBalance);
32 screen.displayMessage("\n - Total balance: ");
33 screen.displayDollarAmount(totalBalance);
34 screen.displayMessageLine("");
35 } // end method execute
36 } // end class BalanceInquiry

```

**Fig. M.9** | Class BalanceInquiry represents a balance inquiry ATM transaction.

Class Withdrawal's constructor (lines 14–24) has five parameters. It uses `super` to pass parameters `userAccountNumber`, `atmScreen` and `atmBankDatabase` to superclass `Transaction`'s constructor to set the attributes that `Withdrawal` inherits from `Transaction`. The constructor also takes references `atmKeypad` and `atmCashDispenser` as parameters and assigns them to reference-type attributes `keypad` and `cashDispenser`.

Class `Withdrawal` overrides `Transaction`'s abstract method `execute` with a concrete implementation (lines 27–84) that performs the steps involved in a withdrawal. Line 29 declares and initializes a local `boolean` variable `cashDispensed`. This variable indicates whether cash has been dispensed (i.e., whether the transaction has completed successfully) and is initially `false`. Line 30 declares local `double` variable `availableBalance`, which will store the user's available balance during a withdrawal transaction. Lines 33–34 get references to the bank database and the ATM's screen by invoking methods inherited from superclass `Transaction`.

### LXIII Appendix M ATM Case Study Code

Lines 37–82 contain a `do...while` statement that executes its body until cash is dispensed (i.e., until `cashDispensed` becomes `true`) or until the user chooses to cancel (in which case, the loop terminates). We use this loop to continuously return the user to the start of the transaction if an error occurs (i.e., the requested withdrawal amount is greater than the user's available balance or greater than the amount of cash in the cash dispenser). Line 40 displays a menu of withdrawal amounts and obtains a user selection by calling private utility method `displayMenuOfAmounts` (declared in lines 88–132). This method displays the menu of amounts and returns either an `int` withdrawal amount or an `int` constant `CANCELED` to indicate that the user has chosen to cancel the transaction.

```

94 // array of amounts to correspond to menu numbers
95 int amounts[] = { 0, 20, 40, 60, 100, 200 };
96
97 // loop while no valid choice has been made
98 while (userChoice == 0)
99 {
100 // display the menu
101 screen.displayMessageLine("\nWithdrawal Menu:");
102 screen.displayMessageLine("1 - $20");
103 screen.displayMessageLine("2 - $40");
104 screen.displayMessageLine("3 - $60");
105 screen.displayMessageLine("4 - $100");
106 screen.displayMessageLine("5 - $200");
107 screen.displayMessageLine("6 - Cancel transaction");
108 screen.displayMessage("\nChoose a withdrawal amount: ");
109
110 int input = keypad.getInput(); // get user input through keypad
111
112 // determine how to proceed based on the input value
113 switch (input)
114 {
115 case 1: // if the user chose a withdrawal amount
116 case 2: // (i.e., chose option 1, 2, 3, 4 or 5), return the
117 case 3: // corresponding amount from amounts array
118 case 4:
119 case 5:
120 userChoice = amounts[input]; // save user's choice
121 break;
122 case CANCELED: // the user chose to cancel
123 userChoice = CANCELED; // save user's choice
124 break;
125 default: // the user did not enter a value from 1-6
126 screen.displayMessageLine(
127 "\nInvalid selection. Try again.");
128 } // end switch
129 } // end while
130
131 return userChoice; // return withdrawal amount or CANCELED
132 } // end method displayMenuOfAmounts
133 } // end class Withdrawal

```

**Fig. M.10** | Class Withdrawal represents a withdrawal ATM transaction. (Part 3 of 3.)

Method `displayMenuOfAmounts` (lines 88–132) first declares local variable `userChoice` (initially 0) to store the value that the method will return (line 90). Line 92 gets a reference to the screen by calling method `getScreen` inherited from superclass `Transaction`. Line 95 declares an integer array of withdrawal amounts that correspond to the amounts displayed in the withdrawal menu. We ignore the first element in the array (index 0) because the menu has no option 0. The `while` statement at lines 98–129 repeats until `userChoice` takes on a value other than 0. We will see shortly that this occurs when the user makes a valid selection from the menu. Lines 101–108 display the withdrawal menu on the screen and prompt the user to enter a choice. Line 110 obtains integer `input`

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## M.12 Class Deposit LXVI

through the keypad. The `switch` statement at lines 113–128 determines how to proceed based on the user’s input. If the user selects a number between 1 and 5, line 120 sets `userChoice` to the value of the element in `amounts` at index `input`. For example, if the user enters 3 to withdraw \$60, line 120 sets `userChoice` to the value of `amounts[ 3 ]` (i.e., 60). Line 120 terminates the `switch`. Variable `userChoice` no longer equals 0, so the `while` at lines 98–129 terminates and line 131 returns `userChoice`. If the user selects the cancel menu option, lines 123–124 execute, setting `userChoice` to `CANCELED` and causing the method to return this value. If the user does not enter a valid menu selection, lines 126–127 display an error message and the user is returned to the withdrawal menu.

The `if` statement at line 43 in method `execute` determines whether the user has selected a withdrawal amount or chosen to cancel. If the user cancels, lines 79–80 execute and display an appropriate message to the user before returning control to the calling method (i.e., ATM method `performTransactions`). If the user has chosen a withdrawal amount, lines 46–47 retrieve the available balance of the current user’s Account and store it in variable `availableBalance`. Next, the `if` statement at line 50 determines whether the selected amount is less than or equal to the user’s available balance. If it is not, lines 72–74 display an appropriate error message. Control then continues to the end of the `do...while`, and the loop repeats because `cashDispensed` is still `false`. If the user’s balance is high enough, the `if` statement at line 53 determines whether the cash dispenser has enough money to satisfy the withdrawal request by invoking the `cashDispenser`’s `isSufficientCashAvailable` method. If this method returns `false`, lines 66–68 display an appropriate error message and the `do...while` repeats. If sufficient cash is available, then the requirements for the withdrawal are satisfied, and line 56 debits `amount` from the user’s account in the database. Lines 58–59 then instruct the cash dispenser to dispense the cash to the user and set `cashDispensed` to `true`. Finally, lines 62–63 display a message to the user that cash has been dispensed. Because `cashDispensed` is now `true`, control continues after the `do...while`. No additional statements appear below the loop, so the method returns control to class `ATM`.

### M.12 Class Deposit

`Class Deposit` (Fig. M.11) extends `Transaction` and represents a deposit ATM transaction. Recall from the class diagram of Fig. 10.22 that class `Deposit` has one attribute `amount`, which line 6 implements as an `int` field. Lines 7–8 create reference-type attributes `keypad` and `depositSlot` that implement the associations between class `Deposit` and classes `Keypad` and `DepositSlot` modeled in Fig. 10.21. Line 9 declares a constant `CANCELED` that corresponds to the value a user enters to cancel. We will soon discuss how the class uses this constant.

Like class `Withdrawal`, class `Deposit` contains a constructor (lines 12–22) that passes three parameters to superclass `Transaction`’s constructor using `super`. The constructor also has parameters `atmKeypad` and `atmDepositSlot`, which it assigns to corresponding attributes (lines 20–21).

Method `execute` (lines 25–65) overrides abstract method `execute` in superclass `Transaction` with a concrete implementation that performs the steps required in a deposit transaction. Lines 27–28 get references to the database and the screen. Line 30 prompts the user to enter a deposit amount by invoking `private` utility method `promptForDepositAmount` (declared in lines 68–84) and sets attribute `amount` to the value

M.12 Class Deposit **LXVIII**

```

52 // credit account to reflect the deposit
53 bankDatabase.credit(getAccountNumber(), amount);
54 } // end if
55 else // deposit envelope not received
56 {
57 screen.displayMessageLine("\nYou did not insert an " +
58 "envelope, so the ATM has canceled your transaction.");
59 } // end else
60 } // end if
61 else // user canceled instead of entering amount
62 {
63 screen.displayMessageLine("\nCanceling transaction...");
64 } // end else
65 } // end method execute
66
67 // prompt user to enter a deposit amount in cents
68 private double promptForDepositAmount()
69 {
70 Screen screen = getScreen(); // get reference to screen
71
72 // display the prompt
73 screen.displayMessage("\nPlease enter a deposit amount in " +
74 "CENTS (or 0 to cancel): ");
75 int input = keypad.getInput(); // receive input of deposit amount
76
77 // check whether the user canceled or entered a valid amount
78 if (input == CANCELED)
79 return CANCELED;
80 else
81 {
82 return (double) input / 100; // return dollar amount
83 } // end else
84 } // end method promptForDepositAmount
85 } // end class Deposit

```

**Fig. M.11** | Class Deposit represents a deposit ATM transaction. (Part 2 of 2.)

returned. Method `promptForDepositAmount` asks the user to enter a deposit amount as an integer number of cents (because the ATM's keypad does not contain a decimal point; this is consistent with many real ATMs) and returns the `double` value representing the dollar amount to be deposited.

Line 70 in method `promptForDepositAmount` gets a reference to the ATM's screen. Lines 73–74 display a message on the screen asking the user to input a deposit amount as a number of cents or “0” to cancel the transaction. Line 75 receives the user's input from the keypad. The `if` statement at lines 78–83 determines whether the user has entered a real deposit amount or chosen to cancel. If the user chooses to cancel, line 79 returns the constant `CANCELED`. Otherwise, line 82 returns the deposit amount after converting from the number of cents to a dollar amount by casting `input` to a `double`, then dividing by 100. For example, if the user enters 125 as the number of cents, line 82 returns 125.0 divided by 100, or 1.25—125 cents is \$1.25.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**LXIX** [Appendix M ATM Case Study Code](#)

The `if` statement at lines 33–64 in method `execute` determines whether the user has chosen to cancel the transaction instead of entering a deposit amount. If the user cancels, line 63 displays an appropriate message, and the method returns. If the user enters a deposit amount, lines 36–39 instruct the user to insert a deposit envelope with the correct amount. Recall that `Screen` method `displayDollarAmount` outputs a `double` formatted as a dollar amount.

Line 42 sets a local `boolean` variable to the value returned by `depositSlot`'s `isEnvelopeReceived` method, indicating whether a deposit envelope has been received. Recall that we coded method `isEnvelopeReceived` (lines 8–11 of Fig. M.5) to always return `true`, because we are simulating the functionality of the deposit slot and assume that the user always inserts an envelope. However, we code method `execute` of class `Deposit` to test for the possibility that the user does not insert an envelope—good software engineering demands that programs account for all possible return values. Thus, class `Deposit` is prepared for future versions of `isEnvelopeReceived` that could return `false`. Lines 47–53 execute if the deposit slot receives an envelope. Lines 47–50 display an appropriate message to the user. Line 53 then credits the deposit amount to the user's account in the database. Lines 57–58 will execute if the deposit slot does not receive a deposit envelope. In this case, we display a message to the user stating that the ATM has canceled the transaction. The method then returns without modifying the user's account.

### M.13 Class ATMCaseStudy

Class `ATMCaseStudy` (Fig. M.12) is a simple class that allows us to start, or “turn on,” the ATM and test the implementation of our ATM system model. Class `ATMCaseStudy`'s `main` method (lines 7–11) does nothing more than instantiate a new `ATM` object named `theATM` (line 9) and invoke its `run` method (line 10) to start the ATM.

```

1 // ATMCaseStudy.java
2 // Driver program for the ATM case study
3
4 public class ATMCaseStudy
5 {
6 // main method creates and runs the ATM
7 public static void main(String[] args)
8 {
9 ATM theATM = new ATM();
10 theATM.run();
11 } // end main
12 } // end class ATMCaseStudy

```

**Fig. M.12** | `ATMCaseStudy.java` starts the ATM.

### M.14 Wrap-Up

Congratulations on completing the entire software engineering ATM case study! We hope you found this experience to be valuable and that it reinforced many of the concepts that you learned in Chapters 1–10. We would sincerely appreciate your comments, criticisms and suggestions. You can reach us at `deitel@deitel.com`. We will respond promptly.

# Labeled break and continue Statements

## N.1 Introduction

In Chapter 5, we discussed Java's `break` and `continue` statements, which enable programmers to alter the flow of control in control statements. Java also provides the labeled `break` and `continue` statements for cases in which a programmer needs to conveniently alter the flow of control in nested control statements. This appendix demonstrates the labeled `break` and `continue` statements with examples using nested `for` statements.

## N.2 Labeled break Statement

The `break` statement presented in Section 5.7 enables a program to break out of the `while`, `for`, `do...while` or `switch` in which the `break` statement appears. Sometimes these control statements are nested in other repetition statements. A program might need to exit the entire nested control statement in one operation, rather than wait for it to complete execution normally. To break out of such nested control statements, you can use the **labeled break statement**. This statement, when executed in a `while`, `for`, `do...while` or `switch`, causes immediate exit from that control statement and any number of enclosing statements. Program execution resumes with the first statement after the enclosing **labeled statement**. The statement that follows the label can be either a repetition statement or a block in which a repetition statement appears. Figure N.1 demonstrates the labeled `break` statement in a nested `for` statement.

The block (lines 7–26 in Fig. N.1) begins with a **label** (an identifier followed by a colon) at line 7; here we use the `stop:` label. The block is enclosed in braces (lines 8 and 26) and includes the nested `for` (lines 10–22) and the output statement at line 25. When the `if` at line 15 detects that `row` is equal to 5, the `break` statement at line 16 executes. This statement terminates both the `for` at lines 13–19 and its enclosing `for` at lines 10–22. Then the program proceeds immediately to the first statement after the labeled block—in this case, the end of `main` is reached and the program terminates. The outer `for` fully executes its body only four times. The output statement at line 25 never executes, because it is in the labeled block's body, and the outer `for` never completes.

**LXXI** Appendix N Labeled break and continue Statements

```

1 // Fig. N.1: BreakLabelTest.java
2 // Labeled break statement exiting a nested for statement.
3 public class BreakLabelTest
4 {
5 public static void main(String args[])
6 {
7 stop: // labeled block
8 {
9 // count 10 rows
10 for (int row = 1; row <= 10; row++)
11 {
12 // count 5 columns
13 for (int column = 1; column <= 5 ; column++)
14 {
15 if (row == 5) // if row is 5,
16 break stop; // jump to end of stop block
17
18 System.out.print("*");
19 } // end inner for
20
21 System.out.println(); // outputs a newline
22 } // end outer for
23
24 // following line is skipped
25 System.out.println("\nLoops terminated normally");
26 } // end labeled block
27 } // end main
28 } // end class BreakLabelTest

```

```

* * * * *
* * * * *
* * * * *
* * * * *

```

**Fig. N.1** | Labeled break statement exiting a nested for statement.**Good Programming Practice N.1**

*Too many levels of nested control statements can make a program difficult to read. As a general rule, try to avoid using more than three levels of nesting.*

**N.3 Labeled continue Statement**

The `continue` statement presented in Section 5.7 proceeds with the next iteration (repetition) of the immediately enclosing `while`, `for` or `do...while`. The **labeled continue statement** skips the remaining statements in that statement's body and any number of enclosing repetition statements and proceeds with the next iteration of the enclosing **labeled repetition statement** (i.e., a `for`, `while` or `do...while` preceded by a label). In labeled `while` and `do...while` statements, the program evaluates the loop-continuation test of the labeled loop immediately after the `continue` statement executes. In a labeled `for`, the increment expression is executed and the loop-continuation test is evaluated. Figure N.2

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

N.3 Labeled continue Statement **LXXII**

uses a labeled `continue` statement in a nested `for` to enable execution to continue with the next iteration of the outer `for`.

```

1 // Fig. N.2: ContinueLabelTest.java
2 // Labeled continue statement terminating a nested for statement.
3 public class ContinueLabelTest
4 {
5 public static void main(String args[])
6 {
7 nextRow: // target label of continue statement
8
9 // count 5 rows
10 for (int row = 1; row <= 5; row++)
11 {
12 System.out.println(); // outputs a newline
13
14 // count 10 columns per row
15 for (int column = 1; column <= 10; column++)
16 {
17 // if column greater than row, start next row
18 if (column > row)
19 continue nextRow; // next iteration of labeled loop
20
21 System.out.print("*");
22 } // end inner for
23 } // end outer for
24
25 System.out.println(); // outputs a newline
26 } // end main
27 } // end class ContinueLabelTest

```

```

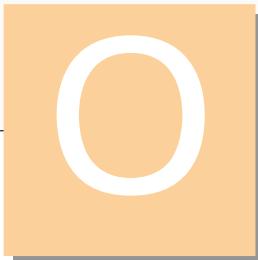

*
*
* *
* * *
* * * *
* * * * *

```

**Fig. N.2** | Labeled `continue` statement terminating a nested `for` statement.

The labeled `for` (lines 7–23) actually starts at the `nextRow` label. When the `if` at line 18 in the inner `for` (lines 15–22) detects that `column` is greater than `row`, the `continue` statement at line 19 executes, and program control continues with the increment of the control variable `row` of the outer `for` loop. Even though the inner `for` counts from 1 to 10, the number of `*` characters output on a row never exceeds the value of `row`, creating an interesting triangle pattern.

# UML 2: Additional Diagram Types

## O.1 Introduction

If you read the optional Software Engineering Case Study sections in Chapters 2–8 and 10, you should now have a comfortable grasp on the UML diagram types that we use to model our ATM system. The case study is intended for use in first- or second-semester courses, so we limit our discussion to a concise, subset of the UML. The UML 2 provides a total of 13 diagram types. The end of Section 2.9 summarizes the six diagram types that we use in the case study. This appendix lists and briefly defines the seven remaining diagram types.

## O.2 Additional Diagram Types

The following are the seven diagram types that we have chosen not to use in our Software Engineering Case Study.

- **Object diagrams** model a “snapshot” of the system by modeling a system’s objects and their relationships at a specific point in time. Each object represents an instance of a class from a class diagram, and there may be several objects created from one class. For our ATM system, an object diagram could show several distinct Account objects side by side, illustrating that they are all part of the bank’s account database.
- **Component diagrams** model the **artifacts** and **components**—resources (which include source files)—that make up the system.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

O.2 Additional Diagram Types **LXXIV**

- **Deployment diagrams** model the runtime requirements of the system (such as the computer or computers on which the system will reside), memory requirements for the system, or other devices the system requires during execution.
- **Package diagrams** model the hierarchical structure of **packages** (which are groups of classes) in the system at compile-time and the relationships that exist between the packages.
- **Composite structure diagrams** model the internal structure of a complex object at runtime. Composite structure diagrams are new in UML 2 and allow system designers to hierarchically decompose a complex object into smaller parts. Composite structure diagrams are beyond the scope of our case study. Composite structure diagrams are more appropriate for larger industrial applications, which exhibit complex groupings of objects at execution time.
- **Interaction overview diagrams**, which are new in UML 2, provide a summary of control flow in the system by combining elements of several types of behavioral diagrams (e.g., activity diagrams, sequence diagrams).
- **Timing diagrams**, also new in UML 2, model the timing constraints imposed on stage changes and interactions between objects in a system.

If you are interested in learning more about these diagrams and advanced UML topics, please visit [www.uml.org](http://www.uml.org) and the Web resources listed at the ends of Section 1.16 and Section 2.9.

# Design Patterns

## P.1 Introduction

Most of the examples provided in this book are relatively small. These examples do not require an extensive design process, because they use only a few classes and illustrate introductory programming concepts. However, some programs are more complex—they can require thousands of lines of code or even more, contain many interactions among objects and involve many user interactions. Larger systems, such as air-traffic control systems or the systems that control a major bank's thousands of automated teller machines, could contain millions of lines of code. Effective design is crucial to the proper construction of such complex systems.

Over the past decade, the software-engineering industry has made significant progress in the field of [design patterns](#)—proven architectures for constructing flexible and maintainable object-oriented software. Using design patterns can substantially reduce the complexity of the design process. Designing an air-traffic control system will be a somewhat less formidable task if developers use design patterns. Design patterns benefit system developers by

- helping to construct reliable software using proven architectures and accumulated industry expertise.
- promoting design reuse in future systems.
- helping identify common mistakes and pitfalls that occur when building systems.
- helping to design systems independently of the language in which they will ultimately be implemented.
- establishing a common design vocabulary among developers.
- shortening the design phase in a software-development process.

The notion of using design patterns to construct software systems originated in the field of architecture. Architects use a set of established architectural design elements, such as arches and columns, when designing buildings. Designing with arches and columns is a proven strategy for constructing sound buildings—these elements may be viewed as architectural design patterns.

**LXXVI** [Appendix P Design Patterns](#)

In software, design patterns are neither classes nor objects. Rather, designers use design patterns to construct sets of classes and objects. To use design patterns effectively, designers must familiarize themselves with the most popular and effective patterns used in the software-engineering industry. In this appendix, we discuss fundamental object-oriented design patterns and architectures, as well as their importance in constructing well-engineered software.

This appendix presents several design patterns in Java, but these can be implemented in any object-oriented language, such as C++ or Visual Basic. We describe several design patterns used by Sun Microsystems in the Java API. We use design patterns in many programs in this book, which we will identify throughout our discussion. These programs provide examples of the use of design patterns to construct reliable, robust object-oriented software.

#### *History of Object-Oriented Design Patterns*

During 1991–1994, Erich Gamma, Richard Helm, Ralph Johnson, and John Vlissides—collectively known as the “Gang of Four”—used their combined expertise to write the book *Design Patterns: Elements of Reusable Object-Oriented Software*. This book describes 23 design patterns, each providing a solution to a common software design problem in industry. The book groups design patterns into three categories—[creational design patterns](#), [structural design patterns](#) and [behavioral design patterns](#). Creational design patterns describe techniques to instantiate objects (or groups of objects). Structural design patterns allow designers to organize classes and objects into larger structures. Behavioral design patterns assign responsibilities to classes and objects.

The gang-of-four book showed that design patterns evolved naturally through years of industry experience. In his article *Seven Habits of Successful Pattern Writers*,<sup>1</sup> John Vlissides states that “the single most important activity in pattern writing is reflection.” This statement implies that, to create patterns, developers must reflect on, and document, their successes (and mistakes). Developers use design patterns to capture and employ this collective industry experience, which ultimately helps them avoid repeating the same mistakes. New design patterns are being created all the time and are introduced rapidly to designers worldwide via the Internet.

Design patterns are a somewhat advanced topic that might not appear in most introductory course sequences. As you proceed in your Java studies, design patterns will surely increase in value. If you are a student and your instructor does not plan to include this material in your course, we encourage you to read this material on your own.

Section P.8 presents a list of Web resources pertaining to design patterns and their relevance to Java programming. As you proceed through this appendix, you may want to consult the provided URLs to learn more about a particular design pattern introduced in the text, or to read about new developments in the design patterns community.

## P.2 Creational, Structural and Behavioral Design Patterns

In Section P.1, we mentioned that the “Gang of Four” described 23 design patterns using three categories—creational, structural and behavioral. In this and the remaining sections of this appendix, we discuss design patterns in each category and their importance, and

1. Vlissides, J. *Pattern Hatching: Design Patterns Applied*. Reading, MA: Addison-Wesley, 1998.

## P.2 Creational, Structural and Behavioral Design Patterns

**LXXVII**

how each pattern relates to the Java material in the book. For example, several Java Swing components that we introduce in Chapter 11 and Chapter 22 use the Composite design pattern. Figure P.1 identifies the 18 Gang of Four design patterns discussed in this appendix.

Many popular patterns have been documented since the Gang-of-Four book—these include the [concurrency design patterns](#), which are especially helpful in the design of multithreaded systems. Section P.4 discusses some of these patterns used in industry. Architectural patterns, as we discuss in Section P.5, specify how subsystems interact with each other. Figure P.2 lists the concurrency patterns and architectural patterns that we discuss in this appendix.

Section	Creational design patterns	Structural design patterns	Behavioral design patterns
Section P.2	Singleton	Proxy	Memento, State
Section P.3	Factory Method	Adapter, Bridge, Composite	Chain of Responsibility, Command, Observer, Strategy, Template Method
Section P.5	Abstract Factory	Decorator, Facade	
Section P.6	Prototype		Iterator

**Fig. P.1** | 18 Gang-of-Four design patterns discussed in this appendix.

Section	Concurrency design patterns	Architectural patterns
Section P.4	Single-Threaded Execution, Guarded Suspension, Balkling, Read/Write Lock, Two-Phase Termination	
Section P.5		Model-View-Controller, Layers

**Fig. P.2** | Concurrency design patterns and architectural patterns discussed in this appendix.

### P.2.1 Creational Design Patterns

**Creational design patterns** address issues related to the creation of objects, such as preventing a system from creating more than one object of a class (the Singleton creational design pattern) or deferring until execution time the decision as to what types of objects are going to be created (the purpose of the other creational design patterns discussed here). For example, suppose we are designing a 3-D drawing program, in which the user can create several 3-D geometric objects, such as cylinders, spheres, cubes, tetrahedrons, etc. Further suppose that each shape in the drawing program is represented by an object. At compile time, the program does not know what shapes the user will choose to draw. Based

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## LXXVIII Appendix P Design Patterns

on user input, this program should be able to determine the class from which to instantiate an appropriate object for the shape the user selected. If the user creates a cylinder in the GUI, our program should “know” to instantiate an object of class `Cylinder`. When the user decides what geometric object to draw, the program should determine the specific subclass from which to instantiate that object.

The Gang-of-Four book describes five creational patterns (four of which we discuss in this appendix):

- Abstract Factory (Section P.5)
- Builder (not discussed)
- Factory Method (Section P.3)
- Prototype (Section P.6)
- Singleton (Section P.2)

### *Singleton*

Occasionally, a system should contain exactly one object of a class—that is, once the program instantiates that object, the program should not be allowed to create additional objects of that class. For example, some systems connect to a database using only one object that manages database connections, which ensures that other objects cannot initialize unnecessary connections that would slow the system. The [Singleton design pattern](#) guarantees that a system instantiates a maximum of one object of a class.

Figure P.3 demonstrates Java code using the Singleton design pattern. Line 4 declares class `Singleton` as `final`, so subclasses cannot be created that could provide multiple instantiations. Lines 10–13 declare a `private` constructor—only class `Singleton` can instantiate a `Singleton` object using this constructor. Line 7 declares a static reference to a `Singleton` object and invokes the private constructor. This creates the one instance of

```

1 // Singleton.java
2 // Demonstrates Singleton design pattern
3
4 public final class Singleton
5 {
6 // Singleton object to be returned by getInstance()
7 private static final Singleton singleton = new Singleton();
8
9 // private constructor prevents instantiation by clients
10 private Singleton()
11 {
12 System.out.println("Singleton object created.");
13 } // end Singleton constructor
14
15 // return static Singleton object
16 public static Singleton getInstance()
17 {
18 return singleton;
19 } // end method getInstance
20 } // end class Singleton

```

**Fig. P.3** | Class `Singleton` ensures that only one object of its class is created.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## P.2 Creational, Structural and Behavioral Design Patterns

**LXXIX**

class Singleton that will be provided to clients. When invoked, static method `getSingletonInstance` (lines 16–19) simply returns a copy of this reference.

Lines 9–10 of class `SingletonTest` (Fig. P.4) declare two references to `Singleton` objects—`firstSingleton` and `secondSingleton`. Lines 13–14 call method `getSingletonInstance` and assign `Singleton` references to `firstSingleton` and `secondSingleton`, respectively. Line 17 tests whether these references both refer to the same `Singleton` object. Figure P.4 shows that `firstSingleton` and `secondSingleton` indeed are both references to the same `Singleton` object, because each time method `getSingletonInstance` is called, it returns a reference to the same `Singleton` object.

```

1 // SingletonTest.java
2 // Attempt to create two Singleton objects
3
4 public class SingletonTest
5 {
6 // run SingletonExample
7 public static void main(String args[])
8 {
9 Singleton firstSingleton;
10 Singleton secondSingleton;
11
12 // create Singleton objects
13 firstSingleton = Singleton.getInstance();
14 secondSingleton = Singleton.getInstance();
15
16 // the "two" Singletons should refer to same Singleton
17 if (firstSingleton == secondSingleton)
18 System.out.println("firstSingleton and secondSingleton " +
19 "refer to the same Singleton object");
20 } // end main
21 } // end class SingletonTest

```

Singleton object created.  
 firstSingleton and secondSingleton refer to the same Singleton object

**Fig. P.4** | Class `SingletonTest` creates a `Singleton` object more than once.

### P.2.2 Structural Design Patterns

Structural design patterns describe common ways to organize classes and objects in a system. The Gang of Four book describes seven structural design patterns (six of which we discuss in this appendix):

- Adapter (Section P.3)
- Bridge (Section P.3)
- Composite (Section P.3)
- Decorator (Section P.5)
- Facade (Section P.5)
- Flyweight (not discussed)
- Proxy (Section P.2)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**LXXX** [Appendix P Design Patterns](#)***Proxy***

An applet should always display something while images load to provide positive feedback to users, so they know the applet is working. Whether that “something” is a smaller image or a string of text informing the user that the images are loading, the [Proxy design pattern](#) can be applied to achieve this effect. Consider loading several large images (several megabytes) in a Java applet. Ideally, we would like to see these images instantaneously—however, loading large images into memory can take time to complete (especially across a network). The Proxy design pattern allows the system to use one object—called a [proxy object](#)—in place of another. In our example, the proxy object could be a gauge that shows the user what percentage of a large image has been loaded. When this image finishes loading, the proxy object is no longer needed—the applet can then display an image instead of the proxy. Class `javax.swing.JProgressBar` can be used to create such proxy objects.

**P.2.3 Behavioral Design Patterns**

**Behavioral design patterns** provide proven strategies to model how objects collaborate with one another in a system and offer special behaviors appropriate for a wide variety of applications. Let us consider the Observer behavioral design pattern—a classic example illustrating collaborations between objects. For example, GUI components collaborate with their listeners to respond to user interactions. GUI components use this pattern to process user interface events. A listener observes state changes in a particular GUI component by registering to handle its events. When the user interacts with that GUI component, the component notifies its listeners (also known as its observers) that its state has changed (e.g., a button has been pressed).

We also consider the Memento behavioral design pattern—an example of offering special behavior for many applications. The Memento pattern enables a system to save an object’s state, so that state can be restored at a later time. For example, many applications provide an “undo” capability that allows users to revert to previous versions of their work.

The Gang-of-Four book describes 11 behavioral design patterns (eight of which we discuss in this appendix):

- Chain of Responsibility (Section P.3)
- Command (Section P.3)
- Interpreter (not discussed)
- Iterator (Section P.2)
- Mediator (not discussed)
- Memento (Section P.2)
- Observer (Section P.3)
- State (Section P.2)
- Strategy (Section P.3)
- Template Method (Section P.3)
- Visitor (not discussed)

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## P.2 Creational, Structural and Behavioral Design Patterns

**LXXXI**

### *Memento*

Consider a painting program, which allows a user to create graphics. Occasionally the user may position a graphic improperly in the drawing area. Painting programs offer an “undo” feature that allows the user to unwind such an error. Specifically, the program restores the drawing area to its state before the user placed the graphic. More sophisticated painting programs offer a history, which stores several states in a list, allowing the user to restore the program to any state in the history. The [Memento design pattern](#) allows an object to save its state, so that—if necessary—the object can be restored to its former state.

The Memento design pattern requires three types of objects. The [originator object](#) occupies some state—the set of attribute values at a specific time in program execution. In our painting-program example, the drawing area acts as the originator, because it contains attribute information describing its state—when the program first executes, the area contains no elements. The [memento object](#) stores a copy of necessary attributes associated with the originator’s state (i.e., the memento saves the drawing area’s state). The memento is stored as the first item in the history list, which acts as the [caretaker object](#)—the object that contains references to all memento objects associated with the originator. Now, suppose that the user draws a circle in the drawing area. The area contains different information describing its state—a circle object centered at specified *x-y* coordinates. The drawing area then uses another memento to store this information. This memento becomes the second item in the history list. The history list displays all mementos on screen, so the user can select which state to restore. Suppose that the user wishes to remove the circle—if the user selects the first memento, the drawing area uses it to restore the blank drawing area.

### *State*

In certain designs, we must convey an object’s state information or represent the various states that an object can occupy. The [State design pattern](#) uses an abstract superclass—called the [State class](#)—which contains methods that describe behaviors for states that an object (called the [context object](#)) can occupy. A [State subclass](#), which extends the State class, represents an individual state that the context can occupy. Each State subclass contains methods that implement the State class’s abstract methods. The context contains exactly one reference to an object of the State class—this object is called the [state object](#). When the context changes state, the state object references the State subclass object associated with that new state.

### P.2.4 Conclusion

In this section, we listed the three types of design patterns introduced in the Gang-of-Four book, we identified 18 of these design patterns that we discuss in this appendix and we discussed specific design patterns, including Singleton, Proxy, Memento and State. In the next section, we introduce some design patterns associated with AWT and Swing GUI components. After reading this section, you should understand better how Java GUI components take advantage of design patterns.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**LXXXII** Appendix P Design Patterns

## P.3 Design Patterns in Packages `java.awt` and `javax.swing`

This section introduces those design patterns associated with Java GUI components. It should help you understand better how these components take advantage of design patterns and how developers integrate design patterns with Java GUI applications.

### P.3.1 Creational Design Patterns

Now, we continue our treatment of creational design patterns, which provide ways to instantiate objects in a system.

#### *Factory Method*

Suppose that we are designing a system that opens an image from a specified file. Several different image formats exist, such as GIF and JPEG. We can use method `createImage` of class `java.awt.Component` to create an `Image` object. For example, to create a JPEG and GIF image in an object of a `Component` subclass—such as a `JPanel` object—we pass the name of the image file to method `createImage`, which returns an `Image` object that stores the image data. We can create two `Image` objects, each containing data for two images having entirely different structures. For example, a JPEG image can hold up to 16.7 million colors, a GIF image up to only 256. Also, a GIF image can contain transparent pixels that are not rendered on screen, whereas a JPEG image cannot.

Class `Image` is an abstract class that represents an image we can display on screen. Using the parameter passed by the programmer, method `createImage` determines the specific `Image` subclass from which to instantiate the `Image` object. We can design systems to allow the user to specify which image to create, and method `createImage` will determine the subclass from which to instantiate the `Image`. If the parameter passed to method `createImage` references a JPEG file, method `createImage` instantiates and returns an object of an `Image` subclass suitable for JPEG images. If the parameter references a GIF file, `createImage` instantiates and returns an object of an `Image` subclass suitable for GIF images.

Method `createImage` is an example of the **Factory Method design pattern**. The sole purpose of this **factory method** is to create objects by allowing the system to determine which class to instantiate at runtime. We can design a system that allows a user to specify what type of image to create at runtime. Class `Component` might not be able to determine which `Image` subclass to instantiate until the user specifies the image to load. For more information on method `createImage`, visit

[java.sun.com/javase/6/docs/api/java/awt/Component.html](http://java.sun.com/javase/6/docs/api/java/awt/Component.html)

### P.3.2 Structural Design Patterns

We now discuss three more structural design patterns. The Adapter design pattern helps objects with incompatible interfaces collaborate with one another. The Bridge design pattern helps designers enhance platform independence in their systems. The Composite design pattern provides a way for designers to organize and manipulate objects.

#### *Adapter*

The **Adapter design pattern** provides an object with a new interface that *adapts* to another object's interface, allowing both objects to collaborate with one another. We might liken

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

### P.3 Design Patterns in Packages `java.awt` and `javax.swing` LXXXIII

the adapter in this pattern to an adapter for a plug on an electrical device—electrical sockets in Europe are shaped differently from those in the United States, so an adapter is needed to plug an American device into a European socket and vice versa.

Java provides several classes that use the Adapter design pattern. Objects of the concrete subclasses of these classes act as adapters between objects that generate certain events and objects that handle the events. For example, a `MouseAdapter`, which we explained in Section 11.14, adapts an object that generates `MouseEvents` to an object that handles `MouseEvents`.

#### *Bridge*

Suppose that we are designing class `Button` for both the Windows and Macintosh operating systems. Class `Button` contains specific button information such as an `ActionListener` and a label. We design classes `Win32Button` and `MacButton` to extend class `Button`. Class `Win32Button` contains “look-and-feel” information on how to display a `Button` on the Windows operating system, and class `MacButton` contains “look-and-feel” information on how to display a `Button` on the Macintosh operating system.

Two problems arise here. First, if we create new `Button` subclasses, we must create corresponding `Win32Button` and `MacButton` subclasses. For example, if we create class `ImageButton` (a `Button` with an overlapping `Image`) that extends class `Button`, we must create additional subclasses `Win32ImageButton` and `MacImageButton`. In fact, we must create `Button` subclasses for every operating system we wish to support, which increases development time. Second, when a new operating system enters the market, we must create additional `Button` subclasses specific to it.

The [Bridge design pattern](#) avoids these problems by dividing an abstraction (e.g., a `Button`) and its implementations (e.g., `Win32Button`, `MacButton`, etc.) into separate class hierarchies. For example, the Java AWT classes use the Bridge design pattern to enable designers to create AWT `Button` subclasses without needing to create additional operating-system specific subclasses. Each AWT `Button` maintains a reference to a `ButtonPeer`, which is the superclass for platform-specific implementations, such as `Win32ButtonPeer`, `MacButtonPeer`, etc. When a programmer creates a `Button` object, class `Button` calls factory method `createButton` of class `Toolkit` to create the platform-specific `ButtonPeer` object. The `Button` object stores a reference to its `ButtonPeer`—this reference is the “bridge” in the Bridge design pattern. When the programmer invokes methods on the `Button` object, the `Button` object delegates the work to the appropriate lower-level method on its `ButtonPeer` to fulfill the request. A designer who creates a `Button` subclass called, e.g., `ImageButton`, does not need to create a corresponding `Win32ImageButton` or `MacImageButton` with platform-specific image-drawing capabilities. An `ImageButton` is a `Button`. Therefore, when an `ImageButton` needs to display its image, the `ImageButton` uses its `ButtonPeer`'s `Graphics` object to render the image on each platform. This design pattern enables designers to create new cross-platform GUI components using a “bridge” to hide platform-specific details.

#### Portability Tip P.1

Designers often use the Bridge design pattern to enhance the platform independence of their systems. This design pattern enables designers to create new cross-platform components using a “bridge” to hide platform-specific details.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## LXXXIV Appendix P Design Patterns

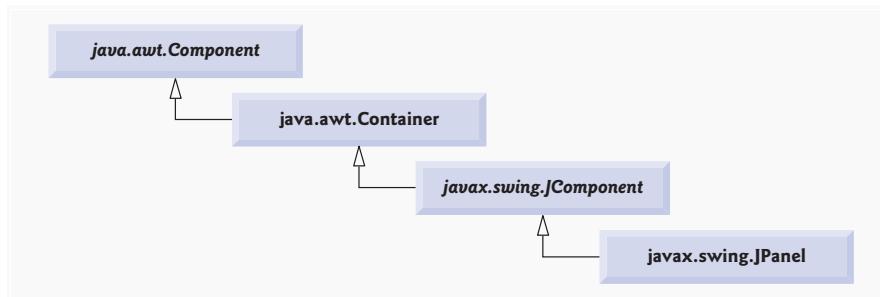

### *Composite*

Designers often organize components into hierarchical structures (e.g., a hierarchy of directories and files in a file system)—each node in the structure represents a component (e.g., a file or directory). Each node can contain references to one or more other nodes, and if it does so, it is called a **branch** (e.g., a directory containing files); otherwise, it is called a **leaf** (e.g., a file). Occasionally, a structure contains objects from several different classes (e.g., a directory can contain files and directories). An object—called a **client**—that wants to traverse the structure must determine the particular class for each node. Making this determination can be time consuming, and the structure can become hard to maintain.

In the **Composite design pattern**, each component in a hierarchical structure implements the same interface or extends a common superclass. This polymorphism (introduced in Chapter 10) ensures that clients can traverse all elements—branch or leaf—uniformly in the structure and does not have to determine each component type, because all components implement the same interface or extend the same superclass.

Java GUI components use the Composite design pattern. Consider the Swing component class `JPanel`, which extends class `JComponent`. Class `JComponent` extends class `java.awt.Container`, which extends class `java.awt.Component` (Fig. P.5). Class `Container` provides method `add`, which appends a `Component` object (or `Component` subclass object) to that `Container` object. Therefore, a `JPanel` object may be added to any object of a `Component` subclass, and any object from a `Component` subclass may be added to that `JPanel` object. A `JPanel` object can contain any GUI component while remaining unaware of its specific type. Nearly all GUI classes are both containers and components, enabling arbitrarily complex nesting and structuring of GUIs.

A client, such as a `JPanel` object, can traverse all components uniformly in the hierarchy. For example, if the `JPanel` object calls method `repaint` of superclass `Container`, method `repaint` displays the `JPanel` object and all components added to the `JPanel` object. Method `repaint` does not have to determine each component's type, because all components inherit from superclass `Container`, which contains method `repaint`.

**Fig. P.5** | Inheritance hierarchy for class `JPanel`.

### P.3.3 Behavioral Design Patterns

This section continues our discussion on behavioral design patterns. We discuss the Chain of Responsibility, Command, Observer, Strategy and Template Method design patterns.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

### P.3 Design Patterns in Packages `java.awt` and `javax.swing` LXXXV

#### *Chain of Responsibility*

In object-oriented systems, objects interact by sending messages to one another. Often, a system needs to determine at runtime the object that will handle a particular message. For example, consider the design of a three-line office phone system. When a person calls the office, the first line handles the call—if the first line is busy, the second line handles the call, and if the second line is busy, the third line handles the call. If all lines in the system are busy, an automated speaker instructs the caller to wait for the next available line. When a line becomes available, that line handles the call.

The [Chain of Responsibility design pattern](#) enables a system to determine at run time the object that will handle a message. This pattern allows an object to send a message to several objects in a [chain](#). Each object in the chain either may handle the message or pass it to the next object. For instance, the first line in the phone system is the first object in the chain of responsibility, the second line is the second object, the third line is the third object and the automated speaker is the fourth object. The final object in the chain is the next available line that handles the message. The chain is created dynamically in response to the presence or absence of specific message handlers.

Several Java AWT GUI components use the Chain of Responsibility design pattern to handle certain events. For example, class `java.awt.Button` overrides method `processEvent` of class `java.awt.Component` to process `AWTEvent` objects. Method `processEvent` attempts to handle the `AWTEvent` upon receiving it as an argument. If method `processEvent` determines that the `AWTEvent` is an `ActionEvent` (i.e., the `Button` has been pressed), it handles the event by invoking method `processActionEvent`, which informs any `ActionListener` registered with the `Button` that the `Button` has been pressed. If method `processEvent` determines that the `AWTEvent` is not an `ActionEvent`, the method is unable to handle it and passes it to method `processEvent` of superclass `Component` (the next listener in the chain).

#### *Command*

Applications often provide users with several ways to perform a given task. For example, in a word processor there might be an `Edit` menu with menu items for cutting, copying and pasting text. A toolbar or a popup menu could also offer the same items. The functionality the application provides is the same in each case—the different interface components for invoking the functionality are provided for the user's convenience. However, the same GUI component instance (e.g., `JButton`) cannot be used for menus, toolbars and popup menus, so the developer must code the same functionality three times. If there were many such interface items, repeating this functionality would become tedious and error prone.

The [Command design pattern](#) solves this problem by enabling developers to encapsulate the desired functionality (e.g., copying text) once in a reusable object; that functionality can then be added to a menu, toolbar, popup menu or other mechanism. This design pattern is called Command because it defines a command, or instruction, to be executed. It allows a designer to encapsulate a command, so that it may be used among several objects.

#### *Observer*

Suppose that we want to design a program for viewing bank account information. This system includes class `BankStatementData` to store data pertaining to bank statements and classes `TextDisplay`, `BarGraphDisplay` and `PieChartDisplay` to display the data. [Note: This approach is the basis for the Model-View-Controller architecture pattern, discussed

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**LXXXVI** Appendix P Design Patterns

in Section P.5.3.] Figure P.6 shows the design for our system. The data is displayed by class `TextDisplay` in text format, by class `BarGraphDisplay` in bar-graph format and by class `PieChartDisplay` as a pie chart. We want to design the system so that the `BankStatementData` object notifies the objects displaying the data of a change in the data. We also want to design the system to loosen **coupling**—the degree to which classes depend on each other in a system.

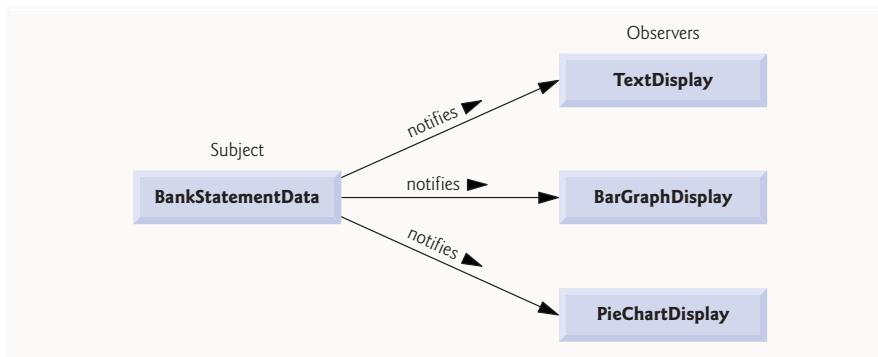

**Software Engineering Observation P.1**

*Loosely coupled classes are easier to reuse and modify than are tightly coupled classes, which depend heavily on each other. A modification in a class in a tightly coupled system usually results in modifying other classes in that system. A modification to one of a group of loosely coupled classes would require little or no modification to the other classes.*

The **Observer design pattern** is appropriate for systems like that of Fig. P.6. This pattern promotes loose coupling between a **subject object** and **observer objects**—a subject notifies the observers when the subject changes state. When notified by the subject, the observers change in response. In our example, the `BankStatementData` object is the subject, and the objects displaying the data are the observers. A subject can notify several observers; therefore, the subject has a one-to-many relationship with the observers.

The Java API contains classes that use the Observer design pattern. Class `java.util.Observable` represents a subject. Class `Observable` provides method `addObserver`, which takes a `java.util.Observer` argument. Interface `Observer` allows the `Observable` object to notify the `Observer` when the `Observable` object changes state. The `Observer` can be an instance of any class that implements interface `Observer`; because the `Observable` object invokes methods declared in interface `Observer`, the objects remain loosely coupled. If a developer changes the way in which a particular `Observer` responds to changes in the `Observable` object, the developer does not need to change the object. The `Observable` object interacts with its `Observers` only through interface `Observer`, which enables the loose coupling.

The Swing GUI components use the Observer design pattern. GUI components collaborate with their listeners to respond to user interactions. For example, an `ActionListener` observes state changes in a `JButton` (the subject) by registering to handle that

**Fig. P.6** | Basis for the Observer design pattern.

### P.3 Design Patterns in Packages `java.awt` and `javax.swing` LXXXVII

`JButton`'s events. When pressed by the user, the `JButton` notifies its `ActionListener` objects (the observers) that the `JButton`'s state has changed (i.e., the `JButton` has been pressed).

#### *Strategy*

The [Strategy design pattern](#) is similar to the State design pattern (discussed in Section P.2.3). We mentioned that the State design pattern contains a state object, which encapsulates the state of a context object. The Strategy design pattern contains a [strategy object](#), which is analogous to the State design pattern's state object. The key difference is that the strategy object encapsulates an algorithm rather than state information.

For example, `java.awt.Container` components implement the Strategy design pattern using `LayoutManagers` (discussed in Section 11.17) as strategy objects. In package `java.awt`, classes `FlowLayout`, `BorderLayout` and `GridLayout` implement interface `LayoutManager`. Each class uses method `addLayoutComponent` to add GUI components to a `Container` object. However, each method uses a different algorithm to display these GUI components: A `FlowLayout` displays them in a left-to-right sequence, a `BorderLayout` displays them in five regions and a `GridLayout` displays them in row-column format.

Class `Container` contains a reference to a `LayoutManager` object (the strategy object). An interface reference (i.e., the reference to the `LayoutManager` object) can hold references to objects of classes that implement that interface (i.e., the `FlowLayout`, `BorderLayout` or `GridLayout` objects), so the `LayoutManager` object can reference a `FlowLayout`, `BorderLayout` or `GridLayout` at any time. Class `Container` can change this reference through method `setLayout` to select different layouts at runtime.

Class `FlowLayoutFrame` (Fig. 11.39) demonstrates the application of the Strategy pattern—line 23 declares a new `FlowLayout` object and line 25 invokes the `Container` object's method `setLayout` to assign the `FlowLayout` object to the `Container` object. In this example, the `FlowLayout` provides the strategy for laying out the components.

#### *Template Method*

The [Template Method design pattern](#) also deals with algorithms. The Strategy design pattern allows several objects to contain distinct algorithms. However, the Template Method design pattern requires all objects to share a single algorithm defined by a superclass.

For example, consider the design of Fig. P.6, which we presented in the Observer design pattern discussion earlier in this section. Objects of classes `TextDisplay`, `BarGraphDisplay` and `PieChartDisplay` use the same basic algorithm for acquiring and displaying the data—get all statements from the `BankStatementData` object, parse the statements, then display the statements. The Template Method design pattern allows us to create an abstract superclass called `BankStatementDisplay` that provides the common algorithm for displaying the data. In this example, the algorithm invokes abstract methods `getData`, `parseData` and `displayData`. Classes `TextDisplay`, `BarGraphDisplay` and `PieChartDisplay` extend class `BankStatementDisplay` to inherit the algorithm, so each object can use the same algorithm. Each `BankStatementDisplay` subclass then overrides each method in a way specific to that subclass, because each class implements the algorithm differently. For example, classes `TextDisplay`, `BarGraphDisplay` and `PieChartDisplay` might get and parse the data identically, but each displays that data differently.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**LXXXVIII** Appendix P Design Patterns

The Template Method design pattern allows us to extend the algorithm to other `BankStatementDisplay` subclasses—e.g., we could create classes, such as `LineGraphDisplay` or class `3DimensionalDisplay`, that use the same algorithm inherited from class `BankStatementDisplay` and provide different implementations of the abstract methods the algorithm calls.

#### P.3.4 Conclusion

In this section, we discussed how Swing components take advantage of design patterns and how developers can integrate design patterns with GUI applications in Java. In the next section, we discuss concurrency design patterns, which are particularly useful for developing multithreaded systems.

### P.4 Concurrency Design Patterns

Many additional design patterns have been discovered since the publication of the Gang of Four book, which introduced patterns involving object-oriented systems. Some of these new patterns involve specific types of object-oriented systems, such as concurrent, distributed or parallel systems. In this section, we discuss concurrency patterns to complement our discussion of multithreaded programming in Chapter 23.

#### *Concurrency Design Patterns*

Multithreaded programming languages such as Java allow designers to specify concurrent activities—that is, those that operate in parallel with one another. Designing concurrent systems improperly can introduce concurrency problems. For example, two objects attempting to alter shared data at the same time could corrupt that data. In addition, if two objects wait for one another to finish tasks, and if neither can complete their task, these objects could potentially wait forever—a situation called **deadlock**. Using Java, Doug Lea<sup>2</sup> and Mark Grand<sup>3</sup> documented **concurrency patterns** for multithreaded design architectures to prevent various problems associated with multithreading. We provide a partial list of these design patterns:

- The **Single-Threaded Execution design pattern** (Grand, 2002) prevents several threads from executing the same method of another object concurrently. Chapter 23 discusses various techniques that can be used to apply this pattern.
- The **Guarded Suspension design pattern** (Lea, 2000) suspends a thread’s activity and resumes that thread’s activity when some condition is satisfied. Lines 87–90 and lines 41–44 of class `RunnableObject` (Fig. 23.17) use this design pattern—methods `await` and `signal` suspend and resume the program threads, and line 72 of class `RandomCharacters` (Fig. 23.18) toggles the guard variable that the condition evaluates.
- The **Balking design pattern** (Lea, 2000) ensures that a method will **balk**—that is, return without performing any actions—if an object occupies a state that can-

## P.5 Design Patterns Used in Packages `java.io` and `java.net` LXXXIX

not execute that method. A variation of this pattern is that the method throws an exception describing why that method is unable to execute—for example, a method throwing an exception when accessing a data structure that does not exist.

- The [Read/Write Lock design pattern](#) (Lea, 2000) allows multiple threads to obtain concurrent read access on an object but prevents multiple threads from obtaining concurrent write access on that object. Only one thread at a time may obtain write access to an object—when that thread obtains write access, the object is [locked](#) to all other threads.
- The [Two-Phase Termination design pattern](#) (Grand, 98) uses a two-phase termination process for a thread to ensure that a thread has the opportunity to free resources—such as other spawned threads—in memory (phase one) before termination (phase two). In Java, a `Runnable` object can use this pattern in method `run`. For instance, method `run` can contain an infinite loop that is terminated by some state change—upon termination, method `run` can invoke a `private` method responsible for stopping any other spawned threads (phase one). The thread then terminates after method `run` terminates (phase two).

In the next section, we return to the Gang of Four design patterns. Using the material introduced in Chapter 14 and Chapter 24, we identify those classes in package `java.io` and `java.net` that use design patterns.

## P.5 Design Patterns Used in Packages `java.io` and `java.net`

This section introduces those design patterns associated with the Java file, streams and networking packages.

### P.5.1 Creational Design Patterns

We now continue our discussion of creational design patterns.

#### *Abstract Factory*

Like the Factory Method design pattern, the [Abstract Factory design pattern](#) allows a system to determine the subclass from which to instantiate an object at runtime. Often, this subclass is unknown during development. However, Abstract Factory uses an object known as a [factory](#) that uses an interface to instantiate objects. A factory creates a product, which in this case is an object of a subclass determined at runtime.

The Java socket library in package `java.net` uses the Abstract Factory design pattern. A socket describes a connection, or a stream of data, between two processes. Class `Socket` references an object of a `SocketImpl` subclass (Section 24.5). Class `Socket` also contains a static reference to an object implementing interface `SocketImplFactory`. The `Socket` constructor invokes method `createSocketImpl` of interface `SocketImplFactory` to create the `SocketImpl` object. The object that implements interface `SocketImplFactory` is the factory, and an object of a `SocketImpl` subclass is the product of that factory. The system cannot specify the `SocketImpl` subclass from which to instantiate until runtime, because the system has no knowledge of what type of `Socket` implementation is required (e.g., a

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## **XC** Appendix P Design Patterns

socket configured to the local network's security requirements). Method `createSocketImpl` decides the `SocketImpl` subclass from which to instantiate the object at runtime.

### P.5.2 Structural Design Patterns

This section concludes our discussion of structural design patterns.

#### *Decorator*

Let us reexamine class `CreateSequentialFile` (Fig. 14.18). Lines 20–21 of this class allow a `FileOutputStream` object, which writes bytes to a file, to gain the functionality of an `ObjectOutputStream`, which provides methods for writing entire objects to an `OutputStream`. Class `CreateSequentialFile` appears to “wrap” an `ObjectOutputStream` object around a `FileOutputStream` object. The fact that we can dynamically add the behavior of an `ObjectOutputStream` to a `FileOutputStream` obviates the need for a separate class called `ObjectFileOutputStream`, which would implement the behaviors of both classes.

Lines 20–21 of class `CreateSequentialFile` show an example of the **Decorator design pattern**, which allows an object to gain additional functionality dynamically. Using this pattern, designers do not have to create separate, unnecessary classes to add responsibilities to objects of a given class.

Let us consider a more complex example to discover how the Decorator design pattern can simplify a system's structure. Suppose that we wanted to enhance the I/O performance of the previous example by using a `BufferedOutputStream`. Using the Decorator design pattern, we would write

```
output = new ObjectOutputStream(
 new BufferedOutputStream(
 new FileOutputStream(fileName)));
```

We can combine objects in this manner, because `ObjectOutputStream`, `BufferedOutputStream` and `FileOutputStream` extend abstract superclass `OutputStream`, and each subclass constructor takes an `OutputStream` object as a parameter. If the stream objects in package `java.io` did not use the Decorator pattern (i.e., did not satisfy these two requirements), package `java.io` would have to provide classes `BufferedFileOutputStream`, `ObjectBufferedOutputStream`, `ObjectBufferedFileOutputStream` and `ObjectFileOutputStream`. Consider how many classes we would have to create if we combined even more stream objects without applying the Decorator pattern.

#### *Facade*

When driving, you know that pressing the gas pedal accelerates your car, but you are unaware of exactly how it does so. This principle is the foundation of the **Facade design pattern**, which allows an object—called a **facade object**—to provide a simple interface for the behaviors of a **subsystem** (an aggregate of objects that comprise collectively a major system responsibility). The gas pedal, for example, is the facade object for the car's acceleration subsystem, the steering wheel is the facade object for the car's steering subsystem and the brake is the facade object for the car's deceleration subsystem. A **client object** uses the facade object to access the objects behind the facade. The client remains unaware of how the objects behind the facade fulfill responsibilities, so the subsystem complexity is hidden from the client. When you press the gas pedal, you act as a client object. The Facade design

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## P.5 Design Patterns Used in Packages `java.io` and `java.net` XCI

pattern reduces system complexity, because a client interacts with only one object (the facade) to access the behaviors of the subsystem the facade represents. This pattern shields applications developers from subsystem complexities. Developers need to be familiar with only the operations of the facade object, rather than with the more detailed operations of the entire subsystem. The implementation behind the facade may be changed without changes to the clients.

In package `java.net`, an object of class `URL` is a facade object. This object contains a reference to an `InetAddress` object that specifies the host computer's IP address. The `URL` facade object also references an object from class `URLStreamHandler`, which opens the URL connection. The client object that uses the `URL` facade object accesses the `InetAddress` object and the `URLStreamHandler` object through the facade object. However, the client object does not know how the objects behind the `URL` facade object accomplish their responsibilities.

### P.5.3 Architectural Patterns

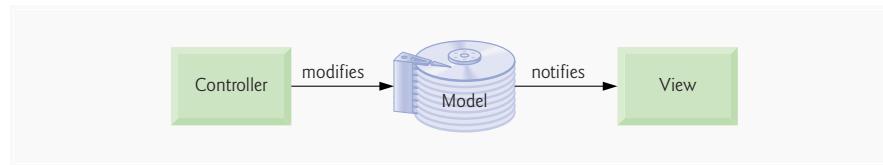

Design patterns allow developers to design specific parts of systems, such as abstracting object instantiations or aggregating classes into larger structures. Design patterns also promote loose coupling among objects. [Architectural patterns](#) promote loose coupling among subsystems. These patterns specify how subsystems interact with one another.<sup>4</sup> We introduce the popular Model-View-Controller and Layers architectural patterns.

#### MVC

Consider the design of a simple text editor. In this program, the user enters text from the keyboard and formats it using the mouse. Our program stores this text and format information into a series of data structures, then displays this information on screen for the user to read what has been inputted.

This program adheres to the [Model-View-Controller \(MVC\) architectural pattern](#), which separates application data (contained in the `model`) from graphical presentation components (the `view`) and input-processing logic (the `controller`). Figure P.7 shows the relationships between components in MVC.

The controller implements logic for processing user inputs. The model contains application data, and the view presents the data stored in the model. When a user provides some input, the controller modifies the model with the given input. With regard to the text-editor example, the model might contain only the characters that make up the document. When the model changes, it notifies the view of the change so that it can update its pre-

**Fig. P.7** | Model-View-Controller Architecture.

4. R. Hartman. "Building on Patterns." *Application Development Trends*, May 2001: 19–26.

## XCIID [Appendix P Design Patterns](#)

smentation with the changed data. The view in a word processor might display characters using a particular font, with a particular size, etc.

MVC does not restrict an application to a single view and a single controller. In a more sophisticated program (such as a word processor), there might be two views of a document model. One view might display an outline of the document and the other might display the complete document. The word processor also might implement multiple controllers—one for handling keyboard input and another for handling mouse selections. If either controller makes a change in the model, both the outline view and the print-preview window will show the change immediately when the model notifies all views of changes.

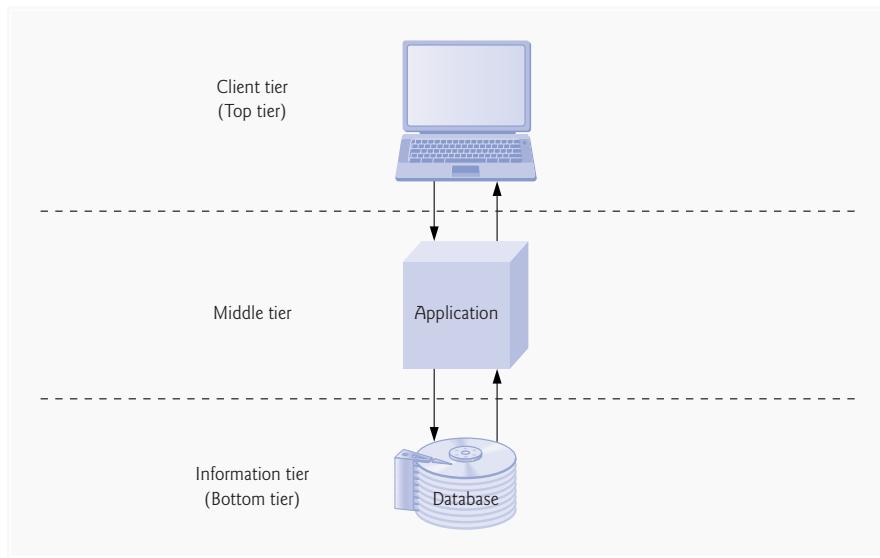

Another key benefit to the MVC architectural pattern is that developers can modify each component individually without having to modify the others. For example, developers could modify the view that displays the document outline without having to modify either the model or other views or controllers.

### *Layers*

Consider the design in Fig. P.8, which presents the basic structure of a [three-tier application](#), in which each tier contains a unique system component.

The [information tier](#) (also called the “bottom tier”) maintains data for the application, typically storing it in a database. The information tier for an online store may contain product information, such as descriptions, prices and quantities in stock, and customer information, such as user names, billing addresses and credit-card numbers.

The [middle tier](#) acts as an intermediary between the information tier and the client tier. The middle tier processes client-tier requests, and reads data from and writes data to the database. It then processes data from the information tier and presents the content to the client tier. This processing is the application’s [business logic](#), which handles such tasks

**Fig. P.8** | Three-tier application model.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## P.6 Design Patterns Used in Package `java.util` XCIII

as retrieving data from the information tier, ensuring that data is reliable before updating the database and presenting data to the client tier. For example, the business logic associated with the middle tier for the online store can verify a customer's credit card with the credit-card issuer before the warehouse ships the customer's order. This business logic could then store (or retrieve) the credit information in the database and notify the client tier that the verification was successful.

The **client tier** (also called the “top tier”) is the application’s user interface, such as a standard Web browser. Users interact directly with the application through the user interface. The client tier interacts with the middle tier to make requests and retrieve data from the information tier. The client tier then displays data retrieved from the middle tier.

Figure P.8 is an implementation of the **Layers architectural pattern**, which divides functionality into separate **layers**. Each layer contains a set of system responsibilities and depends on the services of only the next lower layer. In Fig. P.8, each tier corresponds to a layer. This architectural pattern is useful, because a designer can modify one layer without having to modify the others. For example, a designer could modify the information tier in Fig. P.8 to accommodate a particular database product but would not have to modify either the client tier or the middle tier.

### P.5.4 Conclusion

In this section, we discussed how packages `java.io` and `java.net` take advantage of specific design patterns and how developers can integrate design patterns with networking/file-processing applications in Java. We also introduced the Model-View-Controller and Layers architectural patterns, which both assign system functionality to separate subsystems. These patterns make designing a system easier for developers. In the next section, we conclude our presentation of design patterns by discussing those patterns used in package `java.util`.

## P.6 Design Patterns Used in Package `java.util`

In this section, we use the material on data structures and collections discussed in Chapters 17–19 to identify classes from package `java.util` that use design patterns.

### P.6.1 Creational Design Patterns

We conclude our discussion of creational design patterns by presenting the Prototype design pattern.

#### *Prototype*

Sometimes a system must make a copy of an object but will not “know” that object’s class until execution time. For example, consider the drawing program design of Exercise 10.1 in the optional GUI and Graphics Case Study—classes `MyLine`, `MyOval` and `MyRect` represent “shape” classes that extend abstract superclass `MyShape`. We could modify this exercise to allow the user to create, copy and paste new instances of class `MyLine` into the program. The **Prototype design pattern** allows an object—called a **prototype**—to return a copy of that prototype to a requesting object—called a **client**. Every prototype must belong to a class that implements a common interface that allows the prototype to clone itself. For example, the Java API provides method `clone` from class `java.lang.Object` and

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**XCIV** Appendix P Design Patterns

interface `java.lang.Cloneable`—any object from a class implementing `Cloneable` can use method `clone` to copy itself. Specifically, method `clone` creates a copy of an object, then returns a reference to that object. If we designate class `MyLine` as the prototype for Exercise 10.1, then class `MyLine` must implement interface `Cloneable`. To create a new line in our drawing, we clone the `MyLine` prototype. To copy a preexisting line, we clone that object. Method `clone` also is useful in methods that return a reference to an object, but the developer does not want that object to be altered through that reference—method `clone` returns a reference to the copy of the object instead of returning that object's reference. For more information on interface `Cloneable`, visit

[java.sun.com/javase/6/docs/api/java/lang/Cloneable.html](http://java.sun.com/javase/6/docs/api/java/lang/Cloneable.html)

### P.6.2 Behavioral Design Patterns

We conclude our discussion of behavioral design patterns by discussing the Iterator design pattern.

#### *Iterator*

Designers use data structures such as arrays, linked lists and hash tables to organize data in a program. The [Iterator design pattern](#) allows objects to access individual objects from any data structure without “knowing” the data structure’s behavior (such as traversing the structure or removing an element from that structure) or how that data structure stores objects. Instructions for traversing the data structure and accessing its elements are stored in a separate object called an [iterator](#). Each data structure can create an iterator—each iterator implements methods of a common interface to traverse the data structure and access its data. A client can traverse two differently structured data structures—such as a linked list and a hash table—in the same manner, because both data structures provide an iterator object that belongs to a class implementing a common interface. Java provides interface `Iterator` from package `java.util`, which we discussed in Section 19.3—class `CollectionTest` (Fig. 19.3) uses an `Iterator` object.

## P.7 Wrap-Up

In this appendix, we have introduced the importance, usefulness and prevalence of design patterns. In their book *Design Patterns, Elements of Reusable Object-Oriented Software*, the “Gang of Four” described 23 design patterns that provide proven strategies for building systems. Each pattern belongs to one of three pattern categories—creational patterns address issues related to object creation; structural patterns provide ways to organize classes and objects in a system; and behavioral patterns offer strategies for modeling how objects collaborate with one another in a system.

Of the 23 design patterns, we discussed 18 of the more popular ones used by the Java community. The discussion was divided according to how certain packages of the Java API—such as package `java.awt`, `javax.swing`, `java.io`, `java.net` and `java.util`—use these design patterns. Also discussed were patterns not described by the “Gang of Four,” such as concurrency patterns, which are useful in multithreaded systems, and architectural patterns, which help designers assign functionality to various subsystems in a system. We motivated each pattern—explained why it is important and explained how it may be used. When appropriate, we supplied several examples in the form of real-world analogies (e.g.,

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## P.8 Web Resources XCV

the adapter in the Adapter design pattern is similar to an adapter for a plug on an electrical device). You learned also how Java API packages take advantage of design patterns (e.g., Swing GUI components use the Observer design pattern to collaborate with their listeners to respond to user interactions). We provided examples of how certain programs in this book used design patterns.

We hope that you view this appendix as a beginning to further study of design patterns. Design patterns are used most prevalently in the J2EE (Java 2 Platform, Enterprise Edition) community, where systems tend to be exceedingly large and complex, and where robustness, portability and performance are so critical. However, even beginner programmers can benefit from early exposure to design patterns. We recommend that you visit the many URLs we have provided in Section P.8, and that you then read the Gang of Four book. This information will help you build better systems using the collective wisdom of the object-technology industry.

We hope you continue your study of design patterns. Be sure to send your comments, criticisms and suggestions for improvement of *Java How to Program* to [deitel@deitel.com](mailto:deitel@deitel.com). Good luck!

# Using the Debugger

## OBJECTIVES

In this appendix you will learn:

- To set breakpoints to debug applications.
- To use the `run` command to run an application through the debugger.
- To use the `stop` command to set a breakpoint.
- To use the `cont` command to continue execution.
- To use the `print` command to evaluate expressions.
- To use the `set` command to change variable values during program execution.
- To use the `step`, `step up` and `next` commands to control execution.
- To use the `watch` command to see how a field is modified during program execution.
- To use the `clear` command to list breakpoints or remove a breakpoint.

*And so shall I catch the fly.*

**Outline**

- Q.1** Introduction
- Q.2** Breakpoints and the `run`, `stop`, `cont` and `print` Commands
- Q.3** The `print` and `set` Commands
- Q.4** Controlling Execution Using the `step`, `step up` and `next` Commands
- Q.5** The `watch` Command
- Q.6** The `clear` Command
- Q.7** Wrap-Up

[Self-Review Exercises](#) | [Answers to Self-Review Exercises](#)

**Q.1 Introduction****XCVIII**

## Q.1 Introduction

In Chapter 2, you learned that there are two types of errors—syntax errors and logic errors—and you learned how to eliminate syntax errors from your code. Logic errors do not prevent the application from compiling successfully, but they do cause an application to produce erroneous results when it runs. The JDK 5.0 includes software called a **debugger** that allows you to monitor the execution of your applications so you can locate and remove logic errors. The debugger will be one of your most important application development tools. Many IDEs provide their own debuggers similar to the one included in the JDK or provide a graphical user interface to the JDK's debugger.

This appendix demonstrates key features of the JDK's debugger using command-line applications that receive no input from the user. The same debugger features discussed here can be used to debug applications that take user input, but debugging such applications requires a slightly more complex setup. To focus on the debugger features, we have opted to demonstrate the debugger with simple command-line applications involving no user input. You can also find more information on the Java debugger at [java.sun.com/javase/6/docs/tooldocs/windows/jdb.html](http://java.sun.com/javase/6/docs/tooldocs/windows/jdb.html).

## Q.2 Breakpoints and the run, stop, cont and print Commands

We begin our study of the debugger by investigating **breakpoints**, which are markers that can be set at any executable line of code. When application execution reaches a breakpoint, execution pauses, allowing you to examine the values of variables to help determine whether logic errors exist. For example, you can examine the value of a variable that stores the result of a calculation to determine whether the calculation was performed correctly. Note that setting a breakpoint at a line of code that is not executable (such as a comment) causes the debugger to display an error message.

To illustrate the features of the debugger, we use application `AccountTest` (Fig. Q.1), which creates and manipulates an object of class `Account` (Fig. 3.13). Execution of `AccountTest` begins in `main` (lines 7–24). Line 9 creates an `Account` object with an initial balance of \$50.00. Recall that `Account`'s constructor accepts one argument, which specifies the `Account`'s initial `balance`. Lines 12–13 output the initial account balance using `Account` method `getBalance`. Line 15 declares and initializes a local variable `depositAmount`. Lines 17–19 then print `depositAmount` and add it to the `Account`'s `balance` using

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**XCIX** Appendix Q Using the Debugger

its credit method. Finally, lines 22–23 display the new balance. [Note: The Appendix Q examples directory contains a copy of Account.java identical to the one in Fig. 3.13.]

In the following steps, you will use breakpoints and various debugger commands to examine the value of the variable depositAmount declared in AccountTest (Fig. Q.1).

1. *Opening the Command Prompt window and changing directories.* Open the Command Prompt window by selecting Start > Programs > Accessories > Command Prompt. Change to the directory containing the appendix's examples by typing cd C:\examples\debugger [Note: If your examples are in a different directory, use that directory here.]
2. *Compiling the application for debugging.* The Java debugger works only with .class files that were compiled with the -g compiler option, which generates information that is used by the debugger to help you debug your applications. Compile the application with the -g command-line option by typing javac -g AccountTest.java Account.java. Recall from Chapter 2 that this command compiles both AccountTest.java and Account.java. The command java -g \*.java compiles all of the working directory's .java files for debugging.

```

1 // Fig. N.1: AccountTest.java
2 // Create and manipulate an Account object.
3
4 public class AccountTest
5 {
6 // main method begins execution
7 public static void main(String args[])
8 {
9 Account account = new Account(50.00); // create Account object
10
11 // display initial balance of Account object
12 System.out.printf("initial account balance: $%.2f\n",
13 account.getBalance());
14
15 double depositAmount = 25.0; // deposit amount
16
17 System.out.printf("\nadding %.2f to account balance\n\n",
18 depositAmount);
19 account.credit(depositAmount); // add to account balance
20
21 // display new balance
22 System.out.printf("new account balance: $%.2f\n",
23 account.getBalance());
24 } // end main
25
26 } // end class AccountTest

initial account balance: $50.00
adding 25.00 to account balance
new account balance: $75.00

```

**Fig. Q.1** | AccountTest class creates and manipulates an Account object.

## Q.2 Breakpoints and the run, stop, cont and print Commands

**C**

3. *Starting the debugger.* In the Command Prompt, type **jdb** (Fig. Q.2). This command will start the Java debugger and enable you to use its features. [Note: We modified the colors of our Command Prompt window to allow us to highlight in yellow the user input required by each step.]
4. *Running an application in the debugger.* Run the AccountTest application through the debugger by typing **run** AccountTest (Fig. Q.3). If you do not set any breakpoints before running your application in the debugger, the application will run just as it would using the **java** command.
5. *Restarting the debugger.* To make proper use of the debugger, you must set at least one breakpoint before running the application. Restart the debugger by typing **jdb**.
6. *Inserting breakpoints in Java.* You set a breakpoint at a specific line of code in your application. The line numbers used in these steps are from the source code in Fig. Q.1. Set a breakpoint at line 12 in the source code by typing **stop at AccountTest:12** (Fig. Q.4). The **stop command** inserts a breakpoint at the line number specified after the command. You can set as many breakpoints as necessary. Set another breakpoint at line 19 by typing **stop at AccountTest:19** (Fig. Q.4). When the application runs, it suspends execution at any line that contains a breakpoint. The application is said to be in **break mode** when the debugger pauses the application's execution. Breakpoints can be set even after the debugging process has begun. Note that the debugger command **stop in**, followed by a class name, a period and a method name (e.g., **stop in Account.credit**) instructs the debugger to set a breakpoint at the first executable statement in the specified method. The debugger pauses execution when program control enters the method.

**Fig. Q.2** | Starting the Java debugger.

**Fig. Q.3** | Running the AccountTest application through the debugger.

## CI Appendix Q Using the Debugger

```
C:\examples\debugger>jdb
Initializing jdb ...
> stop at AccountTest:12
Deferring breakpoint AccountTest:12.
It will be set after the class is loaded.
> stop at AccountTest:19
Deferring breakpoint AccountTest:19.
It will be set after the class is loaded.
> -
```

**Fig. Q.4** | Setting breakpoints at lines 12 and 19.

7. *Running the application and beginning the debugging process.* Type run AccountTest to execute your application and begin the debugging process (Fig. Q.5). Note that the debugger prints text indicating that breakpoints were set at lines 12 and 19. The debugger calls each breakpoint a “deferred breakpoint” because each was set before the application began running in the debugger. The application pauses when execution reaches the breakpoint on line 12. At this point, the debugger notifies you that a breakpoint has been reached and it displays the source code at that line (12). That line of code is the next statement that will execute.
8. *Using the cont command to resume execution.* Type cont. The **cont** command causes the application to continue running until the next breakpoint is reached (line 19), at which point the debugger notifies you (Fig. Q.6). Note that AccountTest’s normal output appears between messages from the debugger.
9. *Examining a variable’s value.* Type print depositAmount to display the current value stored in the depositAmount variable (Fig. Q.7). The **print** command allows you to peek inside the computer at the value of one of your variables. This command will help you find and eliminate logic errors in your code. Note that the value displayed is 25.0—the value assigned to depositAmount in line 15 of Fig. Q.1.
10. *Continuing application execution.* Type cont to continue the application’s execution. There are no more breakpoints, so the application is no longer in break mode. The application continues executing and eventually terminates (Fig. Q.8). The debugger will stop when the application ends.

```
It will be set after the class is loaded.
> run AccountTest
run AccountTest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred breakpoint AccountTest:19
Set deferred breakpoint AccountTest:12
Breakpoint hit: "thread=main", AccountTest.main(), line=12 bci=11
12 System.out.printf("initial account balance: %2f\n",
main[1] -
Breakpoint is reached
```

Next line of code to execute

**Fig. Q.5** | Restarting the AccountTest application.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

### Q.3 The print and set Commands

CII

Another breakpoint is reached

```

Command Prompt - jdb
main[1] cont
initial account balance: $> 50.00
adding 25.00 to account balance

Breakpoint hit: "thread=main", AccountTest.main(), line=19 bci=58
19 account.credit(depositAmount); // add to account balance
main[1] -

```

**Fig. Q.6** | Execution reaches the second breakpoint.

```

Command Prompt - jdb
main[1] print depositAmount
depositAmount = 25.0
main[1] -

```

**Fig. Q.7** | Examining the value of variable `depositAmount`.

```

Command Prompt
depositAmount = 25.0
main[1] cont
new account balance: $75.00
>
The application exited
C:\examples\debugger>-

```

**Fig. Q.8** | Continuing application execution and exiting the debugger.

In this section, you learned how to enable the debugger and set breakpoints so that you can examine variables with the `print` command while an application is running. You also learned how to use the `cont` command to continue execution after a breakpoint is reached.

### Q.3 The print and set Commands

In the preceding section, you learned how to use the debugger's `print` command to examine the value of a variable during program execution. In this section, you will learn how to use the `print` command to examine the value of more complex expressions. You will also learn the `set` command, which allows the programmer to assign new values to variables.

For this section, we assume that you have followed *Step 1* and *Step 2* in Section Q.2 to open the **Command Prompt** window, change to the directory containing this appendix's examples (e.g., `C:\examples\debugger`) and compile the `AccountTest` application (and class `Account`) for debugging.

1. *Starting debugging.* In the **Command Prompt**, type `jdb` to start the Java debugger.
2. *Inserting a breakpoint.* Set a breakpoint at line 19 in the source code by typing `stop at AccountTest:19`.
3. *Running the application and reaching a breakpoint.* Type `run AccountTest` to begin the debugging process (Fig. Q.9). This will cause `AccountTest`'s `main` to execute until the breakpoint at line 19 is reached. This suspends application execution and switches the application into break mode. At this point, the statements in lines 9–13 created an `Account` object and printed the initial balance of

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

### CIII Appendix Q Using the Debugger

the Account obtained by calling its `getBalance` method. The statement in line 15 (Fig. Q.1) declared and initialized local variable `depositAmount` to 25.0. The statement in line 19 is the next statement that will execute.

4. *Evaluating arithmetic and boolean expressions.* Recall from Section Q.2 that once the application has entered break mode, you can explore the values of the application's variables using the debugger's `print` command. You can also use the `print` command to evaluate arithmetic and `boolean` expressions. In the **Command Prompt** window, type `print depositAmount - 2.0`. Note that the `print` command returns the value 23.0 (Fig. Q.10). However, this command does not actually change the value of `depositAmount`. In the **Command Prompt** window, type `print depositAmount == 23.0`. Expressions containing the `==` symbol are treated as `boolean` expressions. The value returned is `false` (Fig. Q.10) because `depositAmount` does not currently contain the value 23.0—`depositAmount` is still 25.0.
5. *Modifying values.* The debugger allows you to change the values of variables during the application's execution. This can be valuable for experimenting with different values and for locating logic errors in applications. You can use the debugger's `set` command to change the value of a variable. Type `set depositAmount = 75.0`. The debugger changes the value of `depositAmount` and displays its new value (Fig. Q.11).

```

C:\examples\debugger>jdb
Initializing jdb ...
>stop at AccountTest:19
Deferring breakpoint AccountTest:19.
It will be set after the class is loaded.
>run AccountTest
run AccountTest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred breakpoint AccountTest:19
initial account balance: $50.00
adding 25.00 to account balance

Breakpoint hit: "thread=main", AccountTest.main(), line=19 bci=58
19 account.credit(depositAmount); // add to account balance
main@1 =

```

**Fig. Q.9** | Application execution suspended when debugger reaches the breakpoint at line 19.

```

main@1 print depositAmount = 2.0
depositAmount = 2.0 = 23.0
main@1 print depositAmount == 23.0
depositAmount == 23.0 = false
main@1 =

```

**Fig. Q.10** | Examining the values of an arithmetic and `boolean` expression.

```

main@1 print depositAmount = 2.0
depositAmount == 23.0 = false
main@1 set depositAmount = 75.0
depositAmount = 25.0 = 25.0
main@1 =

```

**Fig. Q.11** | Modifying values.

#### Q.4 Controlling Execution Using the `step`, `step up` and `next` Commands CIV

6. *Viewing the application result.* Type `cont` to continue application execution. Line 19 of `AccountTest` (Fig. Q.1) executes, passing `depositAmount` to `Account` method `credit`. Method `main` then displays the new balance. Note that the result is \$125.00 (Fig. Q.12). This shows that the preceding step changed the value of `depositAmount` from its initial value (25.0) to 75.0.

In this section, you learned how to use the debugger's `print` command to evaluate arithmetic and `boolean` expressions. You also learned how to use the `set` command to modify the value of a variable during your application's execution.

#### Q.4 Controlling Execution Using the `step`, `step up` and `next` Commands

Sometimes you will need to execute an application line by line to find and fix errors. Walking through a portion of your application this way can help you verify that a method's code executes correctly. In this section, you will learn how to use the debugger for this task. The commands you learn in this section allow you to execute a method line by line, execute all the statements of a method at once or execute only the remaining statements of a method (if you have already executed some statements within the method).

Once again, we assume you are working in the directory containing this appendix's examples and have compiled for debugging with the `-g` compiler option.

1. *Starting the debugger.* Start the debugger by typing `jdb`.
2. *Setting a breakpoint.* Type `stop` at `AccountTest:19` to set a breakpoint at line 19.
3. *Running the application.* Run the application by typing `run AccountTest`. After the application displays its two output messages, the debugger indicates that the breakpoint has been reached and displays the code at line 19 (Fig. Q.13). The debugger and application then pause and wait for the next command to be entered.
4. *Using the `step` command.* The `step` command executes the next statement in the application. If the next statement to execute is a method call, control transfers to the called method. The `step` command enables you to enter a method and study the individual statements of that method. For instance, you can use the `print` and `set` commands to view and modify the variables within the method. You will now use the `step` command to enter the `credit` method of class `Account` (Fig. 3.13) by typing `step` (Fig. Q.14). The debugger indicates that the step has been completed and displays the next executable statement—in this case, line 21 of class `Account` (Fig. 3.13).

```

c:\ Command Prompt
depositAmount = 25.0 = 75.0
main[1] cont
> new account balance: $125.00
The application exited
C:\examples\debugger>-

```

New account balance based on altered  
value of variable `depositAmount`

**Fig. Q.12** | Output displayed after the debugging process.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

**CV**    Appendix Q Using the Debugger

```
C:\examples\debugger>jdb
Initializing jdb ...
> stop at AccountTest:19
Deferring breakpoint AccountTest:19.
It will be set after the class is loaded.
> run AccountTest
run AccountTest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred breakpoint AccountTest:19
initial account balance: $50.00
adding 25.00 to account balance

Breakpoint hit: "thread=main", AccountTest.main(), line=19 bci=58
19 account.credit(depositAmount); // add to account balance
main[1] -
```

**Fig. Q.13** | Reaching the breakpoint in the AccountTest application.

```
main[1] step
>
Step completed: "thread=main", Account.credit(), line=21 bci=8
21 balance = balance + amount; // add amount to balance
main[1] -
```

**Fig. Q.14** | Stepping into the credit method.

5. *Using the step up command.* After you have stepped into the credit method, type **step up**. This command executes the remaining statements in the method and returns control to the place where the method was called. The credit method contains only one statement to add the method's parameter amount to instance variable balance. The step up command executes this statement, then pauses before line 22 in AccountTest. Thus, the next action to occur will be to print the new account balance (Fig. Q.15). In lengthy methods, you may want to look at a few key lines of code, then continue debugging the caller's code. The step up command is useful for situations in which you do not want to continue stepping through the entire method line by line.
6. *Using the cont command to continue execution.* Enter the **cont** command (Fig. Q.16) to continue execution. The statement at lines 22–23 executes, displaying the new balance, then the application and the debugger terminate.
7. *Restarting the debugger.* Restart the debugger by typing **jdb**.
8. *Setting a breakpoint.* Breakpoints persist only until the end of the debugging session in which they are set—once the debugger exits, all breakpoints are removed.

```
main[1] step up
>
Step completed: "thread=main", AccountTest.main(), line=22 bci=63
22 System.out.printf("new account balance: %x.%2f\n",
main[1] -
```

**Fig. Q.15** | Stepping out of a method.

#### Q.4 Controlling Execution Using the `step`, `step up` and `next` Commands

**CVI**

(In Section Q.6, you'll learn how to manually clear a breakpoint before the end of the debugging session.) Thus, the breakpoint set for line 19 in *Step 2* no longer exists upon restarting the debugger in *Step 7*. To reset the breakpoint at line 19, once again type `stop at AccountTest:19`.

9. *Running the application.* Type `run AccountTest` to run the application. As in *Step 3*, `AccountTest` runs until the breakpoint at line 19 is reached, then the debugger pauses and waits for the next command (Fig. Q.17).
10. *Using the `next` command.* Type `next`. This command behaves like the `step` command, except when the next statement to execute contains a method call. In that case, the called method executes in its entirety and the application advances to the next executable line after the method call (Fig. Q.18). Recall from *Step 4* that the `step` command would enter the called method. In this example, the `next` command causes `Account` method `credit` to execute, then the debugger pauses at line 22 in `AccountTest`.

```
cmd * Command Prompt
main[1] cont
new account balance: $75.00
>
The application exited
C:\examples\debugger>_
```

**Fig. Q.16** | Continuing execution of the `AccountTest` application.

```
jdb * Command Prompt - jdb
C:\examples\debugger>jdb
Initializing jdb ...
> stop at AccountTest:19
Deferring breakpoint AccountTest:19.
It will be set after the class is loaded.
> run AccountTest
run AccountTest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred breakpoint AccountTest:19
initial account balance: $50.00
adding 25.00 to account balance

Breakpoint hit: "thread=main", AccountTest.main(), line=19 bci=58
19 account.credit(depositAmount); // add to account balance
main[1] _
```

**Fig. Q.17** | Reaching the breakpoint in the `AccountTest` application.

```
jdb * Command Prompt - jdb
main[1] next
>
Step completed: "thread=main", AccountTest.main(), line=22 bci=63
22 System.out.printf("new account balance: %.2f\n");
main[1] _
```

**Fig. Q.18** | Stepping over a method call.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## CVII Appendix Q Using the Debugger

- 11. Using the `exit` command.** Use the `exit` command to end the debugging session (Fig. Q.19). This command causes the `AccountTest` application to immediately terminate rather than execute the remaining statements in `main`. Note that when debugging some types of applications (e.g., GUI applications), the application continues to execute even after the debugging session ends.

In this section, you learned how to use the debugger's step and step up commands to debug methods called during your application's execution. You saw how the `next` command can be used to step over a method call. You also learned that the `exit` command ends a debugging session.

### Q.5 The `watch` Command

In this section, we present the `watch` command, which tells the debugger to watch a field. When that field is about to change, the debugger will notify you. In this section, you will learn how to use the `watch` command to see how the `Account` object's field `balance` is modified during the execution of the `AccountTest` application.

As in the preceding two sections, we assume that you have followed *Step 1* and *Step 2* in Section Q.2 to open the **Command Prompt**, change to the correct examples directory and compile classes `AccountTest` and `Account` for debugging (i.e., with the `-g` compiler option).

1. *Starting the debugger.* Start the debugger by typing `jdb`.
2. *Watching a class's field.* Set a watch on `Account`'s `balance` field by typing `watch Account.balance` (Fig. Q.20). You can set a watch on any field during execution of the debugger. Whenever the value in a field is about to change, the debugger enters break mode and notifies you that the value will change. Watches can be placed only on fields, not on local variables.
3. *Running the application.* Run the application with the command `run AccountTest`. The debugger will now notify you that field `balance`'s value will change (Fig. Q.21). When the application begins, an instance of `Account` is created with an initial balance of \$50.00 and a reference to the `Account` object is assigned to the local variable `account` (line 9, Fig. Q.1). Recall from Fig. 3.13 that when the

```
main[1] exit
C:\examples\debugger>
```

**Fig. Q.19** | Exiting the debugger.

```
C:\examples\debugger>jdb
Initializing jdb ...
> watch Account.balance
Deferring watch notification of Account.balance.
It will be set after the class is loaded.
> -
```

**Fig. Q.20** | Setting a watch on `Account`'s `balance` field.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## Q.5 The watch Command

CVIII

```
Command Prompt - jdb
It will be set after the class is loaded.
> run AccountTest
run AccountTest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred watch modification of Account.balance
Field <Account.balance> is 0.0, will be 50.0: "thread=main", Account.<init>(), 1
line=15 bci=12
 balance = initialBalance;
main[1] -
```

**Fig. Q.21** | AccountTest application stops when account is created and its balance field will be modified.

constructor for this object runs, if parameter `initialBalance` is greater than 0.0, instance variable `balance` is assigned the value of parameter `initialBalance`. The debugger notifies you that the value of `balance` will be set to 50.0.

4. *Adding money to the account.* Type `cont` to continue executing the application. The application executes normally before reaching the code on line 19 of Fig. Q.1 that calls `Account` method `credit` to raise the `Account` object's `balance` by a specified amount. The debugger notifies you that instance variable `balance` will change (Fig. Q.22). Note that although line 19 of class `AccountTest` calls method `credit`, it is line 21 in `Account`'s method `credit` that actually changes the value of `balance`.
5. *Continuing execution.* Type `cont`—the application will finish executing because the application does not attempt any additional changes to `balance` (Fig. Q.23).
6. *Restarting the debugger and resetting the watch on the variable.* Type `jdb` to restart the debugger. Once again, set a watch on the `Account` instance variable `balance` by typing the `watch Account.balance`, then type `run AccountTest` to run the application (Fig. Q.24).

```
Command Prompt - jdb
main[1] cont
> initial account balance: $50.00
adding 25.00 to account balance

Field <Account.balance> is 50.0, will be 75.0: "thread=main", Account.credit(), 21
 balance = balance + amount; // add amount to balance
main[1] -
```

**Fig. Q.22** | Changing the value of `balance` by calling `Account` method `credit`.

```
Command Prompt
main[1] cont
> new account balance: $75.00
>
The application exited
C:\examples\debugger>
```

**Fig. Q.23** | Continuing execution of `AccountTest`.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## CIX Appendix Q Using the Debugger

```

C:\examples\debugger>jdb
Initializing jdb ...
> watch Account.balance
Deferring watch modification of Account.balance.
It will be set after the class is loaded.
> run AccountTest
run AccountTest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred watch modification of Account.balance
Field <Account.balance> is 0.0, will be 50.0: "thread=main", Account.<init>(), l
ine=15 bci=12
15 balance = initialBalance;
main[1] -

```

**Fig. Q.24** | Restarting the debugger and resetting the watch on the variable `balance`.

7. *Removing the watch on the field.* Suppose you want to watch a field for only part of a program's execution. You can remove the debugger's watch on variable `balance` by typing `unwatch Account.balance` (Fig. Q.25). Type `cont`—the application will finish executing without reentering break mode.
8. *Closing the Command Prompt window.* Close the Command Prompt window by clicking its close button.

In this section, you learned how to use the `watch` command to enable the debugger to notify you of changes to the value of a field throughout the life of an application. You also learned how to use the `unwatch` command to remove a watch on a field before the end of the application.

## Q.6 The `clear` Command

In the preceding section, you learned to use the `unwatch` command to remove a watch on a field. The debugger also provides the `clear` command to remove a breakpoint from an application. You will often need to debug applications containing repetitive actions, such as a loop. You may want to examine the values of variables during several, but possibly not all, of the loop's iterations. If you set a breakpoint in the body of a loop, the debugger will pause before each execution of the line containing a breakpoint. After determining that the loop is working properly, you may want to remove the breakpoint and allow the remaining iterations to proceed normally. In this section, we use the compound interest application in Fig. 5.6 to demonstrate how the debugger behaves when you set a breakpoint in the body of a `for` statement and how to remove a breakpoint in the middle of a debugging session.

```

main[1] unwatch Account.balance
Removed: watch modification of Account.balance
main[1] cont
> initial account balance: $50.00
adding 25.00 to account balance
new account balance: $75.00
The application exited
C:\examples\debugger>_

```

**Fig. Q.25** | Removing the watch on variable `balance`.

© 2007 by Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.

## Q.6 The clear Command CX

- 1. Opening the Command Prompt window, changing directories and compiling the application for debugging.** Open the Command Prompt window, then change to the directory containing this appendix's examples. For your convenience, we have provided a copy of the `Interest.java` file in this directory. Compile the application for debugging by typing `javac -g Interest.java`.
- 2. Starting the debugger and setting breakpoints.** Start the debugger by typing `jdb`. Set breakpoints at lines 13 and 22 of class `Interest` by typing `stop at Interest:13`, then `stop at Interest:22` (Fig. Q.26).
- 3. Running the application.** Run the application by typing `run Interest`. The application executes until reaching the breakpoint at line 13 (Fig. Q.27).
- 4. Continuing execution.** Type `cont` to continue—the application executes line 13, printing the column headings "Year" and "Amount on deposit". Note that line 13 appears before the `for` statement at lines 16–23 in `Interest` (Fig. 5.6) and thus executes only once. Execution continues past line 13 until the breakpoint at line 22 is reached during the first iteration of the `for` statement (Fig. Q.28).
- 5. Examining variable values.** Type `print year` to examine the current value of variable `year` (i.e., the `for`'s control variable). Print the value of variable `amount` too (Fig. Q.29).
- 6. Continuing execution.** Type `cont` to continue execution. Line 22 executes and prints the current values of `year` and `amount`. After the `for` enters its second iteration, the debugger notifies you that the breakpoint at line 22 has been reached a second time. Note that the debugger pauses each time a line where a breakpoint has been set is about to execute—when the breakpoint appears in a loop, the debugger pauses during each iteration. Print the values of variables `year` and `amount` again to see how the values have changed since the first iteration of the `for` (Fig. Q.30).

```
C:\examples\debugger>javac -g Interest.java
C:\examples\debugger>jdb
Initializing jdb ...
> stop at Interest:13
Deferring breakpoint Interest:13.
It will be set after the class is loaded.
> stop at Interest:22
Deferring breakpoint Interest:22.
It will be set after the class is loaded.
>
```

**Fig. Q.26** | Setting breakpoints in the `Interest` application.

```
It will be set after the class is loaded.
> run Interest
run Interest
Set uncaught java.lang.Throwable
Set deferred uncaught java.lang.Throwable
>
VM Started: Set deferred breakpoint Interest:22
Set deferred breakpoint Interest:13

Breakpoint hit: "thread=main", Interest.main(), line=13 hci=9
13 System.out.printf("%s%20s\n", "Year", "Amount on deposit");
main[1] =
```

**Fig. Q.27** | Reaching the breakpoint at line 13 in the `Interest` application.

**CXI** Appendix Q Using the Debugger

```
Command Prompt - jdb
main[1] cont
> Year Amount on deposit
Breakpoint hit: "thread=main", Interest.main(), line=22 hci=55
22 System.out.printf("%4dx.20.2f\n", year, amount);
main[1] =
```

**Fig. Q.28** | Reaching the breakpoint at line 22 in the Interest application.

```
Command Prompt - jdb
main[1] print year
year = 1
main[1] print amount
amount = 1050.0
main[1] =
```

**Fig. Q.29** | Printing year and amount during the first iteration of Interest's for.

```
Command Prompt - jdb
amount = 1050.0
main[1] cont
1 1,050.00
> Breakpoint hit: "thread=main", Interest.main(), line=22 hci=55
22 System.out.printf("%4dx.20.2f\n", year, amount);
main[1] print year
year = 2
main[1] print amount
amount = 1102.5
main[1] =
```

**Fig. Q.30** | Printing year and amount during the second iteration of Interest's for.

7. *Removing a breakpoint.* You can display a list of all of the breakpoints in the application by typing `clear` (Fig. Q.31). Suppose you are satisfied that the `Interest` application's `for` statement is working properly, so you want to remove the breakpoint at line 22 and allow the remaining iterations of the loop to proceed normally. You can remove the breakpoint at line 22 by typing `clear Interest:22`. Now type `clear` to list the remaining breakpoints in the application. The debugger should indicate that only the breakpoint at line 13 remains (Fig. Q.31). Note that this breakpoint has already been reached and thus will no longer affect execution.
8. *Continuing execution after removing a breakpoint.* Type `cont` to continue execution. Recall that execution last paused before the `printf` statement in line 22. If the breakpoint at line 22 was removed successfully, continuing the application will produce the correct output for the current and remaining iterations of the `for` statement without the application halting (Fig. Q.32).

```
Command Prompt - jdb
amount = 1102.5
main[1] clear
Breakpoints set:
breakpoint Interest:13
breakpoint Interest:22
main[1] clear Interest:22
Removed: breakpoint Interest:22
main[1] clear
Breakpoints set:
breakpoint Interest:13
main[1] =
```

[Q.7 Wrap-Up](#)**CXII**

**Fig. Q.32** | Application executes without a breakpoint set at line 22.

In this section, you learned how to use the `clear` command to list all the breakpoints set for an application and remove a breakpoint.

## Q.7 Wrap-Up

In this appendix, you learned how to insert and remove breakpoints in the debugger. Breakpoints allow you to pause application execution so you can examine variable values with the debugger's `print` command. This capability will help you locate and fix logic errors in your applications. You saw how to use the `print` command to examine the value of an expression and how to use the `set` command to change the value of a variable. You also learned debugger commands (including the `step`, `step up` and `next` commands) that can be used to determine whether a method is executing correctly. You learned how to use the `watch` command to keep track of a field throughout the life of an application. Finally, you learned how to use the `clear` command to list all the breakpoints set for an application or remove individual breakpoints to continue execution without breakpoints.

### Self-Review Exercises

**Q.1** Fill in the blanks in each of the following statements:

- A breakpoint cannot be set at a(n) \_\_\_\_\_.
- You can examine the value of an expression by using the debugger's \_\_\_\_\_ command.
- You can modify the value of a variable by using the debugger's \_\_\_\_\_ command.
- During debugging, the \_\_\_\_\_ command executes the remaining statements in the current method and returns program control to the place where the method was called.
- The debugger's \_\_\_\_\_ command behaves like the `step` command when the next statement to execute does not contain a method call.
- The `watch` debugger command allows you to view all changes to a(n) \_\_\_\_\_.

**Q.2** State whether each of the following is *true* or *false*. If *false*, explain why.

- When application execution suspends at a breakpoint, the next statement to be executed is the statement after the breakpoint.
- Watches can be removed using the debugger's `clear` command.
- The `-g` compiler option must be used when compiling classes for debugging.
- When a breakpoint appears in a loop, the debugger pauses only the first time that the breakpoint is encountered.

**CXIII** [Appendix Q](#) Using the Debugger**Answers to Self-Review Exercises**

**Q.1** a) comment. b) print. c) set. d) step up. e) next. f) field.

**Q.2** a) False. When application execution suspends at a breakpoint, the next statement to be executed is the statement at the breakpoint. b) False. Watches can be removed using the debugger's unwatch command. c) True. d) False. When a breakpoint appears in a loop, the debugger pauses during each iteration.
